<b>EcmpEnable</b>	Globally enables or disables the Equal Cost Multipath (ECMP) feature. The default is disabled. After ECMP is disabled, the EcmpMaxPath is reset to the default value of 1.

Name	Description
<b>EcmpMaxPath</b>	Globally configures the maximum number of ECMP paths. You cannot configure this feature unless ECMP is enabled globally. Different hardware platforms can support a different number of ECMP paths. For more information, see <a href="#">VOSS Release Notes</a> .
<b>Ecmp1PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp2PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp3PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp4PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp5PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp6PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp7PathList</b>	Selects a preconfigured ECMP path.
<b>Ecmp8PathList</b>	Selects a preconfigured ECMP path.
<b>EcmpPathListApply</b>	Applies changes in the ECMP pathlist configuration, or in the prefix lists configured as the pathlists.
<b>TcpAdjustMssEnable</b>  <b>Note:</b> Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.	Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. The default varies depending on hardware platform: <ul style="list-style-type: none"> <li>• For XA1400 Series, the default value is enabled when at least one Fabric Extend (FE) tunnel with a MTU less than or equal to 1500 is configured.</li> <li>• For VSP 4900 Series and VSP 7400 Series, the default is disabled.</li> </ul>
<b>TcpAdjustMssStatus</b>  <b>Note:</b> Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.	Displays the activation status of the MSS adjustment functionality. On XA1400 Series, the MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) less than or equal to 1500 is configured.

Name	Description
<b>TcpAdjustMssType</b> <b>Note:</b> Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.	Displays if the MSS adjustment value is manually configured or auto-derived.
<b>TcpAdjustMssValue</b> <b>Note:</b> Exception: Only supported on VSP 4900 Series, VSP 7400 Series, and XA1400 Series.	Configures the MSS adjustment value. The default varies depending on hardware platform: <ul style="list-style-type: none"> <li>For XA1400 Series, the default value is auto-derived.</li> <li>For VSP 4900 Series and VSP 7400 Series, the default value is 1300.</li> </ul>

### Display the Logical Interface Next Hop

Use the following procedure to display the next hop for the logical interface.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric > IS-IS**.
2. Select the **Logical Interfaces NextHop** tab.

### Logical Interfaces NextHop field descriptions

Use the data in the following table to use the **Logical Interfaces NextHop** tab.

Name	Description
<b>Id</b>	Shows a unique value that identifies the logical interface tunnel.
<b>Ip</b>	Shows a unique value that identifies the next hop IP address of the logical interface tunnel.
<b>DestIfIndex</b>	Shows the next hop destination interface index to reach the next hop IP of the logical interface tunnel.
<b>DestVid</b>	Shows the next hop destination VLAN ID to reach the next hop IP of the logical interface tunnel.

## Fabric Extend Configuration Examples

This section provides configuration examples to configure Fabric Extend in the following deployment scenarios:

- [Fabric Extend over IP using the GRT](#) on page 1205
- [Fabric Extend over IP using a VRF](#) on page 1208
- [Fabric Extend over VPLS](#) on page 1211

- [Fabric Extend over Layer 2 Pseudowire](#) on page 1213
- [Fabric Extend with ONAs in the Core and Branches](#) on page 1215
- [Fabric Extend Over IPsec](#) on page 1218

For more configuration examples, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

### Fabric Extend over IP using the GRT

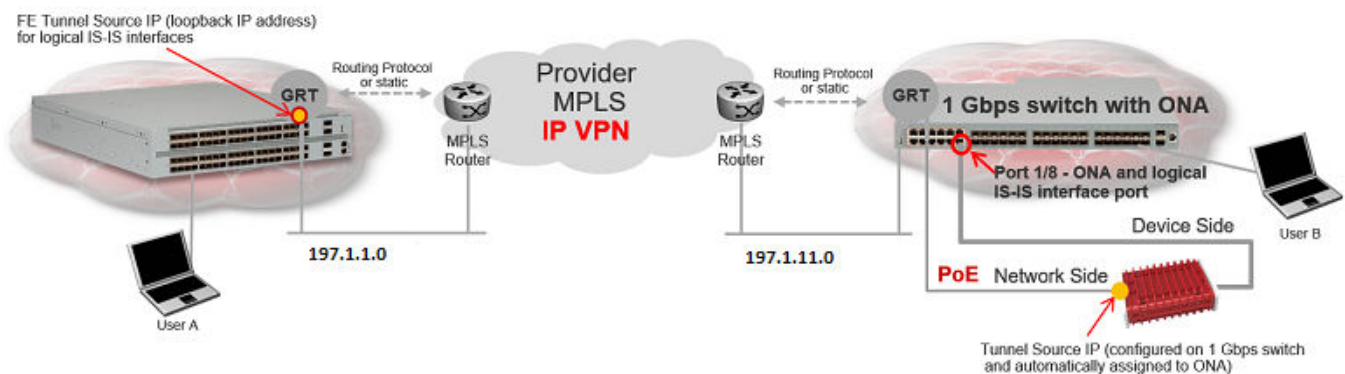

This example shows a typical Fabric Extend deployment with a 10/40/100 Gbps switch in the core and a 1 Gbps switch in one of the branch offices. The 10/40/100 Gbps switch supports Fabric Extend natively and is connected over an IP network to a 1 Gbps switch, which requires an ONA to encapsulate SPB traffic with a VXLAN header. The ONA sets up a bridge between the ONA device-side port and the ONA network-side port. Fabric Extend uses a VXLAN tunnel to send traffic to and from the 10/40/100 Gbps switch through the 1 Gbps switch to the ONA.

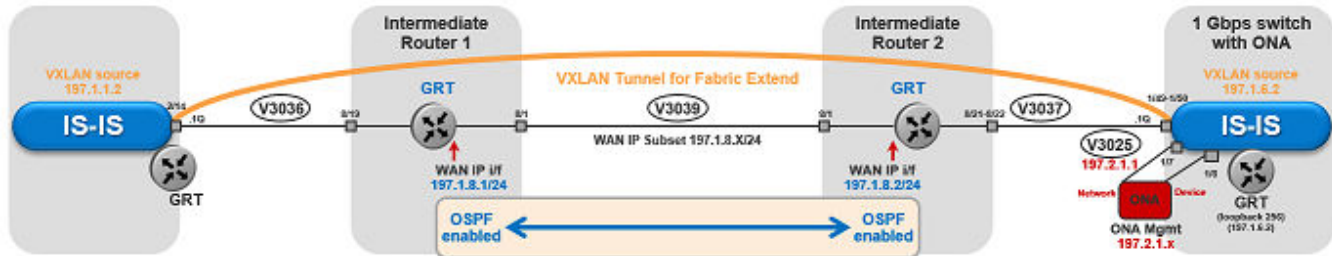

#### Note

- This deployment uses the **GRT** so the tunnel source IP address must be on the GRT, not on a VRF.
- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.
- Add any IP address used for setting up the logical tunnel (such as local network and loopback IP addresses) to the IS-IS accept policy or exclude route-map to prevent these addresses from being advertised into IS-IS.

The following figure shows a sample Fabric Extend deployment over IP using the GRT.

**Figure 74: IP using GRT traffic flow**

**Figure 75: IP (GRT) traffic flow component view**

#### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured in the GRT.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept
```

#### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the GRT. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# interface loopback 256
Switch(config-if)# ip address 256 197.1.6.2/255.255.255.0
Switch(config-if)# ip ospf 256
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
```

```

Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept

```

### For Intermediate Router 1

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

**For Intermediate Router 2**

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

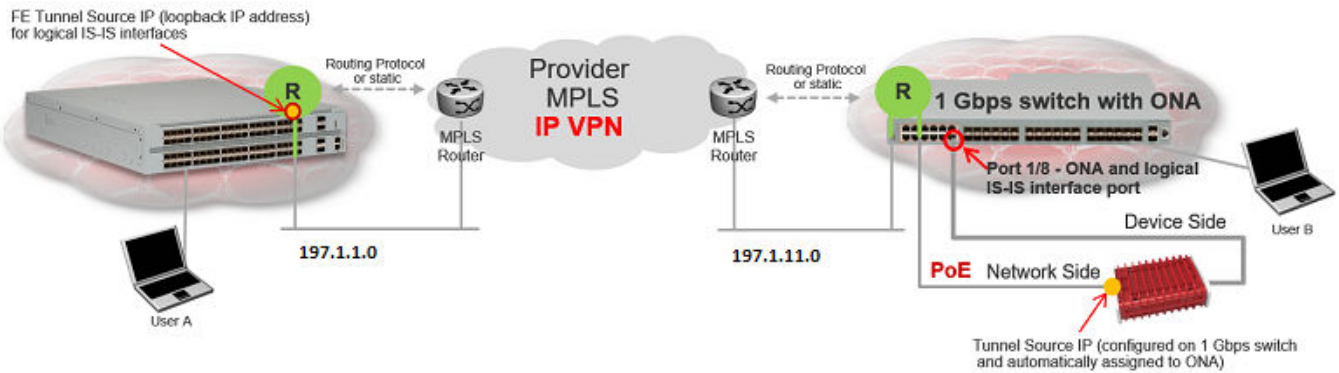

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

*Fabric Extend over IP using a VRF*

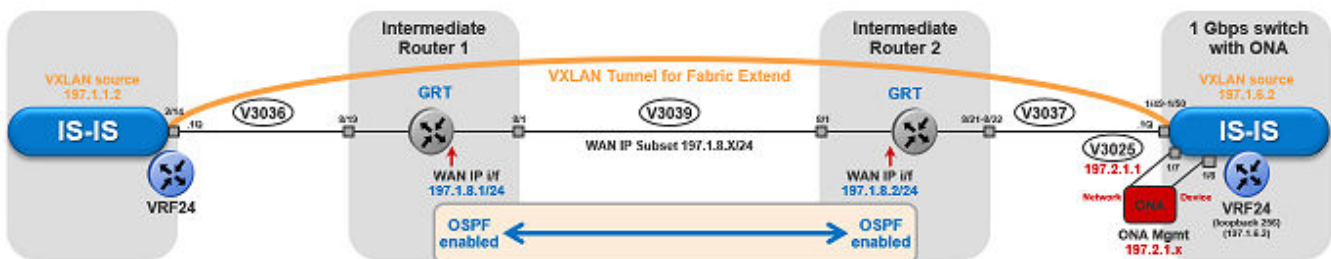

This example is the same as the previous IP example except this Fabric Extend deployment uses a VRF instead of the GRT. Because this deployment is using a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the same VRF.
- Remote management of the 1 Gbps switch is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

The following figure shows a sample Fabric Extend deployment over IP using a VRF.

**Figure 76: IP using VRF traffic flow**

**Figure 77: IP (VRF) traffic flow component view**

### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured as a router address in the VRF.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
```

```
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit
```

#### For Intermediate Router 2

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend over VPLS

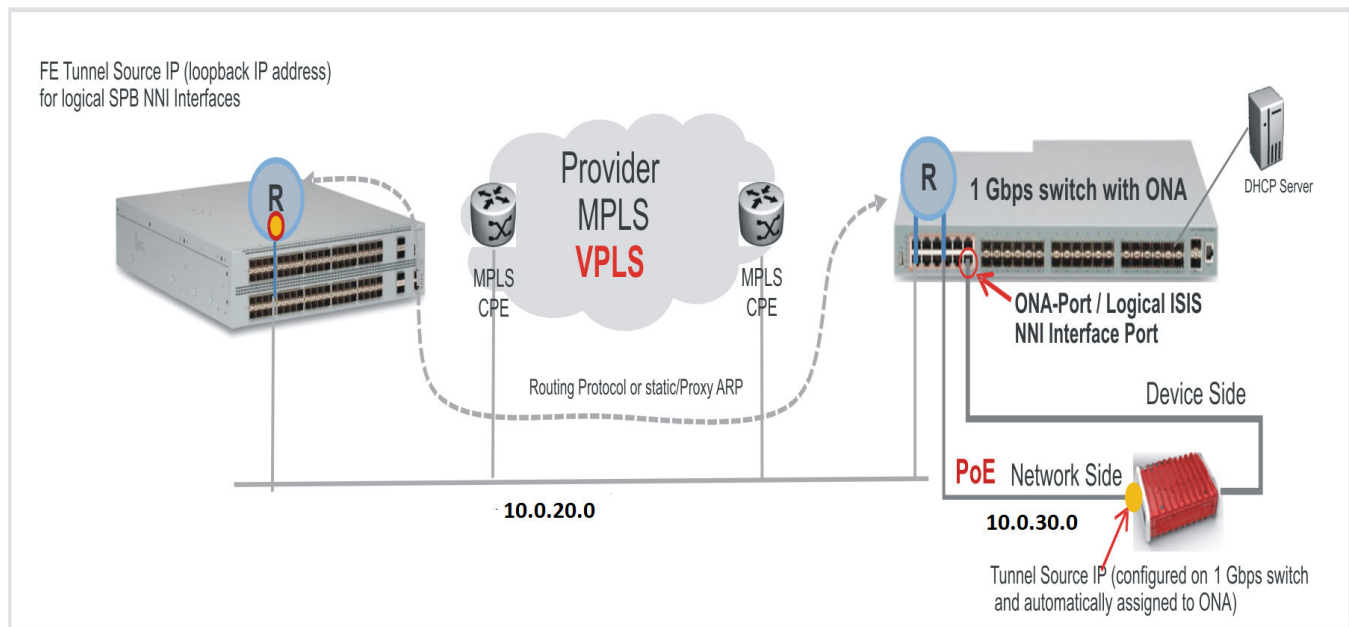

This example shows a Fabric Extend deployment over MPLS Virtual Private LAN Service (VPLS). In this scenario, VPLS emulates a LAN with full mesh connectivity. The SPB nodes connect with point-to-point Ethernet links and also use MPLS for normal forwarding.

#### Note

On the Core side, the 10/40/100 Gbps switches require a single next hop IP address as a default gateway for all tunnels. To ensure the single next hop, VPLS uses a loopback IP address and an additional VRF.

The following figure shows a sample Fabric Extend deployment over VPLS.

**Figure 78: FE over VPLS traffic flow**

#### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured as a brouter address in the VRF.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
```

```
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf tunnel
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### For Intermediate Router 1

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
```

```

Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

### For Intermediate Router 2

```

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit

```

### Fabric Extend over Layer 2 Pseudowire

This example shows a Fabric Extend deployment using service provider VLAN tunnels over MPLS Pseudowire. In this scenario, you map two dedicated VLAN IDs (VIDs) from the Hub to the Spoke sites. Then the logical IS-IS interfaces translate the BVIDs to map them to the per branch provider VIDs.

Because the tunnels are point-to-point VLAN connections, not VXLAN, there is no need to encapsulate a VXLAN header to SPB packets. Therefore, the 1 Gbps switches in this type of deployment do not require ONAs.

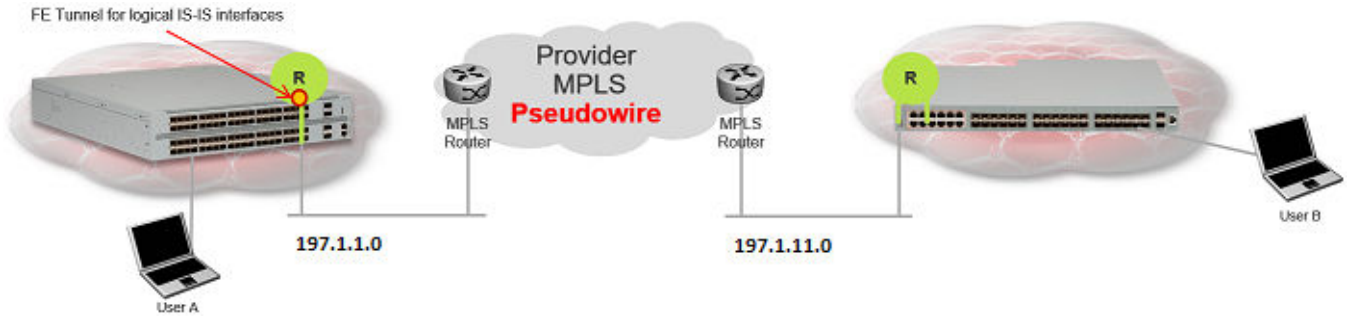

#### Important

10/40/100 Gbps switch — — — — — Core — — — — — 1 Gbps switch

- You cannot have IS-IS in the Core.
- Do not create the two VLANs represented in the logical interface connection on the BEBs. If you do, you will not be able add any Fabric Extend ports to be members of those VLANs. One links the port that is facing the core and those VLANs in the logical interface connection.

The following figure shows a sample Fabric Extend deployment over Pseudowire.

**Figure 79: FE over Pseudowire traffic flow**

**Figure 80: FE over Pseudowire traffic flow component view**

**For 10/40/100 Gbps Switches**

**Note**

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 port 2/14 name fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

**For 1 Gbps Switches**

**Note**

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# router isis enable

Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 mlt 11 name fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
```

```
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

### For Intermediate Router 1

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

```
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1,8/19
Switch(config)# vlan member add 300 8/1,8/19
```

### For Intermediate Router 2

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1
Switch(config)# vlan mlt 200 11
Switch(config)# vlan member add 300 8/1
Switch(config)# vlan mlt 300 11
```

## Fabric Extend with ONAs in the Core and Branches

This example shows a Fabric Extend deployment with 1 Gbps switches in the core of the network and in the branch sites. This type of deployment is not only a lower cost Fabric Extend solution, it also addresses situations where large MTU sizes (over 1594 bytes) are a problem for the Service Provider.

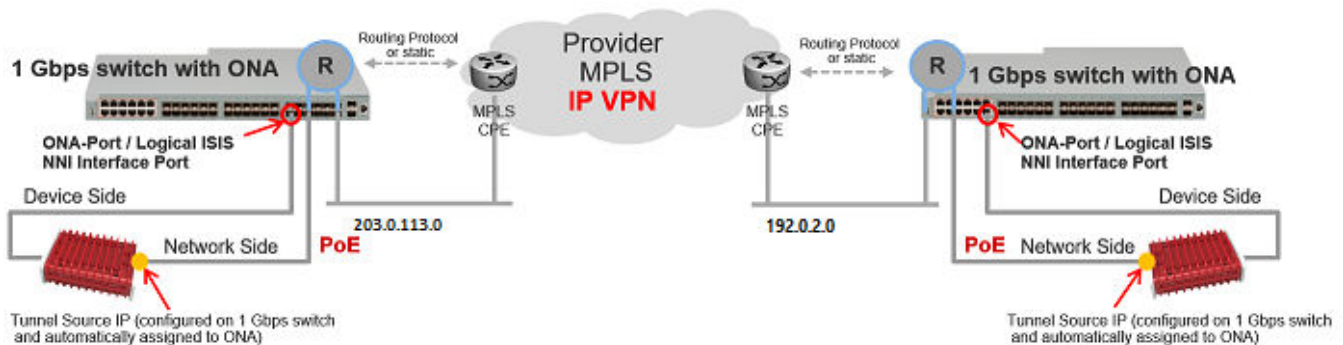

MTU sizes less than 1594 bytes require fragmentation and reassembly of packets and the 1 Gbps switch with ONA supports fragmentation and reassembly. However, you must have 1 Gbps switches with ONAs at BOTH ends of the IP WAN connection.

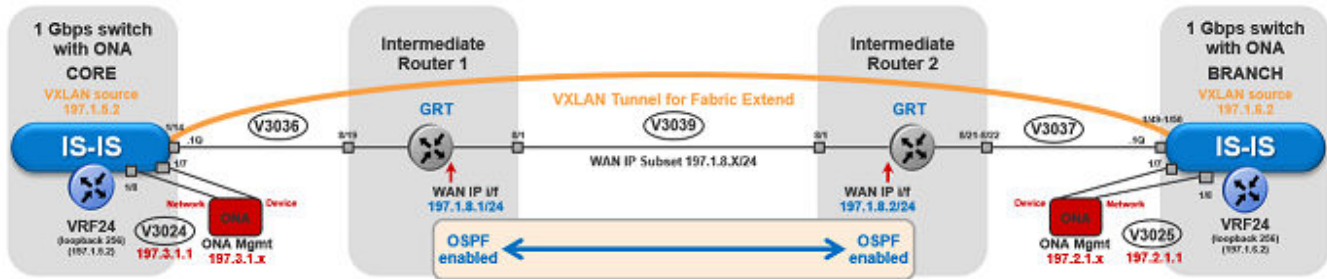

### Important

There is no fragmentation/reassembly support in Layer 2 core solutions.

The following figure shows a sample Fabric Extend deployment using VRFs with both switches.

**Figure 81: Fabric Extend traffic flow**

**Figure 82: Fabric Extend traffic flow component view**

### Core switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.5.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3036 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3036 1/14 portmember
Switch(config)# interface vlan 3036
Switch(config)# vrf vrf24
Switch(config-if)# ip address 197.1.1.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3024 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3024 1/8 portmember
Switch(config)# interface vlan 3024
Switch(config-if)# ip address 197.3.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.5.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.2.1.1)# exit
```

### Branch switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/8 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.5.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### Intermediate Router 1 Configuration

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
```

```
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Intermediate Router 2 Configuration

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend Over IPsec

The following example shows a Fabric Extend deployment using service provider VLAN tunnels and IPsec.

#### Note

Fabric Extend over IPsec limitations:

- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- The key exchange only uses the Internet Key Exchange (IKE) v2 protocol.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular layer 3 routed packets.

### Global SPBM for Fabric Extend over IPsec Configuration

The global SPBM parameters must be configured before you can configure the Fabric Extend over IPsec tunnel.

#### Note

The **ipsec** command is only available after the **auth-key** command is configured.

```
Switch> enable
Switch# configure terminal

Switch(config)# spbm
Switch(config-isis)# router isis
Switch(config-isis)# spbm 1
Switch(config-isis)# spbm 1 nick-name 1.11.40
Switch(config-isis)# spbm 1 b-vid 2,3 primary 2
```

```
Switch(config-isis)# is-type 11
Switch(config-isis)# manual-area c0.2000.0000.00
Switch(config-isis)# sys-name SwitchB
Switch(config-isis)# exit

Switch(config)# vlan create 2 type spbm-bvlan
Switch(config)# vlan create 3 type spbm-bvlan
Switch(config)# router isis enable
```

### Fabric Extend tunnel and IPsec configuration

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

```
Switch> enable
Switch# configure terminal

Switch(config)# interface GigabitEthernet 1/1
Switch(config-if)# brouter port 1/1 vlan 2500 subnet 192.0.2.0/255.255.255.0 mac-offset 0
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 192.0.2.0
Switch(config-isis)# exit

Switch(config)# logical-intf isis 1 dest-ip 198.51.100.0
Switch(config-isis-1-198.51.100.0)# isis
Switch(config-isis-1-198.51.100.0)# isis spbm 1
Switch(config-isis-1-198.51.100.0)# isis enable
Switch(config-isis-1-198.51.100.0)# auth-key 12345678
Switch(config-isis-1-198.51.100.0)# ipsec encryption-key-length 256
Switch(config-isis-1-198.51.100.0)# ipsec
Switch(config-isis-1-198.51.100.0)# exit
```

#### Note

Product Notice: 256-bit IPsec Encryption for Fabric Extend Tunnels is only supported on XA1400 Series devices.

## Fabric Attach

**Table 114: Fabric Attach product support**

Feature	Product	Release introduced
Fabric Attach Server	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 5.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.0
	VSP 8400 Series	VOSS 5.0
	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Supported

With Fabric Attach, network edge devices that do not support Shortest Path Bridging (SPB), MAC-in-MAC encapsulation (802.1ah) or service identifiers (I-SIDs) can take advantage of SPB infrastructure. To attach to an SPB network, edge devices signal an SPB-aware FA Server to automatically configure the I-SIDs. The edge devices can then utilize existing SPB features across the fabric and leverage SPB infrastructure capabilities without manual configuration. Fabric Attach uses the IEEE 802.1AB Logical Link Discovery Protocol (LLDP) to signal a desire to join the SPB network.

FA uses the client-server model. An initial handshake occurs between the FA Server and the FA Client. After the discovery phase is complete, the FA Server accepts requests (from FA Clients) to add the C-VID (VLAN ID) and I-SID elements in the SPB network, and also automatically configures the necessary C-VID and I-SID. The FA Server then responds with an acknowledgement of whether the request succeeded. FA Clients can also be aggregated into a proxy device that handles the handshakes and requests on behalf of many clients, to the server. All of the discovery handshakes and I-SID mapping requests are then transferred using LLDP Type, Length, Value (TLV) fields.

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP Protocol Data Units (PDU).

## FA Zero Touch Client Attachment

**Table 115: Fabric Attach Zero Touch Client Attachment product support**

Feature	Product	Release introduced
Fabric Attach Zero Touch Client Attachment	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Supported

FA Zero Touch Client Attachment eases the configuration process on FA-capable devices by automating specific configuration tasks required for FA functionality.

### Note

Only the base functionality of Zero Touch Client Attachment is supported.

After you initially configure Zero Touch Client Attachment on the FA Server, the settings are exported to receiving FA devices, where the required configuration tasks are automatically performed.

Base Zero Touch Client Attachment operation is tightly coupled with FA operation. Although you can enable or disable Zero Touch Client Attachment separately from FA, the feature is dependant on data that is only available during exchanges between the FA Server and FA Proxies, after a primary FA Server has been selected. By default, base Zero Touch Client Attachment support is enabled.

Base Zero Touch Client Attachment operation, when enabled, extracts management VLAN data from the primary FA Server advertisements and uses this data to update the in-use management VLAN if applicable. An FA Client can also utilize FA-provided management VLAN data after the FA Proxy or Server is discovered.

Zero Touch is active when the following criteria are met:

- On an FA Proxy:
  - Zero Touch Client Attachment is enabled
  - Fabric Attach is enabled

- A primary FA Server is discovered and selected
- On an FA Server:
  - Zero Touch Client Attachment is enabled
  - FA is enabled
  - FA Proxies or FA Clients are discovered

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

**Note**

You must enable Base Zero Touch **auto-client attach** and define the target Fabric Attach client in order to initiate Zero Touch Client Attachment processing.

FA Signaling generated by an FA Proxy or Server contains management VLAN data. If the management VLAN advertised by the primary FA Server differs from the management VLAN currently configured on the FA Proxy, Zero Touch Client Attachment initiates the following:

- VLAN creation — If the FA Server-specified management VLAN does not exist on the FA Proxy, Zero Touch Client Attachment creates a port-based VLAN.
- Management VLAN update — The created port-based VLAN becomes the designated management VLAN for the FA Proxy. No operations related to the previous management VLAN, such as port membership updates or VLAN deletion, are performed.
- Port VLAN membership update (FA Proxy/Server) — If required, Zero Touch Client Attachment updates the port VLAN membership to ensure that the uplink port through which the primary FA Server is accessed is a member of the management VLAN, for network accessibility.
- Port Default VLAN (PVID) update — The port-based PVID is automatically updated based on the VLAN ID value.
- Port Default Priority update — The default 802.1p user priority for the port is updated based on the specified port priority value of the Zero Touch client (range is 0–7).
- Zero Touch Client Specification removal — All Zero Touch client-related settings are updated based on the FA client discovery. Deleting a Zero Touch client specification

or disabling any related Zero Touch option does not result in the immediate removal of any previously applied settings.

### Note

The FA Proxy does not update the acquired management VLAN if the primary FA Server is lost. This data is updated if the management VLAN advertised by the current primary FA Server changes or if another primary FA Server is selected and new management VLAN data is advertised by the server.

Management VLAN and port membership updates performed by Zero Touch are maintained in non-volatile storage and are restored following a system reset. You must remove or update these configuration settings if they are deemed unnecessary at a later time.

- IP Address Source Mode Update — Updates the IP address source mode of the receiving device to DHCP-When-Needed, to initiate DHCP-based IP address acquisition if necessary.
- Automation of the FA Client Port Mode — Automates the configuration of EAP port modes based on the type of discovered FA Clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- ZTC Installation — Initiates ZTC installation on applicable ports on the receiving device. Applies to FA Proxy and, in a limited manner, to FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto Trusted FA Client Port Mode — Initiates automatic QoS interface class update based on the type of discovered FA clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto PVID FA Client Port Mode — Initiates automatic port PVID, port management VLAN membership and port tagging mode based on the type of discovered FA device. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports. This configuration is incompatible with the automatic FA Client Port Mode and ZTC Automatic attach options.

## Fabric Attach Components

FA components dynamically communicate with each other using FA signaling.

### *FA Signaling*

FA has defined organizational specific TLVs within the standard LLDP protocol, to exchange messages and data amongst components of an FA solution. The FA TLVs facilitate handshaking and authentication, processing of requests for the creation of services, and providing responses on whether the requests succeeded. In addition, these services are deleted when the service requests are terminated, or when the authentication criteria are no longer valid. All components that participate in FA must be able to send, receive, and interpret the FA TLVs.

### *FA Components*

FA includes the following network elements as components:

- FA Server:

An SPB-capable switch at the edge of a Fabric Connect cloud.

An FA Server receives requests from FA Clients or FA Proxies to create services with specific I-SID-to-VLAN bindings. The FA Server completes the association between conventional networks and fabric-based virtual service networks. For more details on the operation of an FA Server, see [Fabric Attach Server](#) on page 1224.

- FA Proxy:

A network switch that supports the definition of I-SID-to-VLAN assignments and has the ability to advertise these assignments for possible use by an FA Server. FA Proxy switches also support the client mode for directly attached users or end devices. Typically, FA Proxies support downstream FA Client devices, while being directly connected to an upstream FA Server device.

- FA Client:

A network attached end-point device that advertises I-SID-to-VLAN binding requests for service creation, to an FA Proxy or an FA Server. FA Clients use FA signaling to automatically attach to fabric services.

## Fabric Attach Server

### *FA Server operation*

In an FA solution, the FA Server performs the role of connecting FA Clients and FA Proxies to the SPB fabric, with minimal configuration. As part of the discovery handshake between the FA Server and client or proxy devices, LLDP PDUs are exchanged. Using standard LLDP, the FA Server learns neighbors, that include the proxy and client devices. In addition, the FA Server transmits organizational-specific element-discovery TLVs that are used by the client or proxy device to recognize its attachment to the FA Server.

**Figure 83: Fabric Attach Server connecting client or proxy devices to the Fabric network**

After the initial discovery handshake is complete, the client or proxy device transmits I-SID-to-VLAN assignment mapping requests to the FA Server to join the SPB fabric. These requests include the C-VID (VLAN ID) and the I-SID that the client or proxy device needs to join. The FA Server then creates the requested C-VID and I-SID on its device. It

then responds with a PDU (containing the FA-specific TLV) to indicate whether the request succeeded. The I-SID thus created is a ELAN I-SID with endpoints of type Switched UNI. After I-SID creation, the I-SID is also advertised to the SPB network by IS-IS.

The traffic that is sent to or received from the SPB cloud is MAC-in-MAC (MiM) encapsulated. The FA Server, being SPB-capable, decapsulates the MiM traffic. If the I-SID matches the I-SID created on behalf of the client or proxy, the FA Server sends the traffic to that client or proxy and passes it on the C-VID that it expects.

#### *FA Server configuration*

An FA Server can be configured at two levels—global and interface.

Configuration at the global level enables or disables FA on the entire switch. However, for attachment of clients or proxy devices, you must also configure FA at the interface level. Interfaces can be ports (including channelized ports), MLTs, SMLT or LACP MLTs. Enabling FA on an interface also enables transmission of LLDP packets that contain the FA-specific TLVs.

When you disable FA on an interface, LLDP transmission automatically stops on that interface.

#### **Caution**

Disabling FA or IS-IS triggers a flush of FA information on the switch. Disabling FA at the global level flushes all FA element-discovery information and mappings. Disabling at the interface level flushes element-discovery information and mappings associated with that interface.

#### **Important**

The only provisioning mode supported on the FA Server is SPB.

## FA Proxies and FA Clients

The configuration mode of FA Proxies and FA Clients is not supported. However, in an FA solution, the FA Server interacts with FA Proxies and FA Clients by accepting LLDP PDUs (containing FA TLVs) and using them to automatically create Switched UNI I-SIDs and endpoints, based on the mapping requests contained in those TLVs. For more information, see [FA TLVs](#) on page 1225.

## Fabric Attach operation

The following sections detail FA operation.

### *FA TLVs*

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA amongst those peers. FA information is transmitted using company-specific proprietary organizational Type, Length, Value (TLV) fields

within LLDP Protocol Data Units (PDU). The following section describes the TLVs for FA.

FA uses two TLVs:

- FA Element TLV
- FA Assignment TLV

#### FA Element TLV

The FA Element TLV is used by FA elements to advertise Fabric Attach capabilities. This data forms the basis for FA element discovery and is used in the initial handshake between the FA Server and a client or proxy device.

TLV Type [127]	TLV Length [50 octets]	OUI [00-04-0D]	Subtype [11]	HMAC-SHA Digest	Element Type	State	Mgmt VLAN	Rsvd	System ID
7 bits	9 bits	3 octets	1 octet	32 octets	6 bits	6 bits	12 bits	1 octet	10 octets

**Figure 84: FA Element TLV format**

**Table 116: FA Element TLV field descriptions**

Field	Description
TLV Type	Indicates whether the discovered element is a client or a proxy device.
OUI and Subtype	The information in these fields is used in LLDP packet handling.
HMAC-SHA Digest	<p>Data integrity and source validation is supported through the use of the HMAC-SHA256 message authentication. This field supports a digest exchange between the source and destination devices. Symmetric private keys are used for digest generation. The HMAC-SHA256 generated digest size is 32 octets.</p> <p>The HMAC-SHA256 digest is computed starting with the Element Type data, that is, it starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing commences. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b> If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA Element TLV is discarded before it is processed by the system operating in secure mode.</p>

**Table 116: FA Element TLV field descriptions (continued)**

Field	Description
Element Type	<p>Indicates the supported element type. The primary element types are the FA Server, FA Proxy and FA Client.</p> <p>An FA Server is an SPB capable device that accepts externally generated I-SID-to-VLAN assignments. An FA Proxy is a non-SPBM device that supports I-SID-to-VLAN assignment definitions and advertises these assignments for possible use by an FA Server. An FA Client, also a non-SPBM device, advertises I-SID-to-VLAN assignments to a directly connected FA Proxy or an FA Server. Both tagged and untagged FA Client connections are supported.</p> <p>The list of supported element types and their values are:</p> <ul style="list-style-type: none"> <li>• FA Element Type - Other (1)</li> <li>• FA Server (2)</li> <li>• FA Proxy (3)</li> <li>• FA Server No Authentication (4)</li> <li>• FA Proxy No Authentication (5)</li> <li>• FA Client - Wireless Access Point Type 1, which directly attaches to the SPBM network.</li> <li>• FA Client - Wireless Access Point Type 2, which is tunneled to a controller.</li> <li>• FA Client - Switch (8)</li> <li>• FA Client - Router (9)</li> <li>• FA Client - IP Phone (10)</li> <li>• FA Client - IP Camera (11)</li> <li>• FA Client - IP Video (12)</li> <li>• FA Client - Security Device (13)</li> <li>• FA Client - Virtual Switch (14)</li> <li>• FA Client - Server/Endpoint (15)</li> </ul>
State	<p>Indicates the link tagging requirements in FA Client-sourced frames. This field also indicates the current provisioning mode. The Link VLAN Tagging bit (bit 1) has one of the following values:</p> <ul style="list-style-type: none"> <li>• 0 — indicates that all traffic on the link is tagged. In this case, all discovered FA Clients are treated as tagged.</li> <li>• 1 — indicates that traffic on the link is either tagged or untagged. Here, all discovered FA Clients are treated as untagged.</li> </ul> <p>The automatic provisioning mode bits (bits 2 and 3) always have the value 1 for SPB provisioning. The switch only supports the SPB provisioning mode.</p>
Mgmt VLAN	<p>When you configure a management VLAN on the FA Server, it is included in this field in FA Server or FA Proxy sourced frames, and is used to support management VLAN auto-configuration on the downstream proxy and client devices.</p>
System ID	<p>This field contains connection information that a TLV recipient can use to enforce connectivity restrictions.</p> <p>It contains the system MAC address (6 octets) for MLT configurations and the virtual BMAC address for vIST and SMLT configurations. It also contains information on the connection type such as MLT or SMLT.</p>

### Limitations

- The FA Element TLV exists only once in an LLDP PDU and is included in all PDUs when the FA service is enabled.
- The maximum length of the FA Element TLV is 56 bytes.

### FA I-SID-to-VLAN Assignment TLV

The FA I-SID-to-VLAN Assignment TLV is used by FA Clients to distribute I-SID-to-VLAN assignments that need to be supported by an FA Proxy or an FA Server.

TLV Type [127]	TLV Length [41-506 octets]	OUI [00-04-0D]	Subtype [12]	HMAC-SHA Digest	Assignment Status	VLAN	I-SID
7 bits	9 bits	3 octets	1 octet	32 octets	4 bits	12 bits	3 octets

**Figure 85: FA Assignment TLV format**

### FA I-SID-to-VLAN Assignment TLV fields

Some fields are common to both the FA Element and FA Assignment TLVs. The following fields are specific only to the FA Assignment TLV.

TLV Field	Description
HMAC-SHA Digest	<p>The HMAC-SHA256 digest is computed for the series 1 to 94 of I-SID-to-VLAN assignments, that is, the data for the digest computation starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed for the series 1 to 94 of I-SID-to-VLAN assignments in the received TLV and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing can commence. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b> If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA I-SID-toVLAN Assignment TLV is discarded before it is processed by the system operating in secure mode.</p>
Assignment status	Indicates whether the FA Server accepted or rejected the I-SID-to-VLAN mapping request from a client or proxy device.
VLAN	Indicates the C-VID value advertised by the client or proxy device in the FA I-SID-to-VLAN mapping request.
I-SID	<p>Indicates the I-SID that is advertised by a client or proxy device in the FA I-SID-to-VLAN mapping request. This I-SID is used to create a Switched UNI (ELAN) I-SID.</p> <p><b>Note:</b> This I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.</p>

### Limitations

- The FA I-SID-to-VLAN Assignment TLV is included in an LLDP PDU only if the FA Server and proxy or client devices are directly connected to each other.
- This TLV can exist only once in an LLDP PDU.
- The size limit of this TLV is 511 bytes. This limits the maximum number of I-SID-to-VLAN assignments supported in an LLDP PDU to 94.
- For an FA I-SID-to-VLAN Assignment TLV to be processed, the FA Element TLV must also be present in the LLDP PDU.

### FA Element Discovery

The first stage of establishing FA connectivity is element discovery.

On an FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface. After FA is enabled, the FA Server begins transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices.

An FA Server can communicate with multiple different FA Client and FA Proxy devices.

### FA data processing

In the following FA deployment, a client device (Client 1) attaches to the FA Server (FA Server 1) using a proxy device. Another client device (Client 2) attaches to the FA Server (FA Server 2) at the other edge of the network. The following section describes how data is processed when data traffic is transmitted from Client 1 to Client 2.

When Client 1 successfully attaches to FA Server 1, FA Server 1 creates a unique I-SID-to-VLAN mapping for Client 1 on its device. This mapping contains the I-SID and C-VID advertised by Client 1, using the FA Assignment TLV. For example, assume that Client 1 advertises I-SID 200 and C-VID 250.

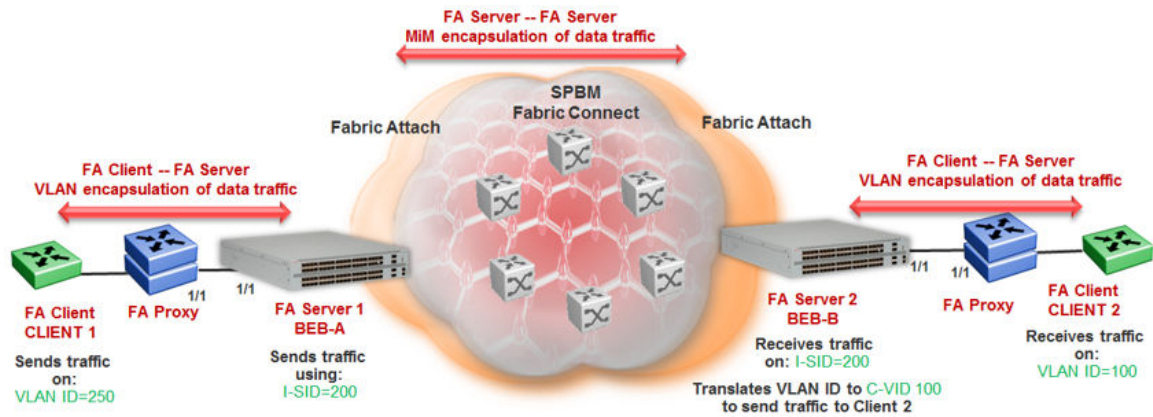

Similarly, when Client 2 attaches to FA Server 2, FA Server 2 creates an I-SID-to-VLAN mapping for Client 2 on its device with, for example, I-SID 200 and C-VID 100. This is depicted in the following figure.

**Figure 86: Learning of I-SID-to-VLAN mappings**

When data traffic ingresses FA Server 1 at the FA-enabled port 1/1, it contains the C-VID of Client 1, which is, 250. The data is VLAN-encapsulated at this stage. As traffic egresses FA Server 1 into the SPB cloud, it is encapsulated with the ELAN I-SID created on FA Server 1 on behalf of Client 1, that is I-SID 200. The traffic is now MiM encapsulated with I-SID 200.

The following figure depicts VLAN encapsulation of data traffic from the FA Client to the FA Server (at either end of the SPB cloud) and its MiM encapsulation as it traverses the SPB cloud.

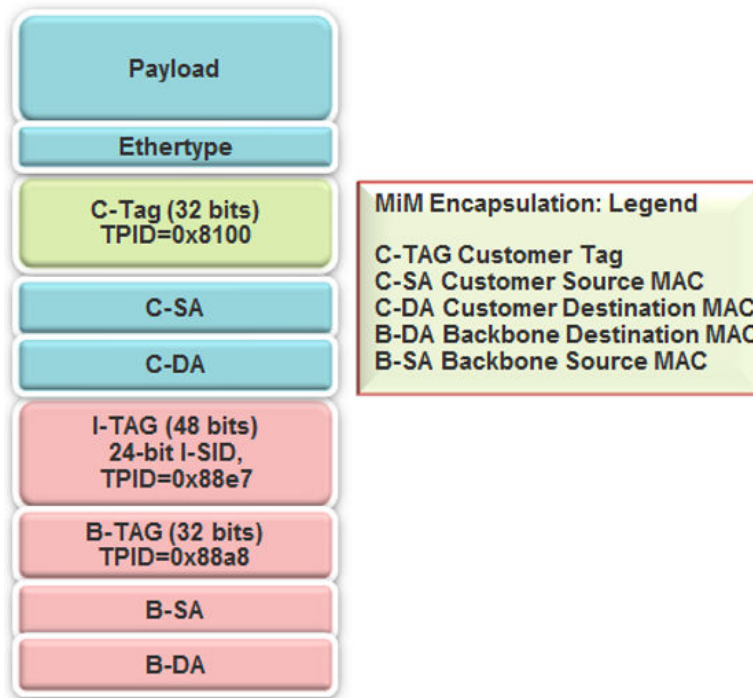

**Figure 87: Data encapsulation — VLAN encapsulation and MiM encapsulation**

As traffic exits the SPB cloud and ingresses the remote FA Server 2, it continues to be MiM encapsulated with I-SID 200.

At FA Server 2, the MiM traffic is decapsulated. Since the I-SID in the data packet matches the I-SID created on its device on behalf of Client 2, FA Server 2 prepares to send traffic to Client 2. At this stage, to successfully transmit the data traffic to Client 2, FA Server 2 must additionally know the C-VID that Client 2 expects traffic on. This information is obtained from the I-SID-to-VLAN mapping on FA Server 2 created on behalf of Client 2, which is C-VID 100. Thus FA Server 2 translates the C-VID in its data packets to this VLAN ID, and then passes it on to Client 2.

The following figure depicts the typical MiM encapsulation of a data packet. The B-DA and B-SA components indicated the system ID of the FA Server running SPB.

**Figure 88: MiM encapsulation**

#### *FA Server and I-SID-to-VLAN Assignments*

FA Client or FA Proxy devices advertise I-SID-to-VLAN assignments to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. All communication between FA Proxies or Clients and the FA Server is using LLDP. Successful assignments result in the creation of a Switched UNI I-SIDs and endpoints based on the mapping requests.

The FA Server rejects I-SID-to-VLAN assignment requests if:

- FA is not configured properly on the port or MLT.
- Router IS-IS is disabled.

#### **Note**

For Fabric Attach to operate properly and for the FA Server to accept I-SID-to-VLAN assignment requests, IS-IS must be enabled.

The following error message is logged immediately after IS-IS is disabled, and displays the error message only once in the log file. The system does not display it again when an assignment request is made from the FA Proxy.

```
CP1 [12/04/15 00:33:49.733:UTC] 0x00374589 00000000
```

```
GlobalRouter FA INFO Fabric Attach Assignments will be rejected since ISIS is disabled.
```

- The C-VID and I-SID are not within the supported range.

Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported. The value 4096 indicates that the port is untagged. An I-SID value of 0 is not supported on the FA Server.

- The I-SID is already assigned to an IP VPN.

The system displays the error message `I-SID is already assigned to an IPVPN.`

- The I-SID is already in use for SPB multicast.

The system displays the error message `SPB Multicast is enabled, ISID 16000000 and greater reserved for dynamic data-isid's used to carry Multicast traffic over SPB.`

- The I-SID has a value that is reserved for internal use.
- The I-SID cannot be used in an IS-IS accept policy.
- The I-SID is associated with a platform VLAN and that VLAN is used as a private VLAN (that is, has a secondary VLAN specified).
- The I-SID is already in use for Transparent Port UNI.
- The port that receives the I-SID-to-VLAN assignment is a member of an MLT, but FA is not successfully enabled on that MLT interface.
- There is a resource error on the FA Server system, such as lack of memory.
- The number of I-SID-to-VLAN assignments on a port exceeds the maximum limit which is 94.
- The number of I-SIDs on the switch exceeds the maximum limit.
- The same endpoint is configured on more than one I-SID.
- The port or MLT is associated with more than one C-VID in the same I-SID.

When the FA Server rejects I-SID-to-VLAN assignments, aside from viewing the log file, you can use trace to troubleshoot the cause of rejection.

For an example on troubleshooting rejection of I-SID-to-VLAN assignments on the FA Server and for more information on using trace, see [Troubleshooting Fabric Attach](#) on page 4008.

### *FA management*

You can configure a management I-SID on an FA-enabled port or MLT. This I-SID includes an optional C-VID parameter, which is a VLAN ID that is locally significant to the port or MLT and does **not** represent a platform VLAN.

Depending on whether the C-VID value is specified, the behavior is as follows:

- If the C-VID value is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN ID for management traffic on the FA Server uplink.

Different hardware platforms support different customer C-VID ranges.

- If the C-VID value is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

If you do not configure a management I-SID, the FA Server transmits a management VLAN ID value of 0 in the FA Element TLV. A client/proxy that receives the FA Element TLV retains the initial management configuration (if any) on its device.

### Limitations of FA management I-SIDs

- A management I-SID value of 0 is not supported on the FA Server.
- You cannot enable BPDU on a management I-SID.

### FA management configuration considerations

A Switched UNI I-SID that is created when an FA assignment is learned on a port or MLT, is uniquely identified by a tuple comprising of one of the combinations of (port, I-SID and C-VID) or (MLT ID, I-SID and C-VID). When you configure FA management, similar tuples are used. You can configure FA management on an FA-enabled port or MLT on which FA assignment mappings are learned, as long as the FA management tuple exactly matches the tuple created by the learned FA mapping.

The following scenarios describe the behavior when you configure FA management on a port or MLT that also receives learned FA mappings, but the tuples do not match.

- **Scenario 1:** You attempt to configure FA management on a port or MLT where an FA assignment mapping is already learned.

For example, consider an FA-enabled port 1/1 on which an assignment mapping is learned, with I-SID 100 and C-VID 20. You can configure FA management on port 1/1 as long as the I-SID and C-VID values exactly match that of the learned FA mapping. However, if you attempt to configure FA management on the port with a different I-SID and C-VID value, the configuration is not successful and an error message displays.

- **Scenario 2:** An FA assignment mapping is learned on a port or MLT that already has FA management configured.

For example, consider that FA management is configured on port 1/1. If an FA assignment mapping is learned on the port with the same I-SID and C-VID values as that of the FA management configuration, then the mapping is accepted. Otherwise the mapping is rejected.

### *FA message authentication and integrity protection*

For the security of FA communication in terms of data integrity and authenticity, a keyed-hash message authentication code can be transmitted within every FA TLV.

It protects the I-SID-to-VLAN assignment exchanges between the FA Server and FA Proxy. The standard HMAC-SHA256 algorithm calculates the message authentication code (digest) involving a cryptographic hash function (SHA-256) in combination with a shared secret key. The key is symmetric, that is, it is known by both the source and destination parties.

By default, on the FA Server, message authentication is enabled at the interface level and a default key is defined to provide secure communication.

You can configure a different authentication key on an interface (port or MLT) on the FA Server, to authenticate a client on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server. For an FA Client to authenticate and attach to the FA Server, the authentication key must match on both

the client and the server. In general, the FA authentication key must match between two FA components exchanging FA TLVs through LLDP.

When you enable FA message authentication, the message authentication key (default or configured) generates a Hash-based Message Authentication Code (HMAC) digest that is included in FA I-SID-to-VLAN Assignment TLV. Upon receipt, the HMAC digest is recomputed for the TLV data and compared against the digest included in the TLV. If the digests are the same, the data is valid. If the digests are not the same, the data is considered invalid and is ignored.

The FA secure communication setting (enabled/disabled) and the symmetric key data are maintained across resets and restored during FA initialization.

## Fabric Attach and Switched UNI

With the C-VLAN UNI feature, I-SID-to-VLAN mappings must be unique across the network. With the Transparent Port UNI (ELAN Transparent) feature, you can map an entire port or MLT to an I-SID.

With the Switched UNI feature, you can associate many different C-VID/port or C-VID/MLT list combinations to a single I-SID.

### *Switched UNI and FA*

FA brings the capability of automatically creating Switched UNI I-SIDs on a switch, without manual intervention. The I-SIDs thus created are ELAN I-SIDs with endpoints of type Switched UNI, and are by default for Layer 2. MAC learning takes place and there is an any-to-any relationship. For Layer 3 participation, you must configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping.

#### **Note**

The number of Switched UNI I-SIDs created are different for different product families. For more information, see [VOSS Release Notes](#).

### *Limitations of FA-created Switched UNI I-SIDs*

- An FA-created Switched UNI I-SID is always ELAN.
- You cannot enable BPDU on an FA-created Switched UNI I-SID.
- The ELAN I-SIDs created are by default for Layer 2. For Layer 3 participation, you must manually configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping. You can configure the platform VLAN with the same VLAN ID as that of the C-VID, or use a different value.
- The Switched UNI (ELAN) I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or a T-UNI.
- You cannot change from one UNI type to another dynamically. The I-SID must be deleted and created with the new UNI type (Customer VLAN (C-VLAN), Transparent Port user-network-interface (T-UNI), ELAN).
- If the port is a member of an MLT, you must add the entire MLT to the C-VID.
- The port is always in the forwarding state.

- You cannot associate a port or MLT with more than one C-VID in the same I-SID.
- The same C-VID, port or MLT cannot be a member of more than one I-SID. Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported and cannot be configured. The value 4096 indicates that the port is untagged.
- An I-SID value of 0 is not supported on the FA Server.

## Fabric Attach Deployment Scenarios

Fabric Attach is typically deployed in the access layer(s) of a Fabric Connect network.

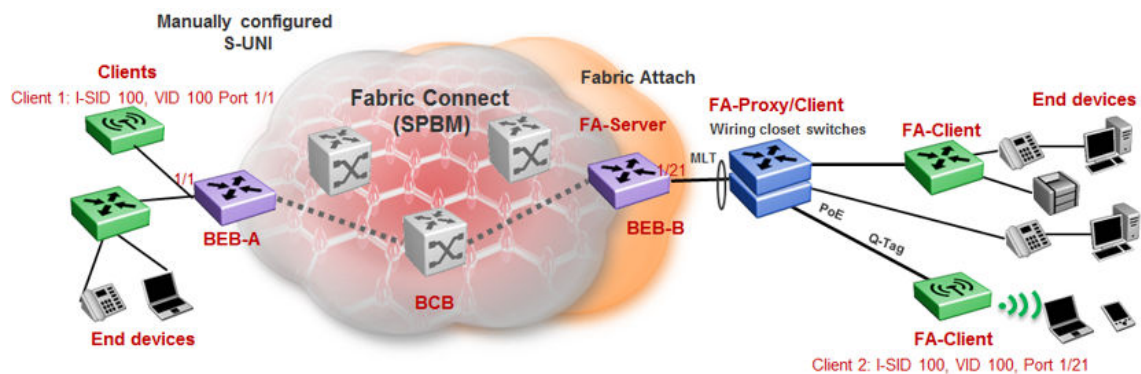

Fabric Attach, when used with a Fabric Connect solution, provides the same capabilities at the access layer, but those services and policies are mapped across the entire network end-to-end. FA makes user and end device attachment simple and creates network configuration and sets up resources only when needed.

An FA Server can be connected to FA Client or FA Proxy devices on three types of interfaces, namely, a port, MLT or an SMLT. The following sections discuss FA in SMLT and non-SMLT deployments.

### *FA and Switched UNI in non-SMLT deployments*

The following deployment shows an SPBM network in which one edge has manually configured Switched UNI I-SIDs and the other edge has Fabric Attach (FA). At the FA edge, the I-SIDs are learned using FA TLVs and are automatically created on the FA Server as ELAN I-SIDs with Switched UNI endpoints.

This deployment demonstrates that the FA-created I-SIDs can communicate with any other I-SID (manually created Switched UNI or a C-VLAN with an I-SID), on the local switch or across the SPBM fabric, as long as the I-SID values are the same.

BEB-B is a switch acting as the FA Server with a network-to-network interface (NNI) to the SPBM cloud. FA Client and FA Proxy devices send I-SID-to-VLAN mapping requests to the FA Server on the respective FA-enabled ports, using LLDP TLVs. This enables the I-SID endpoints to communicate with the SPB cloud.

If several clients are aggregated in an MLT, at least one of the ports must send the mapping requests for the FA Server to create the I-SID endpoints for that MLT. For example, let Client 2 be a wireless FA Client (such as a WLAN 9100 AP device) on port 1/21, that sends an FA mapping request for I-SID 100 and C-VID (VLAN ID) 100. The FA

Server (BEB-B) creates the requested I-SID 100 on its device, and advertises it to the SPB cloud.

BEB-A has manually configured Switched UNI endpoints, one of which is Client 1 (connected at port 1/1) using the same I-SID value 100.

With this setup, data traffic can freely flow between Client 1 and Client 2 through the two BEBs and the BCB.

Thus the Switched UNI I-SIDs learned using FA TLVs on one edge of the Fabric Connect (SPBM) network can communicate with the manually created I-SIDs on the other edge, as long as they both have the same value.

#### *FA and Switched UNI in SMLT deployments*

The following examples discuss FA in dual-homed and single-homed SMLT deployments.

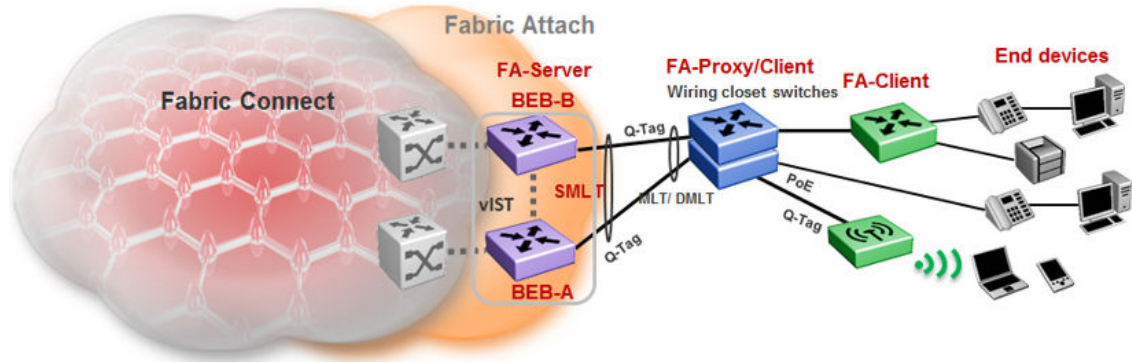

#### **Fabric Attach in a dual-homed SMLT deployment**

The following section describes FA in a dual-homed SMLT deployment. A pair of switches that operate as IST peers act as the FA Server. An FA Proxy (typically a wiring closet switch or an access switch) is connected to FA Clients and in turn to end devices. The FA Clients or FA Proxies advertise I-SID-to-VLAN mappings namely the interface C-VID and the I-SID to the FA Server switches. Both switches receive the mapping information using LLDP TLVs. The switch that learns the mapping first from the LLDP TLV considers the I-SID endpoint to be discovered locally, and creates the I-SID on its device. It then sends the mapping information to its peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID and endpoint on its device. This I-SID however, is considered to be discovered remotely, because the data was synchronized from its peer.

#### **Note**

- For the peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration must be the same on both peers.
- For successful FA operation, configuration of FA message authentication and the authentication key must be the same on both peers.
- For successful operation in Layer 3, a platform VLAN must be configured on both peers. This is necessary for proper MAC learning.

**Figure 89: FA in a dual-homed SMLT deployment**

In the above example deployment, BEB-A and BEB-B are IST peers collectively acting as the FA Server. FA TLVs sent from the clients (through the proxy) are learned on FA-enabled ports on BEB-A and BEB-B. When BEB-A learns the mapping for the first time on its port, it creates an I-SID on its device. This is considered locally discovered. In addition, it sends an SMLT message to its peer BEB-B, which also creates the I-SID on its device. This time, the I-SID is considered remotely discovered. Similarly, if BEB-B receives a mapping from a client for the first time, it creates an I-SID (locally discovered) and also sends an IST message to its peer to create an I-SID (remotely discovered).

Irrespective of whether the I-SID creation on the FA peers is triggered by a local TLV event or by messaging from the IST peer, they can both receive data traffic. Thus in a dual-homed SMLT deployment, any I-SID can be learned irrespective of whether it is discovered locally, discovered remotely or both.

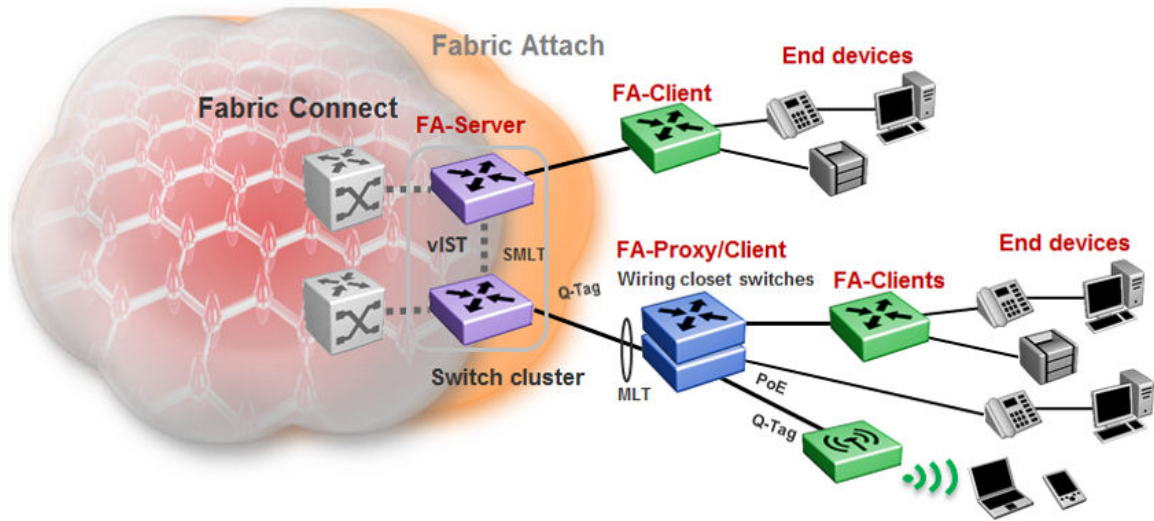

**Note**

On the IST peers, if an FA TLV is learned on a port or normal MLT (instead of the admin SMLT), only the I-SID is sent to the peer switch.

**Fabric Attach in a single-homed SMLT deployment**

In the single-homed SMLT, as shown in the following deployment, the FA Server creates either a locally discovered I-SID (if received from a client using FA TLVs) or a remotely discovered I-SID (if synchronized from its IST peer), but not both.

**Figure 90: Fabric Attach in a single-homed SMLT deployment**

## Fabric Attach Considerations

Review the following restrictions, limitations, and behavioral characteristics for Fabric Attach.

- IS-IS and FA must be globally enabled on the FA Server, for FA to operate successfully.
- Static MAC, Static ARP and configuration of a static IGMP group are not supported on FA-enabled ports.
- An FA port cannot be a BROUTER port.
- You cannot enable FA on an existing Transparent Port UNI or a C-VLAN UNI port.
- On VSP 8600 Series, you cannot enable FA on an existing Switched UNI.
- FA I-SID-to-VLAN assignment mapping requests from a client or proxy device can be accepted or rejected by the FA Server.
- On an FA-enabled port or MLT, you must first disable LACP before you change the LACP key.
- You can only enable VLACP on an FA enabled MLT; VLACP is not supported on FA enabled non-MLT ports.
- On VLACP enabled ports, FA and LLDP signaling run independent of the VLACP state. Therefore, requests and responses are exchanged between the FA Server and client or proxy devices even if VLACP is operationally down. However, forwarding of data traffic is dependent on VLACP being operationally up on the port.

For example, if VLACP is enabled on the FA Server side of the link but not on the proxy or the client side, the FA Server learns the I-SID-to-VLAN assignment mappings and creates the required I-SIDs on its device. However, data traffic is not forwarded on the port until VLACP is operationally up.

- On VSP 4450 Series, you cannot use a port designated as a Fabric Extend tunnel source, configured using the command `ip-tunnel-source-address`, for Fabric Attach.

- FA uses the virtual MAC to create the FA system ID when the FA is on an SMLT. If you delete the SPBM instance, then this information is no longer available. Therefore, you must delete the FA on SMLT before deleting the SPBM instance.
- You cannot enable FA and Endpoint Tracking simultaneously on the same interface.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN:ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

## Fabric Attach Configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using the Command Line Interface (CLI). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using CLI](#) on page 2400.

### *Configure Fabric Attach Globally*

For proper operation, FA must be enabled at both the global level and at the interface level on the FA Server. By default, FA is globally enabled. However, FA is disabled by default at the interface level and must be explicitly enabled on each interface.

Use this procedure to enable Fabric Attach globally on a switch.

#### **Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable FA:

```
fa enable
```

3. (Optional) Disable FA:

```
no fa enable
```

#### **Caution**

Disabling FA flushes all FA element discovery and mappings.

4. View the FA configuration status. Use one of the following commands:

- show fa
- show fa agent

#### **Example**

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa enable
```

```
Switch:1>show fa
```

```
=====
```

```

```

### Configuring Fabric Attach discovery timeout

Use this procedure to configure the Fabric Attach discovery time-out.

#### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Configure the FA discovery time-out in seconds:  
fa discovery-timeout <45-480>

#### Note

The discovery time-out must be greater than or equal to the assignment time-out.

3. (Optional) Configure the default FA discovery time-out:  
default fa discovery-timeout

#### Example

Configure the FA discovery time-out.

```

Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa discovery-timeout 50

```

Verify the configuration.

```

Switch:1(config)#show fa
=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 45
FA Discovery Timeout : 50
FA Provision Mode : spbm

```

## Variable definitions

The following table defines parameters for the **fa discovery-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach discovery time-out in seconds. The default value is 240 seconds.

## Configuring Fabric Attach assignment timeout

Use this procedure to configure the Fabric Attach assignment time-out.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the FA assignment time-out in seconds:  

```
fa assignment-timeout <45-480>
```

### Note

The assignment time-out must be less than or equal to the discovery time-out.

3. (Optional) Configure the default FA assignment time-out value:  

```
default fa assignment-timeout
```

### Example

Configure the FA assignment time-out:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa assignment-timeout 50
```

Verify the configuration:

```
Switch:1(config)#show fa

=====
                          Fabric Attach Configuration
=====

                          FA Service : enabled
                          FA Element Type : server
                          FA Assignment Timeout : 50
                          FA Discovery Timeout : 240
                          FA Provision Mode : spbm
```

## Variable definitions

The following table defines parameters for the **fa assignment-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach assignment time-out in seconds. The default value is 240 seconds.

### Enabling Fabric Attach on an interface

Use this procedure to enable Fabric Attach on an interface (port, static MLT or LACP MLT). Enabling FA on an MLT enables FA on all ports of the MLT. If your platform supports channelization, FA can also be enabled on channelized ports.

#### Before You Begin

Verify that FA is enabled globally on the switch.

#### About This Task

Enabling FA on a port or MLT is necessary for element discovery.

On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on the desired port or MLT interface. FA is successfully enabled on an MLT only if all ports of the MLT have FA successfully enabled. Enabling FA automatically configures LLDP on all ports. Tagging is configured and spanning tree is disabled.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable FA on the interface:

```
fa enable
```

3. (Optional) Disable FA on the interface:

```
no fa enable
```

#### Caution

Disabling FA flushes all FA element discovery and I-SID-to-VLAN mappings associated with the interface.

#### 4. View the FA configuration status:

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port
<{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}>]
```

#### Example

##### Enable FA on a port:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#exit
Switch:1(config)#
```

##### Enable FA on an MLT:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#
```

Verify that FA is enabled on the interfaces.

#### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

```
Switch:1>show fa interface

### Variable definitions

The following table defines parameters for the **show fa interface** command.

Variable	Value
disabled-auth	Displays the FA interfaces (port or MLT) that have authentication disabled.
enabled-auth	Displays the FA interfaces (port or MLT) that have authentication enabled.
<1-512>	The valid range for MLT ID. Displays FA configuration on the specified MLT interface.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays FA configuration on the specified port.

### Configuring FA message authentication on an interface

Use this procedure to configure FA message authentication on an interface (port or MLT).

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} Or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure FA message authentication on a port or MLT:

```
[default] [no] fa message-authentication
```

### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and displays encrypted on the output.

## Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#
```

Enable message authentication on a port.

```
Switch:1(config)#interface gigabitEthernet 1/2

Switch:1(config-if)#fa message-authentication
Switch:1(config-if)#show fa interface port 1/2

=====
                          Fabric Attach Interfaces

```

### Configuring the FA authentication key on an interface

On the FA Server, you can configure an authentication key on an interface (port, static MLT or LACP MLT), to authenticate a client or proxy device on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server.

#### Before You Begin

Ensure that:

- On the FA Server, FA is enabled globally and also on the interface.
- FA message authentication is enabled on the interface.

#### Note

By default, enabling FA enables message authentication. The authentication key is set to the default value and the system displays the encrypted authentication key on the output.

#### About This Task

Use this procedure to configure an FA authentication key on a specified port or on all ports of an MLT, on the switch. If you do not configure an authentication key, the

default value is used. If you specify a key, the default value is overridden and is stored in encrypted format in a separate file other than the configuration file, when you execute the `save config` command.

### Caution

For an FA Client or an FA Proxy device to successfully authenticate and attach to the FA Server, the authentication key must match on both the client and the server. If the authentication key is changed on the FA Server switch, it must correspondingly be changed on the FA Client or Proxy attached to it, for FA to operate properly.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} Or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the FA authentication key:

```
fa authentication-key WORD<0-32>
```

3. (Optional) Configure the default FA authentication key:

```
default fa authentication-key
```

## Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
```

Enable FA and message authentication on a port. Configure the authentication key `phone-network` on the port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key phone-network
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA and message authentication on an MLT. Configure the authentication key `client-network` on the MLT.

```
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key client-network
```

Verify configuration of the FA authentication key. The system displays the encrypted authentication key on the output.

```
Switch:1(config-if)#show fa interface

```

### Variable Definitions

The following table defines parameters for the **fa authentication-key** command.

Variable	Value
WORD<0-32>	Specifies the authentication key on the port or MLT.

### Configure FA Management on a Port or MLT

Use this procedure to configure a management I-SID on a Fabric Attach (FA)-enabled port or MLT.

To configure an FA management I-SID for Auto-sense-enabled ports, see [Configure a Management I-SID for Auto-sense Fabric Attach Proxy Switches](#) on page 38.

### Before You Begin

Ensure that the port or MLT is enabled for FA.

### About This Task

This command applies to all traffic sent or received on a port or MLT, carrying the VLAN ID specified using the *c-vid* parameter. This parameter is optional.

Depending on whether the *c-vid* parameter is specified or not, the behavior is as follows:

- If you specify the *c-vid* parameter, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN-ID for management traffic on the FA Server uplink.
- If you do not specify the *c-vid* parameter, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses untagged traffic for network management on the FA Server uplink.

An FA management I-SID can have a platform VLAN associated with it. For Layer 3 support on the management I-SID, you must create a platform VLAN by port and

associate the platform VLAN with the management I-SID. The C-VID can be of the same value or of a different value than that of the platform VLAN.

If the management I-SID matches one of the FA Switched UNI (ELAN) I-SIDs (as displayed by the command `show i-sid elan`), then the platform VLAN is automatically associated with the FA-enabled interface (port or MLT).

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} Or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the FA management I-SID:

```
fa management i-sid <i-sid><c-vid>
```

### Important

If you do not specify a C-VID value, the port or MLT is untagged.

3. Verify configuration of FA management on the port or MLT, using the following commands:

- `show i-sid <i-sid>`
- `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show mlt i-sid [<1-512>]`

## Examples

Configure FA management on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa management i-sid 101 c-vid 101

Switch:1(config-if)#show i-sid 101

## Variable Definitions

The following table defines parameters for the **fa management** command.

Variable	Value
<code>i-sid &lt;i-sid&gt;</code>	Specifies the management I-SID. Different hardware platforms support different customer I-SID ranges. To see the available range for the switch, use the CLI Help.
<code>&lt;c-vid&gt;</code>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.  <b>Important:</b> If you do not specify a C-VID value, the port or MLT is <b>untagged</b> .

## View Fabric Attach Global Configuration Status

Use this procedure to display the Fabric Attach global configuration status on a switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the FA configuration status using one of the following commands:

- `show fa`
- `show fa agent`

### Example

Sample output for the **show fa** command:

```
Switch:1>show fa

=====
                        Fabric Attach Configuration
=====
                        FA Service : enabled
                        FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
                        FA Provision Mode : spbm
```

Sample output for the **show fa agent** command:

```
Switch:1>show fa agent

=====
                        Fabric Attach Configuration
=====
                        FA Service : enabled
                        FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
                        FA Provision Mode : spbm
```

### Viewing Fabric Attach interface configuration

Use this procedure to view FA interface configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View all FA interfaces (ports and MLTs):  
`show fa interface`
3. To view FA interface configuration on ports, use one of the following commands:

- View FA configuration on all ports:

```
show fa interface port
```

- View FA configuration on a specific port, enter:

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

4. To view FA interface configuration on MLTs, use one of the following commands:

- View FA configuration on all MLTs:

```
show fa interface mlt
```

- View FA configuration on a specific MLT:

```
show fa interface mlt [<1-512>]
```

### Example

The following example displays sample outputs for the **show fa interface** command.

```
Switch:1>show fa interface

## Variable definitions

The following table defines parameters for the `show fa interface port` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the `show fa interface mlt` command.

Variable	Value
<code>&lt;1-512&gt;</code>	The valid range for MLT ID.

## Viewing Fabric Attach Discovered Elements

Use this procedure to view Fabric Attach discovered elements.

### About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or FA Proxies. Standard LLDPs allow neighbors to be learned. With the help of organizational-specific element discovery TLVs, the client or proxy recognizes that it has attached to the FA Server. Only after the discovery handshake is complete, an FA Client or FA Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric network through the FA Server.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display FA discovered elements:  
`show fa elements`
3. Display FA discovered elements on a specific port:  
`show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

### Example

The following example displays the sample output for the `show fa elements` command.

```
Switch:1#show fa elements
=====
Fabric Attach Discovery Elements
=====
PORT      TYPE          MGMT          ELEM ASGN
          VLAN STATE   SYSTEM ID    AUTH AUTH

```

### Variable definitions

The following table defines parameters for the **show fa elements** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Viewing Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to display the I-SID-to-VLAN assignments advertised by an FA Client or an FA Proxy, to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. An assignment that is successfully accepted by the FA Server results in the creation of a Switched UNI I-SID on the interface.

#### Before You Begin

Verify that IS-IS and SPBM are properly configured on the FA Server switch.

- Verify SPBM configuration using the command **show running-config module spbm**.
- Verify IS-IS configuration using one of the following commands:
  - **show isis**
  - **show isis interface**
  - **show isis adjacency**
  - **show isis lsdb**

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display FA I-SID-to-VLAN assignments:  
show fa assignment
3. Display FA I-SID-to-VLAN assignments on specific ports:  
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]]

## Example

The following example displays a sample output for the `show fa assignment` command.

### Note

The state of I-SID-to-VLAN assignments on a client or proxy device is pending until it is changed by the FA Server to `active` or `reject`.

```
Switch:>en
Switch:1#show fa assignment
=====
                          Fabric Attach Assignment Map
=====
Interface  I-SID      Vlan      State      Origin
-----
1/1        2          2         active     proxy
1/2        3          3         active     proxy
1/2        4          4         active     proxy
1/3        5          5         reject     proxy
-----

4 out of 4 Total Num of fabric attach assignment mappings displayed
-----
```

## Variable definitions

The following table defines parameters for the `show fa assignment` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing Fabric Attach Statistics

If FA discovery fails, use this procedure to display FA statistics to determine if FA discovery TLVs were processed. You can also view the FA assignment statistics to determine the number of FA assignments that were accepted or rejected by the FA Server.

You can view the statistics at either the global level or at the port (interface) level.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View global level FA statistics:

```
show fa statistics [summary]
```

3. View FA statistics at the slot/port level:

```
show fa statistics [{slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]]
```

### Note

If a slot is removed from the switch chassis, the FA statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

4. (Optional) Clear FA statistics:

```
clear fa statistics [summary] [{slot/port[/sub-port]} [-slot/port[/sub-
port]] [,...]]
```

### Examples

Viewing FA discovery and assignment statistics:

```
Switch:1>en
Switch:1#show fa statistics

1/2      0      0      0      0      0      0

```

## Variable Definitions

The following table defines parameters for the **show fa statistics** command.

Variable	Value
summary	Displays a summary of Fabric Attach element discovery and assignment statistics at the global level.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Display Learned LLDP Neighbors

Use this procedure to verify details of the LLDP neighbors learned.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Verify details of LLDP neighbors learned:  
show lldp neighbor
3. Verify details of LLDP neighbors learned on a specific port:  
show lldp neighbor port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}

### Example

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors.

Switch A, which is the FA Server is a VSP 7200 Series switch (model 7254XSQ) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples show neighbor discovery on non-channelized ports.

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

```
Switch:1>enable
Switch:1#show lldp neighbor
```

```
=====
                          LLDP Neighbor

```

### Variable Definitions

The following table defines parameters for the **show lldp neighbor** command.

Variable	Value
port {slot/ port[/sub-port] [-slot/port[/ sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays LLDP neighbor information on the specified port.

### Display Switched UNI (ELAN) I-SID Information

Use this procedure to display information on FA-created Switched UNI (ELAN) I-SIDs.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display all Switched UNI (ELAN) I-SIDs:  
show i-sid elan
3. Display ELAN I-SID information on an MLT:  
show mlt i-sid [<1-512>]

#### Note

Viewing ELAN I-SID information on an MLT is useful to understand the origin of the I-SID when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

## 4. Display ELAN I-SID information on ports:

```
show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

**Examples**

Display information on all Switched UNI (ELAN) I-SIDs.

The following sample output displays, for example, the I-SID information on one of the peer switches of the FA Server, in a dual-homed SMLT configuration.

```
Switch:1>enable
Switch:1#show i-sid elan

### Variable Definitions

The following table defines parameters for the `show i-sid` command.

Variable	Value
elan	Displays all ELAN I-SIDs.

The following table defines parameters for the `show mlt i-sid` command.

Variable	Value
<1-512>	The valid range for MLT ID.

The following table defines parameters for the **show interfaces gigabitEthernet i-sid** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Enabling or disabling FA Zero Touch Client Attachment

Use this procedure to enable or disable the global FA Zero Touch Client Attachment feature on an FA Proxy or Server. By default, FA Zero Touch Client Attachment support is enabled.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable an FA Zero Touch client:

```
fa zero-touch-client
```

```
standard <camera|ona-sdn|ona-spb-over-ip|phone|router|security-device|  
srvr-endpt|switch|video|virtual-switch|wap-type1|wap-type2> i-sid <1-  
15999999>
```

3. Disable an FA Zero Touch client:

```
no fa zero-touch-client
```

```
standard <camera|ona-sdn|ona-spb-over-ip|phone|router|security-device|  
srvr-endpt|switch|video|virtual-switch|wap-type1|wap-type2>
```

#### Example

```
Switch:1(config)# fa zero-touch-client standard camera i-sid 1003  
Switch:1(config)# no fa zero-touch-client standard camera
```

### Variable definitions

The following table defines parameters for the **fa zero-touch-client standard** command.

Variable	Value
<code>camera</code>	Specify element type to match camera.
<code>ona-sdn</code>	Specify element type to match ona-sdn.
<code>ona-spb-over-ip</code>	Specify element type to match ona-spb-over-ip.
<code>phone</code>	Specify element type to match phone.

Variable	Value
<code>router</code>	Specify element type to match router.
<code>security-device</code>	Specify element type to match security-device.
<code>svr-endpt</code>	Specify element type to match svr-endpt.
<code>switch</code>	Specify element type to match switch.
<code>video</code>	Specify element type to match video.
<code>virtual-switch</code>	Specify element type to match virtual-switch.
<code>wap-type1</code>	Specify element type to match wap-type1.
<code>wap-type2</code>	Specify element type to match wap-type2.

### Displaying FA Zero Touch Client Attachment

Use this procedure to display the Zero Touch Client Attachment data you have configured on an FA Server.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display Zero Touch Client Attachment data:  
`show fa zero-touch-client`

#### Example

The following example displays sample output for the **show fa zero-touch-client** command.

```
Switch:1#show fa zero-touch-client
=====
Fabric Attach Zero Touch Client
=====
Type      Description      I-SID      VLAN      I-SID Name

```

## Fabric Attach configuration using the EDM

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using Enterprise Device Manager (EDM). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using EDM](#) on page 2425.

*Configure Fabric Attach Globally*

Use this procedure to configure FA globally or view existing FA global configuration.

**Procedure**

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.
3. Click the **Globals** tab.
4. To enable or disable the Fabric Attach service, click **enabled** or **disabled** in the **Service** field.

**Caution**

Disabling FA flushes all FA element discovery and mappings.

5. View the element type in the **ElementType** field.

**Note**

The only supported element type is **faServer** (FA Server).

6. To specify the assignment time-out, enter a time-out value in seconds in the **AsgnTimeout** field.
7. View the provision mode in the **ProvisionMode** field.

**Note**

The supported provision mode is **spbm**.

8. To specify the discovery time-out, enter a time-out value in seconds in the **DiscTimeout** field.
9. To clear the FA statistics, select the **Clear FA Statistics** checkbox.
10. To clear the error counters, select the check boxes **ClearErrorCounters** and/or **ClearGlobalErrorCounters**.
11. Click **Apply**.

**Fabric Attach Globals Field Descriptions**

Use the data in the following table to use the **Fabric Attach Globals** tab.

Name	Description
<b>Service</b>	Enables or disables Fabric Attach service globally. The default is enable.
<b>ElementType</b>	Specifies the Fabric Attach element type. The supported element type is Fabric Attach Server.
<b>AsgnTimeout</b>	Specifies the Fabric Attach assignment time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.
<b>ProvisionMode</b>	Specifies the Fabric Attach provision mode. The supported provision mode is SPB.
<b>DiscTimeout</b>	Specifies the Fabric Attach discovery time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.

Name	Description
<b>Clear FA Statistics</b>	Clears Fabric Attach statistics.
<b>ClearGlobalErrorCounters</b>	Clears Fabric Attach global error counters. Disabled by default.

### Configure Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to view or configure FA I-SID-to-VLAN assignment information.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.
3. Click the **Assignment** tab.
4. If you make configuration changes, click **Apply** to save changes.

### Assignments Field Descriptions

Use the data in the following table to use the **Assignments** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface identifier of the I-SID-to-VLAN assignment.
<b>Isid</b>	Specifies the I-SID value of the I-SID-to-VLAN assignment.
<b>Vlan</b>	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.
<b>State</b>	Specifies the current state of the I-SID-to-VLAN assignment. It can be one of the following values: <ul style="list-style-type: none"> <li>• Other</li> <li>• Pending</li> <li>• Active</li> <li>• Rejected</li> </ul>
<b>Origin</b>	Specifies the origin information of the I-SID-to-VLAN assignment.
<b>Isid name</b>	Specifies the I-SID name.

### Configure Fabric Attach Interface-level Settings

Use this procedure to configure FA interface-level settings or view existing interface-level settings.

You can enable Fabric Attach on a port, static MLT or an LACP MLT. Enabling FA on a port not only enables tagging but also disables spanning tree on that port. Enabling FA on an MLT enables FA on all ports of the MLT. When FA is enabled on ports in an MLT or LACP MLT, tagging is enabled and spanning tree is disabled on all those ports.

#### Before You Begin

Ensure that FA is enabled globally on the switch.

## About This Task

Enabling FA on a port or MLT is necessary for element discovery. On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface, following which the FA Server can begin transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices, on that port or MLT.

## Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.
3. Click the **Ports** tab.

The FA interface-level settings are displayed.

4. To modify existing settings, double-click on the fields on this window. After making the required changes, click **Apply** to save your changes.
5. To configure FA on a new port or MLT interface:
  - a. Click **Insert**.

The **Insert Ports** dialog box opens.

- b. To configure FA on a port, enter a port number in the format slot/port[/sub-port], or click **Port** to select from a list of available ports.
- c. To configure FA on an MLT, enter an MLT ID or click **Mlt** to select from a list of configured MLTs.

### Note

FA is successfully enabled on the MLT, only if all ports of the MLT have FA successfully enabled. Enabling FA enables LLDP on all ports. Tagging is enabled and spanning tree is disabled.

- d. Click **Insert** to save your changes.
6. To remove (delete) FA on a port or MLT:
    - a. In the content pane, select a port or MLT from the list.
    - b. Click **Delete**.

### Caution

Removing FA on an interface flushes all FA element discovery and I-SID-to-VLAN mappings associated with that interface.

## Ports Field Descriptions

Use the data in the following table to use the **Ports** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface (port or MLT) on which Fabric Attach is configured.
<b>State</b>	Specifies the current state of the Fabric Attach port. It is either enabled or disabled. This field indicates whether LLDP PDUs (that include FA TLVs) are generated on the port (enabled) or not (disabled).
<b>MsgAuthStatus</b>	Specifies the Fabric Attach message authentication status on the port. It is either enabled or disabled.
<b>MsgAuthKey</b>	Specifies the Fabric Attach message authentication key for the associated port. The maximum length of this key is 32 characters.
<b>MgmtIsid</b>	Specifies the Fabric Attach management I-SID for the associated port. The range is 0 to 16777215. A zero value indicates that the management I-SID is not specified for the interface.
<b>MgmtCvid</b>	Specifies the Fabric Attach management customer VLAN ID (C-VID) for the interface. A zero value indicates that no C-VID is specified for the interface. Using the maximum configuration value for your switch indicates the port is untagged. Platform support determines the C-VID range.
<b>Origin</b> <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the origin of Fabric Attach port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

### Viewing Fabric Attach discovered elements

Use this procedure to view discovered Fabric Attach elements.

#### About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or Proxies. Standard LLDPs allow neighbors to be learned. In addition, organizational specific element discovery TLVs allow the Client or Proxy to recognize that it has attached to an FA Server. Only after the discovery handshake is complete, an FA Client or Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric through the FA Server.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.

3. In the content pane, click the **Elements** tab.

### Elements field descriptions

Use the data in the following table to use the **Elements** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface (port or MLT) at which the Fabric Attach element was discovered.
<b>ElementType</b>	Specifies the element type of the discovered Fabric Attach element, as advertised using LLDP. The supported element type is the Fabric Attach Server.
<b>ElementVlan</b>	Specifies the VLAN ID of the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementId</b>	Specifies the system ID of the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementState</b>	Specifies the state flag data associated with the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementOperAuthStatus</b>	Specifies the authentication status of the discovered Fabric Attach element.
<b>ElementAsgnsOperAuthStatus</b>	Specifies the authentication status of remote assignments.
<b>ElementAuth</b>	Specifies the discovered element authentication status.
<b>AsgnsAuth</b>	Specifies the assignment authentication status.

### Viewing FA statistics

Use this procedure to view FA statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Stats** tab.

### Stats field descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
<b>PortIndex</b>	Specifies the port for which the FA statistics are displayed.
<b>DiscElemReceived</b>	Specifies the number of element discoveries received on the port.
<b>AsgnReceived</b>	Specifies the number of remote assignments received on the port.
<b>AsgnAccepted</b>	Specifies the number of remote assignments accepted on the port.

Name	Description
<b>AsgnRejected</b>	Specifies the number of remote assignments rejected on the port.
<b>AsgnExpired</b>	Specifies the number of remote assignments that have expired, on the port.
<b>AuthFailed</b>	Specifies the number of authentications that have failed on the port.
<b>DiscElemExpired</b>	Specifies the number of discovery elements that have expired on the port.
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that are deleted on the port.
<b>AsgnDeleted</b>	Specifies the number of remote assignments deleted on the port.
<b>AsgnAuthFailed</b>	Specifies the number of remote assignment authentications that failed on the port.

### View Global FA Statistics Graphically

Use this procedure to view the global FA statistics graphically.

#### Procedure

1. In the navigation pane, expand **Configuration > Graph**.
2. Click **Chassis**.
3. Click the **Fabric Attach** tab.
4. To view a graphical representation of the statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
5. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
6. Click **Export**, to export the statistical data to a file.
7. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

### Fabric Attach field descriptions

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
<b>DiscElemReceived</b>	Specifies the number of discovery elements received globally.
<b>AsgnReceived</b>	Specifies the number of remote I-SID-to-VLAN assignments received globally.
<b>AsgnAccepted</b>	Specifies the number of remote I-SID-to-VLAN assignments accepted globally.
<b>AsgnRejected</b>	Specifies the number of remote I-SID-to-VLAN assignments rejected globally.

Name	Description
<b>AsgnExpired</b>	Specifies the number of remote I-SID-to-VLAN assignments that expired globally.
<b>AuthFailed</b>	Specifies the number of authentications that failed globally.
<b>DiscAuthFailed</b>	Specifies the number of discovery authentications that failed globally.
<b>DiscElemExpired</b>	Specifies the number of discovery elements that expired globally.
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that were deleted globally.
<b>AsgnDeleted</b>	Specifies the number of remote assignments that were deleted globally.

### View FA Port Statistics Graphically

Use this procedure to view the FA port statistics graphically.

#### Before You Begin

Ensure that a switch port is selected in the **Device Physical View** tab.

#### Procedure

1. In the navigation pane, expand **Graph > Port**.
2. Click the **Fabric Attach** tab.  
The FA port statistics are displayed.
3. To view a graphical representation of the port statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
5. Click **Export**, to export the statistical data to a file.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

#### Fabric Attach Field Descriptions

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
<b>DiscElemReceived</b>	Specifies the number of discovery elements received on a given port.
<b>AsgnReceived</b>	Specifies the number of remote I-SID-to-VLAN assignments received on a given port.
<b>AsgnAccepted</b>	Specifies the number of remote I-SID-to-VLAN assignments accepted on a given port.
<b>AsgnRejected</b>	Specifies the number of remote I-SID-to-VLAN assignments rejected on a given port.

Name	Description
<b>AsgnExpired</b>	Specifies the number of remote I-SID-to-VLAN assignments that expired on a given port.
<b>AuthFailed</b>	Indicates the number of received TLVs for which authentication was attempted and failed on the identified port.
<b>DiscElemExpired</b>	Specifies the number of discovery elements that expired on a given port.
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that were deleted on a given port.
<b>AsgnDeleted</b>	Specifies the number of remote assignments that were deleted on a given port.
<b>AsgnAuthFailed</b>	Specifies the number of remote assignment authentications that failed on a given port.

### *Inserting a Zero Touch Client*

Use this procedure to insert a FA Zero Touch Client.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Fabric**.
2. Click **Fabric Attach**.
3. Click the **Zero Touch Client Auto Attach** tab.
4. Click **Insert**.  
The **Insert Zero Touch Client** dialog box opens.
5. In the **Type** field click the ellipsis and select a client. Click **Ok** to select the client or **Refresh** to update the list.
6. In the **Isid** field enter the I-SID value.  
The I-SID value is between 0 and 16777214.
7. Click **Insert**.

### *Configure FA Zero Touch Client Auto Attach*

Use this procedure to configure FA Zero Touch Client auto attach.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **Fabric Attach**
3. Select the **Zero Touch Client Auto Attach** tab.  
From the Zero Touch Client Auto Attach tab you can configure a number of auto attach settings.
4. Select **Insert**.
5. In the **Type** field, select the ellipsis and select a client.
6. Select **Ok** to select the client or **Refresh** to update the list.
7. In the **Isid** field enter the I-SID value.

8. Select **Insert**.
9. (Optional) To **Delete** a FA Zero Touch client select it from the auto attach table and select **Delete**.

### Zero Touch Client Auto Attach Field Descriptions

Use the data in the following table to use the **Zero Touch Client Auto Attach** tab

Field	Description
<b>Type</b>	This column describes the type of client assigned to auto attach. Available FA client types are: <ul style="list-style-type: none"> <li>• Wireless AP (Type 1)</li> <li>• Wireless AP (Type 2)</li> <li>• Switch</li> <li>• Router</li> <li>• IP Phone</li> <li>• IP Camera</li> <li>• IP Video</li> <li>• Security Device</li> <li>• Virtual Switch</li> <li>• Server Endpoint</li> <li>• ONA (SDN)</li> <li>• ONA (spb0IP)</li> </ul>
<b>Vlan</b>	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.
<b>Isid</b>	Specifies the I-SID value of the I-SID-to-VLAN assignment.

## Fabric Attach configuration examples

This section provides configuration examples to configure Fabric Attach.

### *Configure a Fabric Attach Solution*

The following section describes a simple configuration example to configure Fabric Attach (FA) at the edge of a Fabric Connect network. This is a typical deployment at its simplest level and is powerful because of its use in conjunction with a Fabric Connect core.

#### **About This Task**

Configuring FA primarily consists of configuring the FA Server. The FA Server in turn discovers neighboring FA component devices (like the FA Proxies and FA Clients) using FA TLVs within the LLDP PDUs.

In the following deployment, the switch at the edge of the Fabric Connect cloud is configured as the FA Server. On this switch, FA is enabled globally and at the interface (port) level. Another switch, functioning as the FA Proxy connects to the FA enabled port (1/3) on the FA Server. User A is an end user device that needs to send and receive data traffic from User B (another end user device) across the network.

### Before You Begin

Configure SPBM and IS-IS on the edge and core switches. For more information, see [Configure Minimum SPBM and IS-IS Parameters](#) on page 1047.

### Procedure

#### Configure the edge switch (BEB) as the FA Server:

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable FA globally:
 

```
fa enable
```
3. Enter port interface configuration mode:
 

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. Enable FA on the port:
 

```
fa enable
```

#### Note

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

#### Note

Enabling FA on a port not only enables tagging but also disables spanning tree on that port.

#### Verify global and interface level FA configuration:

5. Verify global configuration of FA using one of the following commands:

- show fa
- show fa agent

6. Verify interface level configuration of FA:

```
show fa interface
```

7. Verify the discovery of clients attaching to the FA Server:

```
show fa elements
```

8. Display the FA I-SID-to-VLAN assignments:

```
show fa assignment
```

To verify I-SID-to-VLAN assignments on a specific port, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

9. Verify creation of Switched UNI (ELAN) I-SIDs:

```
show i-sid elan
```

### Example

#### SPBM and IS-IS configuration on the core and edge switches:

SPBM configuration:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#spbm ethertype 0x8100
```

IS-IS SPBM configuration:

```
Switch:1(config)#router isis
Switch:1(config)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 1.00.01
Switch:1(config-isis)#spbm 1 b-vid 41-42 primary 41
Switch:1(config-isis)#spbm 1 ip enable
```

IS-IS router configuration:

```
Switch:1(config-isis)#router isis
Switch:1(config-isis)#sys-name BEB-Switch
Switch:1(config-isis)#ip-source-address 3.3.3.3
Switch:1(config-isis)#is-type 11
Switch:1(config-isis)#system-id 0001.0001.0001
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
```

Interface (port-level) configuration

```
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-isis)#exit
Switch(config)#vlan create 41 type spbm-vlan
Switch(config)#vlan create 42 type spbm-vlan
```

```
Switch(config)#router isis enable
Switch(config)#show isis spbm
```

### Configuration of the edge switch as the FA Server.

Enable FA globally.

```
Switch:1(config)#fa enable
Switch:1(config)#show fa

=====
                        Fabric Attach Configuration
=====
                        FA Service : enabled
                        FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

Enable FA on the port.

Enabling FA automatically enables message authentication. The authentication key is configured with the default value, which the system displays in encrypted format in the output.

```
Switch:1(config)#int gigabitEthernet 1/3
Switch:1(config-if)#fa enable
Switch:1(config-if)#show fa interface port 1/3

=====
                        Fabric Attach Interfaces
=====
INTERFACE      SERVER  MGMT   MGMT   MSG AUTH  MSG AUTH  ORIGIN
                STATUS ISID   CVID   STATUS    KEY
-----
Port1/3        enabled  0      0      enabled   ****

-----
1 out of 1 Total Num of fabric attach interfaces displayed
-----

Switch:1(config-if)#exit
Switch:1(config)#exit
```

Verify that the FA Proxy is discovered by the FA Server.

```
Switch:1(config)#show fa elements

=====
                        Fabric Attach Discovery Elements
=====
PORT   TYPE           MGMT          ELEM ASGN
      VLAN STATE  SYSTEM ID    AUTH AUTH
-----
1/3    proxy         2    T / S  10:cd:ae:09:40:00:20:00:00:01  AP   AP

-----
                        Fabric Attach Authentication Detail
=====

-----
44      2      Proxy           Active

```

### Configure Fabric Attach in an SMLT

The following example describes FA configuration and behavior in a dual-homed SMLT deployment.

The following figure shows a simple FA solution in a dual-homed SMLT deployment. In this deployment, a pair of BEB switches (BEB A and BEB B) operating as IST peers are configured as the FA Server. An access switch or a wiring closet switch configured as an FA Proxy connects to the FA Server. The FA Proxy advertises I-SID-to-VLAN assignment mappings to the FA Server. Both BEB switches receive the mapping information using LLDP PDUs containing assignment TLVs. The switch that learns the mapping first considers the I-SID to be discovered locally and creates the I-SID on its device. The mapping information is then shared with its IST peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID on its device. This I-SID however, is considered to be discovered remotely because it is learnt from synchronization with the peer switch. The mappings can also be learned on the FA Server from both LLDP PDUs and from IST synchronization.

**Figure 91: FA configuration in dual-homed SMLT**

#### Before You Begin

Ensure that the proxy device (for example, an access switch) is properly configured for FA. See the corresponding product documentation for information on how to configure FA on the switch.

#### Procedure

1. Configure SMLT and vIST on switches BEB A and BEB B.

#### Caution

For the IST peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration on both the switches must be the same.

For detailed information on configuring SMLT and vIST, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2571.

#### Configure BEB A and BEB B as the FA Server

Perform the following configuration on each switch.

2. Enter Global Configuration mode:  
enable  
  
configure terminal
3. Enable FA globally:  
fa enable
4. Enter MLT interface configuration mode:  
interface mlt <1-512>
5. Enable FA on the MLT:  
fa enable

**Note**

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and the system displays the encrypted authentication key on the output.

6. (Optional) Configure an FA authentication key with a value different from that of the default value:  
fa authentication-key [WORD<0-32>]

**Caution**

When you configure the FA authentication key, you must configure the same value on both BEB switches in the SMLT.

**Verify global and MLT-level FA configuration on BEB A and BEB B:**

7. Verify global configuration of FA using one of the following commands:
  - show fa
  - show fa agent
8. Verify MLT-level (interface-level) configuration of FA:  
show fa interface

**Verify FA discovery on BEB A and BEB B:**

9. Verify discovery of the FA Proxy.  
show fa elements

**View FA I-SID-to-VLAN assignments on BEB A and BEB B:**

10. View the FA I-SID-to-VLAN assignments:  
show fa assignment

To view FA I-SID-to-VLAN assignments on specific ports, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Verify creation of Switched UNI I-SIDs on BEB A and BEB B:**

## 11. Verify creation of Switched UNI (ELAN) I-SIDs:

- View ELAN I-SID information using `show i-sid elan`.
- View ELAN I-SID information on a specific MLT using `show mlt i-sid [<1-512>]`.

### Note

Viewing ELAN I-SID information on an MLT is very useful to understand the origin of the I-SID, when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

## Examples

### SMLT configuration on BEB A and BEB B:

#### On BEB A:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config)#smlt
```

#### On BEB B:

```
Switch:2>en
Switch:2#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:2(config)#interface mlt 1
Switch:2(config)#smlt
```

### vIST configuration on BEB A and BEB B:

#### On BEB A:

```
Switch:1(config)#vlan create 2261 type port-mstprstp 0
Switch:1(config)#vlan i-sid 2261 1502261
Switch:1(config)#interface vlan 2261
Switch:1(config)#ip address 192.0.2.0 255.255.255.0 2
```

#### Configure BEB B (IP address 192.0.2.1) as the IST peer.

```
Switch:1(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:1(config)#show virtual-ist
Switch:1(config)#exit
```

#### On BEB B:

```
Switch:2(config)#vlan create 2261 type port-mstprstp 0
Switch:2(config)#vlan i-sid 2261 1502261
Switch:2(config)#interface vlan 2261
Switch:2(config)#ip address 192.0.2.1 255.255.255.0 2
```

Configure BEB A (IP address 192.0.2.1) as the IST peer.

```
Switch:2(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:2(config)#show virtual-ist
Switch:2(config)#exit
```

### FA configuration on BEB A:

Enable FA globally and on the MLT:

```
Switch:1(config)#fa enable
Switch:1>show fa
```

```
=====
                          Fabric Attach Configuration
=====
                          FA Service : enabled
                          FA Element Type : server
                          FA Assignment Timeout : 240
                          FA Discovery Timeout : 240
                          FA Provision Mode : spbm
```

Optionally, configure an FA authentication key with the value dual-homed-smlt. Ensure that you configure the **same** value on both switches BEB A and BEB B.

```
Switch:1(config)#interface mlt 1
Switch:1(config-mlt)#fa authentication-key dual-homed-smlt
```

Enable FA on the MLT:

```
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#show fa interface
```

```

	VSP 8600 Series	Not Supported
XA1400 Series	Not Supported	

## Endpoint Tracking Overview

Endpoint Tracking provides dynamic assignment of virtual machines (VMs) to IP subnets as they attach to a Shortest Path Bridging (SPB) cloud. Deployment scenarios include VMs connecting to DvR Leaf nodes, or regular SPBM deployments.

ExtremeCloud IQ - Site Engine is integral to the Endpoint Tracking solution. ExtremeCloud IQ - Site Engine delivers automation; there is no need to manually configure server VLANs on data center access switches. Additionally, ExtremeCloud IQ - Site Engine) provides the ability to see what VM MACs exist, and where they are located.

ExtremeCloud IQ - Site Engine's ExtremeConnect module integrates with third-party virtualization software (such as VMware or Microsoft HyperV) and communicates with the ExtremeControl module to automatically extract all of the VM MACs (including VLAN assignment for each MAC) and then automatically create all of the necessary authentication profiles, rules and mappings.

When the switch detects a new VM on a port, it sends a RADIUS request to ExtremeCloud IQ - Site Engine. ExtremeConnect checks with VCenter for the Port Group, VLAN ID, and I-SID information that corresponds with the VM, communicates

with the ExtremeControl module for the RADIUS authentication, and sends the RADIUS response back to the switch with the VLAN:ISID binding information. Based on the binding, the switch then automatically creates a dynamic Switched UNI (S-UNI). Dynamic S-UNIs are not saved into the configuration file.

## Typical Endpoint Tracking Implementation Example

The following example shows a typical implementation of Endpoint Tracking and the dynamic I-SID assignment process, as provisioned in ExtremeCloud IQ - Site Engine.

**Figure 93: Endpoint Tracking Example**

The sequence within and among the four example VLANs in this configuration is as follows:

1. The RADIUS server authenticates VM1, and the switch automatically creates a Switched UNI with VLAN 10 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM2, which uses the same Switched UNI.
2. Similarly, on the other side of the SPB cloud, the RADIUS server authenticates VM5 and the switch automatically creates a Switched UNI with VLAN 30 and I-

- SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM6, which uses the same Switched UNI.
3. The same sequence occurs for VMs 3 and 4, and PCs 7 and 8, with the first authentication in each VLAN providing the outbound RADIUS attributes needed for the creation of a Switched UNI for that VLAN.
  4. The final result is that VMs 1, 2, 5, and 6 can access each other on I-SID 10, and VMs 3, 4, 7, and 8 can access each other on I-SID 20.

## Static S-UNIs and Visibility Mode

Endpoint Tracking can also be used in cases where static S-UNIs are configured on Endpoint Tracking-enabled ports. In this case, the MACs are allowed by default on the static S-UNI. However, by default, the MACs learned on a static S-UNI are not learned at the Endpoint Tracking level. Endpoint Tracking Visibility Mode allows tracking of MACs that are learned on static S-UNIs. This implies that a binding is created for these MACs, but these bindings do not create dynamic S-UNIs, they are used for tracking purposes only.

## Interface Support

Endpoint Tracking is supported on Ethernet ports, MLTs, and SMLTs.

If the switch is a Virtual IST (vIST) peer, the dynamic Switched UNI is synchronized to its vIST peer as follows:

- If the MAC is learned on an SMLT UNI interface, all Switched UNI information is synchronized to the vIST peer.
- If the MAC is learned on a non-SMLT UNI interface, only the I-SID is synchronized to the vIST peer.

## VM Moves and VLAN:ISID Bindings

When a VM moves to a new switch within a network (with no change to the VLAN segment), the new switch triggers a new RADIUS authentication, which points that VM MAC to the new switch, and new bindings are applied on the new switch. The old switch detects that the VM MAC is moved and automatically deletes the old binding, if the old binding has not already aged out.

However, if a VM remains attached to the same (previously authenticated) switch, but the VLAN segment is changed, you must push a reauthentication request from ExtremeCloud IQ - Site Engine to force the required binding updates. For more information about managing binding updates using RADIUS Change-of-Authorization (CoA) functionality, see [ExtremeCloud IQ - Site Engine Integration](#) on page 1294.

## Operational Considerations

Consider the following when implementing Endpoint Tracking:

- A RADIUS server used for Endpoint Tracking provides authorization only; no accounting processes are supported. Although accounting is enabled by default for

all RADIUS servers, it is not currently supported for use with Endpoint Tracking, even if left enabled.

- Fabric Attach is not supported on ports or MLT/SMLTs that have Endpoint Tracking enabled.

## ExtremeCloud IQ - Site Engine Integration

Endpoint Tracking integrates with ExtremeCloud IQ - Site Engine ExtremeConnect and ExtremeControl modules. The ExtremeConnect module offers API integration with third party products, such as VMware or Microsoft HyperV, from which VM endpoint information is extracted and automatically converted into usable policies for use in the ExtremeControl module, which acts as a RADIUS server for authorizing Endpoint Tracking MACs.

The following diagram illustrates an example of ExtremeCloud IQ - Site Engine interaction with a switch for Endpoint Tracking:

**Figure 94: ExtremeCloud IQ - Site Engine Endpoint Tracking Interaction Example**

### *RADIUS Server Attributes*

The RADIUS attributes to configure in either standard or custom ExtremeCloud IQ - Site Engine RADIUS profiles for Endpoint Tracking depend on your deployment and traffic type:

- For tagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use only the **FA-VLAN-ISID** attribute.
- For tagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use only the **Tunnel-Private-Group-ID** attribute.
- For untagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use the **FA-VLAN-ISID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- For untagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use the **Tunnel-Private-Group-ID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- Use the **Session-Timeout** attribute to override the default timeout period of 24 hours, which is amount of time, in seconds, between a MAC address authentication and the deletion of that MAC address from the Endpoint Tracking binding table.

All other RADIUS attributes are ignored.

#### *Managing Binding Updates using RADIUS Change-of-Authorization*

Endpoint Tracking uses RADIUS RFC 5176 Change-of-Authorization (CoA) functionality to enable forced VLAN:ISID binding updates.

For example, when a VLAN segment is changed on a VM that resides on a previously authenticated switch, that VM requires a new VLAN:ISID binding to reflect the new VLAN segment. Because the switch has previously been authenticated, you must force a new authentication request to update the binding information.

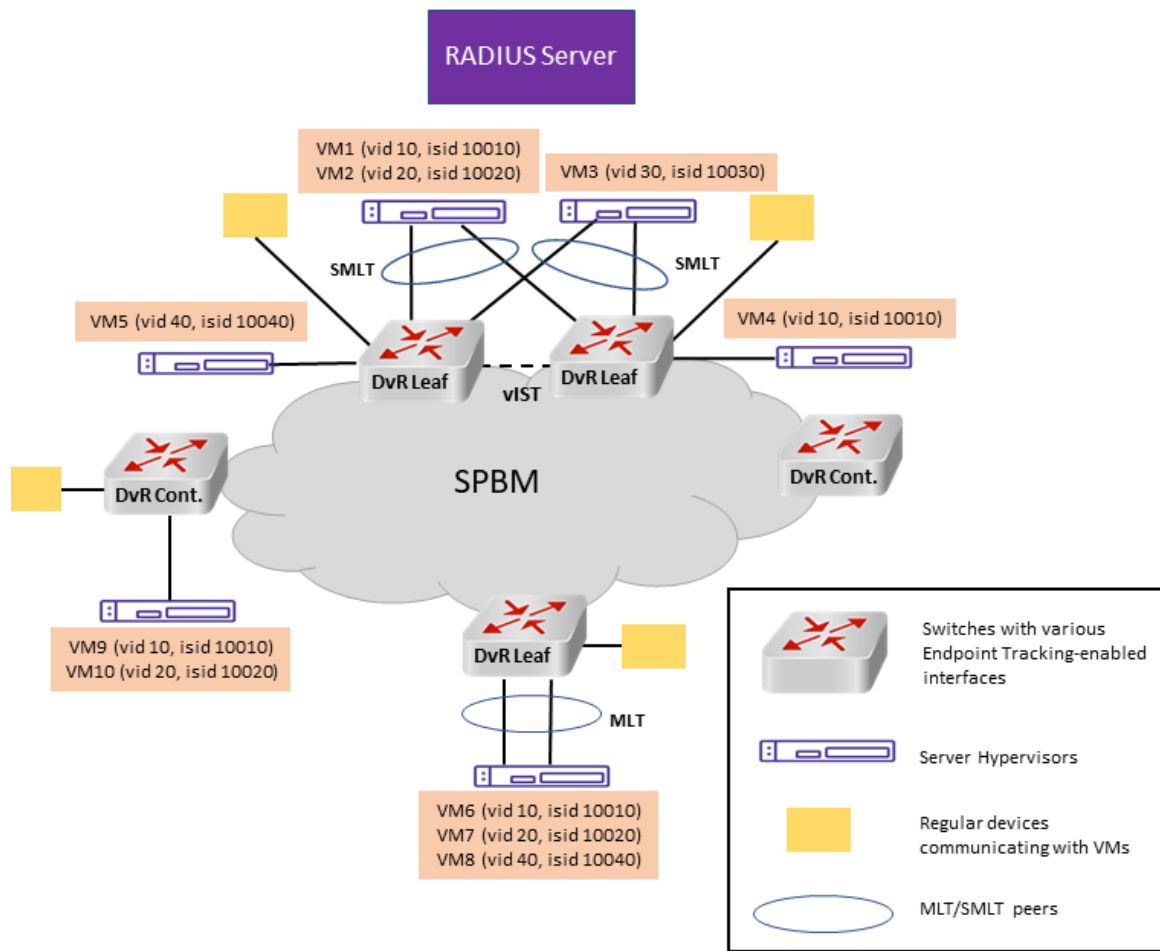

Using ExtremeControl, you can manually push a reauthentication request for the VM MAC. This action sends a disconnect-request from the RADIUS server to the switch, which deletes the old binding. When the switch detects the VM again, a new RADIUS authentication request is sent from the switch to the RADIUS server, resulting in updated binding information upon successful authentication.

For more information about RADIUS Dynamic Session Change Support (RFC 5176), see [RFC 5176 — Dynamic Session Change](#) on page 2974.

## Deployment Examples

Endpoint Tracking deployment scenarios include Distributed Virtual Routing (DvR) deployments, or regular SPBM deployments.

The following example illustrates a DvR deployment:

**Figure 95: DvR Topology Example**

The following example illustrates a regular SPBM deployment:

**Figure 96: SPBM Cloud Example**

## Configuration Fundamentals

### *ExtremeCloud IQ - Site Engine Configuration*

To configure Endpoint Tracking, you must perform the following:

- Using the ExtremeConnect component, configure and manage your third-party virtualization platform.
- Using the ExtremeControl component, configure and manage the RADIUS server used for Endpoint Tracking authentication.

For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.

### *Switch Configuration*

To configure Endpoint Tracking, you must perform the following:

- Add, configure, and enable the RADIUS server host as configured in the ExtremeCloud IQ - Site Engine to function as the switch authentication server

for Endpoint Tracking. Ensure that you select **endpoint-tracking** for the **used-by** variable. Add, configure and enable the RADIUS dynamic-server client. For information about adding a RADIUS server host and a RADIUS dynamic-server client to the switch, see [RADIUS](#) on page 2963.

- Optionally configure a global I-SID offset value.

When you provision the Endpoint Tracking RADIUS server in ExtremeCloud IQ - Site Engine, you choose which outbound attributes the RADIUS server includes in each authentication response. If you always include an I-SID value in those outbound attributes, you do not need to configure an I-SID offset value on the switch.

For MACs that do not receive an I-SID attribute from the RADIUS server, use Auto-ISID-Offset functionality. The configured I-SID offset value is used to calculate an I-SID value for a switched UNI when no I-SID value is provided by the RADIUS server in the outbound attributes. In that case, the I-SID value is calculated as follows:

I-SID = VLAN ID + configured I-SID offset value.

- After optionally configuring a global I-SID offset value, enable Endpoint Tracking globally on the switch.
- Create and enable Endpoint Tracking on each interface. Ensure that you have deleted any existing VLAN bindings on the interfaces, as the Endpoint Tracking bindings are dynamic.

CLI commands provide the functionality to separate the creation, deletion, enabling, and disabling of Endpoint Tracking on interfaces. For example, if you want to flush all VLAN:ISID bindings on a port, you can disable (but not delete) Endpoint Tracking on that port, keeping the port distinct from other ports where Endpoint Tracking is not yet created.

## Configure Endpoint Tracking Using CLI

The following sections provide procedural information to configure Endpoint Tracking using CLI.

### *Configure Endpoint Tracking Interfaces*

Create and enable Endpoint Tracking on ports and MLT/SMLT interfaces. Creating, deleting, enabling, and disabling Endpoint Tracking on interfaces can be accomplished as separate steps using this procedure.

#### **Before You Begin**

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.

## About This Task

Configure ports and MLT/SMLT interfaces to function as Switched UNI interfaces, and then create and enable Endpoint Tracking on those interfaces.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} OR interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Flex UNI on the interface:

```
flex-uni enable
```

3. Create and enable Endpoint Tracking:

- Create Endpoint Tracking on the interface:

```
endpoint-tracking
```

- Create and enable Endpoint Tracking on the interface:

```
endpoint-tracking enable
```

## What to Do Next

Configure Endpoint Tracking globally on the switch.

### *Configure Endpoint Tracking Globally*

Configure Endpoint Tracking globally on the switch.

## Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

## About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is

provided by the RADIUS server. In that case, the I-SID value is calculated as follows:  
I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:  

```
endpoint-tracking auto-isid-offset <0-15995903>
```

```
endpoint-tracking auto-isid-offset enable
```
3. Enable Endpoint Tracking globally on the switch:  

```
endpoint-tracking enable
```

### Variable Definitions

The following table defines parameters for the **endpoint-tracking auto-isid-offset** command.

Variable	Value
<code>&lt;0-15995903&gt;</code>	The I-SID offset value. The default is 15990000.
<code>enable</code>	Enables or disables I-SID offset value globally on the switch. The default is disabled.

### Configure Endpoint Tracking Visibility Mode

Configure Endpoint Tracking visibility mode on the switch.

#### Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.

- Create and enable Endpoint Tracking on interfaces.
- Enable Endpoint Tracking globally on the switch.

### About This Task

Enable visibility mode to allow MAC learning on static S-UNIs for Endpoint Tracking.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable Endpoint Tracking visibility mode on the switch:
 

```
endpoint-tracking visibility-mode
```

### *Display Endpoint Tracking Configuration Information*

Perform this procedure to display configuration information for Endpoint Tracking.

### About This Task

Perform this procedure to display global, interface and binding information for Endpoint Tracking.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global status of Endpoint Tracking on the switch, and the configured I-SID offset value, if applicable:
 

```
show endpoint-tracking
```
3. Display the status of all interfaces that have Endpoint Tracking created:
 

```
show endpoint-tracking interfaces [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]]
```
4. Display a summary of the VLAN:ISID binding information for all ports, or MLT/SMLT interfaces:
 

```
show endpoint-tracking bindings summary
```
5. Display the VLAN:ISID binding information for the switch, for ports, or for MLT/SMLT interfaces:
 

```
show endpoint-tracking bindings [gigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] | [mlt <1-512>]]
```

### Example

The following example displays all of the Endpoint Tracking configuration information for a switch.

```
Switch:1>show endpoint-tracking
=====
Endpoint Tracking Configuration
=====

endpoint tracking status : ENABLED
```

```

auto-isid-offset value : 15990000
auto-isid-offset enabled : ENABLED
visibility-mode status : ENABLED

Switch:1>show endpoint-tracking interfaces
=====

1/10      201    00:00:00:00:1b:03  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:04  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00
1/10      201    00:00:00:00:1b:05  accept  27       15990027  autoconfig  0 day(s), 00:01:40  0 day(s), 00:00:00

5 out of 5 Total Num of Endpoint Tracking bindings displayed.

```

**Variable Definitions**

The following table defines parameters for the **show endpoint-tracking bindings** command.

Variable	Value
<code>gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>MLT &lt;1-512&gt;</code>	Specifies the MLT ID.
<code>summary</code>	Provides a summary of the total number and status of bindings for all interfaces.

## Configure Endpoint Tracking Using EDM

The following sections provide procedural information to configure Endpoint Tracking using Enterprise Device Manager (EDM).

### *Configure Endpoint Tracking Interfaces*

#### Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ - Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.

#### About This Task

Enable Endpoint Tracking on ports or MLT/SMLT interfaces.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Interface** tab.
4. Select **Insert**.
5. Select **Port** or **Mlt**, select the slot and port number or MLT ID, and select **OK**.
6. Select **InterfaceEnable**.
7. Select **Insert**.
8. Select **Apply**.

#### What to Do Next

Next, configure Endpoint Tracking globally on the switch.

#### Interface Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>InterfaceIndex</b>	Specifies the interface index of the selected port or MLT.
<b>InterfaceEnable</b>	Enables Endpoint Tracking on the selected port or MLT.

### *Configure Endpoint Tracking Globally*

Configure Endpoint Tracking globally on the switch.

#### Before You Begin

- In ExtremeCloud IQ - Site Engine, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring ExtremeCloud IQ - Site Engine, see the ExtremeCloud IQ -

Site Engine documentation at <https://www.extremenetworks.com/support/documentation/>.

- On the switch, add and configure the RADIUS server as configured in ExtremeCloud IQ - Site Engine.
- Create and enable Endpoint Tracking on interfaces.

### About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Globals** tab.
4. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:  
Enter a value into the **AutosidOffset** field and select **AutosidOffsetEnable**.
5. Select **GlobalEnable**.
6. Select **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AutosidOffset</b>	The I-SID offset value. The default is 15990000.
<b>AutosidOffsetEnable</b>	Enables or disables I-SID offset value globally on the switch. The default is disabled.
<b>GlobalEnable</b>	Enables or disables Endpoint Tracking globally on the switch. The default is disabled.
<b>VisibilityEnable</b>	Enables or disables visibility mode for Endpoint Tracking. The default is disabled.

*Display Binding Information*

Display Endpoint Tracking binding information.

**About This Task**

Display all VLAN:ISID binding information on the switch for Endpoint Tracking.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Binding** tab.

**Binding Field Descriptions**

Use the data in the following table to use the **Binding** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface index of the selected port or MLT.
<b>MacAddress</b>	Specifies the MAC address that corresponds to the VLAN:ISID binding.
<b>Status</b>	Specifies the Endpoint Tracking data binding status as follows: <ul style="list-style-type: none"> <li>• pending: indicates that a request has been sent to the RADIUS server</li> <li>• accept: indicates that the RADIUS server has successfully returned the request</li> <li>• reject: indicates that the RADIUS server has rejected the request</li> <li>• timeout: indicates that the RADIUS server request has timed out. The entry is deleted if it remains in this state for 15 minutes.</li> <li>• serverNotConfigured: indicates that the RADIUS server is not configured for Endpoint Tracking. The entry is deleted if it remains in this state for 15 minutes.</li> </ul>
<b>VlanId</b>	Specifies the VLAN ID.
<b>Isid</b>	Specifies the I-SID value, either provided by the RADIUS server, or calculated using the VLAN ID plus the configured I-SID offset value.
<b>IsidSource</b>	Specifies whether the I-SID value is provided by the RADIUS server (radius), or calculated using the VLAN ID plus the configured endpoint-tracking offset value (autoconfig).
<b>Timeout</b>	Specifies the timeout period that is applied to the MAC in the bindings table when the MAC is aged out. If the MAC is in timeout state (there is no response from the RADIUS server), the timeout triggers immediately with a 15 minute period. Otherwise, the default timeout is one day, and triggers the moment the MAC ages out from the VLAN/I-SID bridge forwarding database (FDB) table. The default timeout of one day can be overridden by the RADIUS server if the Session-Timeout attribute is configured and returned.
<b>TimeRemaining</b>	Specifies the time remaining until the Endpoint Tracking data binding entry expires.

## Multi-area SPB

**Table 118: Multi-area SPB**

Feature	Product	Release introduced

	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The Multi-area SPB feature enables building a scalable Shortest Path Bridging (SPB) network, consisting of multiple Intermediate System-to-Intermediate System (IS-IS) areas that connect to each other through the boundary nodes. The Multi-area SPB feature provides flexible network design through which you can group the nodes in the areas on a need basis.

Each area in the Multi-area SPB network contains the interior nodes and the boundary nodes.

**Figure 97: Boundary nodes in the Multi-area SPB network**

Each boundary node runs two Intermediate-System-to-Intermediate-System (IS-IS) instances, representing the home area and the remote area. Each IS-IS instance runs the Shortest Path First (SPF) computation and uses its own Link State Database (LSDB). The boundary nodes support Backbone Edge Bridge (BEB) functionality in addition to the Backbone Control Bridge (BCB) configuration and the UNIs belong only to the home area. You can configure IS-IS interfaces on each instance.

**Note**

The boundary nodes do not support Auto-sense for remote interfaces. You must manually configure all remote NNI on the boundary nodes.

The multiple areas in the Multi-area SPB network connect in various patterns, for example, the hub and spoke topology and the daisy chain topology.

## Designated and Non-designated Boundary Nodes

Among the boundary nodes in the Multi-area SPB network, the system elects the designated boundary node on basis of the unique chassis MAC value of the node. The nodes in the SPB area advertise their chassis MAC value using the link state packet (LSP) and the system elects the node with the smallest chassis MAC value as the designated boundary node.

The functions of the boundary nodes in the Multi-area SPB network are:

- Designated boundary node:
  - Creates the area virtual node LSPs on each IS-IS instance.
  - Configures the virtual node's adjacency with the other boundary node on basis of the reachability of the node.
  - Advertises the services on the area virtual node on basis of the redistribution policies that you configure.
- Non-designated boundary node:
  - Connects to the area virtual node and the system uses it to forward the traffic on basis of the IS-IS computation.
  - Takes over as the designated boundary node if the designated boundary node is no longer available in any area.

For more information about the area virtual node, see [Area Virtual Node](#) on page 1308.

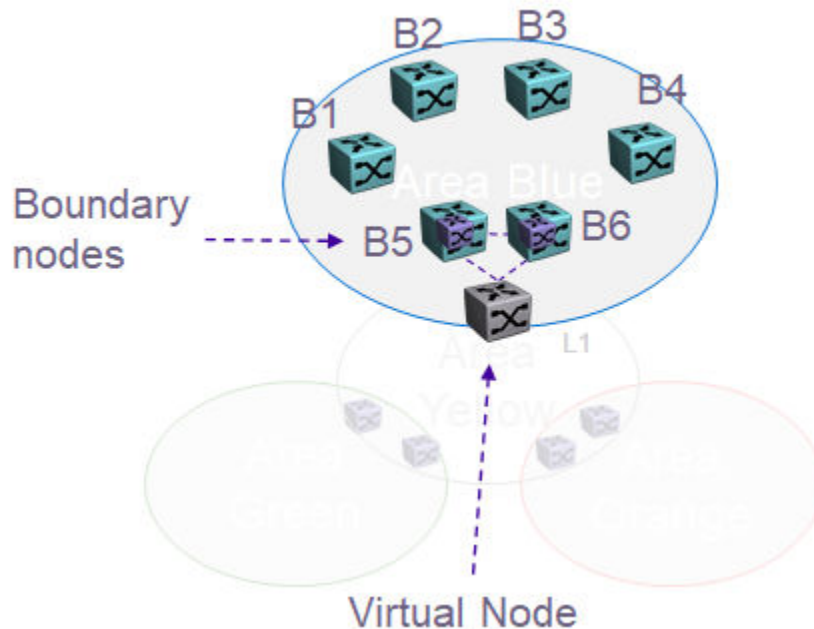

## Minimum Requirements

The minimum requirements for the Multi-area SPB to function are:

- Two boundary nodes to provide redundancy.
- Multi-area SPB redistribution policies between areas, like Layer 2 redistribution, Layer 3 unicast redistribution, multicast redistribution, Distributed Virtual Routing (DvR) backbone redistribution and so on. For more information, see [Multi-area SPB Redistribution and Policies](#) on page 1310.

## Area Virtual Node

The designated boundary node in the Multi-area SPB network creates the area virtual node. The area virtual node sums up an entire network topology in a single virtual node representing all the services from the represented area.

**Figure 98: Representation of area virtual node**

When considering the shortest path between two nodes in different areas in the Multi-area SPB network, the area virtual node logically connects the shortest path within one area to the shortest path within another area. The area virtual nodes help the Multi-area SPB network to visualize any external area as a single IS-IS entity.

The boundary nodes in the Multi-area SPB network exposes one virtual node in each of two connected areas, to represent a collection of nodes from the other area. On the basis of the policies that you configure on the boundary nodes, you can control the services that the system exports from one area to the other area as the system includes the configuration in the Link State Packets (LSP) of the corresponding area virtual node.

You can configure the area virtual node parameters on both home and remote IS-IS instances. For more information about configuring the area virtual node, see [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1319.

#### *Layer 2 Ping and Layer 2 Traceroute Support*

Multi-area SPB supports Connectivity Fault Management (CFM) on boundary nodes in both home and remote area. For the remote area, the boundary nodes respond to the Layer 2 ping and Layer 2 traceroute messages that contain the remote area system ID. You must enable CFM on the boundary nodes for the functionality to work.

Multi-area SPB supports the following Layer 2 ping, Layer 2 traceroute, and Layer 2 tracertree interactions:

- from boundary node to remote area Backbone Edge Bridge (BEB)

- from remote area BEB to boundary node

**Note**

Multi-area SPB does not support CFM between the home and remote area.

The following list identifies CFM restrictions for virtual node interactions:

- The boundary node cannot use Layer 2 ping or Layer 2 traceroute to the virtual node.
- The virtual node does not reply to Layer 2 tracertree or Layer 2 tracemroute.
- The virtual node does not initiate CFM messages.

For more information about CFM, see [Connectivity Fault Management](#) on page 3819.

## Remote IS-IS Instance

The Multi-area SPB feature introduces the remote Intermediate-System-to-Intermediate-System (IS-IS) instance. You can configure the manual area, system ID, nickname, and area virtual node parameters on the remote IS-IS instance. When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different. To configure the remote IS-IS instance on the switch, you must:

- Configure manual area and nickname manually on the switch.
- Enable IS-IS and remote IS-IS instances on the switch, globally.
- Configure Shortest Path Bridging MAC (SPBM) instance globally.
- Configure Backbone-VLANs (B-VLANs) globally on both home and remote instances.

For more information, see [Enable Remote IS-IS Router Configuration Globally](#) on page 1326.

## Multi-area SPB Redistribution and Policies

The Multi-area SPB redistribution and policies govern the process of importing routes in the Multi-area SPB network across the boundary nodes, that is from the home area to the remote area or vice versa. The traffic flow between the areas within the Multi-area SPB network is the same as the packet flow between the source and destination in a flat SPB network. If more than one boundary node connects to same two areas then the redistribution configuration on the boundary nodes must be consistent, that is the system must permit or deny the same routes to the cross area boundaries. With Multi-area SPB you can configure layer 2 redistribution, layer 3 unicast redistribution, multicast over SPB redistribution, and Distributed Virtual Routing backbone redistribution on the switch.

### *Layer 2 Redistribution*

In the Multi-area SPB network the layer 2 redistribution identifies the services that the system transports from the home area to the remote area and the I-SIDs that the system extends across the boundary nodes in an area. The destination area permits or denies the services on basis of the Layer 2 redistribution policies that you configure.

You can configure the Layer 2 I-SID redistribution on the switch globally. The Layer 2 redistribution policies are bidirectional, which means only one redistribution filter applies to both the home area and the remote area.

**Note**

Any changes in the Layer 2 I-SIDs in the home area will trigger updates to the redistributed I-SIDs in the remote area or vice versa.

For more information about configuring Multi-area SPB Layer 2 redistribution, see:

- [Configure Multi-area SPB Layer 2 I-SID Redistribution](#) on page 1327
- [Configure Multi-area SPB Layer 2 I-SID List](#) on page 1327

### *Layer 3 Unicast Redistribution*

The layer 3 VSN functionality within the Multi-area SPB network is same as the layer 3 VSN functionality in the flat SPB network. In the Multi-area SPB network, for the layer 3 services to pass the area boundary, you must explicitly configure them on the boundary nodes. Inter-VRF routes on the boundary node will not be redistributed across area boundaries. You can configure redistribution unidirectionally on the boundary nodes. You can also apply different policies from home to remote and remote to home.

The configuration guidelines for the layer 3 Multi-area SPB redistribution are:

- To redistribute inter-area routes in GRT, configure IPSC on the boundary nodes.
- To redistribute inter-area routes in a specific VRF, configure IPSC and layer 3 VSN for that VRF.

**Note**

The system does not redistribute inter-vrf routes on the boundary nodes across the area boundaries.

For information about configuring layer 3 unicast redistribution, see:

- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution](#) on page 1328
- [Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance](#) on page 1331
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution](#) on page 1330
- [Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance](#) on page 1333

### *Multicast over SPB Redistribution*

Multicast over Shortest Path Bridging (SPB) redistribution manages filtering of the IP multicast streams that the system transports from one area to another. The IP multicast services pass through to the other area on the boundary node depending on the policy that you configure specific to the sender IP address, the multicast group IP address and the Virtual Router Forwarding (VRF) ID.

Multicast over SPB policy is a unidirectional solution, the system filters the IP multicast streams from the area that they originate to the other area or vice versa, independently.

Each IP multicast stream that the system advertises in one area will also be advertised on the corresponding area virtual node after it passes the multicast over SPB policy.

Following are the configuration guidelines for the multicast over SPB redistribution:

- Enable multicast on the boundary nodes.
- For layer 3 VSNs, configure Multicast Virtual Private Network (MVPN) on the boundary nodes.
- For layer 2 multicast, the scope I-SID must pass the layer 2 VSN policy.
- Configure the same policies as on the designated boundary node on the peer boundary nodes.

For information about configuring Multi-area SPB multicast redistribution, see:

- [Configure Multi-area SPB IPv4 Routed Multicast Redistribution](#) on page 1337
- [Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance](#) on page 1339

### *Distributed Virtual Routing Backbone Redistribution*

The Distributed Virtual Routing (DvR) functionality within the Multi-area SPB network is same as the DvR functionality in the flat SPB network. For more information, see [Distributed Virtual Routing Fundamentals](#) on page 743. To configure Multi-area SPB DvR backbone redistribution, the boundary node must be a functional DvR controller in a domain in the home area or a non-DvR Backbone Edge Bridge.

#### **Note**

DvR domains can only be a part of one area, you must not configure the same DvR domain in multiple areas.

When you enable the Multi-area SPB DvR backbone redistribution the system extends the DvR backbone across the area boundaries. The boundary node in the Multi-area SPB network performs the DvR controller functions to receive and propagate the hosts in the DvR domain. Since the interior nodes in one area of the Multi-area SPB network are not visible to the interior nodes in other areas, the system sends the area virtual nodes representing the specific area as a gateway in the DvR route TLV. When the system sends the DvR traffic to another DvR domain in a specific destination area, the system sends the traffic to the destination area's boundary nodes and the boundary nodes perform the route lookup and forward the traffic to the correct DvR domain in the destination area.

For information about configuring Multi-area SPB DvR backbone redistribution, see [Configure Multi-area SPB DvR Backbone Redistribution](#) on page 1335.

## Multi-area SPB Considerations and Restrictions

The following list identifies the restrictions and considerations that apply to the Multi-area SPB feature:

- The maximum number of nodes that can perform the functionality of boundary node between any given pair of areas is two. The two boundary nodes can be either

in a vIST configuration (paired with each other) or in a non-vIST configuration. Any other combination of two boundary nodes is not supported.

- You must not connect the same Protocol Independent Multicast (PIM) domain to the SPB-PIM Gateway nodes that are in different Intermediate-System-to-Intermediate-System (IS-IS) areas, to avoid the inter-area redistribution of the same multicast information.
- You can enable the Dynamic Nickname server on the boundary nodes in the home area, but the boundary nodes cannot be clients in any of the two areas. The boundary nodes do not support the Dynamic Nickname server in the remote area.
- You must manually configure the backbone VLANs (B-VLAN) on the boundary nodes, so the system does not learn the dynamic values that it receives through the Link Layer Discovery Protocol (LLDP). However, the system sends the manually configured B-VLANs on the BN through LLDP, so that other neighbors can learn them (both in home and remote areas).
- If you enable Auto-sense on a port connected to remote area node and the port receives a Fabric Connect TLV through LLDP then the port transitions to the NNI pending state and the system logs a message. In this state, the system does not enable IS-IS remote area, and no IS-IS adjacency forms. For more information, see [Auto-sense Port States](#) on page 21.
- If the system forms an adjacency between two boundary nodes that are part of the home and remote area, the hello packets in the home area will use the home manual area and the hello packets in the remote area use the remote manual area.
- If the system forms a home and a remote adjacency on the same port then the Multi-area SPB feature uses different Backbone VLAN IDs (B-VIDs) for each adjacency, the home adjacency uses the primary B-VID and the remote adjacency uses the secondary B-VID.
- If the system forms an IS-IS adjacency in both the home and remote areas on a boundary node, of the same port then the remote adjacency stays up only with another boundary node that also has IS-IS configured on both the home and remote areas of the same port.
- If a boundary node connects to a Backbone Edge Bridge (BEB) in the remote area and if you configure IS-IS in the home area on the same interface, then the remote adjacency goes down.
- On the boundary node, to install a route from a remote area in the routing table manager (RTM), the route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on the specific Virtual Router Forwarding (VRF) instance.
- On the boundary node, to install an inter-VRF route from a remote area in the routing table manager (RTM), the inter-VRF route must pass the accept policy and the Multi-area SPB redistribution policy that you configure on both the source and destination VRF instances.
- Nickname and system ID for the physical node and virtual node must be different.
- When enabling Remote IS-IS Instance, make sure that the physical node nickname, virtual node nickname and system ID are different.

## Duplicate System IDs Between IS-IS Areas

Duplicate system IDs between adjacent IS-IS areas are not supported.

If a duplicate system ID exists between adjacent areas, the boundary node logs an event like the following:

```
1 2021-09-21T02:08:44.734-04:00 GB12 CP1 - 0x001dc705 - 00000000
GlobalRouter ISIS WARNING Duplicate System ID 0022.2222.2415 detected on
Boundary Node between HostName:B15 Chassis MAC:b0:ad:aa:41:c0:00 (HOME
area) and HostName:B14 Chassis MAC:b0:ad:aa:41:b8:00 (REMOTE area)
```

To recover from this event and ensure the information on the boundary node is correctly updated, you must perform the following tasks:

1. Change the system ID on both of the conflicting nodes.
2. Disable and re-enable IS-IS on both of the conflicting nodes.

Delete errors can display on the boundary node but they have no functional impact.

## **NEW!** Duplicate Nick-Names Between IS-IS Areas

Duplicate nick-names between adjacent IS-IS areas are not supported.

If a duplicate nick-name exists between adjacent areas, the boundary node logs an event like the following:

```
GlobalRouter ISIS WARNING Duplicate Nick-name f.f0.3c detected on
Boundary Node between SysId 4088.2fe9.8884 (REMOTE area) and SysId
f4ce.48a1.f084 (HOME area)
```

To recover from this event and ensure the information on the boundary node is correctly updated, you must perform the following tasks:

1. Change the nick-name on both of the conflicting nodes.
2. Disable and re-enable IS-IS on both of the conflicting nodes.

Delete errors can display on the boundary node but they have no functional impact.

## Multi-area SPB Configuration using CLI

Perform the procedures in this section to configure Multi-area SPB parameters like virtual node, router remote Intermediate-System-to-Intermediate-System (IS-IS), layer 2 unicast and multicast redistribution, and IPv4 and IPv6 route redistribution on the switch using the Command Line Interface (CLI).

### Note

The following procedures only applies to VSP 7400 Series.

### *Multi-area SPB Configuration Flow*

Perform the following procedures in sequence to configure the Multi-area SPB feature on the switch.

## Procedure

1. [Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance](#) on page 1315.
2. [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1343.
3. [Configure Remote IS-IS Manual Area](#) on page 1316.
4. [Configure Remote IS-IS System ID](#) on page 1317.
5. [Configure an IS-IS Area Name](#) on page 1318
6. [Display IS-IS Remote Area Configuration](#) on page 1344.
7. [Display IS-IS Area Configuration](#) on page 1344.
8. [Configure IS-IS Multi-area SPB Virtual Node](#) on page 1319.
9. [Display IS-IS Area Virtual Node Configuration](#) on page 1345.
10. [Configure Remote IS-IS Hello Authentication on a Port](#) on page 1320.
11. [Configure Remote IS-IS Layer 1 Designated Router Priority on a Port](#) on page 1321.
12. [Configure Remote IS-IS Hello Interval on a Port](#) on page 1322.
13. [Configure Remote IS-IS Hello Multiplier on a Port](#) on page 1323.
14. [Configure Remote IS-IS SPBM Parameters on a Port](#) on page 1324.
15. [Enable Remote IS-IS on a Port](#) on page 1325.
16. [Enable Remote IS-IS Router Configuration Globally](#) on page 1326.

30. [Configure Multi-area SPB IPv4 Static I-SID Routed Multicast Redistribution](#) on page 1341.

*Configure Remote IS-IS Multi-area SPB Nickname for an SPBM Instance*

### About This Task

Perform this procedure to configure remote IS-IS Multi-area SPB nickname for a specific SPBM instance on the switch.

## Procedure

1. Enter IS-IS Router Remote Configuration mode:
 

```
enable

configure terminal

router isis remote
```
2. Configure IS-IS Multi-area SPB nickname:
 

```
spbm <1-100> nick-name <x.xx.xx>
```

## Example

Configuring remote IS-IS Multi-area SPB nickname for SPBM instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-remote)#spbm 4 nick-name 1.11.16
```

## What to Do Next

To verify the configuration, see [Display the Remote IS-IS SPBM Nickname Configuration](#) on page 1343.

## Variable Definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Specifies the SPBM instance on the remote IS-IS interface.
<i>nick-name</i> <x.xx.xx>	Specifies a nickname for the remote IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format <x.xx.xx>.

## Configure Remote IS-IS Manual Area

### About This Task

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) manual area.

### Procedure

1. Enter IS-IS Router Remote Configuration mode:
 

```
enable

configure terminal

router isis remote
```
2. Configure the manual-area:
 

```
manual-area xx.xxxx.xxxx...xxxx
```

## Example

Configuring remote IS-IS manual area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)#manual-area c1.1000.000.00
```

## What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1344 and [Display IS-IS Area Configuration](#) on page 1344.

## Variable Definitions

The following table defines parameters for the **manual-area** command.

Variable	Value
<xx.xxxx.xxxx...xxx x>	Specifies the remote IS-IS manual-area in the range of 1 to 13 bytes.

## Configure Remote IS-IS System ID

### About This Task

Perform this procedure to configure the remote Intermediate System-to-Intermediate System (IS-IS) system ID on the switch.

### Procedure

1. Enter IS-IS Router Remote Configuration mode:
 

```
enable

configure terminal

router isis remote
```
2. Configure the remote IS-IS system ID:
 

```
system-id xxxx.xxxx.xxxx
```

### Example

Configuring the remote IS-IS system ID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)#system-id 0017.c6ed.44df
```

## What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1344 and [Display IS-IS Area Configuration](#) on page 1344.

## Variable Definitions

The following table defines parameters for the **system-id** command.

Variable	Value
<code>xxxx.xxxx.xxxx</code>	Specifies the remote IS-IS system ID for the switch.

## Configure an IS-IS Area Name

### Before You Begin

- You must disable IS-IS or remote IS-IS.

### About This Task

Perform this procedure to configure the area name for home and remote areas.

### Procedure

- Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:  

```
enable

configure terminal

router isis OR router isis remote
```
- Configure the area name:  

```
area-name WORD<0-255>
```
- Enable IS-IS or remote IS-IS:  

```
router isis enable OR router isis remote enable
```

### Example

Configure the home and remote area names:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router isis
Switch:1(config-isis)#area-name 30
Switch:1(config)#router isis remote
Switch:1(config-isis-remote)# area-name 50
```

## Variable Definitions

The following table defines parameters for the **area-name** command.

Variable	Value
<code>WORD&lt;0-255&gt;</code>	Specifies the area name. The default value is area-manual-area, where manual-area represents the IS-IS or remote IS-IS manual-area value that you configure.

## Configure IS-IS Multi-area SPB Virtual Node

### About This Task

Perform this procedure to configure the IS-IS Multi-area SPB virtual node parameters like nick-name, system ID, and system name in the home or remote area.

### Procedure

1. Enter either IS-IS Router Configuration or IS-IS Router Remote Configuration mode:  
`enable`  
`configure terminal`  
`router isis` OR `router isis remote`
2. Configure the nick-name for the IS-IS Multi-area SPB virtual node:  
`area-vnode nick-name <x.xx.xx>`
3. Configure the system name for the IS-IS Multi-area SPB virtual node:  
`area-vnode sys-name WORD<0-255>`
4. Configure the system ID for the IS-IS Multi-area SPB virtual node:  
`area-vnode system-id xxxx.xxxx.xxxx`

### Examples

Configuring the IS-IS Multi-area SPB virtual node in the home area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#area-vnode nick-name 0.82.40
Switch:1(config-isis)#area-vnode sys-name SwitchC
Switch:1(config-isis)#area-vnode system-id 1222.3300.0000
```

Configuring the IS-IS Multi-area SPB virtual node in the remote area:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote
Switch:1(config-isis)#area-vnode nick-name 0.82.60
Switch:1(config-isis)#area-vnode sys-name SwitchA
Switch:1(config-isis)#area-vnode system-id 1222.3311.2222
```

### What to Do Next

To verify the configuration, see [Display IS-IS Area Virtual Node Configuration](#) on page 1345.

## Variable Definitions

The following table defines parameters for the **area-vnode** command.

Variable	Value
<i>nick-name</i> x.xx.xx	Specifies a nickname for the IS-IS SPBM Multi-area SPB instance. The value is 2.5 bytes in the format x.xx.xx.
<i>sys-name</i> WORD<0-255>	Specifies the name of the system.
<i>system-id</i> xxxx.xxxx.xxxx	Specifies the IS-IS Multi-area SPB virtual node system ID.

### Configure Remote IS-IS Hello Authentication on a Port

#### About This Task

Perform this procedure to configure authentication type used for remote Intermediate-System-to-Intermediate-System (IS-IS) hello packets on the interface. The type can be one of the following: none, simple, hmac-md5, or hmac-sha-256.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the hello authentication type:

```
isis remote hello-auth type {none | simple | hmac-md5 | hmac-sha-256}  
[key WORD<1-16>] [key-id <1-255>]
```

#### Example

Configuring the simple authentication type for remote IS-IS hello packets on port 1/2:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitEthernet 1/2  
Switch:1(config-if)#isis remote hello-auth type simple key Test key-id 125
```

## Variable Definitions

The following table defines parameters for the **isis remote hello-auth** command.

Variable	Value
<code>key WORD&lt;1-16&gt;</code>	Specifies the authentication key (password) that the receiving router uses to verify the packet.
<code>key-id &lt;1-255&gt;</code>	Specifies the optional key ID.
<code>type {none   simple   hmac-md5   hmac-sha-256}</code>	<p>Specifies the authentication type used for remote IS-IS hello packets on the interface. The type can be one of the following:</p> <ul style="list-style-type: none"> <li>• Simple - Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. You can also specify a key value.</li> <li>• hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. You can also specify a key value and key-id.</li> <li>• hmac-sha-256 - With SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. You can also specify a key value and key-id.</li> </ul> <p>The default type is none.</p>

### Configure Remote IS-IS Layer 1 Designated Router Priority on a Port

#### About This Task

Perform this procedure to configure the Level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority to the specified value.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Level 1 remote IS-IS designated router priority:

```
isis remote ll-dr-priority <0-127>
```

## Example

Configuring the remote IS-IS designated router priority for port 1/4:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-dr-priority 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-dr-priority** command.

Variable	Value
<0-127>	Specifies the level 1 remote Intermediate-System-to-Intermediate-System (IS-IS) designated router priority value. The default value is 64.

## Configure Remote IS-IS Hello Interval on a Port

### About This Task

Perform this procedure to configure the remote hello interval to change how often hello packets are sent out from an interface level.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote hello interval:

```
isis remote l1-hello-interval <1-600>
```

## Example

Configuring the remote hello interval on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#isis remote l1-hello-interval 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-hello-interval** command.

Variable	Value
<1-600>	Configures the Level 1 remote hello interval. The default value is 9 seconds.

### Configure Remote IS-IS Hello Multiplier on a Port

#### About This Task

Perform this procedure to configure the remote hello multiplier to specify how many hellos the switch must miss before it considers the adjacency with a neighboring switch down.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the level 1 hello multiplier:

```
isis remote l1-hello-multiplier <1-600>
```

#### Example

Configuring the remote hello multiplier on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote l1-hello-multiplier 1
```

## Variable Definitions

The following table defines parameters for the **isis remote l1-hello-multiplier** command.

Variable	Value
<1-600>	Configures the Level 1 hello multiplier. The default value is 3 seconds.

*Configure Remote IS-IS SPBM Parameters on a Port***About This Task**

Perform this procedure to configure the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) parameters on a specific port.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the remote IS-IS SPBM interface type:

```
isis remote spbm <1-100> interface-type {broadcast | pt-pt}
```

3. Configure the cost of the remote SPBM instance:

```
isis remote spbm <1-100> ll-metric {<1-16777215> | auto}
```

**Example**

Configuring the remote IS-IS SPBM interface type and layer 1 metric on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote spbm 2 interface-type broadcast
Switch:1(config-if)#isis remote spbm 2 ll-metric 2
```

**Variable Definitions**

The following table defines parameters for the **isis remote spbm** command.

Variable	Value
<1-100>	Specifies the SPBM instance.
<i>interface-type</i> { <i>broadcast</i>   <i>pt-pt</i> }	Specifies the IS-IS SPBM interface type as broadcast or point-to-point (pt-pt).
<i>ll-metric</i> {<1-16777215>   <i>auto</i> }	Specifies the SPBM instance Level 1 metric on the IS-IS interface located on a specific port. You can configure a static value, or use auto. When you use the auto setting, the network route is determined by summing the lowest value metrics, which are inversely proportional to port speed.

*Enable Remote IS-IS on a Port***Before You Begin**

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.
- Disable Auto-sense on the port.
- Make sure that the physical node nickname, virtual node nickname and system ID are different.

**About This Task**

Perform this procedure to enable remote Intermediate-System-to-Intermediate-System (IS-IS) interface on the selected port(s).

**Note**

When the switch receives a Fabric Connect TLV through LLDP on a port that has remote IS-IS enabled on it, the port transitions to the Auto-sense NNI pending state. For more information, see [Auto-sense Port States](#) on page 21.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable remote IS-IS interface:

```
isis remote enable
```

**Example**

Enabling remote IS-IS interface on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#isis remote enable
```

## Variable Definitions

The following table defines parameters for the **isis remote** command.

Variable	Value
<i>enable</i>	Enables a remote IS-IS interface on the selected ports.

### Enable Remote IS-IS Router Configuration Globally

#### Before You Begin

- Configure manual-area in both home and remote area.
- Configure the Shortest Path Bridging MAC (SPBM) instance and backbone VLANs (B-VLAN) manually.
- Configure the nickname in both home and remote area manually.

#### About This Task

Perform this procedure to enable remote IS-IS router configuration on the switch, globally.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable IS-IS router remote configuration:
 

```
router isis remote [enable]
```

#### Example

Enabling IS-IS router remote configuration globally:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis remote enable
```

#### What to Do Next

To verify the configuration, see [Display IS-IS Remote Area Configuration](#) on page 1344.

## Variable Definitions

The following table defines parameters for the **router isis remote** command.

Variable	Value
<i>enable</i>	Enables router IS-IS remote configuration globally on the switch.

*Configure Multi-area SPB Layer 2 I-SID List***About This Task**

Perform this procedure to configure the Multi-area SPB layer 2 I-SID list.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the Multi-area SPB layer 2 I-SID list:
 

```
multi-area 12 isid-list WORD<1-32> WORD<1-1024>
```

**Example**

Configuring the Multi-area SPB layer 2 I-SID list that includes specific I-SID values:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area 12 isid-list testlist 1,3,5,100-200
```

**What to Do Next**

To verify the configuration, see [Display IS-IS Multi-area SPB Layer 2 I-SID List Information](#) on page 1345.

**Variable Definitions**

The following table defines parameters for the **multi-area 12 isid-list** command.

Variable	Value
<i>WORD&lt;1-32&gt;</i>	Specifies the name of the I-SID list.
<i>WORD&lt;1-1024&gt;</i>	Specifies the list of I-SID values.

*Configure Multi-area SPB Layer 2 I-SID Redistribution***About This Task**

Perform this procedure to configure Multi-area SPB Layer 2 I-SID redistribution.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```

## 2. Configure the Multi-area SPB Layer2 I-SID redistribution:

```
multi-area l2 redistribute i-sid {deny-all | permit-all} [except-isid-
list WORD<1-32>]
```

## 3. Verify the Multi-area SPB Layer2 I-SID redistribution configuration:

```
show isis multi-area l2 redistribute i-sid
```

## 4. Apply the Layer 2 I-SID redistribution:

```
isis multi-area l2 apply redistribute i-sid
```

**Example**

Configuring Multi-area SPB Layer 2 I-SID redistribution and exclude the I-SID values specified in the I-SID list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area l2 redistribute i-sid permit-all except-isid-list
testlist
Switch:1(config-isis)#show isis multi-area l2 redistribute i-sid
=====
MULTI AREA L2 ISID REDIST POLICY
=====
Permit          Except List Name
-----
permit-all     testlist
-----
Switch:1(config-isis)#isis multi-area l2 apply redistribute i-sid
```

**Variable Definitions**

The following table defines parameters for the **multi-area l2 redistribute i-sid** command.

Variable	Value
<i>deny-all</i>	Denies the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name.
<i>except-isid-list</i> <i>WORD&lt;1-32&gt;</i>	Specifies the name of the I-SID list.
<i>permit-all</i>	Permits the Multi-area SPB IPv6 unicast redistribution configuration for the specified I-SID list name.

*Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution***Before You Begin**

Configure IP Shortcuts on the boundary nodes.

**About This Task**

Perform this procedure to configure Multi-area SPB IPv4 unicast redistribution on the switch.

## Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance:

```
multi-area ip redistribute unicast [home-to-remote | remote-to-home]
enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-
to-home]
```

6. Apply the Multi-area SPB IPv4 unicast redistribution:

```
isis multi-area ip apply redistribute unicast [home-to-remote |
remote-to-home]
```

## Example

Configuring Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ip redistribute unicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ip redistribute home-to-remote
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute unicast home-to-remote
```

## Variable Definitions

The following table defines parameters for the **multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv4 unicast redistribution.
<i>home-to-remote</i>	Specifies the IPv4 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD&lt;1-64&gt;</i>	Specifies the name of the route policy.
<i>vrf WORD&lt;1-16&gt;</i>	Specifies the unicast redistribution configuration for specific VRF instance.

### Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution

#### Before You Begin

Configure IP Shortcuts on the boundary nodes.

#### About This Task

Perform this procedure to configure Multi-area SPB IPv6 unicast redistribution on the switch.

#### Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB IPv6 unicast redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv6 unicast redistribution instance:

```
multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]
enable
```

## 5. Verify the Multi-area SPB IPv6 unicast redistribution configuration:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote |
remote-to-home]
```

## 6. Apply the Multi-area SPB IPv6 unicast redistribution:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote |
remote-to-home]
```

**Example**

Configuring Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(config-isis)#multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ipv6 redistribute home-to-remote
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(config-isis)#isis multi-area ipv6 apply redistribute unicast home-to-remote
```

**Variable Definitions**

The following table defines parameters for the **multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv6 unicast redistribution on the switch.
<i>home-to-remote</i>	Specifies the IPv6 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv6 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD&lt;1-64&gt;</i>	Specifies the name of the route policy.
<i>vrf WORD&lt;1-16&gt;</i>	Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.

*Configure IS-IS Multi-area SPB IPv4 Unicast Redistribution on a VRF Instance***Before You Begin**

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

## About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 unicast redistribution on a specific VRF instance on the switch.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home]
```

### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 unicast redistribution instance on the VRF:

```
isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] enable
```

5. Verify the Multi-area SPB IPv4 unicast redistribution configuration on the VRF:

```
show isis multi-area ip redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the Multi-area SPB IPv4 unicast redistribution on the VRF:

```
isis multi-area ip apply redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

## Example

Configuring IS-IS Multi-area SPB IPv4 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ip redistribute unicast home-to-remote vrf VRF1
=====
                ISIS Multiarea Redistribute List for ip unicast - VRF VRF1
=====
DIRECTION          ENABLE          RPOLICY
```

```

-----
home-to-remote      TRUE      test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute unicast home-to-remote vrf VRF1

```

## Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute unicast** and the **isis multi-area ip apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables IPv4 unicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv4 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 unicast redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD&lt;1-64&gt;</i>	Specifies the name of the route policy.
<i>vrf WORD&lt;1-16&gt;</i>	Specifies the IPv4 unicast redistribution configuration for specific VRF instance.

## Configure IS-IS Multi-area SPB IPv6 Unicast Redistribution on a VRF Instance

### Before You Begin

Configure IP Shortcuts and layer 3 VSN on the Virtual Router Forwarding (VRF) instance.

### About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv6 unicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```

enable

configure terminal

router vrf WORD<1-16>

```

2. Create the IS-IS Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```

isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home]

```

### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

## 3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] route-map WORD<1-64>
```

## 4. Enable the Multi-area SPB IPv6 unicast redistribution instance on the VRF:

```
isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] enable
```

## 5. Verify the Multi-area SPB IPv6 unicast redistribution configuration on the VRF:

```
show isis multi-area ipv6 redistribute unicast [home-to-remote | remote-to-home] vrf WORD<1-16>
```

## 6. Exit to Global Configuration mode:

```
exit
```

## 7. Apply the Multi-area SPB IPv6 unicast redistribution on the VRF:

```
isis multi-area ipv6 apply redistribute unicast [home-to-remote | [remote-to-home] vrf WORD<1-16>
```

## Example

Configuring IS-IS Multi-area SPB IPv6 unicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote route-map test
Switch:1(router-vrf)#isis multi-area ipv6 redistribute unicast home-to-remote enable
Switch:1(router-vrf)#show isis multi-area ipv6 redistribute unicast home-to-remote vrf VRF1
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - VRF VRF1
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote      TRUE        test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ipv6 apply redistribute unicast home-to-remote vrf VRF1
```

## Variable Definitions

The following table defines parameters for the **isis multi-area ipv6 redistribute unicast** and the **isis multi-area ipv6 apply redistribute unicast** commands.

Variable	Value
<i>enable</i>	Enables IPv6 unicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv6 unicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv6 unicast redistribution configuration for remote to home direction.

Variable	Value
<code>route-map WORD&lt;1-64&gt;</code>	Specifies the name of the route policy.
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the IPv6 unicast redistribution configuration for a specific VRF instance.

### Configure Multi-area SPB DvR Backbone Redistribution

#### About This Task

Perform this procedure to configure Multi-area SPB Distributed Virtual Routing (DvR) backbone redistribution on the switch.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure IS-IS Multi-area SPB DvR backbone redistribution:
 

```
multi-area dvr redistribute backbone
```

#### Example

Configuring Multi-area SPB DvR backbone redistribution:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area dvr redistribute backbone
```

#### What to Do Next

To verify the configuration, see [Display IS-IS Multi-area SPB DvR Configuration](#) on page 1348.

### Configure Multi-area SPB Layer 2 Multicast Snooping Redistribution

#### About This Task

Perform this procedure to configure Multi-area SPB layer 2 multicast snooping redistribution for specific I-SID values or a specific I-SID list.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```

2. Create the Multi-area SPB layer 2 snooping multicast redistribution for a specific I-SID or I-SID list:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>}
```

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} route-map WORD<1-64>
```

4. Enable the Multi-area SPB layer 2 snooping multicast redistribution instance:

```
multi-area l2 redistribute snoop-multicast {home-to-remote | remote-to-home} {i-sid <1-16777215> | isid-list WORD<1-32>} enable
```

5. Verify the Multi-area SPB layer 2 snooping multicast redistribution configuration:

```
show isis multi-area l2 redistribute snoop-multicast
```

6. Apply the Multi-area SPB layer 2 snooping multicast redistribution:

```
isis multi-area l2 apply redistribute snoop-multicast [home-to-remote | remote-to-home]
```

## Examples

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID 1100:

```
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote i-sid 1100
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote i-sid 1100
route-map test
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote i-sid 1100
enable
```

Configuring Multi-area SPB layer 2 home to remote multicast snooping redistribution for I-SID list List1:

```
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote isid-list List1
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote isid-list List1 route-map test
Switch:1(config-isis)#multi-area l2 redistribute snoop-multicast home-to-remote isid-list List1 enable
```

Verifying the Multi-area SPB layer 2 home to remote multicast snooping redistribution configuration:

```
Switch:1(config-isis)#show isis multi-area l2 redistribute snoop-multicast
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID
=====
ISID          DIRECTION          ENABLE          RPOLICY
-----
1100          home-to-remote      TRUE           test
=====
```

MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID LIST			
ISID LIST	DIRECTION	ENABLE	RPOLICY
List1	home-to-remote	TRUE	test

Applying the Multi-area SPB layer 2 home to remote multicast snooping redistribution:

```
Switch:1(config-isis)#isis multi-area l2 apply redistribute snoop-multicast home-to-remote
```

### Variable Definitions

The following table defines parameters for the **multi-area l2 redistribute snoop-multicast** and the **isis multi-area l2 apply redistribute snoop-multicast** commands.

Variable	Value
<i>enable</i>	Enables Multi-area SPB layer 2 multicast snooping redistribution.
<i>i-sid</i> <1-16777215>	Specifies the I-SID value.
<i>isis-list</i> <i>WORD</i> <1-32>	Specifies the name of the I-SID list.
<i>home-to-remote</i>	Specifies the layer 2 multicast snooping redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the layer 2 multicast snooping redistribution configuration for remote to home direction.
<i>route-map</i> <i>WORD</i> <1-64>	Specifies the name of the route policy.

### Configure Multi-area SPB IPv4 Routed Multicast Redistribution

#### Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.
- Configure the same policies as the boundary node on the peer boundary nodes.

#### About This Task

Perform this procedure to configure Multi-area SPB IPv4 routed multicast redistribution on the switch.

#### Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

2. Create the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-
to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-
to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance:

```
multi-area ip redistribute routed-multicast [home-to-remote | remote-
to-home] enable
```

5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration:

```
show isis multi-area ip redistribute routed-multicast [home-to-remote
| remote-to-home]
```

6. Apply the Multi-area SPB IPv4 routed multicast redistribution:

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| remote-to-home]
```

## Example

Configuring Multi-area SPB IPv4 routed multicast redistribution for home to remote direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote route-
map test
Switch:1(config-isis)#multi-area ip redistribute routed-multicast home-to-remote enable
Switch:1(config-isis)#show isis multi-area ip redistribute routed-multicast home-to-remote
=====
          ISIS Multiarea Redistribute List for routed multicast - GlobalRouter
=====
DIRECTION          ENABLE          RPOLICY
-----
home-to-remote     TRUE           test
-----
Switch:1(config-isis)#isis multi-area ip apply redistribute routed-multicast home-to-
remote
```

## Variable Definitions

The following table defines parameters for the **multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** command.

Variable	Value
<code>enable</code>	Enables Multi-area SPB IPv4 routed multicast redistribution.
<code>home-to-remote</code>	Specifies the IPv4 routed multicast redistribution configuration for home to remote direction.
<code>remote-to-home</code>	Specifies the IPv4 routed multicast redistribution configuration for remote to home direction.
<code>route-map</code> <code>WORD&lt;1-64&gt;</code>	Specifies the name of the route policy.
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the multicast routing redistribution configuration for specific VRF instance.

### Configure IS-IS Multi-area SPB IPv4 Routed Multicast Redistribution on a VRF Instance

#### Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multiprotocol Label Switching Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.
- Configure the same policies as the boundary node on the peer boundary nodes.

#### About This Task

Perform this procedure to configure IS-IS Multi-area SPB IPv4 routed multicast redistribution on a specific Virtual Router Forwarding (VRF) instance on the switch.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the IS-IS Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home]
```

#### Note

If you do not specify the direction for redistribution then the system applies the redistribution in both directions by default.

3. (Optional) Configure a route policy to govern the redistribution:

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] route-map WORD<1-64>
```

4. Enable the Multi-area SPB IPv4 routed multicast redistribution instance on the VRF:
 

```
isis multi-area ip redistribute routed-multicast [home-to-remote |
remote-to-home] enable
```
5. Verify the Multi-area SPB IPv4 routed multicast redistribution configuration on the VRF:
 

```
show isis multi-area ip redistribute routed-multicast [home-to-remote
| remote-to-home] [vrf WORD<1-16> | vrfids WORD<0-512>]
```
6. Exit to Global Configuration mode:
 

```
exit
```
7. Apply the Multi-area SPB IPv4 routed multicast redistribution on the VRF:
 

```
isis multi-area ip apply redistribute routed-multicast [home-to-remote
| [remote-to-home] vrf WORD<1-16>
```

### Example

Configuring IS-IS Multi-area SPB IPv4 routed multicast redistribution for home to remote direction on VRF VRF1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
route-map test
Switch:1(router-vrf)#isis multi-area ip redistribute routed-multicast home-to-remote
enable
Switch:1(router-vrf)#show isis multi-area ip redistribute routed-multicast home-to-remote
vrf VRF1
=====
                ISIS Multiarea Redistribute List for routed multicast - VRF VRF1
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE       test
-----
Switch:1(router-vrf)#exit
Switch:1(config)#isis multi-area ip apply redistribute routed-multicast home-to-remote
vrf VRF1
```

### Variable Definitions

The following table defines parameters for the **isis multi-area ip redistribute routed-multicast** and the **isis multi-area ip apply redistribute routed-multicast** commands.

Variable	Value
<i>enable</i>	Enables IPv4 routed multicast redistribution on the VRF instance.
<i>home-to-remote</i>	Specifies the IPv4 routed multicast redistribution configuration for home to remote direction.
<i>remote-to-home</i>	Specifies the IPv4 routed multicast redistribution configuration for remote to home direction.

Variable	Value
<code>route-map</code> <code>WORD&lt;1-64&gt;</code>	Specifies the name of the route policy.
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the multicast routing redistribution configuration for specific VRF instance.

### Configure Multi-area Flags Functionality

#### About This Task

Perform this procedure to configure the Multi-area SPB node as a boundary node to forward traffic from the UNIs to the remote-area and from the remote-area to the UNIs without requiring an established adjacency in the home area.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable
configure terminal
router isis
```
2. Configure the multi-area flags functionality:
 

```
multi-area flags home-always-up
```

### Configure Multi-area SPB IPv4 Static I-SID Routed Multicast Redistribution

#### Before You Begin

- Enable multicast on the boundary nodes.
- Configure Multicast Virtual Private Network (MVPN) on the boundary nodes, for layer 3 VSN.

#### About This Task

Perform this procedure to configure Multi-area SPB IPv4 static I-SID routed multicast redistribution on the switch.

#### Note

- Routed multicast redistribution is available for IPv4 only.
- Multi-area SPB boundary nodes can redistribute static data I-SIDs, and the static data I-SID multicast redistribution policy takes precedence over the Layer 2 multicast redistribution.
- Multi-area SPB boundary nodes with remote IS-IS enabled do not support IP SPB Multicast Policy .

## Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```

2. Configure the Multi-area SPB IPv4 static I-SID list to redistribute on the switch:

```
multi-area ip redistribute static-isid-routed-multicast [home-to-remote | remote-to-home] isid-list WORD<1-32>
```

The system displays the warning message while configuring the Multi-area SPB IPv4 static I-SID routed multicast redistribution:

```
WARNING: L3 static i-sid routed multicast will not be inter-area redistributed until apply command is issued after enable command.
```

3. Enable the Multi-area SPB IPv4 static I-SID routed multicast redistribution instance:

```
multi-area ip redistribute static-isid-routed-multicast [home-to-remote | remote-to-home] enable
```

4. Verify the Multi-area SPB IPv4 static I-SID routed multicast redistribution configuration:

```
show isis multi-area ip redistribute static-isid-routed-multicast [home-to-remote | remote-to-home]
```

5. Apply the Multi-area SPB IPv4 static I-SID routed multicast redistribution:

```
isis multi-area ip apply redistribute static-isid-routed-multicast
```

## Example

Configuring Multi-area SPB IPv4 static I-SID list to redistribute for remote to home direction:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#multi-area ip redistribute static-isid-routed-multicast remote-to-home isid-list list2
WARNING: L3 static i-sid routed multicast will not be inter-area redistributed until apply command is issued after enable command.

## Variable Definitions

The following table defines parameters for the **multi-area ip redistribute static-isis-routed-multicast** command.

Variable	Value
<i>enable</i>	Enables Multi-area SPB IPv4 static I-SID routed multicast redistribution.
<i>home-to-remote</i>	Specifies the IPv4 static I-SID routed multicast redistribution configuration for home to remote direction.
<i>isis-list</i> WORD<1-32>	Specifies the name of the I-SID list.
<i>remote-to-home</i>	Specifies the IPv4 static I-SID routed multicast redistribution configuration for remote to home direction.

## Multi-area SPB Verification using CLI

Perform the procedures in this section to verify the Multi-area SPB configuration on the switch using the Command Line Interface (CLI).

### Note

The following procedures only applies to VSP 7400 Series.

### Display the Remote IS-IS SPBM Nickname Configuration

#### About This Task

Perform this procedure to display the remote Intermediate-System-to-Intermediate-System (IS-IS) Shortest Path Bridging MAC (SPBM) nickname configuration on the switch.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display the remote IS-IS SPBM nickname configuration:

```
show isis spbm nick-name remote
```

#### Example

Displaying the remote IS-IS SPBM nickname configuration:

```
Switch:1>show isis spbm nick-name remote
=====
ISIS SPBM NICK-NAME
=====
LSP ID                LIFETIME  NICK-NAME  VIRTUAL-BMAC  HOST-NAME  AREA  AREA NAME

*Display IS-IS Remote Area Configuration***About This Task**

Perform this procedure to display the IS-IS remote area configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS remote configuration:

```
show isis remote
```

**Example**

Displaying IS-IS remote area information:

```
Switch:1>show isis remote
=====
                        ISIS Remote Area Info
=====
                        AdminState   : disabled
                        System ID    : 209e.f77e.2086
                        Num of Interfaces : 4
                        Num of Area Addresses : 1
                        Dynamically Learned Area : 49.0002
                        Multi-Area OperState : designated
```

*Display IS-IS Area Configuration***About This Task**

Perform this procedure to display the IS-IS area configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS area configuration:

```
show isis area
```

**Example**

Displaying IS-IS area configuration:

```
Switch:1>show isis area
=====
                        ISIS Area Address
=====
ADDRESS                ORIGIN   AREA     AREA-NAME
-----

49.0050                 config   REMOTE   50
=====
```

*Display IS-IS Area Virtual Node Configuration***About This Task**

Perform this procedure to display the IS-IS area virtual node configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS area virtual node configuration:

```
show isis area-vnode
```

**Example**

Displaying IS-IS area virtual node configuration:

```
Switch:1>show isis area-vnode
=====
                        ISIS SPBM Multi-Area VNode Info

### *Display IS-IS Multi-area SPB IPv4 Redistribution Configuration*

#### About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv4 redistribution configuration for home to remote, remote to home, unicast, routed multicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv4 home to remote redistribution configuration:
 

```
show isis multi-area ip redistribute [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv4 remote to home redistribution configuration:
 

```
show isis multi-area ip redistribute [remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv4 routed multicast redistribution configuration:
 

```
show isis multi-area ip redistribute routed-multicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv4 unicast redistribution configuration:
 

```
show isis multi-area ip redistribute unicast [home-to-remote [vrf WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
6. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF instance:
 

```
show isis multi-area ip redistribute vrf WORD<1-16>
```
7. Display the IS-IS Multi-area SPB IPv4 redistribution configuration for VRF ID:
 

```
show isis multi-area ip redistribute vrfids WORD<0-512>
```

## Example

Displaying the IS-IS Multi-area SPB IPv4 unicast redistribution configuration on the switch:

```
Switch:1>show isis multi-area ip redistribute unicast
=====
                ISIS Multiarea Redistribute List for ip unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE
remote-to-home     TRUE
```

### Display IS-IS Multi-area SPB IPv6 Redistribution Configuration

#### About This Task

Perform this procedure to display the IS-IS Multi-area SPB IPv6 redistribution configuration for home to remote, remote to home, unicast, specific Virtual Router Forwarding (VRF) instance, and VRF IDs on the switch.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB IPv6 home to remote redistribution configuration:  

```
show isis multi-area ipv6 redistribute [home-to-remote [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
3. Display the IS-IS Multi-area SPB IPv6 remote to home redistribution configuration:  

```
show isis multi-area ipv6 redistribute [remote-to-home [vrf WORD<1-16>
| vrfids WORD<0-512>]]
```
4. Display the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:  

```
show isis multi-area ipv6 redistribute unicast [home-to-remote [vrf
WORD<1-16> | vrfids WORD<0-512>] | remote-to-home [vrf WORD<1-16> |
vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]
```
5. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF instance:  

```
show isis multi-area ipv6 redistribute [vrf WORD<1-16>]
```
6. Display the IS-IS Multi-area SPB IPv6 redistribution configuration for VRF ID:  

```
show isis multi-area ipv6 redistribute [vrfids WORD<0-512>]
```

## Example

Displaying the IS-IS Multi-area SPB IPv6 unicast redistribution configuration:

```
Switch:1>show isis multi-area ipv6 redistribute unicast
=====
                ISIS Multiarea Redistribute List for ipv6 unicast - GlobalRouter
=====
DIRECTION          ENABLE      RPOLICY
-----
home-to-remote     TRUE      Test1
remote-to-home     TRUE      Test2
```

*Display IS-IS Multi-area SPB DvR Configuration***About This Task**

Perform this procedure to display the IS-IS Multi-area SPB Distributed Virtual Routing (DvR) redistribution configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS Multi-area SPB DvR redistribution configuration:

```
show isis multi-area dvr redistribute
```

**Example**

Displaying the IS-IS Multi-area SPB DvR redistribution configuration on the switch:

```
Switch:1>show isis multi-area dvr redistribute
=====
MULTI-AREA DVR BACKBONE REDISTRIBUTE
=====
Admin State
-----
Enabled
-----
```

*Display IS-IS Multi-area SPB Layer 2 Multicast Snooping Redistribution Configuration***Note**

The following procedure only applies to VSP 7400 Series.

**About This Task**

Perform this procedure to display the IS-IS Multi-area SPB layer 2 multicast snooping redistribution configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast snooping redistribution configuration:

```
show isis multi-area l2 redistribute snoop-multicast
```

**Example**

Displaying the IS-IS Multi-area SPB layer 2 multicast snooping redistribution configuration on the switch:

```
Switch:1>show isis multi-area l2 redistribute snoop-multicast
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID
=====
ISID          DIRECTION          ENABLE    RPOLICY
-----
1100         home-to-remote     TRUE      test
=====
MULTI-AREA L2 SNOOP MULTICAST REDISTRIBUTE BY ISID LIST
=====
ISID LIST      DIRECTION          ENABLE    RPOLICY
```

```
-----
List1          home-to-remote    TRUE    test
-----
```

## Multi-area SPB Configuration using EDM

Perform the procedures in this section to configure Multi-area SPB parameters like area virtual node, remote Intermediate-System-to-Intermediate-System (IS-IS), remote Shortest Path Bridging MAC (SPBM), layer 2 unicast and multicast redistribution, and IPv4 and IPv6 route redistribution on the switch using the Enterprise Device Manager (EDM).

### Note

The following procedures only apply to VSP 7400 Series.

### Configure Multi-area SPB Layer 2 I-SID List

#### About This Task

Perform this procedure to configure layer 2 I-SID list.

#### Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 ISID List** tab.
4. Select **Insert**.
5. Configure the layer 2 I-SID list parameters.
6. Select **Insert**.

#### L2 I-SID List Field Descriptions

Use data in the following table to use the **L2 I-SID List** tab.

Name	Description
<b>Name</b>	Specifies the name of the layer 2 I-SID list.
<b>RangeStart</b>	Specifies the I-SID value as the starting range for the layer 2 I-SID list.
<b>RangeEnd</b>	Specifies the I-SID value as the ending range for the layer 2 I-SID list.

### Configure Layer 2 Multi-area SPB I-SID Redistribution

#### About This Task

Perform this procedure to configure Multi-area SPB layer 2 redistribution.

#### Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 ISID Redist** tab.

4. Select **Insert**.
5. Configure the layer 2 I-SID redistribution parameters.
6. Select **Insert**.

### L2 Redistribute Field Descriptions

Use the data in the following table to use the **L2 Redistribute** tab.

Name	Description
<b>Type</b>	Specifies the layer 2 Redistribution type.
<b>Permit</b>	Configures the Multi-area SPB layer 2 I-SID redistribution policy as permit or deny.
<b>ExceptListName</b>	Configures the name of layer 2 I-SID list. The system does not apply the Multi-area SPB layer 2 I-SID redistribution policy to I-SID values or the range of I-SID values in the layer 2 I-SID list.

*Configure Multi-area SPB Layer 2 Multicast I-SID Redistribution for Home Area*

#### About This Task

Perform this procedure to configure the Multi-area SPB layer 2 multicast redistribution for specific I-SID value(s) in the home area.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Home ISID** tab.
4. Select **Insert**.
5. In the **I-sid** field, type the I-SID value.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the name of the redistribution policy.
8. Select **Insert**.

### L2 MC Redist Home ISID Field Descriptions

Use the data in the following table to use the **L2 MC Redist Home ISID** tab.

Name	Description
<b>I-sid</b>	Specifies the I-SID value.
<b>Enable</b>	Enables layer 2 multicast redistribution for specific I-SID value in the home area.
<b>PolicyName</b>	Specifies the name of the redistribution policy.

*Configure Multi-area SPB L2 Multicast I-SID List Redistribution for Home Area*

#### About This Task

Perform this procedure to configure the Multi-area SPB layer 2 multicast I-SID list redistribution for the home area.

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Home ISID List** tab.
4. Select **Insert**.
5. In the **ISID List Name** field, type the name of the I-SID list.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the policy name.
8. Select **Insert**.

### L2 MC Redist Home ISID List Field Descriptions

Use the data in the following table to use the **L2 MC Redist Home ISID List** tab.

Name	Description
<b>ISID List Name</b>	Specifies the name of the I-SID list.
<b>Enable</b>	Enables Multi-area SPB layer 2 multicast redistribution for the specific I-SID list in the home area.
<b>PolicyName</b>	Specifies the name of the redistribution policy.

### *Apply Multi-area SPB Layer 2 Multicast Redistribution in Home Area*

#### About This Task

Perform this procedure to apply the Multi-area SPB layer 2 multicast redistribution that you configure in the home area.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**
3. Select the **L2 MC Apply Home** tab.
4. In the **McastApply** field, select **apply**.

### L2 MC Apply Home Field Descriptions

Use data in the following table to use the **L2 MC Apply Home** tab.

Name	Description
<b>McastApply</b>	Applies or disables the Multi-area SPB layer 2 multicast redistribution in the home area. <ul style="list-style-type: none"> <li>• noAction</li> <li>• apply</li> </ul>

*Configure Multi-area SPB Layer 2 Multicast I-SID Redistribution for Remote Area***About This Task**

Perform this procedure to configure the Multi-area SPB layer 2 multicast redistribution for specific I-SID value(s) in the remote area.

**Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Remote ISID** tab.
4. Select **Insert**.
5. In the **I-sid** field, type the I-SID value.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the name of the redistribution policy.
8. Select **Insert**.

**L2 MC Redist Remote ISID Field Descriptions**

Use the data in the following table to use the **L2 MC Redist Remote ISID** tab.

Name	Description
<b>I-sid</b>	Specifies the I-SID value.
<b>Enable</b>	Enables layer 2 multicast redistribution for specific I-SID value in the remote area.
<b>PolicyName</b>	Specifies the name of the redistribution policy.

*Configure Multi-area SPB L2 Multicast I-SID List Redistribution for Remote Area***About This Task**

Perform this procedure to configure the Multi-area SPB layer 2 multicast I-SID list redistribution for the remote area.

**Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L2 MC Redist Remote ISID List** tab.
4. Select **Insert**.
5. In the **ISID List Name** field, type the name of the I-SID list.
6. Select **Enable**.
7. (Optional) In the **PolicyName** field, type the policy name.
8. Select **Insert**.

**L2 MC Redist Remote ISID List Field Descriptions**

Use the data in the following table to use the **L2 MC Redist Remote ISID List** tab.

6

Name	Description
<b>ISID List Name</b>	Specifies the name of the I-SID list.
<b>Enable</b>	Enables Multi-area SPB layer 2 multicast redistribution for the specific I-SID list in the remote area.
<b>PolicyName</b>	Specifies the name of the redistribution policy.

### *Apply Multi-area SPB Layer 2 Multicast Redistribution in Remote Area*

#### About This Task

Perform this procedure to apply the Multi-area SPB layer 2 multicast redistribution that you configure in the remote area.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **MultiArea**
3. Select the **L2 MC Apply Remote** tab.
4. In the **McastApply** field, select **apply**.

#### L2 MC Apply Remote Field Descriptions

Use data in the following table to use the **L2 MC Apply Remote** tab.

Name	Description
<b>McastApply</b>	Applies or disables the Multi-area SPB layer 2 multicast redistribution in the remote area. <ul style="list-style-type: none"> <li>• noAction</li> <li>• apply</li> </ul>

### *Configure Multi-area SPB Layer 3 Redistribution in Home Area*

#### About This Task

Perform this procedure to configure Multi-area SPB layer 3 redistribution in the home area.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L3 Redist Home** tab.
4. Select **Insert**.
5. In the **Vrflid** field, type the Virtual Router Forwarding ID.
6. In the **Type** field, select the layer 3 redistribution type.
7. (Optional) In the **RoutePolicy** field, type the name of the redistribution policy.
8. Select **Enable**.

9. In the **Apply** field, select **apply**.
10. Select **Insert**.

### L3 Redist Home Field Descriptions

Use the data in the following table to use the **L3 Redist Home** tab.

Name	Description
<b>Vrflid</b>	Specifies the Virtual Router Forwarding ID.
<b>Type</b>	Specifies the layer 3 redistribution type. The options are: <ul style="list-style-type: none"> <li>• <b>ip-ucast</b> - IPv4 unicast</li> <li>• <b>ip-mcast</b> - IPv4 multicast</li> <li>• <b>ipv6-ucast</b> - IPv6 unicast</li> </ul>
<b>RoutePolicy</b>	Associates a route policy to a specific layer 3 redistribution entry in the home area.
<b>Enable</b>	Enables layer 3 redistribution in the home area. The default value is disabled.
<b>Apply</b>	Applies the Multi-area SPB layer 3 redistribution filters in the home area. The default value is noAction.

### Configure Multi-area SPB Layer 3 Redistribution in Remote Area

#### About This Task

Perform this procedure to configure Multi-area SPB layer 3 redistribution in the remote area.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**.
3. Select the **L3 Redist Remote** tab.
4. Select **Insert**.
5. In the **Vrflid** field, type the Virtual Router Forwarding ID.
6. In the **Type** field, select the layer 3 redistribution type.
7. (Optional) In the **RoutePolicy** field, type the name of the redistribution policy.
8. Select **Enable**.
9. In the **Apply** field, select **apply**.
10. Select **Insert**.

### L3 Redist Remote Field Descriptions

Use the data in the following table to use the **L3 Redist Remote** tab.

Name	Description
<b>Vrflid</b>	Specifies the Virtual Router Forwarding ID.
<b>Type</b>	Specifies the layer 3 redistribution type. The options are: <ul style="list-style-type: none"> <li>• <b>ip-ucast</b> - IPv4 unicast</li> <li>• <b>ip-mcast</b> - IPv4 multicast</li> <li>• <b>ipv6-ucast</b> - IPv6 unicast</li> </ul>
<b>RoutePolicy</b>	Associates a route policy to a specific layer 3 redistribution entry in the remote area.
<b>Enable</b>	Enables layer 3 redistribution in the remote area. The default value is disabled.
<b>Apply</b>	Applies the Multi-area SPB layer 3 redistribution filters in the remote area. The default value is noAction.

*Configure Multi-area SPB Layer 3 Static I-SID Routed Multicast Redistribution Policy in Home Area*

### About This Task

Perform this procedure to configure Multi-area SPB Layer 3 static I-SID routed multicast redistribution policy in the home area.

#### Note

Routed multicast redistribution is available for IPv4 only. With the MAC learning disabled, the static data I-SID multicast redistribution policy takes precedence over the Layer 2 multicast redistribution.

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric**.
2. Select **MultiArea**.
3. Select the **L3 MC Redist Home Static ISID List** tab.
4. Select **Insert**.
5. In the **Type** field, select **staticisid**.
6. Select **Enable**.
7. In the **IsidListName** field, type the name of the I-SID list.
8. In the **Apply** field, select **apply**.
9. Select **Insert**.

### L3 MC Redist Home Static ISID List Field Descriptions

Use the data in the following table to use the **L3 MC Redist Home Static ISID List** tab.

Name	Descriptions
<b>Type</b>	Specifies the layer 3 static I-SID routed multicast redistribution type. The default type is <code>staticisid</code> .
<b>Enable</b>	Enables layer 3 static I-SID routed multicast redistribution in the home area. The default value is disabled.
<b>IsidListName</b>	Specifies the name of the I-SID list. The default I-SID list name is <code>htr</code> .
<b>Apply</b>	Applies the Multi-area SPB layer 3 static I-SID routed multicast redistribution filters in the home area. The default value is <code>noAction</code> .

Configure Multi-area SPB Layer 3 Static I-SID Routed Multicast Redistribution Policy in Remote Area

### About This Task

Perform this procedure to configure Multi-area SPB Layer 3 static I-SID routed multicast redistribution policy in the remote area.

#### Note

Routed multicast redistribution is available for IPv4 only. With the MAC learning disabled, the static data I-SID multicast redistribution policy takes precedence over the Layer 2 multicast redistribution.

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric**.
2. Select **MultiArea**.
3. Select the **L3 MC Redist Remote Static ISID List** tab.
4. Select **Insert**.
5. In the **Type** field, select **staticisid**.
6. Select **Enable**.
7. In the **IsidListName** field, type the name of the I-SID list.
8. In the **Apply** field, select **apply**.
9. Select **Insert**.

### L3 MC Redist Remote Static ISID List Field Descriptions

Use the data in the following table to use the **L3 MC Redist Remote Static ISID List** tab.

Name	Descriptions
<b>Type</b>	Specifies the layer 3 static I-SID routed multicast redistribution type. The default type is <code>staticisid</code> .
<b>Enable</b>	Enables layer 3 static I-SID routed multicast redistribution in the remote area. The default value is disabled.

Name	Descriptions
<b>IsidListName</b>	Specifies the name of the I-SID list. The default I-SID list name is htr.
<b>Apply</b>	Applies the Multi-area SPB layer 3 static I-SID routed multicast redistribution filters in the remote area. The default value is noAction.

### *Configure Multi-area SPB DvR Redistribution*

#### **About This Task**

Perform this procedure to configure the Multi-area SPB Distributed Virtual Routing (DvR) backbone redistribution on the switch.

#### **Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **MultiArea**
3. Select the **DVR Redistribute** tab.
4. Select **DvrBbRedistribute**.
5. Select **Apply**.

#### **DVR Redistribute Field Descriptions**

Use data in the following table to use the **DVR Redistribute** tab.

Name	Description
<b>DvrBbRedistribute</b>	Configures the Multi-area SPB DvR redistribution on the switch. The default is disabled.

### *Display Remote IS-IS and SPBM Summary*

#### **About This Task**

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) and SPBM summary.

#### **Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Protocol Summary** tab.

#### **Protocol Summary Field Descriptions**

Use data in the following table to use the **Protocol Summary** tab.

Name	Description
<b>AdminState</b>	Indicates the global status of remote IS-IS on the switch.
<b>SystemId</b>	Indicates the remote IS-IS system ID of the switch.
<b>NodeNickName</b>	Indicates the nickname for the remote SPBM instance globally.
<b>Circuit Index</b>	Indicates the identifier of the IS-IS circuit. This value is for SNMP indexing purposes only and does not have any relation to any protocol value.
<b>IfIndex</b>	Indicates the interface to which the circuit corresponds.
<b>AdminState</b>	Indicates the administrative state of the circuit. <ul style="list-style-type: none"> <li>• on</li> <li>• off</li> </ul>
<b>OperState</b>	Indicates the operational state of the circuit. <ul style="list-style-type: none"> <li>• up</li> <li>• down</li> </ul>
<b>Circuit Index</b>	Indicates the unique identifier of the remote IS-IS circuit. This value is for SNMP Indexing purposes only and does not have any relation to any protocol value.
<b>AdjIndex</b>	Indicates value identifying the IS-IS adjacency from all other such adjacencies on the circuit. The system dynamically assigns this value when it forms an adjacency.
<b>Interface</b>	Indicates the remote IS-IS interface.
<b>AdjState</b>	Indicates the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>
<b>AdjNeighSysID</b>	Indicates the system ID of the neighboring IS-IS.
<b>AdjHostName</b>	Indicates the host name listed in the LSP, or the IS-IS system name. The IS-IS system name uses global system name, if the host name is not configured.

*Configure Remote IS-IS Global Parameters***About This Task**

Perform this procedure to configure remote IS-IS global parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

**Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Globals** tab.
4. Configure the remote IS-IS global parameters.
5. Click **Apply**.

**Globals Field Descriptions**

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AdminState</b>	Specifies the global status of remote IS-IS on the switch. The default is off.
<b>SystemId</b>	<p>Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format &lt;xxxx.xxxx.xxxx&gt;.</p> <p><b>Important:</b> After you configure the SPBM nickname and enable remote IS-IS, if you change the system ID, you must also change the nickname. However, changing the nickname could impact the naming convention or configuration. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 1052.</p>
<b>DynamicallyLearnedArea</b>	For FAN members, specifies the remote IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.

Name	Description
<b>MAOperState</b>	<p>Specifies the Multi-area SPB operational state:</p> <ul style="list-style-type: none"> <li>• Disabled – Multi-area SPB is disabled on the switch.</li> <li>• Init – the switch is initializing to function as a boundary node.</li> <li>• Designated – the switch is up and running as a designated boundary node.</li> <li>• Non-designated – the switch is up and running as a non-designated boundary node.</li> </ul> <p>The default is disabled.</p>
<b>MAFlags</b>	<p>Specifies the Multi-area SPB as a boundary node to forward traffic from the UNIs to the remote-area and from the remote-area to the UNIs without requiring an established adjacency in the home area.</p> <p>The default is disabled.</p>

### Configure Remote IS-IS Interfaces

#### About This Task

Perform this procedure to configure the remote IS-IS interfaces. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select **Insert** to create a remote IS-IS instance.
5. Configure the IS-IS interface parameters.
6. Select **Insert**.

#### Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>Index</b>	<p>Specifies the identifier of the circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.</p>
<b>IfIndex</b>	<p>Specifies the interface on which the circuit is configured (port or MLT).</p>

Name	Description
<b>Type</b>	Specifies the IS-IS circuit type. Only the point-to-point (PtToPt) interface type is supported.
<b>AdminState</b>	Specifies the administrative state of the circuit: on or off.
<b>OperState</b>	Specifies the operational state of the circuit.

Name	Description
<b>AuthType</b>	<p>Specifies the authentication type:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value, but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value, but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b> Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default is none.</p>
<b>AuthKey</b>	Specifies the authentication key.
<b>KeyId</b>	Specifies the authentication key ID.

Name	Description
<b>LevelType</b>	Specifies the router type globally: <ul style="list-style-type: none"> <li>level1: Level-1 router type</li> <li>level 1and2: Level-1/2 router type. This type is not supported.</li> </ul> The default value is level1.
<b>NumAdj</b>	Specifies the number of adjacencies on this circuit.
<b>NumUpAdj</b>	Specifies the number of adjacencies that are up.
<b>AutoNniEnable</b>	Enable to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface. This field displays on the Insert Interfaces dialog box and applies to port interfaces only.
<b>Origin</b>	Specifies the origin of the IS-IS circuit configuration on the port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

### Configure Remote IS-IS Interface Level Parameters

#### About This Task

Perform this procedure to configure remote IS-IS interface level parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces Level** tab.
4. Configure the remote IS-IS interface level parameters.
5. Select **Apply**.

#### Interfaces Level Field Descriptions

Use the data in the following table to use the **Interfaces Level** tab.

Name	Description
<b>Index</b>	Specifies the identifier of the circuit, the value is unique within the remote IS-IS. The value is for SNMP Indexing purposes only and does not relate to any protocol value.
<b>Level</b>	Specifies the router type globally: <ul style="list-style-type: none"> <li>• l1: Level1 router type</li> <li>• l12: Level1/Level2 router type. This type is not supported.</li> </ul> The default value is l1.
<b>ISPriority</b>	Specifies an integer sub-range for remote IS-IS priority. The default is 64.
<b>HelloTimer</b>	Configures the level 1 hello interval. Specifies the maximum period, in milliseconds, between IS-IS Hello Packets (IIS) PDUs on multiaccess networks at this level for LANs. The value at Level1 is used as the period between Hellos on Level1/Level2 point to point circuits. Setting this value at Level 2 on an Level1/Level2 point-to-point circuit results in an error of InconsistentValue. The default value is 9000 milliseconds or 9 seconds.
<b>HelloMultiplier</b>	Configures the level 1 hello multiplier. The default value is 3 seconds.
<b>DRHelloTimer</b>	Indicates the period, in milliseconds, between Hello PDUs on multiaccess networks when this Intermediate System is the Designated Intermediate System. The default is 3.

### Configure Remote SPBM on an Interface

#### About This Task

Perform this procedure to configure remote Shortest Path Bridging MAC (SPBM) on an interface.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select the **SPBM** button.
5. Select **Insert**
6. Configure the interfaces SPBM parameters.
7. Select **Insert**.

#### SPBM Field Descriptions

Use data in the following table to use the **Interfaces SPBM** tab.

Name	Description
<b>Index</b>	Specifies an Index value for the remote SPBM interface.
<b>SpbmId</b>	Specifies the remote SPBM ID.
<b>State</b>	Specifies whether the remote SPBM interface is enabled or disabled.
<b>Type</b>	Configures the remote SPBM instance interface-type on the IS-IS interface on the specific port or MLT, the values are point-to-point (ptpt) or broadcast (bcst). The system supports the ptpt interface type only.
<b>LIMetric</b>	Configures the remote SPBM instance l1-metric on the IS-IS interface on the specific port or MLT. The default value is 10.
<b>Origin</b>	Specifies the source of the remote SPBM instance configuration. <ul style="list-style-type: none"> <li>• config - configure manually through CLI or EDM.</li> <li>• dynamic - configure dynamically through Auto-sense.</li> </ul>

### *View Statistical Graph of Remote IS-IS Interface Counters*

#### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface counters.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.

#### Interface Counters Field Descriptions

The following table describes the fields in the **Interface Counters** tab.

Name	Description
<b>InitFails</b>	Indicates the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures.
<b>RejAdjs</b>	Indicates the number of times an adjacency has been rejected on this circuit.

Name	Description
<b>IDFieldLenMismatches</b>	Indicates the number of times an Intermediate-System-to-Intermediate-System (IS-IS) control PDU with an ID field length different from that for this system has been received.
<b>MaxAreaAddrMismatches</b>	Indicates the number of times an IS-IS control PDU with a max area address field different from that for this system has been received.
<b>AuthFails</b>	Indicates the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
<b>LANDesISChanges</b>	Indicates the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

### *View Statistical Graph of Remote IS-IS Interface Sending Control Packets*

#### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface sending control packets.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Sending Control Packets** tab.

#### Interface Sending Control Packets Field Descriptions

Use data in the following table to use the **Interface Sending Control Packets** tab.

Name	Description
<b>Hello</b>	Indicates the number of IS-IS Hello (IIH) PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on Layer 1 or L1L2 circuits, and at Layer 2 otherwise.
<b>LSP</b>	Indicates the number of IS-IS LSP frames seen in this direction at this level.
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

#### *View Statistical Graph of Remote IS-IS Interface Receiving Control Packet*

##### About This Task

Perform this procedure to view statistical graph of the remote IS-IS interface receiving control packets.

##### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Interfaces** tab.
4. Select an interface.
5. Select the **Graph** button.
6. Select the **Interface Receiving Control Packets** tab.

##### Interface Receiving Control Packets Field Descriptions

Use data in the following table to use the **Interface Receiving Control Packets** tab.

Name	Description
<b>Hello</b>	Indicates the number of IS-IS Hello PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on L1 or L1L2 circuits, and at L2 otherwise.
<b>LSP</b>	Indicates the number of IS-IS link-state packet (LSP) frames seen in this direction at this level.

Name	Description
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

### Configure Remote IS-IS Manual Area

#### About This Task

Perform this procedure to configure a remote IS-IS manual area.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Manual Area** tab.
4. Select **Insert**.
5. In the **AreaAddr** field, type the Area Address.
6. Select **Insert**.

#### Manual Area Field Descriptions

Use the data in the following table to use the **Manual Area** tab.

Name	Description
<b>AreaAddr</b>	Specifies the remote IS-IS manual-area in the range of 1 to 13 bytes.

### View Level 1 Remote Area Information

#### About This Task

Perform this procedure to display Level 1 remote area information. Remote Intermediate-System-to-Intermediate-System (IS-IS) provides support for hierarchical routing, which enables the system to partition large routing domains into smaller areas. Remote IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas

and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

### Important

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **L1 Area** tab.

### L1 Area Remote Field Descriptions

Use the data in the following table to use the **L1 Area Remote** tab.

Name	Description
<b>AreaAddr</b>	Specifies an area address reported in a Level 1 link-state packets (LSP) that the system generates or receives through the Intermediate System.

### *View Remote LSP Summary Information*

#### About This Task

Perform this procedure to view the remote link-state packet (LSP) summary information. Link State Packets (LSP) contain information about the state of adjacencies or defined and distributed static routes. Intermediate-System-to-Intermediate-System (IS-IS) exchanges this information with neighboring IS-IS routers at periodic intervals.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **LSP Summary** tab.

### LSP Summary Field Descriptions

Use the data in the following table to use the **LSP Summary** tab.

Name	Description
<b>Level</b>	Specifies the level at which the system displays the remote LSP.
<b>ID</b>	Specifies the 8-byte LSP ID, consisting of the system ID, circuit ID, and Fragment Number.
<b>Seq</b>	Specifies the sequence number for the LSP.
<b>Checksum</b>	Specifies the 16-bit Fletcher Checksum for the LSP.

Name	Description
<b>LifetimeRemain</b>	Specifies the remaining lifetime in seconds for the LSP.
<b>HostName</b>	Specifies the host name.

### View Remote IS-IS Adjacencies

#### About This Task

Perform this procedure to view remote IS-IS adjacency information. The platform sends IS-IS Hello (IIH) packets to discover IS-IS neighbors and establish and maintain the IS-IS adjacency. The platform continues to send IIH packets to maintain the adjacencies that the system establishes. For two nodes to form an adjacency the B-VLAN pairs for the primary B-VLAN and secondary B-VLAN must match.

#### Procedure

1. In the navigation pane, expand the **Configuration** > **Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Adjacency** tab.

#### Adjacency Field Descriptions

Use the data in the following table to use the **Adjacency** tab.

Name	Description
<b>Interface</b>	Specifies the remote IS-IS interface on which the adjacency is found.
<b>Level</b>	Indicates the level of the remote IS-IS interface (Level 1 [default] or Level 2).
<b>State</b>	Specifies the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>
<b>LastUpTime</b>	Indicates when the adjacency most recently entered the state <b>up</b> , measured in hundredths of a second since the last re-initialization of the network management subsystem. Displays 0 if the adjacency has never been in state <b>up</b> .
<b>NeighPriority</b>	Specifies the priority of the neighboring Intermediate System to transition to the Designated Intermediate System.
<b>HoldTimer</b>	Specifies the holding time in seconds for this adjacency. This value is based on received IS-IS Hello (IIH) PDUs and the elapsed time since receipt.
<b>NeighSysID</b>	Specifies the system ID of the neighboring Intermediate System.

Name	Description
<b>AdjHostName</b>	Specifies the host name listed in the LSP.
<b>ParallelActive</b>	Specifies if the current adjacency among all the parallel adjacencies between two nodes is active. The values are: <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>

### Configure IS-IS Area Virtual Node

#### About This Task

Perform this procedure to configure the area virtual node parameters like system name, system ID, and nickname on the Intermediate-System-to-Intermediate-System (IS-IS) instance.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS**.
3. Select the **Area VNode** tab.
4. Configure the parameters.
5. Select **Apply**.

#### Area VNode Field Descriptions

Use the data in the following table to use the **Area VNode** tab.

Name	Description
<b>VNodeNickName</b>	Specifies the nickname of the virtual node on the IS-IS instance.
<b>VNodeSysId</b>	Specifies the system ID of the virtual node on the IS-IS instance.
<b>VNodeSysName</b>	Specifies the system name of the virtual node on the IS-IS instance.

### Configure Remote IS-IS Area Virtual Node

#### About This Task

Perform this procedure to configure the area virtual node parameters like system name, system ID, and nickname on the remote Intermediate-to-Intermediate-System (IS-IS) instance.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **IS-IS Remote**.
3. Select the **Area VNode** tab.
4. Configure the parameters.
5. Select **Apply**.

## Area VNode Field Descriptions

Use the data in the following table to use the **Area VNode** tab.

Name	Description
<b>VNodeNickName</b>	Specifies the nickname of the virtual node on remote IS-IS instance.
<b>VNodeSysId</b>	Specifies the system ID of the virtual node on remote IS-IS instance.
<b>VNodeSysName</b>	Specifies the system name of the virtual node on remote IS-IS instance.

### Configure Remote SPBM Parameters

#### About This Task

Perform this procedure to configure remote SPBM global parameters. SPBM uses the remote Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **SPBM** tab.
4. Select **Insert** to create a remote SPBM instance.
5. Configure the remote SPBM parameters.
6. Select **Insert**.

## SPBM Field Descriptions

Use data in the following table to use the **SPBM** tab.

Name	Description
<b>Id</b>	Specifies the remote SPBM instance ID.
<b>NodeNickName</b>	Specifies a nickname for the remote SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>.
<b>PrimaryVlan</b>	Specifies the primary SPBM B-VLANs to add to the remote SPBM instance.
<b>Vlans</b>	Specifies the SPBM B-VLANs to add to the remote SPBM instance.
<b>LsdbTrap</b>	Enables or disables a trap when the SPBM LSDB changes. The default is disable.
<b>IpShortcut</b>	Enables or disables SPBM IP shortcut state. The default is disable.
<b>SmltSplitBEB</b>	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.

Name	Description
<b>SmltVirtualBmac</b>	Specifies a virtual MAC address that can be used by both peers.
<b>SmltPeerSysId</b>	Specifies the system ID of the SPBM SMLT for this remote SPBM instance.
<b>Mcast</b>	Specifies if IP multicast over remote SPBM is enabled. The default is disabled.
<b>McastFwdCacheTimeout</b>	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
<b>Ipv6Shortcut</b>	Enables or disables SPBM IPv6 shortcut state. The default is disable.
<b>McastSpbPimGwControllerEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
<b>McastSpbPimGwGatewayEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.
<b>StpMultiHoming</b>	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
<b>BVlanOrigin</b>	Specifies the origin of the B-VLAN. The values are: <ul style="list-style-type: none"> <li>• config - manual configuration using CLI or SNMP.</li> <li>• dynamic - through Auto-sense or Zero Touch Fabric Configuration.</li> </ul> The default is dynamic.

### Configure Remote SPBM Parameters on the Interface

#### About This Task

Perform this procedure to configure the remote SPBM interface parameters.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **Interfaces SPBM** tab.
4. Select **Insert** to create a remote SPBM instance on the interface.
5. Configure the remote SPBM interface parameters.
6. Select **Insert**.

#### Interfaces SPBM Field Descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
<b>Index</b>	Specifies an Index value for the remote SPBM interface.
<b>SpbmId</b>	Specifies the remote SPBM ID.
<b>State</b>	Specifies whether the remote SPBM interface is enabled or disabled.
<b>Type</b>	Configures the remote SPBM instance interface-type on the IS-IS interface on the specific port or MLT, the values are point-to-point (ptpt) or broadcast (bcast). The system supports the ptpt interface type only.
<b>LIMetric</b>	Configures the remote SPBM instance l1-metric on the IS-IS interface on the specific port or MLT. The default value is 10.
<b>Origin</b>	Specifies the source of the remote SPBM instance configuration. <ul style="list-style-type: none"> <li>• config - configure manually through CLI or EDM.</li> <li>• dynamic - configure dynamically through Auto-sense.</li> </ul>

#### View Remote SPBM I-SID Information

##### About This Task

Perform this procedure to view the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

##### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **I-SID** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

##### I-SID Field Descriptions

Use data in the following table to use the **I-SID** tab.

Name	Description
<b>SysId</b>	Indicates the system identifier.
<b>Vlan</b>	Indicates the B-VLAN where the remote I-SID is configured or discovered.
<b>Isid</b>	Indicates the remote IS-IS SPBM I-SID identifier.
<b>NickName</b>	Indicates the nickname of the node where the remote I-SID is configured or discovered.

Name	Description
<b>HostName</b>	Indicates the host name listed in the LSP, or the IS-IS system name. The IS-IS system name uses global system name, if you do not configure the host name.
<b>Type</b>	Indicates the remote SPBM I-SID type. The values are discover or configure.

### View Remote SPBM Nicknames

#### About This Task

Perform this procedure to view remote SPBM nicknames on the switch.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **Nick Names** tab.

#### Nick Names Field Descriptions

Use the data in the following table to use the **Nick Names** tab.

Name	Description
<b>Level</b>	Indicates the level at which the system displays this LSP.
<b>ID</b>	Indicates the 8 byte LSP ID, consisting of the System ID, Circuit ID, and Fragment Number.
<b>LifetimeRemain</b>	Indicates the remaining lifetime in seconds for the LSP.
<b>NickName</b>	Indicates the nickname for the remote SPBM node.
<b>HostName</b>	Indicates the hostname that the system displays in the LSP, or the system name if the host name is not configured.

### View Remote IP Unicast FIB

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB). When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

The system adds the routes within the same VSN to the LSDB with a default preference of 7 and the inter-VSN routes with a route preference of 200. With IS-IS accept policies you can change the route preference for incoming routes. If the system learns the same route from multiple sources with different route preferences, then the routes are not equal cost multipath (ECMP) routes. The system prefers the route with the lowest route preference. In Layer 2, if there is a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

### About This Task

Perform this procedure to display the remote IP unicast FIB. You can view the IP routes from remote Backbone Edge Bridges (BEBs)

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **IP Unicast FIB** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### IP Unicast FIB Field Descriptions

Use the data in the following table to use the **IP Unicast FIB** tab.

Name	Description
<b>Vrfid</b>	Specifies the VRF ID of the remote IP unicast FIB entry, 0 indicates NRE.
<b>DestinationIpAddrType</b>	Specifies the address type of the destination IP address.
<b>DestinationIpAddr</b>	Specifies the destination IP Address of the remote IP unicast FIB entry.
<b>DestinationMask</b>	Specifies the destination IP mask of the remote IP unicast FIB entry
<b>NextHopBmac</b>	Specifies the nexthop B-MAC of the remote IP unicast FIB entry.
<b>DestIsid</b>	Specifies the destination I-SID of the remote IP unicast FIB entry.
<b>Vlan</b>	Specifies the VLAN of the remote IP unicast FIB entry.
<b>Isid</b>	Specifies the I-SID of the remote IP unicast FIB entry.
<b>NextHopName</b>	Specifies the nexthop hostname of the remote IP unicast FIB entry.
<b>OutgoingPort</b>	Specifies the outgoing port of the remote IP unicast FIB entry.
<b>PrefixCost</b>	Specifies the prefix cost of the remote IP unicast FIB entry.

Name	Description
<b>SpbmCost</b>	Specifies the B-MAC cost of the remote IP unicast FIB entry.
<b>Preference</b>	Specifies the IP Route preference of the remote IP unicast FIB entry
<b>MetricType</b>	Specifies the IP Metric Type of the remote IP unicast FIB entry.

### View Remote IPv6 Unicast FIB

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB). When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are not exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

### About This Task

Perform this procedure to display the remote IPv6 unicast FIB. You can view the IPv6 routes from remote Backbone Edge Bridges (BEBs).

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **IPv6 Unicast FIB** tab.
4. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

### IPv6 Unicast FIB Field Descriptions

Use the data in the following table to use the **IPv6 Unicast FIB** tab.

Name	Description
<b>VrfId</b>	Specifies the VRF ID of the remote IPv6 unicast FIB entry, 0 indicates NRE.
<b>DestinationIpAddrType</b>	Specifies the address type of the destination IPv6 address.
<b>DestinationIpAddr</b>	Specifies the destination IPv6 Address of the remote IPv6 unicast FIB entry.
<b>DestinationMask</b>	Specifies the destination IPv6 mask of the remote IPv6 unicast FIB entry

Name	Description
<b>NextHopBmac</b>	Specifies the nexthop B-MAC of the remote IPv6 unicast FIB entry.
<b>DestIsid</b>	Specifies the destination I-SID of the remote IPv6 unicast FIB entry.
<b>Vlan</b>	Specifies the VLAN of the remote IPv6 unicast FIB entry.
<b>Isid</b>	Specifies the I-SID of the IPv6 unicast FIB entry.
<b>NextHopName</b>	Specifies the nexthop hostname of the remote IPv6 unicast FIB entry.
<b>OutgoingPort</b>	Specifies the outgoing port of the remote IPv6 unicast FIB entry.
<b>PrefixCost</b>	Specifies the prefix cost of the remote IPv6 unicast FIB entry.
<b>SpbmCost</b>	Specifies the B-MAC cost of the remote IPv6 unicast FIB entry.
<b>MetricType</b>	Specifies the Metric Type of the remote IPv6 unicast FIB entry.

#### *View Remote Unicast FIB*

In SPBM, the IS-IS link-state database carries the B-MAC addresses. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

#### **About This Task**

Perform this procedure to view the remote unicast FIB.

#### **Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **Unicast FIB** tab.

#### **Unicast FIB Remote Field Descriptions**

Use the data in the following table to use the **Unicast FIB Remote** tab.

Name	Description
<b>SysId</b>	Specifies the system ID of the node where the remote unicast FIB entry originates.
<b>Vlan</b>	Specifies the VLAN of the remote unicast FIB entry.
<b>DestinationMacAddr</b>	Specifies the destination MAC Address of the remote unicast FIB entry.
<b>OutgoingPort</b>	Specifies the outgoing port of the remote unicast FIB entry.
<b>HostName</b>	Specifies the host name of the node where the remote unicast FIB entry originates.
<b>Cost</b>	Specifies the cost of the remote unicast FIB entry.

### *View Remote Multicast FIB*

In SPBM, the IS-IS link-state database carries the B-MAC addresses. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. The system populates these Backbone MAC addresses into the SPBM VLAN Forwarding Information Base (FIB).

When the system discovers a network topology and stores it in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information that it receives from SPBM into the FIB for forwarding purposes.

The system produces the remote multicast FIB only after you configure the virtual services and the system learns them.

### About This Task

Perform this procedure to view the remote multicast FIB.

### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **Multicast FIB** tab.

### Multicast FIB Field Descriptions

Use the data in the following table to use the **Multicast FIB** tab.

Name	Description
<b>SysId</b>	Specifies the system ID of the node where the remote multicast FIB entry originates.
<b>Vlan</b>	Specifies the VLAN ID of the remote multicast FIB entry.

Name	Description
<b>McastDestMacAddr</b>	Specifies the multicast destination MAC Address of the remote multicast FIB entry.
<b>Isid</b>	Specifies the I-SID value in the remote multicast FIB entry.
<b>Isid Name</b>	Specifies the name that the system assigns to the I-SID.
<b>HostName</b>	Specifies the host name of the node where the multicast FIB entry originates.
<b>OutgoingInterfaces</b>	Specifies the switched UNI port outgoing interface of the remote multicast FIB entry.
<b>IncomingInterface</b>	Specifies the incoming interface (port or MLT) of the remote multicast FIB entry.

### *View Remote IP Multicast over Fabric Connect Routes*

#### About This Task

Perform this procedure to view the remote IP Multicast over Fabric Connect routes.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **IpMcastRoutes** tab.

#### IpMcastRoutes Field Descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

Name	Description
<b>VsnIsid</b>	Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.
<b>Group</b>	Specifies the group IP address for the IP Multicast over Fabric Connect route.
<b>Source</b>	Specifies the IP address where the IP Multicast over Fabric Connect route originated.
<b>SourceBeb</b>	Specifies the source BEB for the IP multicast route.
<b>VlanId</b>	Specifies the ID for the C-VLAN.
<b>VrfName</b>	Specifies the VRF name.

Name	Description
<b>Datalsid</b>	Specifies the data I-SID for the IP Multicast over Fabric Connect route. A BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID.
<b>Type</b>	Specifies the type for the IP Multicast over Fabric Connect route.
<b>Bvlan</b>	Specifies the B-VLAN for the IP Multicast over Fabric Connect route.
<b>NniInterfaces</b>	Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.

*View UNI Ports for remote IP Multicast Routes*

#### About This Task

Perform this procedure to view the UNI ports associated with particular remote IP multicast routes.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **SPBM Remote**.
3. Select the **IpMcastRoutes** tab.
4. Select an entry.
5. Select the **UNI Ports** button.

#### IpMcastRoutes-Uni Ports Field Descriptions

Use data in the following table to use the **IpMcastRoutes-Uni Ports** tab.

Name	Description
<b>Vsnlsid</b>	Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.
<b>Group</b>	Specifies the group IP address for the IP Multicast over Fabric Connect route.
<b>Source</b>	Specifies the IP address where the IP Multicast over Fabric Connect route originates.
<b>NickName</b>	Specifies the nickname.

Name	Description
<b>EgressVlan</b>	Specifies the egress VLAN of the IP multicast route.
<b>EgressActivePorts</b>	Specifies the egress active ports.

### View Remote IS-IS System Statistics

#### About This Task

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) system statistics.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **Stats Remote**.
3. Select the **System Stats** tab.

#### System Stats Field Descriptions

Use the data in the following table to use the **System Stats** tab.

Name	Description
<b>CorrLSPs</b>	Indicates the number of corrupted in-memory link-state packets (LSPs) detected. LSPs received from the wire with a bad checksum are silently dropped and not counted.
<b>AuthFails</b>	Indicates the number of authentication key failures recognized by this Intermediate System.
<b>LSPDbaseOloads</b>	Indicates the number of times the LSP database has become overloaded.
<b>ManAddrDropFromAreas</b>	Indicates the number of times a manual address has been dropped from the area.
<b>AttmptToExMaxSeqNums</b>	Indicates the number of times the IS has attempted to exceed the maximum sequence number.
<b>SeqNumSkips</b>	Indicates the number of times a sequence number skip has occurred.
<b>OwnLSPPurges</b>	Indicates the number of times a zero-aged copy of the system's own LSP is received from some other node.
<b>IDFieldLenMismatches</b>	Indicates the number of times a PDU is received with a different value for ID field length to that of the receiving system.
<b>PartChanges</b>	Indicates partition changes.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.

Name	Description
<b>Average/sec</b>	Displays the average value for each second.
<b>Minimum/sec</b>	Displays the minimum value for each second.
<b>Maximum/sec</b>	Displays the maximum value for each second.
<b>LastVal/sec</b>	Displays the last value for each second.

### View Remote IS-IS Interface Counters

#### About This Task

Perform this procedure to view the remote Intermediate-System-Intermediate-System (IS-IS) interface counters.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **Stats Remote**.
3. Select the **Interface Counters** tab.

#### Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
<b>Index</b>	Shows a unique value identifying the IS-IS interface.
<b>Level</b>	Shows the type of circuit that discovered the interface counters. The point to point Hello PDU includes both Layer 1 and Layer 2, and IS from a single adjacency on point to point links, therefore combining counts on point to point links into one group.
<b>AdjChanges</b>	Shows the number of times an adjacency state change has occurred on this circuit.
<b>InitFails</b>	Shows the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures. Failures to form an adjacency are counted by isisCircRejAdjs.
<b>RejAdjs</b>	Shows the number of times an adjacency has been rejected on this circuit.
<b>IDFieldLenMismatches</b>	Shows the number of times an IS-IS control PDU with an ID field length different to that for this system has been received.
<b>MaxAreaAddrMismatches</b>	Shows the number of times an IS-IS control PDU with a max area address field different to that for this system has been received.

Name	Description
<b>AuthFails</b>	Shows the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
<b>LANDesISChanges</b>	Shows the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.

### *View Remote IS-IS Interface Control Packets*

#### About This Task

Perform this procedure to view the remote Intermediate-System-to-Intermediate-System (IS-IS) interface control packets.

#### Procedure

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **Stats Remote**.
3. Select the **Interface Control Packets** tab.

#### Interface Control Packets Field Descriptions

Use the data in the following table to use the **Interface Control Packets** tab.

Name	Description
<b>Index</b>	Shows a unique value identifying the Intermediate-System-to-Intermediate-System (IS-IS) interface.
<b>Level</b>	Specifies the level.
<b>Direction</b>	Indicates whether the switch is sending or receiving the PDUs.
<b>Hello</b>	Indicates the number of IS-IS Hello frames seen in this direction at this level.
<b>LSP</b>	Indicates the number of IS-IS LSP frames seen in this direction at this level.
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packets (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNP) frames seen in this direction at this level.

*View the Remote I-SID Forwarding Database***About This Task**

Perform this procedure to view the remote I-SID forwarding database (FDB) on the switch.

**Note**

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

**Procedure**

1. In the navigation pane, expand the **Configuration > Fabric** folders.
2. Select **ISID Remote**.
3. (Optional) Select the **Filter** button to filter the rows on basis of specific criteria.

**FDB Field Descriptions**

Use data in the following table to use the **FDB** tab.

Name	Description
<b>IsidId</b>	Specifies the service interface identifier (I-SID).
<b>Address</b>	Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID.
<b>Status</b>	Specifies the learning status of the associated MAC.
<b>Port</b>	Specifies the port on which the MAC is learned for the specific I-SID.
<b>PortType</b>	Specifies if the MAC address is learned locally or on an NNI port from a remote destination.
<b>RemoteMacDestAddr</b>	Specifies the virtual B-MAC address or system-ID of the remote destination.
<b>RemoteMacBVlanId</b>	Specifies the B-VLAN ID on which the remote destination was discovered.
<b>RemoteMacDestSysName</b>	Specifies the remote destination system name.
<b>Cvid</b>	Specifies the customer VLAN ID of the associated Switched UNI port.

**Multi-area SPB Configuration Example**

The following figure is an example of the devices connecting to each other in the Multi-area SPB network.

**Note**

The example applies to VSP 7400 Series only.

**Figure 99: Multi-area SPB network example**

The following sections display an example to configure the two boundary nodes in the Multi-area SPB network (BG1 and BG2), to enable remote Intermediate-System-to-Intermediate-System (IS-IS), and to configure the layer 2 and layer 3 unicast redistribution.

#### Note

You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM configuration examples](#) on page 1125.

## Layer 2 VSN configuration fundamentals

This section provides fundamentals concepts for Layer 2 VSN.

### *SPBM Layer 2 VSN*

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the Backbone Edge Bridges (BEBs), customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

In the backbone VLAN (B-VLAN), Backbone Core Bridges (BCBs) forward the encapsulated traffic based on the BMAC-DA, using the shortest path topology learned using IS-IS.

The following figure shows a sample campus SPBM Layer 2 VSN network.

**Figure 100: SPBM L2 VSN in a campus**

One of the key advantages of the SPBM Layer 2 VSN is that network virtualization provisioning is achieved by configuring only the edge of the network (BEBs). As a result, the intrusive core provisioning that other Layer 2 virtualization technologies require is not needed when new connectivity services are added to the SPBM network. For example, when new virtual server instances are created and need their own VLAN instances, they are provisioned at the network edge only and do not need to be configured throughout the rest of the network infrastructure.

Based on its I-SID scalability, this solution can scale much higher than any 802.1Q tagging based solution. Also, due to the fact that there is no need for Spanning Tree in the core, this solution does not need any core link provisioning for normal operation.

Redundant connectivity between the C-VLAN domain and the SPBM infrastructure can be achieved by operating two SPBM switches in switch clustering (SMLT) mode. This

allows the dual homing of any traditional link aggregation capable device into an SPBM network.

### Fabric Connect Service Types

The Fabric Connect technology delivers Layer 2 and Layer 3 virtualization. These virtualized Layer 2 and Layer 3 instances are referred to as Virtual Service Networks (VSNs). A Service Identifier (I-SID) is used to uniquely distinguish these service instances network-wide, and a User Network Interface (UNI) is the boundary or demarcation point between the “service layer” of traditional networks, that is VLANs and VRFs, and the Fabric Connect “service layer”, that is Layer 2 & Layer 3 VSNs.

- Layer 2 VSNs are virtual broadcast domains interconnecting UNI members that share the same Layer 2 VSN I-SID. MAC learning/aging is applied to all Layer 2 VSNs.
- Layer 3 VSNs are virtual routed Layer 3 networks (Layer 3 VPN) leveraging IS-IS as the routing protocol between VRFs that share the same Layer 3 VSN I-SID.

Fabric Connect uses the User-Network-Interface (UNI) to denote the capabilities and attributes of the service interfaces. Fabric connect devices support the following UNI types:

- VLAN UNI (C-VLAN) — a device-specific VLAN-ID maps to a Layer 2 VSN I-SID – all device physical ports that are associated with the VLAN are therefore associated with the UNI.
- Flex UNI — it has the following sub-types:
  - Switched UNI — a VLAN-ID and a given port (VID, port) maps to a Layer 2 VSN I-SID. With this UNI type, VLAN-IDs can be reused on other ports and therefore mapped to different I-SIDs.
  - Transparent Port UNI — a physical port maps to a Layer 2 VSN I-SID (all traffic through that port, 802.1Q tagged or untagged, ingress and egress is mapped to the I-SID). Note: All VLANs on a Transparent Port UNI interface now share the same single MAC learning table of the Transparent Port UNI I-SID.
- E-Tree UNI — it extends Private VLANs beyond one Switch to form a network-wide E-Tree service infrastructure. An E-Tree UNI is a Layer 2 VSN where broadcast traffic flows from Hub sites to Spokes sites, and from Spokes to Hubs, but not between Spoke sites. E-Tree Hubs can be formed with any VLAN UNI, while E-Tree Spokes must be configured as Private VLAN UNIs.
- Layer 3 VSN UNI — a device-specific VRF maps to an I-SID, and the control plane exchanges the Layer 3 routes belonging to the same I-SID. All VRFs in a network sharing the same Layer 3 I-SID effectively form an Layer 3 VPN. Layer 3 VSNs can be configured to simultaneously support both IP Unicast and IP Multicast.

### Transparent Port UNI

Use a Transparent Port User-Network-Interface (Transparent Port UNI or T-UNI) to map an entire port or an MLT to an I-SID. CMAC learning is done against the I-SID. T-UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. No VLAN is involved in this process. Devices switch tagged and untagged traffic in the assigned I-SID regardless of the VLAN ID. The T-UNI port or MLT can be either static or LACP and is not a member of any VLAN or Spanning Tree Group (STG). The T-UNI port or MLT is always in the forwarding state.

You can map multiple ports to a T-UNI I-SID. Multiple ports on the same switch and on other BEBs can use the common I-SID to switch traffic.

T-UNI is a point to point service and all traffic that ingress the UNI egress from the remote UNI end-point

For information about QoS re-marking, see [QoS re-marking on a Transparent Port UNI](#) on page 2913.

#### Transparent

T-UNI is transparent because the MAC learning occurs within the I-SID, and packets that ingress from any CVLAN are processed in an identical manner. Devices switch tagged and untagged traffic in the assigned I-SID. Devices switch control protocols, such as BPDU, LACP, LLDP, and others, in the assigned I-SID, rather than forwarding to the CP.

The service classification of packets that are received on a T-UNI port, is independent of the VLAN ID values present in those packets. All data packets received on a T-UNI port are classified into the same service. When data packets enter and exit the T-UNI service, no VLAN tag modifications are performed on the data packets.

#### T-UNI based MAC learning

When a packet ingresses a port or MLT associated with a T-UNI I-SID, the system performs MAC lookup based on the I-SID. A packet that ingresses a T-UNI port on a BEB can transfer through the SPB network, or can egress out another T-UNI port configured to the same I-SID.

When a packet ingresses a network-to-network interface (NNI) port, before egressing a T-UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all T-UNI ports.

#### Considerations

Consider the following design requirements when you configure a T-UNI:

- Only E-LAN based T-UNI is supported. All T-UNI I-SID end points for a given I-SID become members of the same shared E-LAN service. If an E-LINE type of service is required, provision T-UNI at the two end points comprising the point-to-point service.
- You cannot configure a T-UNI on the same I-SID as a C-VLAN.
- A port or MLT associated with a T-UNI I-SID cannot be part of any VLAN and does not belong to any STG.
- Ensure that you always associate a T-UNI LACP MLT with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.
- No Layer 3 processing takes place on packets ingressing on a T-UNI port.
- Pause frames do not switch through the T-UNI I-SID.
- Multiple ports or MLTs can be associated with same T-UNI I-SID.
- One port or MLT cannot be part of multiple T-UNI I-SIDs.

- An I-SID mapped to a T-UNI service must not be mapped to any other service, such as Layer 2 VSN and Layer 3 VSN, on any of the remote BEBs in the SPBM network.
- Any Spanning Tree Protocol implementation is disabled on the port or MLT associated with the T-UNI I-SID. The port will always be in a Forwarding state.
- No additional IS-IS TLVs are added to advertise or withdraw T-UNI I-SID services. Extreme Networks makes use of the existing IS-IS TLV-144 and sub TLV-3 to carry I-SID information.
- MACs are learned against the combination of the I-SID and port or MLT.
- The MAC address limit is supported on a per-I-SID basis. For example, the MAC addresses learned on the T-UNI I-SID can be limited.

#### Note

MAC learning limit for T-UNI service is not supported on all hardware platforms.

- Static MAC is not supported for a T-UNI port.
- IP traffic and control packets are transparently bridged over T-UNI endpoints.
- Untagged traffic ingressing on the T-UNI port will use COS 0. B-TAG and I-TAG priorities are derived from the best effort queue that is assigned. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned.
- The 802.1p bits of the incoming traffic are used to derive the B-TAG and I-TAG priorities for tagged traffic.
- LACP, VLACP and LLDP PDUs are extracted to the CP and all other control packets are transparently bridged over the T-UNI port or MLT.

This feature handles control PDUs in the following manner:

All the Layer 2 and Layer 3 control packets are transparently bridged over the T-UNI port or MLT with the exception of LACP, VLACP and LLDP PDUs. LACP PDUs, VLACP PDUs and LLDP PDUs are not transparently bridged over the T-UNI port or MLT if LACP, VLACP or LLDP is enabled on the port or MLT.

- If an LACP MLT is associated with a T-UNI I-SID, LACP PDUs are extracted to CP and processed locally.
- If LACP is not enabled globally and LACP MLT is not associated with the T-UNI I-SID, LACP PDUs are transparently bridged across the T-UNI port or MLT.
- If a VLACP enabled port is added to a T-UNI I-SID, VLACP PDUs are extracted to the CP for local processing. If a port that is not VLACP enabled is added to the T-UNI I-SID, VLACP PDUs are transparently bridged across T-UNI port.
- If a LLDP enabled port is added to a T-UNI I-SID, LLDP PDUs are extracted to the CP for local processing.
- If LLDP is not enabled on the port or MLT interface associated to TUNI I-SID , LLDP PDUs are transparently bridged across the T-UNI port or MLT.

The following list of control packet types are transparently bridged across the T-UNI I-SID:

- SLPP
- VRRP

- OSPF
- RIP
- BGP
- IS-IS
- CFM
- STP
- SONMP

Use T-UNI when either of the following apply:

- All tagged and untagged traffic on a port must be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

An example of an application for T-UNI is a typical Ethernet provider deployment with port-based classification and transparent forwarding.

### Transparent Port UNI over vIST

Virtual IST (vIST) provides the ability to dual-home hosts, servers and other network devices to a pair of Multi-Chassis Link Aggregation (MC-LAG) enabled devices. The system displays the MC-LAG nodes to the connected devices as one link-aggregated group. So, although the physical connection is spread between two individual network nodes, logically the system displays them as a single connection.

Transparent Port UNI (T-UNI) over vIST peers extends the capability of dual-home hosts on the SPB cloud to achieve higher network resiliency. The MACs learnt on the T-UNI interface of any one vIST peer is synchronized with the other peer through MAC synchronization.

In the following figure, the T-UNI access switch ACCESS-1 is dual-homed into vIST peer hosts VIST-PEER 1 and VIST-PEER 2. At ACCESS-1, a link aggregation is created to connect to the SPBM cluster. On the VIST peers, an SMLT is created towards ACCESS-1. Depending on the link aggregation hashing logic, traffic is hashed on to VIST-PEER 1 and VIST-PEER 2. The MACs learnt on the T-UNI interfaces of either host is synchronized with the other host.

**Figure 101: Example of Transparent Port UNI over vIST**

If one of the links between ACCESS-1 and the vIST cluster goes down, all traffic is serviced through the other link. The same applies when any of the vIST peers go down.

Since MAC learning on both peers are synchronized, both peers can switch traffic with the same efficiency.

#### Single-homed T-UNI service on a vIST-enabled node

If you configure a T-UNI service as a single-homed service on a vIST-enabled node, you must configure the same I-SID service without port/MLT being mapped to I-SID, on the other vIST peer node. Failure to perform this configuration on the vIST peer node can result in the loss of traffic to the single-homed T-UNI service in various scenarios.

### Switched UNI

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Switched UNI summary:

- Switched UNI is a VLAN and ports associated with I-SIDs.
- Local significance on the ports.
- You can re-use the same VLAN to associate different ports with different I-SIDs.
- You can use a different VLAN to the same ports, or you can assign different ports to the same I-SID.
- Supports VLAN mapping on the local switch.
- To accept untagged traffic, the port needs to be configured as untagged-traffic in the I-SID.

Use Switched UNI when either of the following apply:

- Vlan ID (VID) reuse is required. The same VID is used on different broadcast domains (multi-tenant applications).
- Multiple VLANs must be part of the same broadcast domain.
- VID translation is required.

An example of an application for Switched UNI is a typical host and provider deployment, with a port and VID-based classification.

#### Switched UNI based MAC learning

MAC learning is done on I-SID MAC. When a packet ingresses on a port or MLT which is associated with Switched UNI I-SID, the system performs MAC look up based on the I-SID. Switched UNI operates on Any-To-Any (ELAN) mode, there can be one or more ports associated to a Switched UNI I-SID. A packet that ingresses to a Switched UNI port on a BEB can transfer through the SPBM cloud, or can egress out another Switched UNI port configured to the same I-SID.

When a packet ingresses an network-to-network interface (NNI) port, before egressing a Switched UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all Switched UNI ports in the I-SID.

#### Considerations

Consider the following when you configure a Switched UNI:

- The VLAN tag is removed before the traffic egresses out on the untagged-traffic port or MLT.
- VLAN priority received on the packet is maintained across VLAN IDs.
- Spanning tree is disabled on all Switched UNI ports, and the ports remain in forwarding state.
- The Switched UNI I-SID is advertised to the SPBM cloud.
- The Broadcast and unknown Unicast packets are flooded to all ports in the I-SID.

#### Limitations

- You cannot change from one UNI type to another dynamically. The I-SID has to be deleted and created with new UNI type (Customer VLAN (C-VLAN), Transparent port user-network-interface (T-UNI), ELAN).
- I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.
- If the port is a member of MLT, the entire MLT has to be added to the VID.
- The port is always in the forwarding state.
- The same VID, port, or MLT cannot be member of more than one I-SID.
- Static MAC, Static ARP and static IGMP group are not supported on Switched UNI enabled ports.
- For a Switched UNI endpoint without a platform VLAN on the VSP 7400 Series, when MAC-in-MAC terminated traffic is sent out to the UNI endpoint the packet is re-marked based on existing QoS rules.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN:ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

#### BPDU handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

#### Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

*SPBM sample operation—L2 VSN*

The following section shows how a SPBM network is established, in this case, a Layer 2 VSN.

1. Discover network topology

**Figure 102: SPBM topology discover**

IS-IS runs on all nodes of the SPBM domain. Since IS-IS is the basis of SPBM, the IS-IS adjacency must be formed first. After the neighboring nodes see hellos from each other they look for the same Level (Level 1) and the same area (for example, Area 2f.8700.0000.00). After the hellos are confirmed both nodes send Link State Protocol Data Units, which contain connectivity information for the SPBM node. These nodes also send copies of all other LSPs they have in their databases. This establishes a network of connectivity providing the necessary information for each node to find the best and proper path to all destinations in the network.

Each node has a system ID, which is used in the topology announcement. This same System ID also serves as the switch Backbone MAC address (B-MAC), which is used as the source and destination MAC address in the SPBM network.

- Each IS-IS node automatically builds trees from itself to all other nodes

When the network topology is discovered and stored in the IS-IS link state database (LSDB), each node calculates shortest path trees for each source node. A unicast path now exists from every node to every other node

With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes. Multicast FIB is not produced until Layer 2 VSN services are configured and learned.

- IS-IS advertises new service communities of interest

When a new service is provisioned, its membership is flooded throughout the topology with an IS-IS advertisement.

**Figure 103: SPBM BMAC and I-SID population**

BMAC and I-SID information is flooded throughout the network to announce new I-SID memberships. In this case, VLAN 20 is mapped to I-SID 100.

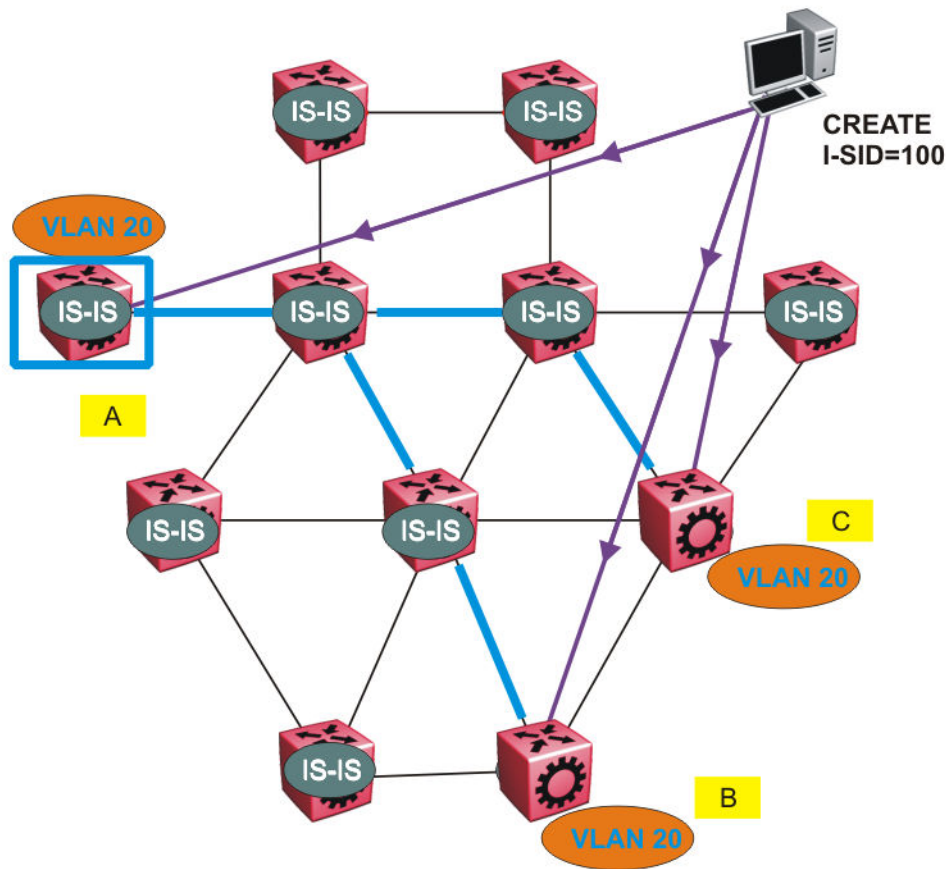

**Note**

I-SIDs are only used for virtual services (Layer 2 and Layer 3 VSNs). If IP Shortcuts only is enabled on the BEBs, I-SIDs are never exchanged in the network as IP Shortcuts allow for IP networks to be transported across IS-IS.

Each node populates its FDB with the BMAC information derived from the IS-IS shortest path tree calculations. Thus there is no traditional flooding and learning mechanism in place for the B-VLAN, but FDBs are programmed by the IS-IS protocol.

4. When a node receives notice of a new service AND is on the shortest path, it updates the FDB

In this scenario, where there are three source nodes having a membership on I-SID 100, there are three shortest path trees calculated (not counting the Equal Cost Trees (ECTs)).

**Figure 104: Shortest path tree for source node A**

Figure 105: Shortest path tree for source node B

**Figure 106: Shortest path tree for source node C**

The paths between any two nodes are always the shortest paths. Also, the paths in either direction are congruent, thus a bidirectional communication stream can be monitored easily by mirroring ingress and egress on a link to a network analyzer.

VLAN traffic arriving on switch A and VLAN 20 is forwarded following the blue path, traffic arriving on switch B and VLAN 20 the orange path and on switch C VLAN 20 traffic is following the green path.

If the destination CMAC is unknown at the SPBM ingress node or the traffic is of type broadcast or multicast, then it is flooded to all members of the topology which spans VLAN 20. If the destination CMAC is already known, then the traffic is only forwarded as a unicast to the appropriate destination. In the SPBM domain, the traffic is switched on the BMAC header only. The bridge filtering database (FDB) at the VLAN to I-SID boundary (backbone edge bridge BEB), maintains a mapping between CMACs and corresponding BMACs.

For example, Switch B learns all CMACs which are on VLAN 20 connected to switch A with the BMAC of A in its FDB and the CMACs which are behind C are learned with the BMAC of C.

## Layer 2 VSN configuration using the CLI

This section provides procedures to configure Layer 2 VSNs using the CLI.

### Configure SPBM Layer 2 VSN

SPBM supports Layer 2 Virtual Service Network (VSN) functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

3. Display C-VLAN information:

```
show vlan i-sid
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan i-sid 10 100
Switch:1(config)#show vlan i-sid

Switch:1>show vlan i-sid
=====
Vlan I-SID
```

```

=====
VLAN_ID      I-SID      I-SID NAME
-----
1
10           100        Hospital-Server-10
90           1000       ISID-1000

3 out of 3 Total Num of Vlans displayed

```

## Variable Definitions

The following table defines parameters for the `vlan i-sid` command.

Variable	Value
<1-4059>	Specifies the primary VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID).  <b>Note:</b> The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.  This value is the same for the primary and secondary VLANs.
<i>force</i>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

### Configure a Global I-SID Name

Use this procedure to provide a descriptive name for the Service Identifier (I-SID).

#### Note

Product Notice: This procedure does not apply to VSP 8600 Series.

You can configure a service name for I-SIDs, loopback interfaces, and static routes. You can configure the service name can before or after you create the I-SID for the following services:

- Layer 2 VSN
- Layer 3 VSN
- ELAN I-SID or Switched UNI I-SID
- ELAN transparent I-SID or Transparent UNI I-SID

- IPv4 and IPv6 static routes
- IPv4 and IPv6 loopback CLIP interface

**Note**

The service name for I-SIDs does not support the following special characters:  
 " " # \$ % ' / [ \ ] ^ { | } ~ @.

By default, the service name is ISID-x, where x correlates to the I-SID number of the service.

**Note**

Product Notice: For XA1400 Series, you can configure a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter a name for the global I-SID.  

```
i-sid name <1-6777215> WORD<1-64>
```
3. Display I-SID names for all configured I-SIDs.  

```
show i-sid name
```
4. Display I-SID name by I-SID.  

```
show i-sid name <1-6777215>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#i-sid name 1 ExtremeServer1
Switch:1(config)#i-sid name 20 ExtremeServer7
```

View the configured I-SID names:

```
Switch:1(config)#show i-sid name
=====
I-SID Name
=====
I-SID          I-SID NAME          TYPE
-----
1              ExtremeServer1      adminName
2              ExtremeServer2      adminName
3              ExtremeServer3      config adminName
4              ISID-4              config
23             ISID-23             config
25             ExtremeServer4      config adminName

Total number of I-SID Name entries: 6.
```

View the configured I-SID by number:

```
Switch:1#show i-sid name 1
```

```

=====
                                I-SID Name
=====
I-SID          I-SID NAME          TYPE
-----
1              ExtremeServer1      adminName

Switch:1#show i-sid name 20
=====
                                I-SID Name
=====
I-SID          I-SID NAME          TYPE
-----
20             ExtremeServer7      adminName
    
```

**Variable Definitions**

Use the data in the following table to use the **i-sid name** command.

Variable	Value
<1-6777215>	Specifies the I-SID number.
WORD<1-64> <b>Note:</b> This parameter does not apply to all hardware platforms.	Specifies the name of the I-SID. The I-SID can be named before or after the I-SID is created. By default, for an I-SID in use, the service is named ISID-x, where x correlates to the I-SID number of the service.

*Displaying C-VLAN I-SID information*

Use the following procedure to display C-VLAN I-SID information.

**Procedure**

1. Display the C-VLAN to I-SID associations:  
`show vlan i-sid <1-4059>`
2. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  
`show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]`
3. Discover where entries are learned:  
`show vlan mac-address-entry [spbm-tunnel-as-mac]`
4. Display the VLAN remote MAC table for a C-VLAN:  
`show vlan remote-mac-table <1-4059>`

**Example**

```

Switch:1>show vlan i-sid
=====
                                Vlan I-SID
=====

## Variable definitions

The following table defines parameters for the **show vlan** commands.

Variable	Value
<code>i-sid &lt;1-4059&gt;</code>	Displays I-SID information for the specified C-VLAN.
<code>mac-address-entry [spbm-tunnel-as-mac]</code>	Displays the bridging forwarding database. Use the optional parameter, <code>spbm-tunnel-as-mac</code> to display the B-MAC in the <code>TUNNEL</code> column. If you do not use this optional parameter, the <code>TUNNEL</code> column displays the host name. If an entry is not learned in the SPBM network, the <code>TUNNEL</code> column will be empty (-).
<code>remote-mac-table &lt;1-4059&gt;</code>	Displays C-VLAN remote-mac-table information.

The following table defines parameters for the **show isis** commands.

Variable	Value
<code>spbm i-sid {all config discover}</code>	<ul style="list-style-type: none"> <li>• all: displays all I-SID entries</li> <li>• config: displays configured I-SID entries</li> <li>• discover: displays discovered I-SID entries</li> </ul>
<code>vlan &lt;1-4059&gt;</code>	Displays I-SID information for the specified SPBM VLAN.
<code>id &lt;1-16777215&gt;</code>	Displays I-SID information for the specified I-SID.
<code>nick-name &lt;x.xx.xx&gt;</code>	Displays I-SID information for the specified nickname.

## Configuring an SPBM Layer 2 Transparent Port UNI

Use this procedure to configure a Transparent Port UNI or E-LAN Transparent service.

### Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes creating the SPBM B-VLANs.

- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

### Caution

In the case of T-UNI LACP SMLT, before you configure SMLT on switch peers, ensure that the T-UNI LACP MLT on each peer is always associated with a VLAN, even if it is the default VLAN, and that it is added to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

## About This Task

You can configure Transparent Port UNI when either of the following apply:

- You want all tagged and untagged traffic on a port to be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

## Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure a Transparent Port UNI (Elan-Transparent based service). Enter:

```
i-sid <1-16777215> elan-transparent
```

This command automatically takes you to the Elan-Transparent I-SID Configuration mode.

- Add ports to the Elan-Transparent based service. Enter:

```
port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

A warning message displays indicating that adding a port to a T-UNI I-SID removes the port from all VLANs. Click **y** when prompted, to continue.

- Add an MLT to the Elan-Transparent based service. Enter:

```
mlt <1-512>
```

A warning message displays indicating that adding an MLT to a Transparent Port UNI I-SID removes the MLT from all VLANs. Click **y** when prompted, to continue.

- To verify the Transparent Port UNI configuration, enter:

```
show i-sid <1-16777215>
```

- To remove ports or MLT from the Elan-Transparent based service, enter one of the following commands:

```
no port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

OR

```
no mlt <1-512>
```

- To delete the Elan-Transparent based service, enter:

```
no i-sid <1-16777215>
```

**Example**

Configure a Transparent Port UNI I-SID (elan-transparent based service).

```
Switch:1(config)#i-sid 3 elan-transparent

Switch:1(elan-tp:3)#port 1/25
Adding Ports to Transparent UNI i-sid removes it from all VLANS.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#

Switch:1(elan-tp:3)#mlt 1
Adding MLTs to Transparent UNI i-sid removes it from all VLANS.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#
```

Verify Transparent Port UNI or Elan-Transparent based service configuration.

```
Switch:1(config)#show i-sid 3

```

**Variable definitions**

The following table defines parameters for the **i-sid** command.

**Note**

When SPB is enabled, I-SID IDs 16000000 (0xF42400) and greater, up to 16,777,215 (0xFFFFF), are reserved for dynamic i-sid allocation and used to support IP Multicast traffic over SPB and other advanced Fabric services.

Variable	Value
<i>i-sid</i> <1-16777215> <i>elan-transparent</i>	Creates an Elan-Transparent based service. The service interface identifier (I-SID) range is 1 to 16777215.
<i>port</i> { <i>slot/port</i> [/ <i>sub-port</i> ]}[- <i>slot/port</i> [/ <i>sub-port</i> ]][,...]	Add ports to the Elan-Transparent based service.
<i>mlt</i> <1-512>	Add MLTs to the Elan-Transparent based service. The MLT range is 1 to 512.

*View all Configured I-SIDs*

Perform this procedure to view all the configured I-SIDs including their types, ports, and MLTs.

**About This Task**

View all configured I-SIDs (both CVLAN and T-UNI). View also the I-SID types and the ports or MLTs that are assigned to each I-SID.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. View all configured I-SIDs. This command displays both CVLAN and T-UNI based I-SIDs.  
show i-sid
3. View all T-UNI (Elan-Transparent) I-SIDs.  
show i-sid [elan-transparent]
4. View information for a particular T-UNI I-SID.  
show i-sid [<1-16777215>]
5. View all IS-IS SPBM I-SID information by I-SID ID:  
show isis spbm i-sid {all|config|discover} [vlan <2-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]

## Example

View all configured I-SIDs.

```
Switch:1(config)#show i-sid

**Variable Definitions**

**Note**

When SPB is enabled, I-SID IDs 16777216 and greater are reserved for internal I-SID and SPB multicast.

The following table defines parameters for the **show i-sid** command.

Variable	Value
<code>&lt;1-16777215&gt;</code>	Specifies the service interface identifier (I-SID).
<code>elan-transparent</code>	Displays only all the Elan-Transparent (T-UNI based) I-SIDs.

The following table defines parameters for the **show isis spbm i-sid** command.

Variable	Value
<code>{all config discover}</code>	<ul style="list-style-type: none"> <li>all: displays all I-SID entries</li> <li>config: displays configured I-SID entries</li> <li>discover: displays discovered I-SID entries</li> </ul>
<code>vlan &lt;2-4059&gt;</code>	Displays I-SID information for the specified SPBM VLAN.
<code>id &lt;1-16777215&gt;</code>	Displays I-SID information for the specified I-SID.
<code>nick-name &lt;x.xx.xx&gt;</code>	Displays I-SID information for the specified nickname.

## View C-MACs Learned on T-UNI Ports for an I-SID

Perform this procedure to view the I-SID bridge forwarding database.

### About This Task

The **show i-sid mac-address-entry** command displays the C-MACs learned on T-UNI I-SIDs. It also displays the C-MACs learned on T-UNI I-SIDs for a specific I-SID, MAC address, port or port list or remote MAC address.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View C-MACs learned on the T-UNI I-SIDs:

```
show i-sid mac-address-entry [<1-16777215>] [home] [mac
<0x00:0x00:0x00:0x00:0x00:0x00>] [non-local] [port {slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]] [remote]
```

### Example

View C-MACs learned on all T-UNI I-SIDs.

```
Switch:1#show i-sid mac-address-entry
```

```

### Variable Definitions

The following table defines parameters for the **show i-sid mac-address-entry** command.

Variable	Value
<1-16777215>	Displays the MAC address learned on the service interface identifier (I-SID).
<i>home</i>	Filters the command output to show only MAC addresses learned in the home area.
<i>mac</i> <0x00:0x00:0x00:0x00:0x00:0x00>	Displays the I-SID FDB details for the specified MAC address.
<i>non-local</i>	Filters the command output to show only MAC addresses learned from other nodes; not local nodes.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Displays the MAC address learned on the specified port or port list.
<code>remote</code>	Filters the command output to show only MAC addresses learned in the remote area.

### Viewing I-SID maximum MAC-limit

Perform this procedure to view the maximum MAC learning limit information for an I-SID.

#### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

### About This Task

The total MAC learning limit per switch is 32000. MAC learning on I-SID stops when the maximum limit is reached.

### Procedure

View the maximum MAC learning limit configured for an I-SID:

```
show i-sid limit-fdb-learning <1-16777215>
```

### Example

View maximum MAC learning limit for all I-SIDs.

```
Switch:1#show i-sid limit-fdb-learning

### Variable definitions

The following table defines parameters for the **show i-sid limit-fdb-learning** command.

#### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

Variable	Value
<i>limit-fdb-learning</i>	Displays the I-SID-based maximum MAC limit information.
<1-6777215>	Displays the service interface identifier (I-SID). The I-SID range is 1 to 16777215.

### Configure an SPBM Layer 2 Switched UNI on an MLT

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

#### About This Task

To configure a Switched UNI on an MLT, you must create a Switched UNI I-SID, and map an MLT to the Switched UNI I-SID.

#### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

#### Procedure

- Enter MLT Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface mlt <1-512>
```

## 2. Enable S-UNI on MLT:

```
flex-uni enable
```

**Note**

You cannot enable Switched UNI on EAPoL enabled interface.

## 3. Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

## 4. Add an MLT to a Switched UNI I-SID:

```
c-vid <c-vid> mlt <1-512>
```

**Note**

You can run this command again to map a Switched UNI MLT to multiple I-SIDs.

## 5. Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic mlt <1-512> [bpdu enable]
```

## 6. Display the Switched UNI information:

```
show mlt i-sid
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#mlt 10
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#flex-uni enable
Switch:1(config-mlt)#i-sid 100
Switch:1(elan:100)#c-vid 20 mlt 10
Switch:1(elan:100)#untagged-traffic mlt 10 bpdu enable
Switch:1(elan:100)#show mlt i-sid
```

```

## Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <1-16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid <c-vid> mlt <mlt-id>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic mlt <mlt-id> [bpdu enable]	Add untagged traffic to the Elan-based service.

### Configuring an SPBM Layer 2 Switched UNI on a Port

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

#### Note

EAP and FA can coexist on the same port. EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port. If EAP is currently enabled, FA can only be enabled if the port is a Flex UNI-enabled port.

VSP 4450 Series, VSP 8600 Series, and XA1400 Series do not support EAP and FA on the same port.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

### About This Task

To configure a Switched UNI on a port, you must create a Switched UNI I-SID, and map the port to the Switched UNI I-SID.

#### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Switched UNI on a port:

```
flex-uni enable
```

### Note

You cannot enable enable EAP on a Switched UNI (S-UNI) on the VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

3. Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

4. Add ports to a Switched UNI I-SID:

```
c-vid <c-vid> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

5. Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} [bpdu enable]
```

6. Display the Switched UNI information:

```
show interface gigabitEthernet i-sid {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/1,1/2
Switch:1(config-if)#flex-uni enable
Switch:1(config-if)#i-sid 100
Switch:1(elan:100)#c-vid 10 port 1/1,1/2
Switch:1(elan:100)#untagged-traffic port 1/1,1/2 bpdu enable
```

```
Switch:1#show interface gigabitEthernet i-sid
```

```

### Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <1-16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid <c-vid> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic < port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}> [bpdu enable]	Add untagged traffic to the Elan-based service.

#### View All Configured Switched UNI I-SIDs

Perform this procedure to view all the configured Switched UNI I-SIDs including their types, ports, and MLTs.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View all configured CVLAN, T-UNI, and S-UNI based I-SIDs:  
show i-sid
3. View all S-UNI I-SIDs.  
show i-sid [elan]
4. View all associated MLT on the S-UNI I-SID.  
show mlt i-sid [MLT ID <1-512>]

## 5. View all associated ports on the S-UNI I-SID.

```
show interface gigabitethernet i-sid {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## 6. View all IS-IS SPBM multicast FIB entries.

```
show isis spbm multicast-fib detail
```

**Examples**

## View all configured I-SIDs.

```
Switch:1#show i-sid

### Variable Definitions

The following table defines parameters for the **i-sid** command.

Variable	Value
elan	Displays only all the Elan (S-UNI based) I-SIDs.
MLT ID <1-512>	Specifies the MLT associated with the Switched UNI I-SID.
{slot/port[/sub-port][/-slot/port[/sub-port]][,...]}	Specifies the ports associated with the Switched UNI I-SID.

### Display C-VLAN and Switched UNI I-SID Information

Use the following procedure to display C-VLAN and Switched UNI (S-UNI) I-SID information.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display the C-VLAN to I-SID associations:  

```
show vlan i-sid <1-4059>
```
- Display I-SID information and Switched UNI to I-SID associations:  

```
show i-sid <1-16777215>
```
- Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  

```
show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
```
- Display all elan I-SID:
  - ```
show i-sid elan
```
- Display I-SID configured on MLT:
  - ```
show mlt i-sid
```
- Display I-SID configured on port:
  - ```
show interfaces gigabitethernet i-sid
```

#### Examples

```
Switch# show isis spbm i-sid all
-----
```

```

## Layer 2 VSN configuration using EDM

This section provides procedures to configure Layer 2 Virtual Services Networks (VSNs) using Enterprise Device Manager (EDM).

### Configuring SPBM Layer 2 VSN

After you have configured the SPBM infrastructure, you can enable the SPBM Layer 2 Virtual Service Network (VSN) using the following procedure.

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

#### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. To map a C-VLAN to a Service instance identifier (I-SID), in the **I-sid** field, specify the I-SID to associate with the specified VLAN.
5. Click **Apply**.

#### Important

- When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.
- The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

### Displaying the remote MAC table for a C-VLAN

Use the following procedure to view a the remote MAC table for a C-VLAN.

#### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Remote MAC** tab.

#### Remote MAC field descriptions

Use the data in the following table to use the **Remote MAC** tab.

| Name                        | Description                                                                                                                                                         |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>               | Indicates the VLAN ID for this MAC address.                                                                                                                         |
| <b>Addr</b>                 | Indicates the customer MAC address for which the bridge has forwarding and/or filtering information                                                                 |
| <b>DestAddr</b>             | Indicates the provider MAC address for which the bridge has forwarding and/or filtering information.                                                                |
| <b>PrimaryBVlanId</b>       | Indicates the primary B-VLAN ID for this MAC address.                                                                                                               |
| <b>PrimaryDestSysName</b>   | Indicates the primary system name of the node where the MAC address entry comes from.                                                                               |
| <b>PrimaryPort</b>          | Either displays the value 0, or indicates the primary port on which a frame came from.                                                                              |
| <b>SecondaryBVlanId</b>     | Indicates the secondary B-VLAN ID for this MAC address                                                                                                              |
| <b>SecondaryDestSysName</b> | Indicates the secondary system name of the node where the MAC address entry comes from.                                                                             |
| <b>SecondaryPort</b>        | Either displays the value 0, or indicates the secondary port on which a frame came from.                                                                            |
| <b>SmltRemote</b>           | Indicates the MAC address entry for the remote vIST peer.                                                                                                           |
| <b>Status</b>               | Indicates the status of this entry: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul> |

### Configure UNI

Use the following procedure to configure a Transparent Port UNI or Switched UNI by mapping an I-SID to a port or MLT and VLAN together.

#### Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

### Before You Begin

You must enable Flex UNI to create a Switched UNI service.

## About This Task

You must first create a type of service instance identifier (I-SID) to create the different types of services available. After you create an I-SID you can add members (ports or MLTs) to the I-SID to create end-points for the service.

## Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.
3. Select the **Service** tab.
4. To create a Transparent Port UNI service:
  - a. Select **Insert**.
  - b. Select **elan Transparent** in the **Type** field.
  - c. Enter the I-SID in the **Id** field.
5. To create a Switched UNI service:
  - a. Select **Insert**.
  - b. Select **elan** in the **Type** field.
  - c. Enter the I-SID in the **Id** field.
6. Select **Insert**.

## Service Field Descriptions

Use the data in the following table to use the **Service** tab.

| Name                                                                                | Description                                                                    |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| <b>ID</b>                                                                           | Specifies a unique value to identify the service associated with this entry.   |
| <b>Type</b>                                                                         | Specifies the type of service associated with this entry.                      |
| <b>MacLimitEnable</b>                                                               | Indicates whether the MAC limit is enabled (true) or disabled (false).         |
| <b>MaxMacLimit</b>                                                                  | Indicates the maximum learned value of the MAC address for each service I-SID. |
| <b>Action</b>                                                                       | Specifies I-SID related actions.                                               |
| <b>OriginBitMap</b>                                                                 | Specifies the origin of the I-SID.                                             |
| <b>VnId</b>                                                                         | Identifies the VXLAN service associated with this I-SID.                       |
| <b>Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                               |

### *Associate a Port and MLT with an I-SID for Elan Transparent*

Transparent Port UNI (T-UNI) maps a port or MLT to an I-SID. Transparent Port UNI configures a transparent port where all traffic is MAC switched on an internal virtual

port using the assigned I-SID. Multiple ports on the same unit and on other Backbone Edge Bridges (BEBs) are switched on a common I-SID. No VLAN is involved in this process. The T-UNI port is not a member of any VLAN or STG.

Use the following procedure to associate a port and MLT with an I-SID.

### Before You Begin

- You must configure Transparent Port UNI. For more information, see [Configuring Transparent UNI](#).
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

### Caution

Ensure that a T-UNI LACP MLT is always associated with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elanTransparent.
4. Select **ELAN**.
5. Select port members.
6. Select MLT Ids.
7. Select **Apply**.

### Elan Transparent field descriptions

Use the data in the following table to use the Elan Transparent tab.

| Name        | Description                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| PortMembers | The set of ports that are members of the elanTransparent service type. From the ports available, you can select single or multiple ports.            |
| MltIds      | The set of bits that represent the MLT Ids. From the MLTs available, you can select any, or all of the MLTs to be a part of elan transparent i-sid . |

### Viewing the I-SID forwarding database

View the I-SID forwarding database (FDB).

### Note

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.

3. Select the **FDB** tab.
4. (Optional) Select the **Filter** button to filter rows based on specific filter criteria.

### FDB Field Descriptions

Use data in the following table to use the **FDB** tab.

| Name                        | Description                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>IsidId</b>               | Specifies the service interface identifier (I-SID).                                                                        |
| <b>Address</b>              | Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID.             |
| <b>Status</b>               | Specifies the learning status of the associated MAC.                                                                       |
| <b>Port</b>                 | Specifies the port on which the MAC is learned for the specific I-SID.                                                     |
| <b>PortType</b>             | Specifies if the MAC address is learned locally or on a network-to-network interface (NNI) port from a remote destination. |
| <b>RemoteMacDestAddr</b>    | Specifies the virtual B-MAC address or system-ID of the remote destination.                                                |
| <b>RemoteMacBVlanId</b>     | Specifies the B-VLAN ID on which the remote destination was discovered.                                                    |
| <b>RemoteMacDestSysName</b> | Specifies the remote destination system name.                                                                              |
| <b>Cvid</b>                 | Specifies the customer VLAN ID of the associated Switched UNI port.                                                        |

### *Associate a Port and MLT with an I-SID for Elan*

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Use the following procedure to associate a port and MLT with an I-SID.

### About This Task

You must configure Switched UNI.

### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elan.
4. Select **Switched Uni**.
5. Select **Insert**.
6. Enter the VLAN ID in the **Cvid** field.

7. Select **Port** or **Mlt** to update the interface index in the **IfIndex** field.
8. Select **Insert**.

#### Switched Uni field descriptions

Use the data in the following table to use the **Switched Uni** tab.

| Name                | Description                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------|
| <b>Isid</b>         | Displays the I-SID.                                                                              |
| <b>Cvid</b>         | Specifies the customer VLAN identifier.                                                          |
| <b>IfIndex</b>      | Specifies the interface index of the Elan end point.                                             |
| <b>Bpdu</b>         | Enables or disables for an untagged end point. The default is disabled.                          |
| <b>OriginBitmap</b> | Specifies the origin information of the service associated with the I-SID Elan end point.        |
| <b>MacBased</b>     | Shows if the current entry is associated to a MAC-based Switched User Network Interface (S-UNI). |

#### Viewing the I-SID interface

View the I-SID interface.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.
3. Select the **Interface** tab.  
Select **Filter** to filter rows on specific filter criteria.

#### Interface field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                | Description                                                              |
|---------------------|--------------------------------------------------------------------------|
| <b>IfIndex</b>      | Specifies the interface index                                            |
| <b>Isid</b>         | Specifies the service interface identifier (I-SID).                      |
| <b>Isid Name</b>    | Specifies the service interface identifier name.                         |
| <b>Vlan</b>         | Specifies the platform VLAN.                                             |
| <b>Cvid</b>         | Specifies the customer VID.                                              |
| <b>Type</b>         | Specifies the type of service associated with the I-SID interface.       |
| <b>OriginBitMap</b> | Specifies the origin of the service associated with the I-SID interface. |

| Name            | Description                                                      |
|-----------------|------------------------------------------------------------------|
| <b>Bpdu</b>     | Specifies the BPDU forward option for the untagged traffic port. |
| <b>MacBased</b> | Specifies the Switched UNI MAC address.                          |

### Modify Global I-SID Name

#### Note

This procedure does not apply to VSP 8600 Series.

### About This Task

Use this procedure to modify the assigned name for the Service Identifier (I-SID).

#### Note

Product Notice: For XA1400 Series, you can modify a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only. For information about feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **ISID**.
3. Select **Global Name**.
4. View the name of the I-SID in the **ISID Name** field. To modify, double-click the name of the I-SID and type a new name.
5. Select **Apply**.

### Global Name Field Descriptions

Use the data in the following table to use the **Global Name** tab.

| Name              | Description                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISID Id</b>    | Specifies the index number that uniquely identifies the I-SID.                                                                                                                      |
| <b>ISID Name</b>  | Specifies the name of the I-SID, which can be up to 64 characters.<br>This field is not supported on all hardware platforms.                                                        |
| <b>UsedByType</b> | Specifies the I-SIDs that are in use as services. An I-SID can have one base type or a combination of base types so that multiple services can use the same I-SID at the same time. |

## Layer 2 VSN configuration examples

This section provides configuration examples to configure Layer 2 VSNs.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Layer 2 VSN Configuration Example

The following figure shows a sample Layer 2 VSN deployment.

**Figure 107: Layer 2 VSN**

The following sections show the steps required to configure the Layer 2 VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1125.

#### SwitchC

```
VLAN CONFIGURATION

vlan create 10 type port-mstprstp 1
vlan members 10 1/1 portmember
vlan i-sid 10 12990010
```

#### SwitchD

```
VLAN CONFIGURATION

vlan create 10 type port-mstprstp 1
vlan members 10 1/1 portmember
vlan i-sid 10 12990010
```

### Verifying Layer 2 VSN operation

The following sections show how to verify the Layer 2 VSN operation in this example.

#### SwitchC

```
Switch# show isis spbm i-sid all

## Inter-VSN routing configuration fundamentals

This section provides fundamental concepts on Inter-VSN Routing.

### Inter-VSN routing

Inter-VSN routing with SPBM allows routing between Layer 2 VLANs with different I-SIDs.

**Figure 109: Inter-VSN routing**

Inter-VSN routing provides a routing hub for Layer 2 Virtual Services Network edge devices, Layer 3 devices, routers, or hosts connected to the SPBM cloud using the SPBM

Layer 2 VSN service. To go between a routed network, a Layer 2 VSN termination point provides the routing services to hop onto another Layer 2 VSN, using I-SID.

#### Note

The Layer 2 VLANs must be in the same VRF. You cannot route traffic between two different VRFs with Inter-VSN routing.

In this example, the C-VLANs are associated with I-SIDs on the BEBs using SPBM Layer 2 VSN. With Inter-VSN routing enabled, BCB C can route traffic between VLAN 11 (I-SID 2011) and VLAN 12 (I-SID 2012).

IP interfaces are where the routing instance exists. In this case, on Switch-20.

#### Note

The switch does not support IP multicast over Fabric Connect routing on inter-VSN routing interfaces.

## Inter-VSN routing configuration using the CLI

This section provides a procedure to configure Inter-VSN routing using the CLI.

### *Configure SPBM Inter-VSN Routing*

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. As a best practice, use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

#### Note

To enable inter-VSN routing, you must configure IP interface where the routing instance exists.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Follow the procedures below on the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between.
  - Create a customer VLAN (C-VLAN) by port:
 

```
vlan create <2-4059> type port-mstprstp <0-63>
```
  - Add ports in the C-VLAN:
 

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

- c. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. On the Backbone Core Bridge (BCB), create a VRF and add a VLAN for each VSN:

- a. Create a VRF:

```
ip vrf WORD<1-16> vrfid <1-511>
```

- b. Create a VLAN to associate with each VSN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

- c. Enter VLAN Interface Configuration mode:

```
interface vlan <1-4059>
```

- d. Add a VLAN to the VRF you created in step a:

```
vrf WORD<1-16>
```

- e. Associate an I-SID with the VLAN:

```
vlan i-sid <1-4059> <0-16777215> [force]
```

### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

- f. Configure an IP address for the VLAN:

```
ip address {A.B.C.D/X}
```

- g. Repeat steps b to f for every VLAN you want to route traffic between.

## Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                                    | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>type port-mstprstp</i> <0-63><br>[ <i>color</i> <0-32> ] | Creates a VLAN by port: <ul style="list-style-type: none"> <li>• &lt;0-63&gt; is the STP instance ID.</li> <li>• <i>color</i> &lt;0-32&gt; is the color of the VLAN.</li> </ul>                                                                                                                                                                                                    |

The following table defines parameters for the **vlan members add** command.

| Variable                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/<br><i>sub-port</i> ] [-<br><i>slot/port</i> [/<br><i>sub-port</i> ]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

The following table defines parameters for the **vlan i-sid** command.

| Variable     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>     | Specifies the primary VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0-16777215> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.                                                                                                                                                                                                          |
| <i>force</i> | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                                    |

The following table defines parameters for the **ip vrf** command.

| Variable             | Value                                                    |
|----------------------|----------------------------------------------------------|
| <i>WORD</i> <1-16>   | Create the VRF and specify the name of the VRF instance. |
| <i>vrfid</i> <1-511> | Specifies the VRF instance by number.                    |

The following table defines parameters for the **vrf** command.

| Variable           | Value                                               |
|--------------------|-----------------------------------------------------|
| <i>WORD</i> <1-16> | Specifies the VRF name. Associates a port to a VRF. |

The following table defines parameters for the **ip address** command.

| Variable    | Value                                  |
|-------------|----------------------------------------|
| {A.B.C.D/X} | Configures an IP address for the VLAN. |

## Inter-VSN routing configuration using EDM

This section provides procedures to configure Inter-VSN routing using Enterprise Device Manager (EDM).

### Configure BEBs for Inter-VSN Routing

Use Inter-VSN routing to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

#### Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

### Before You Begin

You must configure the required SPBM and IS-IS infrastructure.

### About This Task

Follow these steps on the BEBs that contain the VSNs you want to route traffic between.

### Procedure

1. Create a customer VLAN (C-VLAN) by port and add ports in the C-VLAN:
  - a. In the navigation pane, expand **Configuration > VLAN**.
  - b. Select **VLANs**.

- c. On the **Basic** tab, select **Insert**.
  - d. For **Id**, type an unused VLAN ID, or use the ID provided.
  - e. For **Name**, type the VLAN name, or use the name provided.
  - f. For **Color Identifier**, select a color from the list, or use the color provided.
  - g. For **Type**, select **byPort**.
  - h. For **PortMembers**, select the ellipsis (...).
  - i. Select the ports to add as member ports.  
The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
  - j. Select **OK**.
  - k. Select **Insert**.
2. Map a C-VLAN to an I-SID:
    - a. From the same **Configuration > VLAN > VLANs** navigation path, select the **Advanced** tab.
    - b. For **Isid**, specify the I-SID to associate with the specified VLAN.  
The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.
    - c. Select **Apply**.

**Important**

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. Configure the Backbone Core Bridge (BCB) for Inter-VSN Routing. For more information, see [Configure BCBs for Inter-VSN Routing](#) on page 1442.

### *Configure BCBs for Inter-VSN Routing*

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

**Note**

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

**Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure.

- You must configure the BEBs that contain the VSNs you want to route traffic between. For more information, see [Configure BEBs for Inter-VSN Routing](#) on page 1441.

### About This Task

Follow these steps to configure the BCB for inter-VSN routing.

### Procedure

1. On the BCB, create a VRF:
  - a. In the navigation pane, expand **Configuration > VRF**.
  - b. Select **VRF**.
  - c. Select **Insert**.
  - d. For **Id**, specify the VRF ID.
  - e. Name the VRF instance.
  - f. Configure the other parameters as required.
  - g. Select **Insert**.
2. Create a VLAN to associate with each VSN:
  - a. In the navigation pane, expand **Configuration > VLAN**.
  - b. Select **VLANs**.
  - c. On the **Basic** tab, select **Insert**.
  - d. For **Id**, type an unused VLAN ID, or use the ID provided.
  - e. For **Name**, type the VLAN name, or use the name provided.
  - f. For **Color Identifier**, select a color from the list, or use the color provided.
  - g. For **Type**, select **byPort**.
  - h. For **PortMembers**, select the ellipsis (...).
  - i. Select the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
  - j. Select **OK**.
  - k. Select **Insert**.
3. Associate the VLAN with an I-SID:
  - a. From the same **Configuration > VLAN > VLANs** navigation path, select the **Advanced** tab.
  - b. For **Isid**, specify the I-SID to associate with the specified VLAN.
  - c. Select **Apply**.
4. Configure a circuitless IP interface (CLIP):
  - a. In the navigation pane, expand **Configuration > IP**.
  - b. Select **IP**.
  - c. Select the **Circuitless IP** tab.
  - d. Select **Insert**.
  - e. For **Interface**, type a CLIP interface number.
  - f. Provide the IP address.

- g. Provide the network mask.
- h. Select **Insert**.

## Inter-VSN Routing Configuration Example

The following topics provide a configuration example for Inter-VSN routing.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Inter-VSN Routing with SPBM Configuration Example

The following figure shows a sample Inter-VSN deployment.

### Figure 110: Inter-VSN routing configuration

The following sections show the steps required to configure the Inter-VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1125.

Note that the IP interfaces are configured where the routing instance exists, namely, on SwitchG.

#### SwitchC

```
VLAN CONFIGURATION

vlan create 11 type port-mstprstp 1
vlan members 11 1/2 portmember

## SBPM Reference Architectures

SPBM has a straightforward architecture that simply forwards encapsulated C-MACs across the backbone. Because the B-MAC header stays the same across the network, there is no need to swap a label or perform a route lookup at each node. This architecture allows the frame to follow the most efficient forwarding path from end to end.

The following reference architectures illustrate SPBM with multiple switches in a network.

For information about solution-specific architectures like Video Surveillance or Data Center implementation using the switch, see [Solution-Specific Reference Architectures](#) on page 1456.

The following figure shows the MAC-in-MAC SPBM domain with BEBs on the boundary and BCBs in the core.

The following figure illustrates an existing edge that connects to an SPBM core.

The boundary between the MAC-in-MAC SPBM domain and the 802.1Q domain is handled by the BEBs. At the BEBs, VLANs or VRFs are mapped into I-SIDs based on the local service provisioning. Services (whether Layer 2 or Layer 3 VSNs) only need to be configured at the edge of the SPBM backbone (on the BEBs). There is no provisioning needed on the core SPBM nodes.

Provisioning an SPBM core is as simple as enabling SPBM and IS-IS globally on all the nodes and on the core facing links. To migrate an existing edge configuration into an SPBM network is just as simple.

**Figure 111: SPBM basic architecture**

**Figure 112: Access to the SPBM Core**

All BEBs that have the same I-SID configured can participate in the same VSN. That completes the configuration part of the migration and all the traffic flows return to normal operation.

For Layer 3 virtualized routing (Layer 3 VSN), map IPv4-enabled VLANs to VRFs, create an IP VPN instance on the VRF, assign an I-SID to the VRF, and then configure the desired IP redistribution of IP routes into IS-IS.

For Layer 2 virtualized bridging (Layer 2 VSN), identify all the VLANs that you want to migrate into SPBM and assign them to an I-SID on the BEB.

## Campus Architecture

For migration purposes, you can add SPBM to an existing network that has SMLT configured. In fact, if there are other protocols already running in the network, such as Open Shortest Path First (OSPF), you can leave them in place too. SPBM uses IS-IS, and operates independently from other protocols. However, as a best practice, eliminate SMLT in the core and eliminate other unnecessary protocols. This reduces the complexity of the network and makes it much simpler to maintain and troubleshoot.

Whether you configure SMLT in the core, the main point to remember is that SPBM separates services from the infrastructure. For example, in a large campus, a user may need access to other sites or data centers. With SPBM you can grant that access by

associating the user to a specific I-SID. With this mechanism, the user can work without getting access to confidential information of another department.

The following figure depicts a topology where the BEBs in the edge and data center distribution nodes are configured in SMLT clusters. Prior to implementing SPBM, the core nodes would also have been configured as SMLT clusters. When migrating SPBM onto this network design, it is important to note that you can deploy SPBM over the existing SMLT topology without network interruption. After the SPBM infrastructure is in place, you can create VSN services over SPBM or migrate them from the previous end-to-end SMLT-based design.

**Figure 113: SPBM campus without SMLT**

After you migrate all services to SPBM, the customer VLANs (C-VLANs) will exist only on the BEB SMLT clusters at the edge of the SPBM network. The C-VLANs will be assigned to an I-SID instance and then associated with either a VLAN in an Layer 2 VSN or terminated into a VRF in an Layer 3 VSN. You can also terminate the C-VLAN into the default router, which uses IP shortcuts to IP route over the SPBM core.

In an SPBM network design, the only nodes where it makes sense to have an SMLT cluster configuration is on the BEB nodes where VSN services terminate. These are the SPBM nodes where C-VLANs exist and these C-VLANs need to be redundantly extended to non-SPBM devices such as Layer 2 edge stackable switches. On the BCB core nodes where no VSNs are terminated and no Layer 2 edge stackables are connected, there is no longer any use for the SMLT clustering functionality. Therefore, in

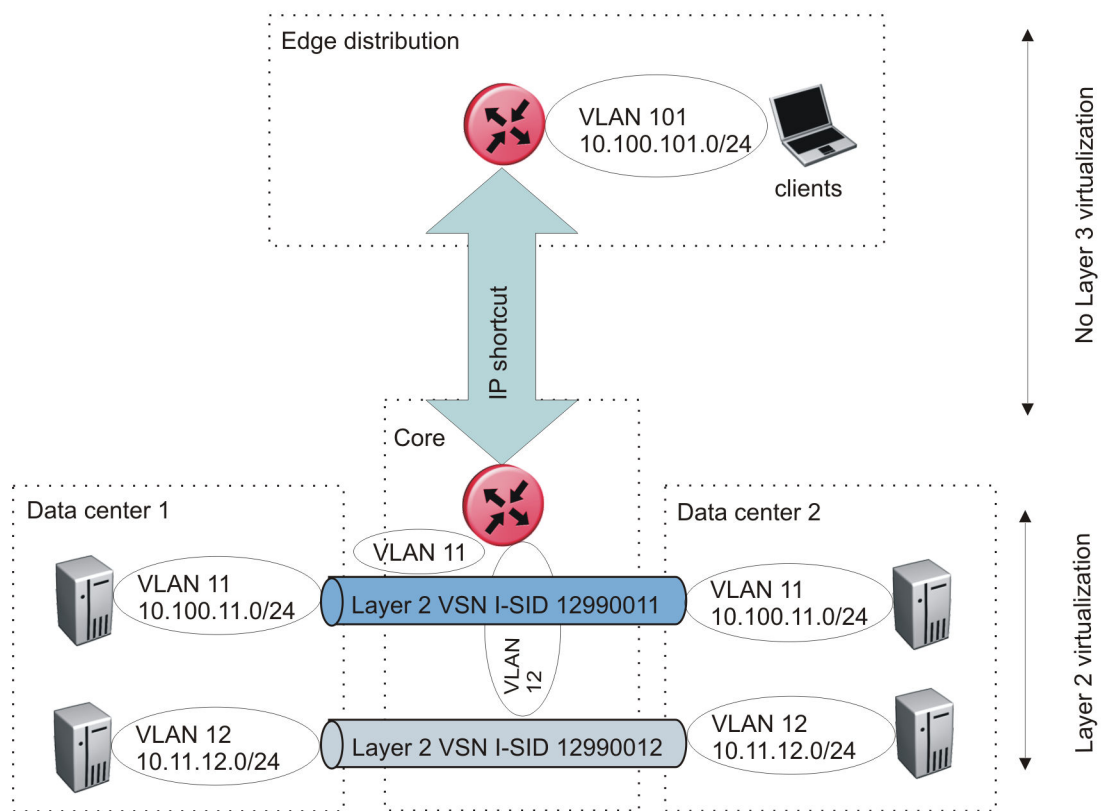

the depicted SPBM design, the SMLT/VIST configuration can be removed from the core nodes because they now act as pure BCBs that simply transport VSN traffic and the only control plane protocol they need to run is IS-IS.

Because SMLT BEB nodes exist in this design (the edge BEBs) and it is desirable to use equal cost paths to load balance VSN traffic across the SPBM core, all SPBM nodes in the network are configured with the same two B-VIDs.

Where the above figure shows the physical topology, the following two figures illustrate a logical rendition of the same topology. In both of the following figures, you can see that the core is almost identical. Because the SPBM core just serves as a transport mechanism that transmits traffic to the destination BEB, all the provisioning is performed at the edge.

In the data center, VLANs are attached to Inter-VSNs that transmit the traffic across the SPBM core between the data center on the left and the data center on the right. A common application of this service is VMotion moving VMs from one data center to another.

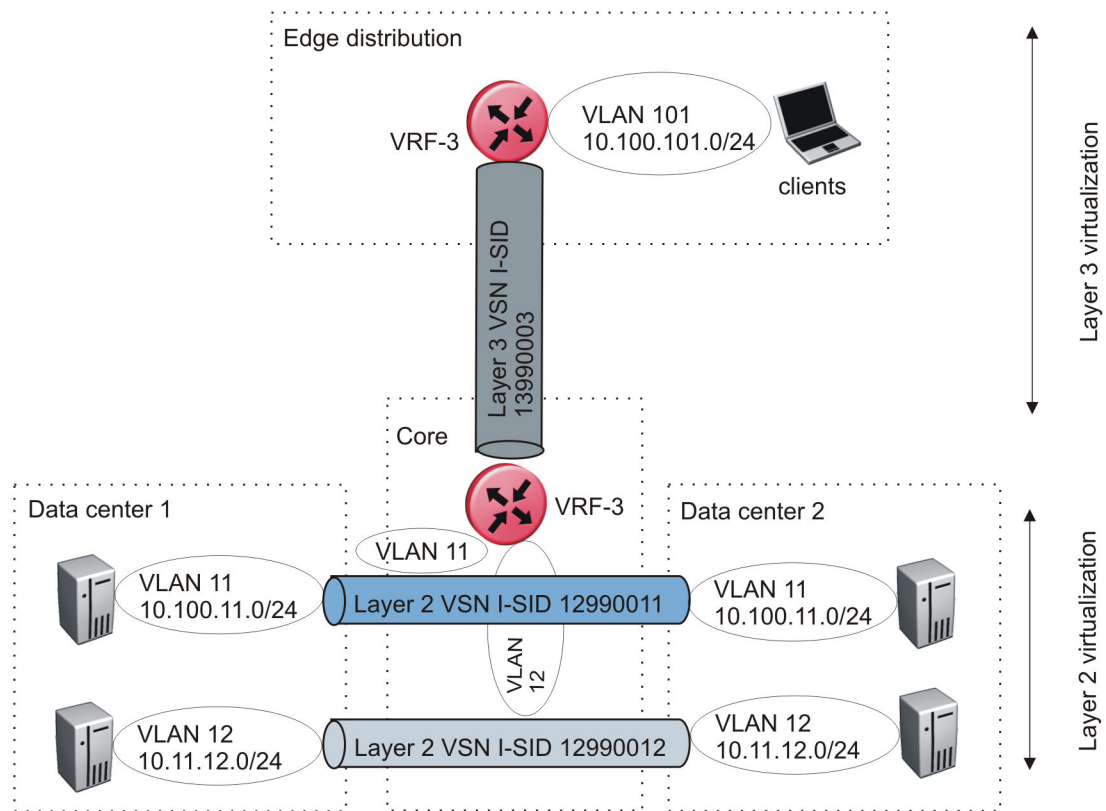

The following figure uses IP shortcuts that route VLANs. There is no I-SID configuration and no Layer 3 virtualization between the edge distribution and the core. This is normal IP forwarding to the BEB.

**Figure 114: IP shortcut scenario to move traffic between data centers**

The following figure uses Layer 3 VSNs to route VRFs between the edge distribution and the core. The VRFs are attached to I-SIDs and use Layer 3 virtualization.

**Figure 115: VRF scenario to move traffic between data centers**

## Large data center architecture

SPBM supports data centers with IP shortcuts, Layer 2 VSNs, or Layer 3 VSNs. If you use vMotion, you must use Layer 2 between data centers (Layer 2 VSN). With Layer 2 VSNs, you can add IP addresses to the VLAN on both data centers and run Virtual Router Redundancy Protocol (VRRP) between them to allow the ESX server to route to the rest of the network.

The following figure shows an SPBM topology of a large data center. This figure represents a full-mesh data center fabric using SPBM for storage over Ethernet. This topology is optimized for storage transport because traffic never travels more than two hops.

### Note

As a best practice, use a two-tier, full-mesh topology for large data centers.

**Figure 116: SPBM data center—full mesh**

*Traditional data center routing of VMs*

In a traditional data center configuration, the traffic flows into the network to a VM and out of the network in almost a direct path.

The following figure shows an example of a traditional data center with VRRP configured. Because end stations are often configured with a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks. VRRP eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost.

**Figure 117: Traditional routing before moving VMs**

A VM is a virtual server. When you move a VM, the virtual server is moved as is. This action means that the IP addresses of that server remain the same after the server is moved from one data center to the other. This in turn dictates that the same IP subnet (and hence VLAN) exist in both data centers.

In the following figure, the VM moved from the data center on the left to the data center on the right. To ensure a seamless transition that is transparent to the user, the VM retains its network connections through the default gateway. This method works, but it adds more hops to all traffic. As you can see in the figure, one VM move results in a complicated traffic path. Multiply this with many moves and soon the network look like a tangled mess that is very inefficient, difficult to maintain, and almost impossible to troubleshoot.

**Figure 118: Traditional routing after moving VMs**

#### *Optimized data center routing of VMs*

Two features make a data center optimized:

- VLAN routers in the Layer 2 domain (green icons)
- VRRP BackupMaster

The VLAN routers use lookup tables to determine the best path to route incoming traffic (red dots) to the destination VM.

VRRP BackupMaster solves the problem of traffic congestion on the vIST. Because there can be only one VRRP Master, all other interfaces are in backup mode. In this case, all traffic is forwarded over the vIST link towards the primary VRRP switch. All traffic that arrives at the VRRP backup interface is forwarded, so there is not enough bandwidth on the vIST link to carry all the aggregated riser traffic. VRRP BackupMaster overcomes this issue by ensuring that the vIST trunk is not used in such a case for primary data forwarding. The VRRP BackupMaster acts as an IP router for packets destined for the logical VRRP IP address. All traffic is directly routed to the destined subnetwork and not through Layer 2 switches to the VRRP Master. This avoids potential limitation in the available vIST bandwidth.

The following figure shows a solution that optimizes your network for bidirectional traffic flows. However, this solution turns two SPBM BCB nodes into BEBs where MAC and ARP learning will be enabled on the Inter-VSN routing interfaces. If you do not

care about top-down traffic flows, you can omit the Inter-VSN routing interfaces on the SPBM BCB nodes. This makes the IP routed paths top-down less optimal, but the BCBs remain pure BCBs, thus simplifying core switch configurations.

**Figure 119: Optimized routing before moving VMs**

In the traditional data center, chaos resulted after many VMs were moved. In an optimized data center as shown in the following figure, the incoming traffic enters the Layer 2 domain where an edge switch uses Inter-VSN routing to attach an I-SID to a VLAN. The I-SID bridges traffic directly to the destination. With VRRP BackupMaster, the traffic no longer goes through the default gateway; it takes the most direct route in and out of the network.

**Figure 120: Optimized routing after moving VMs**

## Solution-Specific Reference Architectures

The following sections describe solution-specific reference architectures, like for example for Video Surveillance or Data Center implementation, using the VSP 4450 Series.

### *Multi-tenant — fabric connect*

This fabric connect-based solution leverages the fabric capabilities of the VSP platforms: a VSP 7000 core and a VSP 4450 Series edge. This solution provides the ability to run, by default, up to 24 VRFs for each wiring closet and is well suited for multi-tenant applications. The zero-touch core is enabled by the fabric connect endpoint provisioning capabilities.

**Note**

You can increase VRF scaling to run more than 24 VRFs. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

If this solution must support IPv6, then a central router-pair routes all IPv6 traffic. The IPv6 traffic is tunneled from each wiring closet to the IPv6 routers by extending Layer 2 VSNs to the q-tagged router interfaces.

**Figure 121: Small core — multi-tenant**

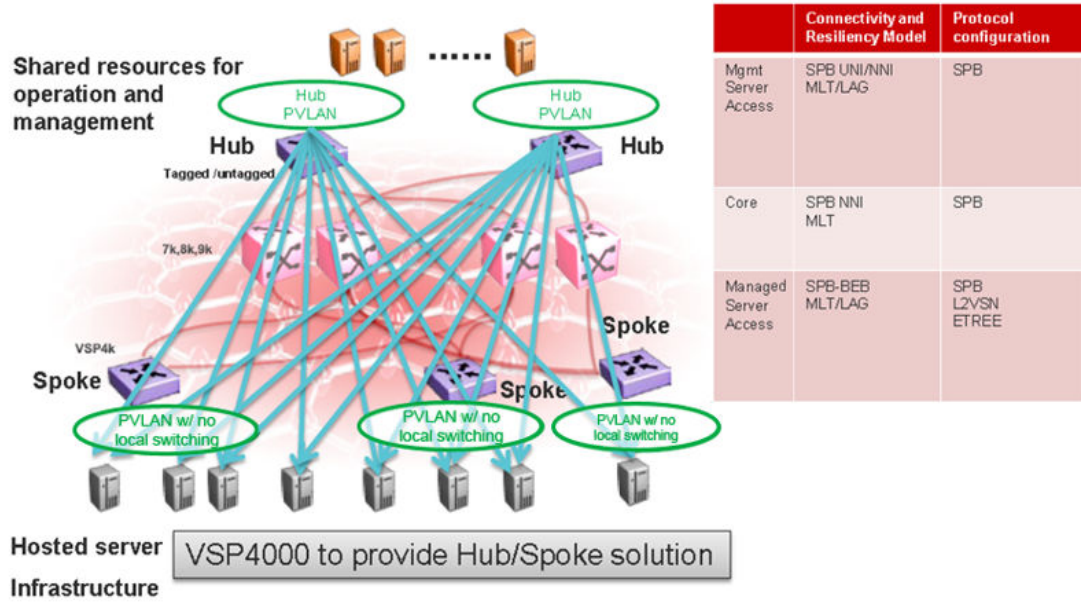

The following list outlines the benefits of the fabric connect-based solution:

- Endpoint provisioning
- Fast failover
- Simple to configure
- Layer 2 and Layer 3 virtualized

#### *Hosted data center management solution — E-Tree*

In some hosted data center solutions, the hosting center operating company takes responsibility for managing customer servers. For this shared management, shown in the following figure, servers that control the operating system level of the production servers, such as the patch level, are deployed. Because customer production servers do not communicate with each other, a distributed private VLAN solution based on fabric connect is deployed to manage all production servers. This solution builds a distributed set of E-Trees for each management domain.

The VSP switches as access, provide an elegant network-wide E-Tree solution. Spokes, or managed servers, cannot communicate to each other over this network, but the shared management servers on the hub ports can access all spokes. Because of the Layer 2 – E-Tree nature of this setup, the managed servers do not require any route entries, and only require one IP interface in this management private VLAN. This solution supports tagged and untagged physical and virtual (VM) servers.

**Figure 122: Data center hosting private VLAN**

The following list outlines the benefits of the hosted data center management solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

*Video surveillance — bridged*

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying a fabric connect based IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone.

**Figure 123: Deployment scenario — bridged video surveillance and IP camera deployment for transportation, airports, and government**

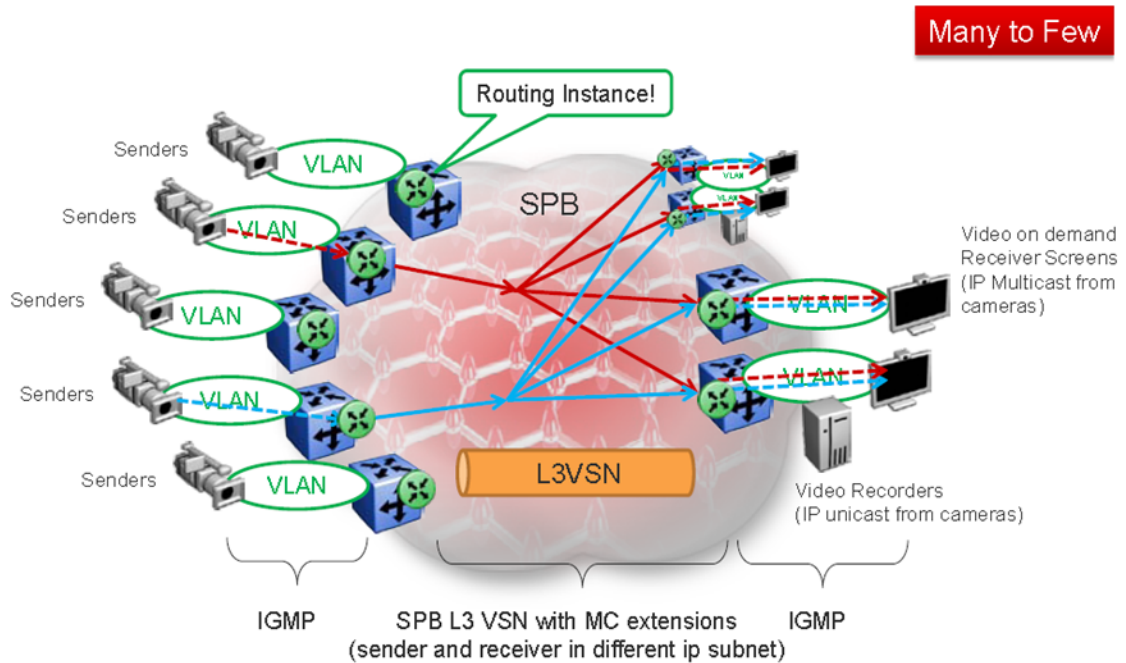

The following list outlines the benefits of the bridged video surveillance solution:

- Easy end-point provisioning
- sub second resiliency and mc forwarding
- secure tenant separation
- quick camera switching

#### *Video surveillance — routed*

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying an IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone. In the topology shown in the following figure, each camera is attached to its own IP subnet. In a larger topology, this can reduce network overhead. To increase network scalability, you can attach a set of cameras to a Layer 2 switch that has IGMP, and then connect the cameras to the fabric edge (BEB) which has a routing instance.

In many customer scenarios, surveillance must be separated from the rest of the infrastructure. This can be achieved by deploying a Layer 3 VSN for the surveillance traffic to keep the surveillance traffic isolated from any other tenant.

**Figure 124: Deployment scenario — Routed video surveillance and IP camera deployment for transportation, airports, and government**

The following list outlines the benefits of the routed video surveillance solution:

- Easy endpoint provisioning
- Optimal resiliency and mc forwarding
- Secure tenant separation
- Rapid channel/camera switching

#### *Metro-Ethernet Provider solution*

VOSS switches provide an end-to-end Metro-Ethernet Provider solution. Leveraging fabric connect throughout the infrastructure enables a scalable and flexible wholesale provider infrastructure.

This use case extends the Transparent Port UNI functionality to transparently forward any customer VLAN across the services.

**Figure 125: Metro ring access solution**

The following list outlines the benefits of the Metro-Ethernet Provider solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

# Fabric Layer 3 Services

---

[IP Shortcuts Configuration](#) on page 1463

[Layer 3 VSN Configuration](#) on page 1537

[Layer 3 Video Surveillance](#) on page 1556

The topics in this section provide conceptual and procedural information about Layer 3 Services:

- IP Shortcuts
- Layer 3 VSN
- Layer 3 Video Surveillance

## IP Shortcuts Configuration

**Table 121: IP Shortcuts product support**

| Feature                            | Product         | Release introduced                                                                                                       |

## IP Shortcuts configuration fundamentals

This section provides fundamental concepts for IP Shortcuts.

Fabric Connect supports both IPv4 Shortcuts and IPv6 Shortcuts. Because IPv6 Shortcuts depend on IPv4 Shortcuts, you should understand how IPv4 Shortcuts work (see [SPBM IP shortcuts](#)) before jumping to the IPv6 section.

### *SPBM IP Shortcuts*

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

Unlike Layer 2 VSN, with SPBM IP shortcuts, no I-SID configuration is required. Instead, SPBM nodes propagate Layer 3 reachability as “leaf” information in the IS-IS LSPs using Extended IP reachability TLVs (TLV 135), which contain routing information such as neighbors and locally configured subnets. SPBM nodes receiving the reachability information can use this information to populate the routes to the announcing nodes. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes.

The following figure shows a network running SPBM IP shortcuts.

**Figure 126: SPBM IP Shortcuts**

In this example, BEB A receives a packet with a destination IP address in the subnet of VLAN 14 and knows to forward the packet to BEB D based on the IP route propagation within IS-IS. After a route lookup, BEB A knows that BEB D is the destination for the subnet and constructs a new B-MAC header with destination B-MAC: D. BCBs B and C need only perform normal Ethernet switching to forward the packet to BEB D. A route lookup is only required once, at the source BEB, to identify BEB D as the node that is closest to the destination subnet.

In contrast to IP routing or Multiprotocol Label Switching (MPLS), SPBM IP shortcuts provide a simpler method of forwarding IP packets in an Ethernet network using the preestablished Ethernet FIBs on the BEBs. SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing SPT. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

In the above example, the SPBM nodes in the core that are not enabled with IP shortcuts can be involved in the forwarding of IP traffic. Since SPBM nodes only forward on the MAC addresses that comprise the B-MAC header, and since unknown TLVs in IS-IS are relayed to the next hop but ignored locally, SPBM nodes need not be aware of IP subnets to forward IP traffic.

With IP shortcuts, there is only one IP routing hop, as the SPBM backbone acts as a virtualized switching backplane.

The following figure shows a sample campus network implementing SPBM IP shortcuts.

**Figure 127: SPBM IP shortcuts in a campus**

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135.

In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct, static, OSPF, RIP, or BGP routes into IS-IS. To advertise IPv6 routes from the BEBs into the SPBM network, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.

### *SPBM IPv6 Shortcuts*

Both IPv4 and IPv6 Shortcuts use IS-IS as the Interior Gateway Protocol (IGP) and the link state packet (LSP) for reachability information. However, IPv4 Shortcuts use TLV 135 and IPv6 Shortcuts use TLV 236. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes. IS-IS transports the IPv6 reachability

information to remote BEBs and uses the shortest path, calculated by SPBM, for data forwarding.

**Note**

You only configure the IPv6 address information on the edges. There is no IPv6 in the SPBM cloud.

IS-IS transports the IPv6 routes through TLV 236 in the LSP advertisements. These routes are installed in the Global Routing Table (GRT) with the node from which the LSPs carrying the IPv6 routes are received as the next hop.

### IPv6 Shortcuts Dependency on IPv4 Shortcuts

IPv6 Shortcuts function in a very similar manner to IPv4 Shortcuts and depends on IPv4 Shortcuts for some functions. For example, IPv6 Shortcuts use the BMAC (local and remote) information created by IPv4 Shortcuts.

**Important**

**IPv4 Shortcuts must be enabled before you enable IPv6 Shortcuts.**

An error is displayed if you try to enable IPv6 Shortcuts but do not have IPv4 Shortcuts already enabled.

IPv6 Shortcuts alone can be disabled while leaving IPv4 Shortcuts enabled. When IPv4 Shortcuts is disabled without disabling IPv6 Shortcuts disabled first, a warning or error message is displayed indicating that IPv6 should be disabled first.

### Circuitless IPv6 (CLIPv6)

To enable IPv6 Shortcuts on the BEBs and to advertise the local BEB to other IS-IS nodes, you must configure a circuitless IPv6 address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236.

IPv6 Shortcuts support Circuitless IPv6 (CLIPv6), which ensures uninterrupted connectivity to the switch as long as there is an actual path to reach it. This route always exists and the circuit is always up because there is no physical attachment.

### Migrating the GRT to IPv6 Shortcuts

Use the following steps to migrate the Global Router Table (GRT) to use IPv6 Shortcuts over the SPBM core:

- Identify the nodes that should be enabled with IPv6 Shortcuts. Apply these steps to all of these nodes.
- Activate and validate basic IPv6 Shortcuts. For information, see [SPBM IPv6 Shortcuts](#) on page 1468.
- Configure IS-IS route preference to ensure that the IPv6 IGP protocol currently being used in the SPBM core is preferred over the IS-IS routes.
- Enable redistribution of direct and static IPv6 routes into IS-IS.
- Create route policies to permit only IPv6 IGP routes from the access side of the SPBM network.

- Configure redistribution of routes from the IPv6 route table from each of the IPv6 IGP protocols into IS-IS along with the appropriate route policy.
- Use the **show isis spbm ipv6-unicast-fib** command to check the IS-IS LSDB, IS-IS routes, and to verify that all the desired IPv6 routes are now in IS-IS.
- Configure redistribution of IS-IS routes from the IPv6 route table into each of the IPv6 IGP protocols in use. This redistribution does not require a route policy since IS-IS is only supported in the SPBM core.
- Change IS-IS route-preference to ensure that IS-IS routes are preferred over other IPv6 IGP routes.
- Disable/delete old IPv6 IGP in the SPBM core.

### Important

Use only one IPv6 routing protocol in the SPBM core to prevent the possibility of routing loops.

### IPv6 Shortcut Restrictions and Considerations

The following features are not supported:

- Disabling and enabling alternate routes for IPv6 routes
- Redistribution of RIP into IS-IS
- 6-in-4 tunnels are not supported when the tunnel destination IP is reachable via IPv4 Shortcuts route.

Keep the following considerations in mind when configuring IPv6 Shortcuts:

- IPv4 Shortcuts must be enabled before enabling IPv6 Shortcuts.
- IPv6 Shortcuts support Circuitless IPv6 (CLIPv6) with the following limitations:
  - Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
  - IPv6 CLIP does not support link-local address configuration.
  - To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.

#### Note

This restriction does not apply to VSP 4450 Series switches.

- Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect when you configure a duplicate IPv6 address.
- Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
- You can configure a maximum of 64 IPv6 CLIP interfaces.
- IPv6 CLIP interface is enabled by default and it cannot be disabled.
- IPv6 with vIST provides the same support as IPv4 with vIST.
- To help with debugging, CFM provides full support for both IPv4 and IPv6 addresses for the **12ping** and **12traceroute** commands.

### ECMP with IS-IS

The Equal Cost Multipath (ECMP) feature supports and complements the IS-IS protocol.

With ECMP, the switch can determine multiple equal-cost paths to the same destination prefix.

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

The number of multiple paths a switch can support differs by hardware platform. For more information about feature support, see [VOSS Release Notes](#).

### ECMP within IS-IS routes

Equal Cost Multipath (ECMP) allows the device to determine up to eight equal cost paths to the same destination prefix. The maximum number of equal cost paths you can configure depends on the hardware platform. For more information, see [VOSS Release Notes](#).

If the device learns the same route from multiple sources, the information is ECMP only if the routes:

- are from the same VSN
- have the same SPBM cost
- have the same prefix cost
- have the same IP route preference

Multiple BEBs can announce the same route, either because the Layer 2 LAN connects to multiple BEBs for redundancy, or because segments of the LAN are Layer 2 bridged. In Layer 2, if the device has to tie-break between multiple sources, the tie-breaking is based on cost and hop count.

In Layer 3, hop count is not used for tie-breaking. Instead, the device uses the following precedence rules to tie-break. In the following order, the device prefers:

1. Routes that do not include nodes with the overload bit set.

When a router node runs out of system resources (memory or CPU), it alerts the other routers in the network by setting the overload bit in its link-state packets (LSPs). When this bit is set, the node is not used for transit traffic but only for traffic packets destined to the node's directly connected networks and IP prefixes.

2. Local routes over remote routes.

If a route is learned locally, for example, through inter-VRF route leaking, it is most preferred.

3. Routes with the lowest route preference.

By default, IS-IS routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. You can however, change the route preference using IS-IS accept policies.

4. Metric type internal (type 1) over metric type external (type 2).
5. Routes with the lowest SPBM cost.
6. Routes with the lowest prefix cost.

If the metric type is internal, then the tie-break is on SPB cost first, and then on the prefix cost. Otherwise the tie-break is only on the prefix cost.

You can either change this using a route-map on the remote advertising node with the **redistribute** command, or using a route-map on the local node with the IS-IS accept policy.

7. Routes within a VSN with a lower Layer 3 VSN I-SID.

The device considers the Global Routing Table (GRT) to have an I-SID equal to zero.

When you use multiple B-VLANs in the SPBM core, multiple paths exist to reach a particular SPBM node, one on each B-VLAN; therefore, any IP prefix or IPv6 prefix that the device receives from a BEB results in multiple ECMP paths. These paths may or may not be physically diverse. SPBM supports up to two B-VLANs; a primary B-VLAN and a secondary B-VLAN.

If more ECMP paths are available than the configured number of paths, then the device adds the routes using the following order: The device selects all routes from the primary B-VLAN and orders the routes learned through that B-VLAN from lowest system ID to the highest IS-IS system ID, then the device moves on to select all routes from the secondary B-VLAN, ordering those routes from lowest IS-IS system ID to the highest IS-IS system ID until you reach the number of equal paths configured.

For example, consider an SPB core configured with two B-VLANs (primary B-VLAN 1000 and secondary B-VLAN 2000), and the device learns routes from two BEBs called BEB-A (with a lower IS-IS system ID) and BEB-B (with a higher IS-IS system ID, then the order in which the next-hop is chosen for those routes are as follows.

If a route is learned only from BEB-A with the maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for that route is:

1. BEB-A B-VLAN 1000
2. BEB-A B-VLAN 2000

If routes are learned from both BEB-A and BEB-B with maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for those routes are:

1. BEB-A B-VLAN 1000
2. BEB-B B-VLAN 1000
3. BEB-A B-VLAN 2000
4. BEB-B B-VLAN 2000

If ECMP is disabled, the maximum number of allowed ECMP paths is 1 and the device adds the route from the lowest system ID with the primary B-VLAN. In this example, the device adds BEB-A B-VLAN 1000.

**Note**

- ECMP is supported for IPv6 Shortcut routes.
- To add IS-IS equal cost paths in the routing table, you must enable IPv6 ECMP feature globally.

**ECMP Impact on IS-IS Route Selection for Inter-VRF Routes with vIST**

This section illustrates the impact ECMP can have on a configuration that implements user-defined VRFs in a vIST cluster and how to avoid incorrect route selection.

**Understanding the Configuration**

Imagine the following configuration:

- A vIST cluster exists with multiple VRF contexts.
- On both nodes, VRF A redistributes routes into IS-IS as external. VRF B uses an IS-IS accept policy to accept these routes.
- Each node learns three paths to the route:
  - The nodes learn one path using local inter-VRF redistribution.
  - The nodes learn the other two paths from the IST peer.
- The routes are treated as ECMP paths because the preference, metric-type, and metric are equal.

IS-IS sorts paths for the same route by source-BEB B-MAC and B-VLAN ID. The primary B-VLAN ID is first installed for each B-MAC, followed by the secondary B-VLAN ID for each B-MAC, as long as the ECMP max-path value is not reached. On the node with the lowest B-MAC, the first path listed is its own local inter-vrf route, while on the other node, the MIM path across the vIST is listed first.

If you disable ECMP, all but the first path is removed. Because IS-IS orders the paths by B-MAC, each node in the vIST cluster selects the same B-MAC as the nexthop. This configuration leads one of the nodes to select itself, the local inter-vrf route, while the other node selects the MIM path across the vIST to get to the inter-vrf route. This situation results in an incorrect route selection.

**Avoiding Incorrect Route Selection**

To avoid this situation, create a policy to prevent IS-IS from determining that the MIM path across the vIST and the local inter-VRF route are ECMP paths. Configure the local inter-VRF path as the preferred path, and the vIST path as the backup. The following list identifies way that you can accomplish this:

- Redistribute the VRF route into IS-IS using the internal metric-type. IS-IS will always select the local inter-VRF route. For more information about the metric type for IS-IS routes, see [Fabric Basics and Layer 2 Services](#) on page 1001.

- If an IS-IS internal metric-type is not an option, configure an IS-IS accept policy to change the preference of inter-VRF routes learned from the IST peer. The local inter-VRF route is preferred over the inter-VRF routes learned from the IST peer.

### IS-IS IP Redistribution Policies

When you connect an SPBM core using IP shortcuts to existing networks running a routing protocol such as OSPF or RIP, a redundant configuration requires two switches:

- One router redistributes IP routes from Routing Information Protocol (RIP)/Open Shortest Path First (OSPF) into IS-IS (IP).
- The second router redistributes from IS-IS (IP) into RIP or OSPF.

The following figure illustrates this configuration.

**Figure 128: Redundant OSPF or RIP Network**

In this scenario it is necessary to take extra care when redistributing through both switches. By default the preference value for IP routes generated by SPBM-IP (IS-IS) is 7. This is a higher preference than OSPF (20 for intra-area, 25 for inter-area, 120 for ext type1, 125 for ext type2) or RIP (100).

#### Important

The lower numerical value determines the higher preference.

In the preceding diagram both nodes (SwitchG and SwitchD) have an OSPF or a RIP route to 192.168.10.0/24 with the next-hop to SwitchA.

As soon as the SwitchG node redistributes that IP route into IS-IS, the SwitchD node learns the same route through IS-IS from SwitchG. (The SwitchG node already has the route through OSPF or RIP). Because IS-IS has a higher preference, SwitchD replaces

its 192.168.10.0 OSPF route with an IS-IS one that points at SwitchG as the next-hop. The following figure illustrates this scenario.

**Figure 129: Redistributing Routes into IS-IS**

Clearly this is undesirable and care needs to be taken to ensure that the two redistributing nodes (SwitchG and SwitchD) do not accept redistributed routes from each other. With IS-IS accept policies, you can associate an IS-IS accept policy on SwitchD to reject all redistributed IP routes received from SwitchG, and SwitchG to reject all redistribute IP routes from SwitchD.

An alternate way to solve the preceding problem with existing functionality is to reverse the problem by lowering the SPBM-IP (IS-IS) preference by configuring it to a value greater than RIP (100) or OSPF (20,25,120,125). For example, log on to Global Configuration mode and use the following command to configure a preference of 130:

```
ip route preference protocol spbm-level1 130
```

**Note**

For IPv6, the command is `ipv6 route preference protocol spbm-level1 130`

Now that the OSPF or RIP routes have a higher preference than SPBM-IP (IS-IS), the above problem is temporarily solved. However, the same issue resurfaces when the IS-IS IP routes are redistributed into OSPF or RIP in the reverse direction as shown in the following figure for OSPF:

### Figure 130: Redistributing Routes into OSPF

In the preceding figure, both SwitchG and SwitchD have an IS-IS IP route for 172.16.0.0/16 with the next hop as SwitchC. As soon as SwitchG redistributes the IS-IS route into OSPF, the SwitchD node learns that same route through OSPF from SwitchG. (The SwitchG node already has the route through IS-IS).

Because OSPF has a higher preference, SwitchD replaces its 172.16.0.0/16 IS-IS route with an OSPF one. (Note that the 172.16.0.0/16 route will be redistributed into OSPF as an AS external route, hence with preference 120 or 125 depending on whether type1 or type2 was used). In this case, however, you can leverage OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. The following is a sample configuration:

```
enable
configure terminal
route-map

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "reject" 1
no permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable

OSPF ACCEPT CONFIGURATION - GlobalRouter

router ospf
accept adv-rtr {A.B.C.D}
```

```
accept adv-rtr {A.B.C.D} enable route-map "reject"  
exit
```

**Note**

Disable alternative routes by issuing the command **no ip alternative-route** to avoid routing loops on the SMLT Backbone Edge Bridges (BEBs).

In the preceding figure, if SwitchA advertises 25000 OSPF routes to SwitchG and SwitchD, then both SwitchG and SwitchD install the 25000 routes as OSPF routes. Since SwitchD and SwitchG have OSPF to IS-IS redistribution enabled, they also learn these 25000 routes as IS-IS routes. IS-IS route preference is configured with a higher numerical value (130) than the OSPF route preference (125), so SwitchD and SwitchG keep IS-IS learned routes as alternative routes.

If SwitchA withdraws its 25000 OSPF routes, SwitchG and SwitchD remove the OSPF routes. While the OSPF routes are removed the routing tables of SwitchG and SwitchD activate the alternative IS-IS routes for the same prefix. Since SwitchG and SwitchD have IS-IS to OSPF redistribution enabled, SwitchA learns these routes as OSPF and this causes a routing loop. Use the **no ip alternative-route** command to disable alternative routes on SwitchG and SwitchD to avoid routing loops.

In the preceding figure, you leveraged OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. In the case of a RIP access network, the preceding solution is not possible because RIP has no concept of external routes and no equivalent of accept policies. However, if you assume that a RIP network acts as an access network to an SPBM core, then it is sufficient to ensure that when IS-IS IP routes are redistributed into RIP they are aggregated into a single default route at the same time. The following figure and sample configuration example illustrates this scenario:

**Figure 131: Redistributing Routes into RIP**

#### SwitchG

```

IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 1/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

```

```

router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip rip apply redistribute isis

```

### SwitchA

```

RIP PORT CONFIGURATION

interface gigabitethernet 1/2
ip rip default-listen enable
exit
interface gigabitethernet 1/3
ip rip default-listen enable
exit

```

### SwitchD

```

IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 2/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

```

```
ip rip apply redistribute isis
```

You can control the propagation of the default route on the RIP network so that both SwitchG and SwitchD supply the default route on their relevant interfaces, and not accept it on the same interfaces. Likewise, SwitchA will accept the default route on its interfaces to both SwitchG and SwitchD but it will not supply the default route back to them. This will prevent the default route advertised by SwitchG from being installed by SwitchD, and vice-versa.

The preceding example where IS-IS IP routes are aggregated into a single default route when redistributed into the RIP network also applies when redistributing IS-IS IP routes into OSPF if that OSPF network is an access network to an SPBM core. In this case use the following redistribution policy configuration as an example for injecting IS-IS IP routes into OSPF:

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable
router ospf
as-boundary-router enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router ospf
redistribute isis
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip ospf apply redistribute isis
```

### IS-IS Accept Policies

You can use Intermediate-System-to-Intermediate-System (IS-IS) accept policies (for IPv4 and IPv6) to filter incoming IS-IS routes over the SPBM cloud and apply route policies to the incoming IS-IS routes. IS-IS accept policies enable the device to determine whether to add an incoming route to the routing table.

### IS-IS Accept Policies and DvR

#### Note

IPv6 IS-IS accept policies for DvR are not supported.

When you configure DvR in an SPB network, you can leverage IS-IS accept policies to control the DvR routes learned from the DvR backbone. The DvR backbone contains the master list of all the host routes learned from various DvR domains.

You can configure accept policies on a DvR Controller or a non-DvR BEB as a filter to determine which DvR host routes to accept into the routing table, from the DvR backbone. Accept policies apply to only those backbone (or inter-domain) host routes that are not part of the Controller's own DvR enabled subnets and do not have the same domain ID as that of the Controller.

For non-DvR BEBs, all the routes present in the backbone are learned, but you can still use the accept policies to filter specific routes.

For information on DvR, see [Distributed Virtual Routing](#) on page 738.

### IS-IS Accept Policy Filters

You can filter traffic with IS-IS accept policies by:

- advertising BEB
- I-SID or I-SID list
- route-map
- backbone-route-map for IPv4 only
- a combination of route-map and backbone-route-map for IPv4 only

You can use IS-IS accept policies to apply at a global default level for all advertising Backbone Edge Bridges (BEBs) or for a specific advertising BEB.

IS-IS accept policies also allow you to use either a service instance identifier (I-SID) or an I-SID list to filter routes. The switch uses I-SIDs to define Virtual Services Networks (VSNs). I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. IS-IS accept policies can use I-SIDs or I-SID lists to filter the incoming virtualized traffic.

IS-IS accept policies can also apply route policies to determine what incoming traffic to accept into the routing table. With route policies the device can determine which routes to accept into the routing table based on the criteria you configure. You can match on the network or the route metric.

On DvR Controllers in a DvR domain, you can configure a backbone route policy to determine what host routes to accept from the DvR backbone, into the routing table.

Also, just like on the route policy, you can configure match criteria, and set preferences on the backbone route policy.

To accept both IS-IS routes and host routes from the DvR backbone, you can configure both a route policy and a backbone route policy in the accept policy instance.

For more information on configuring route policies:

- For IPv4, see [IP routing operations fundamentals](#) on page 2010.
- For IPv6, see [IPv6 Routing Basics](#) on page 2086.

The following table describes IPv4 IS-IS accept policy filters.

| Filters into               | Filter                                                                                                                          | Description                                                                                                                                                                                                                                                        |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Global Routing Table (GRT) | <i>accept route-map WORD&lt;1-64&gt;</i>                                                                                        | By default, the device accepts all routes into the GRT and VRF routing table. This is the default accept policy.                                                                                                                                                   |
|                            | <i>accept route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                                                    | This is the default accept policy with configuration to accept specific DvR host routes from the DvR backbone.                                                                                                                                                     |
|                            | <i>accept adv-rtr &lt;x.xx.xx&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                            | The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                   |
|                            | <i>accept i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                           | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                   |
|                            | <i>accept adv-rtr &lt;x.xx.xx&gt; i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>   | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                  |
|                            | <i>accept isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the list of I-SIDs. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                                                          |
|                            | <i>accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |

| Filters into                                       | Filter                                                                                                                               | Description                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual Routing and Forwarding (VRF) routing table | <i>isis accept adv-rtr &lt;x.xx.xx&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                            | The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                                                          |
|                                                    | <i>isis accept i-sid &lt;0-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                           | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                  |
|                                                    | <i>isis accept adv-rtr &lt;x.xx.xx&gt; i-sid &lt;0-16777215&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>   | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
|                                                    | <i>isis accept isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                |
|                                                    | <i>isis accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                        |
|                                                    | <i>isis accept route-map WORD&lt;1-64&gt; route-map WORD&lt;1-64&gt; backbone-route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the route policy. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.                                                                                                                                   |

The following table describes the IPv6 IS-IS accept policy filters:

| Filters into               | Filter                                                                                           | Description                                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Global Routing Table (GRT) | <i>ipv6 accept route-map WORD&lt;1-64&gt;</i>                                                    | By default, the device accepts all routes advertised. This is the default accept policy.                                                 |
|                            | <i>ipv6 accept adv-rtr &lt;x.xx.xx&gt; route-map WORD&lt;1-64&gt;</i>                            | The device filters based on the specific advertising BEB defined by the SPBM nickname.                                                   |
|                            | <i>ipv6 accept i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt;</i>                           | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN.                                                   |
|                            | <i>ipv6 accept adv-rtr &lt;x.xx.xx&gt; i-sid &lt;1-16777215&gt; route-map WORD&lt;1-64&gt;</i>   | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN.                  |
|                            | <i>ipv6 accept isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt;</i>                         | The device filters based on the list of I-SIDs.                                                                                          |
|                            | <i>ipv6 accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt;</i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). |

| Filters into                                       | Filter                                                                                                      | Description                                                                                                                                                                     |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual Routing and Forwarding (VRF) routing table | <code>ipv6 isis accept route-map WORD&lt;1-64&gt; route-map WORD&lt;1-64&gt;</code>                         | The device filters based on the route policy.                                                                                                                                   |

|                                                    | <code>ipv6 isis accept adv-rtr &lt;x.xx.xx&gt; isid-list WORD&lt;1-32&gt; route-map WORD&lt;1-64&gt;</code> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT).                                        |

### IS-IS Accept Policies for the GRT and VRFs

You can create an IS-IS accept policy for incoming routes for the Global Routing Table (GRT), which accepts routes into the routing table, or for a Virtual Routing and Forwarding (VRF) instance, which accepts incoming routes to the routing table of the VRF.

If you create an IS-IS accept policy on the switch for either the GRT or a VRF that operates at a global default level, the accept policy applies to all routes for all BEBs in the GRT or VRF.

If you create an IS-IS accept policy on the switch for a specific advertising BEB for either the GRT or a VRF, the IS-IS accept policy instance applies for that specific advertising BEB. If you use a more specific filter, the system gives preference to the specific filter over the global default level.

### IS-IS Accept Policies for Inter-VRF Route Redistribution

You can also use the filter mechanism for IS-IS accept policies to redistribute routes between different VRFs, or between a VRF and the GRT. For inter-VRF route redistribution, you match the filter based on the I-SID, which represents the Layer 3 VSN context.

You can apply the filter at the global default level, where the IS-IS accept policy applies to all routes for that I-SID from all BEBs, or at a specific advertising BEB level, where the filter only applies to a specific advertising BEB. The device gives preference to a specific filter for a specific advertising BEB over the global default filter.

For inter-VRF route redistribution, an I-SID value of 0 represents the GRT. For inter-VRF route redistribution between VRFs, the I-SID is the source VRF (or remote VRF).

#### Note

If the primary B-VLAN is down either because you did not configure at least one network-to-network interface (NNI) or all configured NNIs are down, the switch does not redistribute inter-VRF routes through IS-IS accept policies.

### IS-IS Accept Policy Considerations

Consider the following when you configure IS-IS accept policies:

- If a VRF uses a different protocol to redistribute routes from another VRF, the IS-IS accept policy feature cannot be used. You can only use the IS-IS accept policy for inter-VSN route redistribution between VRFs.
- IPv4 and IPv6 IS-IS accept policies can exist on the same VRF and GRT; The I-SID list configuration is shared across both protocol versions.

#### Precedence rules in the same VSN

The following precedence rules apply for IS-IS accept policies used in the same VSN:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply either a default filter for all advertising BEBs or a filter for a specific advertising BEB.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device prefers the **accept adv-rtr** filter, which filters based on a specific advertising BEB, over the default filter for all advertising BEBs.
- The device accepts all routes within the same VSN by default. You can apply a route policy to filter or change the characteristics of the route by metric or preference.
- The **i-sid** or **isid-list** filters are not valid for routes within the same VSN.

#### Precedence rules for inter-VSN route redistribution

The following precedence rules apply for IS-IS accept policies used for inter-VSN route redistribution:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply filters at a global default level for all BEBs for a specific I-SID or I-SID list, or you can apply filters for a specific advertising BEB for a specific I-SID or I-SID list.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device requires a specific filter to redistribute routes between VSNs through the use of the **i-sid** or **isid-list** filters.

- The **i-sid** filter takes precedence over the **isid-list** filter.
- The **adv-rtr** filter for a specific advertising BEB takes precedence over a filter with the same **i-sid** filter without the **adv-rtr** filter.
- The **i-sid** or **isid-list** filters only apply to routes for inter-VSN route redistribution.
- If multiple **isid-list** filters have the same I-SID within the list, the first on the list alphabetically has the higher precedence.

### Route Preference

The relative value of the route preference among different protocols determines which protocol the device prefers. If multiple protocols are in the routing table, the device prefers the route with the lower value. You can change the value at the protocol level, and you can also change the preference of incoming IS-IS routes using the route-map with the IS-IS Accept policy filter for IPv4 only.

### Route Metric

Use route-map to change the metric of a route when you accept a remote IS-IS route with IS-IS accept policies.

You can use route-map to change the metric of a route when you redistribute the route from another protocol to IS-IS through the route redistribution mechanism.

You can also configure the route metric with the base **redistribute** command without the use of route-map.

#### Note

For both IPv4 and IPv6 IS-IS accept policies, if there is a mismatch in the route-map (inbound filtering) configured, all routes are accepted by default. Unlike the redistribute route-map (outbound filtering), where if there is a mismatch, all routes are denied by default. For more information, see [IP routing operations fundamentals](#) on page 2010.

For more information on the configuration of route-map:

- For IPv4, see [IP routing operations fundamentals](#) on page 2010.
- For IPv6, see [IPv6 Routing Basics](#) on page 2086.

## IP Shortcuts configuration using the CLI

This section provides procedures to configure IP Shortcuts using the command line interface (CLI).

### Configuring SPBM IPv4 Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard

Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP (CLIP) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

**Note**

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address.

**Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

**Procedure**

1. Enter Loopback Interface Configuration mode

```
enable

configure terminal

interface Loopback <1-256>
```
2. Configure a CLIP interface to use as the source address for SPBM IP shortcuts:

```
ip address [<1-256>] <A.B.C.D/X>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

```
exit
```
4. Log on to IS-IS Router Configuration mode:

```
router isis
```
5. Specify the CLIP interface as the source address for SPBM IP shortcuts:

```
ip-source-address <A.B.C.D>
```
6. Configure SPBM IP shortcuts:

```
spbm <1-100> ip enable
```
7. Display the status of SPBM IP shortcuts on the switch:

```
show isis spbm
```
8. Identify routes on the local switch to be announced into the SPBM network:

```
redistribute {bgp | direct | ospf | rip | static}
```
9. Enable routes to be announced into the SPBM network

```
redistribute {bgp | direct | ospf | rip | static} enable
```

10. If you want to delete the configuration, use the no option:

```
no redistribute {bgp | direct | ospf | rip | static}
```

```
no redistribute {bgp | direct | ospf | rip | static} enable
```

11. Exit to Global Configuration mode:

```
exit
```

12. Apply the configured redistribution:

```
isis apply redistribute {bgp | direct | ospf | rip | static | vrf  
WORD<1-16>}
```

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# interface loopback 1
```

```
Switch:1(config-if)# ip address 192.0.2.2/8
```

```
Switch:1(config-if)# exit
```

```
Switch:1(config)# router isis
```

```
Switch:1(config-isis)# ip-source-address 192.0.2.2
```

```
Switch:1(config-isis)# spbm 1 ip enable
```

```
Switch:1(config-isis)# show isis spbm
```

```
show isis spbm
```

```

### Variable definitions

The following table defines parameters for the **ip address** command.

| Variable    | Value                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------|
| <1-256>     | Specifies an interface ID value. This value is optional.                                              |
| <A.B.C.D/X> | Specifies an IP address and subnet mask. Use the <b>no</b> option to delete the specified IP address. |
| <A.B.C.D>   | Specifies an IP address. Use the <b>no</b> option to delete the specified IP address.                 |

The following table defines parameters for the **ip-source-address** command.

| Variable  | Value                                                                            |
|-----------|----------------------------------------------------------------------------------|
| <A.B.C.D> | Specifies the CLIP interface to use as the source address for SPBM IP shortcuts. |

The following table defines parameters for the **spbm** command.

| Variable                 | Value                                                                                                                                          |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-100> <i>ip enable</i> | Enables or disables SPBM IP shortcut state. The default is disabled. Use the <b>no</b> or <b>default</b> options to disable SPBM IP shortcuts. |

The following table defines parameters for the **redistribute** command.

| Variable                                    | Value                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{bgp   direct   ospf   rip   static}</i> | Specifies the protocol.                                                                                                                                      |
| <i>enable</i>                               | Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. Use the <b>no</b> option to disable the redistribution. |
| <i>metric &lt;0-65535&gt;</i>               | Configures the metric (cost) to apply to redistributed routes. The default is 1.                                                                             |
| <i>metric-type {external internal}</i>      | Configures the type of route to import into the protocol. The default is internal.                                                                           |

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>route-map WORD&lt;0-64&gt;</code> | Configures the route policy to apply to redistributed routes. Type a name between 0 to 64 characters in length.                                                                                                                                                                                                                                 |
| <code>subnets {allow suppress}</code>   | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose <code>suppress</code> to advertise subnets aggregated to their classful subnet. Choose <code>allow</code> to advertise the subnets individually with the learned or configured mask of the subnet. The default is <code>allow</code> . |

The following table defines parameters for the **isis apply redistribute** command.

| Variable                                          | Value                   |
|---------------------------------------------------|-------------------------|
| <code>{bgp   direct   ospf   rip   static}</code> | Specifies the protocol. |

### Configure SPBM IPv6 Shortcuts

#### Important

You must enable IPv4 Shortcuts before you enable IPv6 Shortcuts because IPv6 Shortcuts depend on IPv4 Shortcuts for some functions.

Configuring IPv6 Shortcuts is essentially the same as the IPv4 procedure except you use the following IPv6 commands instead of their IPv4 equivalents:

- Use **ipv6 interface address** to create a CLIPv6 interface with an IPv6 address.
- Use **ipv6 ipv6-source-address** to specify the CLIPv6 interface as the source address for IPv6 Shortcuts.
- Use **spbm ipv6 enable** to enable IPv6 Shortcuts.
- Use **ipv6 redistribute {bgp | direct | isis | rip | ospf | static} enable** to control the redistribution of GRT IPv6 routes into the SPBM IS-IS domain.
- Use **ipv6 route preference protocol spbm-level11** to change route preference values for IPv6 Shortcut routes learned through IS-IS.

To enable IPv6 Shortcuts on the BEBs, you must configure a circuitless IPv6 (CLIPv6) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

#### Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address, and the CLIPv6 address prefix must be 128.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IPv6 addresses and network masks.

## Procedure

1. Enter Loopback Interface Configuration mode  

```
enable

configure terminal

interface Loopback <1-256>
```
2. Configure a CLIPv6 interface to use as the source address for SPBM IPv6 Shortcuts:  

```
ipv6 interface address WORD<0-255>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:  

```
exit
```
4. Log on to IS-IS Router Configuration mode:  

```
router isis
```
5. Specify the CLIPv6 interface as the source address for SPBM IPv6 Shortcuts:  

```
ipv6-source-address WORD<0-46>
```
6. Enable SPBM IPv6 Shortcuts:  

```
spbm <1-100> ipv6 enable
```
7. Display the status of SPBM IPv6 Shortcuts on the switch:  

```
show isis spbm
```
8. Identify IPv6 routes on the local switch to be announced into the SPBM network.  

```
ipv6 redistribute {bgp | direct | ospf | rip | static}
```
9. Enable the IPv6 routes to be announced into the SPBM network:  

```
ipv6 redistribute {bgp | direct | ospf | rip | static} enable
```
10. Exit to Global Configuration mode:  

```
exit
```
11. (Optional) Change route preference values for IPv6 Shortcut routes learned through IS-IS:  

```
ipv6 route preference protocol spbm-level1 <0-255>
```
12. Apply the configured redistribution:  

```
ipv6 isis apply redistribute {bgp | direct | ospf | rip | static |}
[vrf WORD<1-16>]
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 123
Switch:1(config-if)#ipv6 interface address 123::1/128
Switch:1(config-if)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#ipv6 ipv6-source-address <non-link-local ipv6-address>
Switch:1(config-isis)#spbm 1 ipv6 enable
```

```
Switch:1(config-isis)#show isis spbm

## Variable Definitions

The following table defines parameters for the IPv6 Shortcuts commands.

| Variable                                                                                 | Value                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-source-address</i><br><i>WORD&lt;0-46&gt;</i>                                    | Specifies the source IPv6 address for locally generated IPv6 packets whose egress port is an SPBM NNI port. The <i>WORD&lt;0-46&gt;</i> value must be a locally configured loopback IPv6 address (CLIPv6).<br>Use the <b>no</b> option to delete the specified IPv6 address. |
| <i>spb&lt;1-100&gt; ipv6 enable</i>                                                      | Enables or disables SPBM IPv6 Shortcuts.<br>The default is disabled. Use the <b>no</b> or <b>default</b> options to disable SPBM IPv6 Shortcuts.                                                                                                                             |
| <i>ipv6 route preference</i><br><i>protocol spbm-level1</i><br><i>&lt;0-255&gt;</i>      | Sets the route preference value for IPv6 Shortcut routes learned through IS-IS. The default preference is 7.                                                                                                                                                                 |
| <i>ipv6 redistribute {bgp</i><br><i>  direct   static  </i><br><i>ospf   rip} enable</i> | Specifies the GRT IPv6 route that you want to redistribute into the SPBM IS-IS domain.<br>The default is disabled. Use the <b>no</b> option to disable the redistribution.                                                                                                   |

### Configure Inter-VRF IPv4 Accept Policies on VRFs

Configure IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IS-IS accept policies to redistribute routes between different VRFs,

including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

#### Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **accept** command for inter-VRF routes based on the remote I-SID, the device only accepts routes coming from remote BEBs. For instance, if a local Layer 3 VSN exists with the same I-SID, the device does not add the local routes. The assumption is that the device uses existent methods, either through use of another protocol or static configuration, to obtain those routes.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map to apply.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<0-16777215>][list WORD<1-1024>]
```

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command `show ip isid-list vrf WORD<1-16>` to view the list of truncated I-SIDs.

3. Create an IS-IS accept policy instance to apply to routes from all Backbone Edge Bridges (BEBs):

```
isis accept [i-sid <0-16777215>][isid-list WORD<1-32>]
```

4. Create an IS-IS accept policy instance to apply to routes for a specific BEB:

```
isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list WORD<1-32>]
```

5. Specify an IS-IS route policy to apply to routes from all BEBs:

```
isis accept route-map WORD<1-64>
```

6. Specify an IS-IS route policy to apply for a specific BEB:

```
isis accept adv-rtr <x.xx.xx> route-map WORD<1-64>
```

7. Enable a configured IS-IS accept policy instance:

```
isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list WORD<1-32>] [enable]
```

8. Exit VRF Router Configuration mode:

```
exit
```

You are in Global Configuration mode.

9. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
isis apply accept [vrf WORD<1-16>]
```

## Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#isis accept i-sid 100
Switch:1(router-vrf)#isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept vrf green
```

## Variable definitions

The following table defines parameters for the **ip isid-list** command.

| Variable                       | Value                                                                    |
|--------------------------------|--------------------------------------------------------------------------|
| <i>WORD&lt;1-32&gt;</i>        | Creates a name for your I-SID list.                                      |
| <i>&lt;0-16777215&gt;</i>      | Specifies an I-SID value.                                                |
| <i>list WORD&lt;1-1024&gt;</i> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **isis accept** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i> <x.xx.xx>               | Specifies a specific advertising BEB in which to apply the IS-IS accept policy to routes for a specific advertising BEB. x.xx.xx specifies an SPBM nickname.<br>The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.<br>The system requires an explicit filter to redistribute routes from a particular VSN. If the default global filter or the filter for a specific advertising BEB does not exist, the system does not redistribute the routes from the remote VSN. |
| <i>enable</i>                          | Enables the IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>i-sid</i> <0-16777215>              | Configures the I-SID to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>isid-list</i><br><i>WORD</i> <1-32> | Configures a list of I-SIDs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>route-map</i> <i>WORD</i><br><1-64> | Specifies a route policy. You must configure a route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The following table defines parameters for the **isis apply accept** command.

| Variable                      | Value                              |
|-------------------------------|------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16> | Specifies a specific VRF instance. |

#### Configure Inter-VRF IPv6 Accept Policies on VRFs

Configure IPv6 IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IPv6 IS-IS accept policies to redistribute routes between different

VRFs, including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

#### Note

- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **ipv6 accept** command for inter-VRF routes based on the remote I-SID, the device accepts routes from other local VRFs to the current VRF, therefore if the accepted I-SID is configured on the local BEB, the device accepts its own IPv6 routes advertised under the accepted I-SID.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1492.
- You must configure IPv6 IPVPN.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<0-16777215> | list WORD<1-1024>}
```

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

### 3. Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

#### a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [route-map WORD<1-64>]
```

#### b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

#### c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

### 4. Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

### 5. Exit to Global Configuration mode:

```
exit
```

### 6. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD<1-16>]
```

## Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ipv6 isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#ipv6 isis apply accept vrf red
```

## Variable Definitions

The following table defines parameters for the **ip isid-list** command.

### Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable                       | Value                                                                    |
|--------------------------------|--------------------------------------------------------------------------|
| <i>WORD&lt;1-32&gt;</i>        | Creates a name for your I-SID list.                                      |
| <i>&lt;0-16777215&gt;</i>      | Specifies an I-SID value.                                                |
| <i>list WORD&lt;1-1024&gt;</i> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i><br><x.xx.xx>     | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br><br><b>Note:</b><br>An IPv6 IS-IS accept policy that specifies the adv-rtr without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i>                   | Enables an IPv6 IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>i-sid</i><br><0-16777215>    | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).                                                                                                       |
| <i>isid-list</i><br>WORD<1-32>  | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs, that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).                                                                                   |
| <i>route-map</i> WORD<br><1-64> | Specifies a route policy. You must configure a route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The following table defines parameters for the **ipv6 isis apply accept** command.

| Variable              | Value                              |
|-----------------------|------------------------------------|
| <i>vrf</i> WORD<1-16> | Specifies a specific VRF instance. |

### Configure IS-IS Accept Policies

Use the following procedure to create and enable IS-IS accept policies to apply to routes from all Backbone Edge Bridges (BEBs) or to all routes from a specific BEB.

Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

If DvR is enabled on your switch, and the switch is either a DvR Controller or a non-DvR BEB within the domain, you can configure IS-IS accept policies to accept specific host routes from the DvR backbone. For information on DvR, see [Distributed Virtual Routing](#) on page 738.

IS-IS accept policies are disabled by default.

#### Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless the IS-IS accept policy was the last sequence in the configuration.
- The **isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IS-IS accept policy configuration, you must apply the **isis apply accept [vrf WORD<1-16>]** command at the end.
- The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the IS-IS accept policy filters, which can be configured using the **ip isid-list [ISID#]**, **accept i-sid <value>**, or **accept adv-rtr <isis nn> i-sid <value>** commands.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an ip isid-list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IS-IS accept policy filters, which you implement with the **ip isid-list** or **accept policy** command. The I-SIDs used for Layer 3 VSNs can be reused in IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 4193. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.
- Ensure that DvR is enabled on the switch before you configure an IS-IS accept policy with a backbone route policy, to accept host routes from the DvR backbone.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
```

### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

4. Configure IS-IS accept policies with a route policy or a backbone route policy or a combination of both, to determine which routes the IS-IS accept policy applies to. Configure one of the following types of IS-IS accept policies:

- An IS-IS accept policy with only the route policy:

The IS-IS routes are selectively accepted based on the route policy. Since the backbone route policy is not configured, all host routes from the DvR backbone are denied.

If you do not configure a route policy, by default, all IS-IS routes are accepted.

- An IS-IS accept policy with only the backbone route policy:

The DvR host routes from the DvR backbone are selectively accepted based on the backbone route policy. Since the route policy is not configured, all IS-IS host routes are accepted.

If you do not configure a backbone route policy, all host routes from the DvR backbone are denied.

- An IS-IS accept policy with both route policy and backbone route policy:

IS-IS routes are selectively accepted based on the route policy and host routes from the DvR backbone are selectively accepted based on the backbone route policy.

5. Configure an IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Create an IS-IS accept policy instance to apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>]
```

- b. Create an IS-IS accept policy instance to apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> [i-sid <1-16777215>][isid-list WORD <1-32>]
```

- c. Specify an IS-IS route policy to apply to routes from all BEBs:

```
accept route-map WORD<1-64>
```

- d. Specify an IS-IS route policy to apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx>[route-map WORD<1-64>]
```

- e. Enable an IS-IS route accept instance:

```
accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]
```

6. Configure an IS-IS accept policy instance with a backbone route policy to accept host routes from the DvR backbone:

**Note**

IS-IS accept policies typically apply to all IS-IS routes. However, to accept DvR host routes from the DvR backbone, you must explicitly configure the IS-IS accept policy with a backbone route policy.

Use one of the following options:

- a. Create the default IS-IS accept policy instance to accept host routes from the DvR backbone:

```
accept backbone-route-map WORD <1-64>
```

- b. Create an IS-IS accept policy instance to accept host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map WORD<1-64>
```

- c. Create an IS-IS accept policy instance to accept host routes from the DvR backbone and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> backbone-route-map WORD <1-64>
```

7. Configure an IS-IS accept policy with both route policy and backbone route policy, to selectively accept IS-IS routes as well as host routes from the DvR backbone.

- a. Create the default IS-IS accept policy instance with a route policy to accept IS-IS routes and a backbone route policy to accept host routes from the DvR backbone:

```
accept route-map WORD<1-32> backbone-route-map WORD <1-64>
```

- b. Create an accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map WORD<1-32> backbone-route-map WORD<1-64>
```

- c. Create an IS-IS accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> route-map WORD<1-32> backbone-route-map
WORD <1-64>
```

8. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
isis apply accept [vrf WORD <1-16>]
```

## Example

Configure an I-SID based IS-IS accept policy with the route policy test:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map test 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit

Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 101
Switch:1(config-isis)#accept i-sid 101 route-map test
Switch:1(config-isis)#accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#isis apply accept
```

The following examples show the configuration of an IS-IS accept policy to accept host routes from the DvR backbone

Example 1:

To accept host routes from the DvR backbone, you must configure a backbone route policy and apply it to the IS-IS accept policy.

1. Configure a route policy for DvR:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map dvrmap1 1
Switch:1(route-map)#enable
```

2. Configure an IS-IS accept policy for I-SID 10, and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap1
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
```

**OR**

Configure the default accept policy for IS-IS and DvR, and apply the route policy as a backbone route policy:

```
Switch:1(config)#route-map isismap1 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit
```

```
Switch:1(config)#router isis
Switch:1(config-isis)#accept route-map isismap1 backbone-route-map dvrmap1
```

### 3. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
Switch:1(config)#exit
```

### 4. Verify the configuration:

```
Switch:1#show ip isis accept

=====
                        Isis Accept - GlobalRouter
=====

ADV_RTR  I-SID    ISID-LIST                                ENABLE POLICY                BACKBONE
-----  -
-         10      -   TRUE                          dvrmap1
-         -      -   isismap1                      dvrmap1

2 out of 2 Total Num of Isis Accept Policies displayed
```

### Example 2:

Configure an IS-IS accept policy for I-SID 10 that accepts DvR host routes in a subnet, for example, subnet 126.1.1.0/24.

#### 1. Configure an IP prefix list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24
```

#### 2. Create the route policy dvrmap2 to match the IP prefix list:

```
Switch:1(config)#route-map dvrmap2 1
Switch:1(route-map)#match network listPrefix
Switch:1(route-map)#enable
```

#### 3. Create an IS-IS accept policy with I-SID 10 and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
```

#### 4. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

The above command causes IS-IS to accept all routes with I-SID 10. To deny IS-IS routes and accept only DvR host routes, you can configure an additional IS-IS route policy as follows:

```
Switch:1(config)#route-map isismap2 1
Switch:1(route-map)#no permit
Switch:1(route-map)#enable

Switch:1(route-map)#exit
Switch:1(config)#router isis
```

```
Switch:1(config-isis)#accept i-sid 10 route-map isismap2 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

##### 5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1#show ip isis accept

=====
                        Isis Accept - GlobalRouter
=====

1 out of 1 Total Num of Isis Accept Policies displayed
```

The following examples show the configuration of IS-IS accept policies for a specific VRF instance.

##### Example 1:

Configure IS-IS accept policies to accept host routes from the DVR backbone, for a specific VRF instance.

1. In the VRF green context, configure the route policy dvrmap3 for DVR:

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap3 1
Switch:1(router-vrf-routemap)#enable
```

2. Use one of the following options to configure an IS-IS accept policy, and apply the route policy as a backbone route policy:

Configure an IS-IS accept policy for a specific advertising BEB with nickname 1.11.11:

```
Switch:1(router-vrf-routemap)#isis accept adv-rtr 1.11.11 backbone-route-map dvrmap3
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#isis accept adv-rtr 1.11.11 enable
Switch:1(router-vrf)#show ip isis accept vrf green

1 out of 1 Total Num of Isis Accept Policies displayed

```

**Example 2:**

Configure an accept policy for I-SID 10 that accepts DVR host routes in a subnet, for example, subnet 126.1.1.0/24.

1. Configure an IP prefix list:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24

```

2. For a specific VRF instance, create a route policy to match the IP prefix list:

```

Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap4 1
Switch:1(router-vrf-routemap)#match network listPrefix
Switch:1(router-vrf-routemap)#enable
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#

```

3. Create an IS-IS accept policy with I-SID 10, and apply the route policy as the backbone route policy:

```

Switch:1(router-vrf)#accept i-sid 10 backbone-route-map dvrmap4
Switch:1(router-vrf)#accept i-sid 10 enable

```

4. Apply the IS-IS accept policy:

```

Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept

```

5. Verify the configuration:

```

Switch:1(config)#exit
Switch:1(router-vrf)#show ip isis accept vrf green

**Variable definitions**

The following table defines parameters for the `ip isid-list` command.

| Variable                             | Value                                                                    |
|--------------------------------------|--------------------------------------------------------------------------|
| <code>WORD&lt;1-32&gt;</code>        | Creates a name for your I-SID list.                                      |
| <code>&lt;1-16777215&gt;</code>      | Specifies an I-SID number.                                               |
| <code>list WORD&lt;1-1024&gt;</code> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **accept** command.

| Variable                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>adv-rtr &lt;x.xx.xx&gt;</code>             | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.                                                                                                                                  |
| <code>backbone-route-map WORD&lt;1-64&gt;</code> | Specifies the DvR backbone route map.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>enable</code>                              | Enables an IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>i-sid &lt;1-16777215&gt;</code>            | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).                    |
| <code>isid-list WORD&lt;1-32&gt;</code>          | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT). |
| <code>route-map WORD&lt;1-64&gt;</code>          | Specifies a route policy by name. You must configure the route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the **isis apply accept** command.

| Variable                          | Value                              |
|-----------------------------------|------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies a specific VRF instance. |

#### View IS-IS Accept Policy Information

Use the following procedure to view IS-IS accept policy information on the switch.

#### Procedure

1. Display IS-IS accept policy information:

```
show ip isis accept [vrf WORD<1-16>][vrfids WORD<0-512>]
```

## 2. Display I-SID list information:

```
show ip isid-list [vrf WORD<1-16>][vrfids WORD<0-512>][WORD<1-32>]
```

## 3. Display route information:

```
show ip route [vrf WORD<1-16>]
```

The NH VRF/ISID column displays the I-SID for inter-Virtual Services Network (VSN) routes redistributed with IS-IS accept policies, only if the I-SID redistributed does not have an IP VSN associated with it. If an IP VSN exists for that I-SID, the VRF name displays. If the I-SID is 0, the column represents and displays as the GlobalRouter.

The existing IS-IS routes for Layer 3 VSNs continue to display as the VRF name of the IP VSN.

## 4. Display the SPBM IP unicast Forwarding Information Base (FIB):

```
show isis spbm ip-unicast-fib [all] [id <1-16777215>][spbm-nh-as-mac]
[home|remote]
```

## Example

View IS-IS accept policy information:

```
Switch:1#show ip route vrf test

### Variable Definitions

The following table defines parameters for the **show ip isis accept** command.

| Variable                        | Value                                                         |
|---------------------------------|---------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays I-SID list information for a particular VRF by name. |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays I-SID list information for a particular VRF ID.      |

The following table defines parameters for the **show ip isid-list** command.

| Variable                        | Value                                                             |
|---------------------------------|-------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays I-SID list information for a particular VRF by name.     |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays I-SID list information for a particular VRF ID.          |
| <i>WORD&lt;1-32&gt;</i>         | Displays I-SID list information for a particular I-SID list name. |

The following table defines parameters for the **show ip route** command.

| Variable                    | Value                                                         |
|-----------------------------|---------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i> | Displays I-SID list information for a particular VRF by name. |

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

| Variable                     | Value                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <i>all</i>                   | Displays all IS-IS SPBM IP unicast Forwarding Information Base (FIB) information.                 |
| <i>home</i>                  | Displays the IS-IS SPBM IP unicast FIB information that the system configures in the home area.   |
| <i>id &lt;1-16777215&gt;</i> | Displays IS-IS SPBM IP unicast FIB information by I-SID ID.                                       |
| <i>remote</i>                | Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area. |
| <i>spbm-nh-as-mac</i>        | Displays the next hop B-MAC of the IP unicast FIB entry.                                          |

### Configure IPv6 IS-IS Accept Policies

Perform the following procedure to create and enable IPv6 IS-IS accept policies based on a particular Backbone Edge Bridge (BEB), I-SID, or I-SID list. IPv6 IS-IS accept policies filter incoming IS-IS routes that the device receives over the SPBM cloud. IPv6 IS-IS accept policies apply to incoming traffic and determine whether to add the route to the routing table.

IPv6 IS-IS accept policies are disabled by default.

#### Note

- IPv6 IS-IS accept policies are not supported for DvR.
- The I-SID lists created can be associated with both IPv4 or IPv6 routes.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy associated with an accept policy changes, you must reapply the IPv6 IS-IS accept policy, unless the IPv6 IS-IS accept policy was the last sequence in the configuration.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IPv6 IS-IS accept policy configuration, you must apply the **ipv6 isis apply accept [vrf WORD<1-16>]** command at the end.

The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the IPv6 IS-IS accept policy filters.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an I-SID list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IPv6 IS-IS accept policy filters, which you implement with the **ip isid-list** or **ipv6 accept** command. The I-SIDs used for Layer 3 VSNs can be reused in IPv6 IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs.

For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 4193. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1492.
- You must configure a route-map.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<1-16777215> | list WORD<1-1024>}
```

### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

4. Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [ [route-map WORD<1-64>]
```

- b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

- c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

- d. Specify a particular route-map to use for all IS-IS routes from all BEBs unless a more specific filter exists for the advertising BEB. :

```
ipv6 isis accept route-map WORD<1-64>
```

5. Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

6. Exit to Global Configuration mode:

```
exit
```

7. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD <1-16>]
```

## Example

Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrftest
Switch:1(config-isis)#ipv6 isis accept i-sid 101 route-map test
Switch:1(config-isis)#ipv6 isis accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#ipv6 isis apply accept
```

## Variable Definitions

The following table defines parameters for the **ip isid-list** command.

### Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable                  | Value                                                                    |
|---------------------------|--------------------------------------------------------------------------|
| <i>WORD</i> <1-32>        | Creates a name for your I-SID list.                                      |
| <1-16777215>              | Specifies an I-SID number.                                               |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i><br><x.xx.xx>  | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br><br><b>Note:</b><br>An IPv6 IS-IS accept policy that specifies the <i>adv-rtr</i> without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i>                | Enables an IPv6 IS-IS accept policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>i-sid</i><br><0-16777215> | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).                                                                                                              |

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isid-list</code><br><code>WORD&lt;1-32&gt;</code> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT). |
| <code>route-map</code><br><code>WORD&lt;1-64&gt;</code> | Specifies a route policy by name. You must configure the route policy earlier in a separate procedure.                                                                                                                                                                                                                                                                                                                                       |

The following table defines parameters for the `ipv6 isis apply accept` command.

| Variable                          | Value                     |
|-----------------------------------|---------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies a VRF instance. |

### Displaying IPv6 IS-IS Accept Policy Information

Perform the following procedure to view IPv6 IS-IS accept policy information on the switch.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display IPv6 IS-IS accept policy information:  
`show ipv6 isis accept [vrf WORD<1-16>] [vrfigs WORD<0-512>]`

#### Example

Display IPv6 IS-IS accept policy information for vrfRED:

```
Switch:1>enable
Switch:1#show ipv6 isis accept vrf vrfRED
=====
                        Isis Accept - VRF vrfRED
=====
ADV_RTR  I-SID    ISID-LIST                ENABLE POLICY
-----
1.11.11  1001          -                        TRUE
1 out of 1 Total Num of Isis Accept Policies displayed
```

## IP Shortcuts configuration using EDM

This section provides procedures to configure IP Shortcuts using Enterprise Device Manager (EDM).

### Configure SPBM IP Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

After you have configured the SPBM infrastructure, you can enable SPBM IP shortcuts to advertise IP routes across the SPBM network using the following procedure.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **IS-IS**.
3. From the **Globals** tab, in **IpSourceAddress**, specify the CLIP interface to use as the source address for SBPM IP Shortcuts.

#### Note

For IPv6 Shortcuts, select **ipv6** in **Ipv6SourceAddressType**, and then use **Ipv6SourceAddress** to specify the CLIPv6 interface to use as the source address for SBPM IPv6 Shortcuts.

4. Select **Apply**.
5. In the navigation pane, expand **Configuration > Fabric > SPBM**.
6. Select the **SPBM** tab.
7. In **IpShortcut**, select **enable**.

#### Note

For IPv6 Shortcuts, select **enable** in **Ipv6Shortcut**.

8. Select **Apply**.
9. In the navigation pane, expand **Configuration > IP**.
10. Select **Policy**.
11. Select the **Route Redistribution** tab.

12. Select **Insert** to identify routes on the local switch to be announced into the SPBM network.
13. Using the fields provided, specify the source protocols to redistribute into IS-IS. In **Protocol**, ensure you specify **isis** as the destination protocol.
14. Select **Insert**.

### Configuring IPv4 IS-IS redistribution

Use this procedure to configure IS-IS redistribution. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IP VPN IP reachability information, the routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.

#### IS-IS Redistribute field descriptions

Use the data in the following table to configure the **IS-IS Redistribute** tab.

| Name               | Description                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>    | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in the redistribution.                                           |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                          |
| <b>SrcVrfId</b>    | Specifies the source VRF ID used in the redistribution. For IS-IS, the source VRF ID must be the same as the destination VRF ID.        |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                       |
| <b>Enable</b>      | Enables or disables a redistribution entry. The default is disable.                                                                     |
| <b>RoutePolicy</b> | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain. |

| Name              | Description                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b>     | Specifies the metric for the redistributed route. The value can be a range between 0 to 65535. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                    |
| <b>MetricType</b> | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.         |
| <b>Subnets</b>    | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow. |

### Configure IPv6 IS-IS Redistribution

Use this procedure to configure IS-IS redistribution for IPv6. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the IPv6 routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: v6direct, v6static, RIPng, OSPFv3, or BGPv6, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

#### Note

RIPng is supported only on the Global Router.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IPv6 VPN reachability information, the IPv6 routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

### Before You Begin

Change the VRF instance as required to configure IPv6 IS-IS redistribution on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.
7. Click **Apply**.

## Redistribute Field Descriptions

Use the data in the following table to configure the **Redistribute** tab.

| Name               | Description                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>    | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in redistribution.                                                                                                                                                                                                       |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                                                                                                                                                                                  |
| <b>SrcVrfId</b>    | Specifies the source Virtual Routing and Forwarding (VRF) ID used in redistribution.                                                                                                                                                                                                            |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                                                                                                                                                                               |
| <b>Enable</b>      | Enables or disables a redistribution entry. The default is disabled.                                                                                                                                                                                                                            |
| <b>RoutePolicy</b> | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain.                                                                                                                                                         |
| <b>Metric</b>      | Specifies the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                                                         |
| <b>MetricType</b>  | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2. |

### *Applying IPv4 IS-IS accept policies globally*

Apply IS-IS accept policies globally. Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

After you apply the IS-IS accept filters, the device removes and re-adds all routes with updated filters.

IS-IS accept policies are disabled by default.

#### Note

- After you apply IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IP IS-IS filter exists.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.

#### Accept Global field descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name                             | Description                                                                                                                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultPolicyName</b>         | Specifies the route policy name for the default filter.                                                                                                                                                                                                          |
| <b>DefaultBackbonePolicyName</b> | Specifies the backbone host route policy name for the default filter.                                                                                                                                                                                            |
| <b>Apply</b>                     | Applies the default policy when you configure the field to apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |

#### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IS-IS**.
3. Select the **Accept Nick Name** tab.
4. Select **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Select **Insert**.

#### Accept Nick Name field descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.<br>The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Enable</b>             | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                                                    |
| <b>PolicyName</b>         | Specifies a route policy.<br>You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                                        |
| <b>BackbonePolicyName</b> | Specifies the route policy for the backbone routes.<br>You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                              |

### Configure an IS-IS Accept Policy to Apply for a Specific I-SID

Configure an IS-IS accept policy for a specific I-SID number to represent a local or remote Layer 3 VSN, which allows the system to redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

#### Accept Isid field descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>               | Configures a specific I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT). |
| <b>Enable</b>             | Enables or disables the I-SID entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                                                                      |
| <b>PolicyName</b>         | Specifies the route map name. You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                              |
| <b>BackbonePolicyName</b> | Specifies the backbone route map name. You must configure a policy earlier in a separate procedure.                                                                                                                                                                                                                     |

### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

#### Accept Nick-Name Isid descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name                      | Description                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Isid</b>               | Specifies an I-SID used to filter. The value 0 is used for the Global Router.                                                                                       |
| <b>Enable</b>             | Enables or disables the I-SID entry. The default is disabled.                                                                                                       |
| <b>PolicyName</b>         | Specifies the route policy name. You must configure a policy earlier in a separate procedure.                                                                       |
| <b>BackBonePolicyName</b> | Specifies the backbone route policy name. You must configure a policy earlier in a separate procedure.                                                              |

*Configure an I-SID List for an IPv4 IS-IS Accept Policy*

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IS-IS accept policy.

**Note**

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

**Before You Begin**

- Enable IS-IS globally.
- Ensure the manual area exists.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IS-IS**.
3. Select the **Isid-List** tab.
4. Select **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Select **Insert**.

**Isid-List field descriptions**

Use the data in the following table to configure the **Isid-List** tab.

| Name                            | Description                                                                                                                                                                                                            |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                     | Specifies the name of the I-SID list.                                                                                                                                                                                  |
| <b>Isid</b> or <b>Isid-List</b> | Specifies that you either want to add a particular I-SID or a list of I-SID numbers.                                                                                                                                   |
| <b>Isid</b>                     | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies.<br>An I-SID value of 0 represents the global routing table (GRT). |

### Configure an IPv4 IS-IS Accept Policy for a Specific I-SID List

Configure an IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

#### Accept Isid-List field descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name                      | Description                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Name</b>               | Specifies the name of I-SID list.                                                                       |
| <b>Enable</b>             | Enables or disables the I-SID list entry. The value must be enabled to filter. The default is disabled. |
| <b>PolicyName</b>         | Specifies the route policy name.                                                                        |
| <b>BackBonePolicyName</b> | Specifies the backbone route policy name.                                                               |

### Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID-list

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

### About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

### Accept Nick-Name Isid-List field descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b>     | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter.<br>The value is 2.5 bytes in the format <x.xx.xx>. |
| <b>Name</b>               | Specifies the name of the I-SID list used to filter.                                                                                                                                                                                                                                              |
| <b>Enable</b>             | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled.                                                                                                                                                                     |
| <b>PolicyName</b>         | Specifies a route policy name.                                                                                                                                                                                                                                                                    |
| <b>BackBonePolicyName</b> | Specifies a backbone route policy name.                                                                                                                                                                                                                                                           |

### *Apply IPv6 IS-IS Accept Policies Globally*

Apply IPv6 IS-IS accept policies globally. Use IPv6 IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud.

After you apply the IPv6 IS-IS accept policy filters, the device removes and re-adds all IPv6 routes with updated filters.

IPv6 IS-IS accept policies are disabled by default.

#### Note

- After you apply IPv6 IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IPv6 IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IPv6 IS-IS routes, and adds the IPv6 IS-IS routes again. You should make all the relevant accept policy changes, and then apply IPv6 IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

#### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IPv6 IS-IS filter exists.
- Change the VRF instance as required to apply IPv6 IS-IS accept policies on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IS-IS**.
3. Select the **Accept Global** tab.
4. (Optional) Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.
6. Select **Apply**.

#### Accept Global Field Descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name                     | Description                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultPolicyName</b> | Specifies the route policy name for the default filter.                                                                                                                                                                                          |
| <b>Apply</b>             | Applies the default policy when you select apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |
| <b>NickNameTableSize</b> | Shows the IPv6 IS-IS In Filter Nick Name table size.                                                                                                                                                                                             |
| <b>IsidTableSize</b>     | Shows the IPv6 IS-IS In Filter I-SID table size.                                                                                                                                                                                                 |

| Name                               | Description                                                     |
|------------------------------------|-----------------------------------------------------------------|
| <b>NickNamesI-SIDTableSize</b>     | Shows the IPv6 IS-IS In Filter Nick Name I-SID table size.      |
| <b>I-SIDListTableSize</b>          | Shows the IPv6 IS-IS In Filter I-SID List table size.           |
| <b>NickNamesI-SIDListTableSize</b> | Shows the IPv6 IS-IS In Filter Nick Name I-SID List table size. |

### Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IPv6 IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick Name** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Nick Name Field Descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name                  | Description                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. |
| <b>Enable</b>         | Enables the SPBM nickname advertising router entry. The default is disabled.                                                                                                                                                                                     |
| <b>PolicyName</b>     | Specifies a route policy.                                                                                                                                                                                                                                        |

### Configuring an IPv6 IS-IS Accept Policy for a specific I-SID

Configure an IPv6 IS-IS accept policy for a specific I-SID to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the I-SID value.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Isid Field Descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name              | Description                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>       | Specifies a particular I-SID number that represents local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |
| <b>Enable</b>     | Enables or disables the I-SID entry. The default is disabled.                                                                                                                                  |
| <b>PolicyName</b> | Specifies the route policy name.                                                                                                                                                               |

### Configuring an IPv6 IS-IS accept policy for a specific advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

## Accept Nick-Name Isid Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name                  | Description                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. |
| <b>Isid</b>           | Specifies the I-SID value. The value 0 is used for the Global Router.                                  |
| <b>Enable</b>         | Enables or disables the I-SID entry. The default is disabled.                                          |
| <b>PolicyName</b>     | Specifies the route policy name. You must configure a policy earlier in a separate procedure.          |

### Configure an I-SID List for an IPv6 IS-IS Accept Policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IPv6 IS-IS accept policy.

#### Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Change the VRF instance as required to configure an I-SID list for an IPv6 IS-IS accept policy on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IS-IS**.
3. Select the **Isid-List** tab.
4. Select **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Select **Insert**.
9. Select **Apply**.

## Isid-List Field Descriptions

Use the data in the following table to configure the **Isid-List** tab.

| Name        | Description                                                                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b> | Specifies the name of the I-SID list.                                                                                                                                                                                    |
| <b>Isid</b> | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |

### Configuring an IPv6 IS-IS Accept Policy for a specific I-SID List

Configure an IPv6 IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

## Accept Isid-List Field Descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name              | Description                                                        |
|-------------------|--------------------------------------------------------------------|
| <b>Name</b>       | Specifies the name of I-SID list.                                  |
| <b>Enable</b>     | Enables or disables the I-SID list entry. The default is disabled. |
| <b>PolicyName</b> | Specifies the route policy name.                                   |

### Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB and I-SID List

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

#### Note

If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

### Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

### Accept Nick-Name Isid-List Field Descriptions

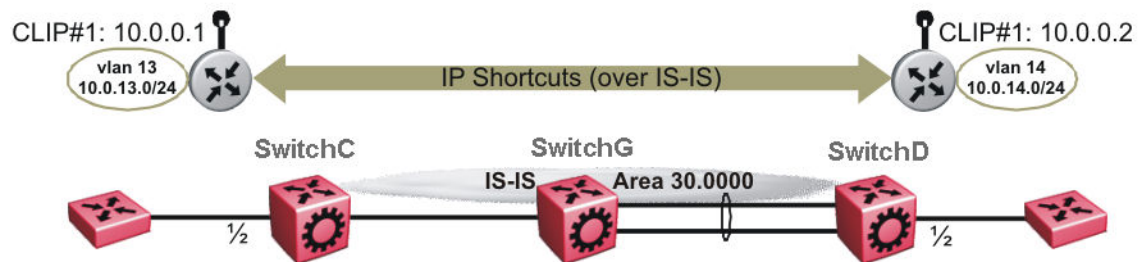

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name                  | Description                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisingRtr</b> | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. |
| <b>Name</b>           | Specifies the I-SID list name.                                                                                                                                                                                                    |
| <b>Enable</b>         | Enables or disables the SPBM nickname advertising router entry. The default is disabled.                                                                                                                                          |
| <b>PolicyName</b>     | Specifies a route policy name.                                                                                                                                                                                                    |

### IP Shortcuts SPBM Configuration Example

The following figure shows a sample IP Shortcuts over SPBM deployment.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

**Figure 132: SPBM IP Shortcuts**

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM and IS-IS Infrastructure Fundamentals](#) on page 1001.

Note the following:

- IP IS-IS redistribution needs to be configured to inject IP shortcuts routes into IS-IS. The one exception is the circuitless IP address configured as the IS-IS ip-source-address. This address is automatically advertised without the need for a redistribution rule.

- In the displayed configuration, only direct routes are injected (the same configuration is possible for static routes). To inject IPv6 routes, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.
- No IP address needs to be configured on SwitchG.

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example.

### SwitchC

#### CIRCUITLESS INTERFACE CONFIGURATION - GlobalRouter

```
interface loopback 1
ip address 1 10.0.0.1/255.255.255.255
exit
```

#### ISIS CONFIGURATION

```
router isis
ip-source-address 10.0.0.1
```

#### ISIS SPBM CONFIGURATION

```
spbm 1 ip enable
exit
```

#### VLAN CONFIGURATION

```
vlan create 13 type port-mstprstp 0
vlan members 13 1/2 portmember
interface Vlan 13
ip address 10.0.13.1 255.255.255.0
exit
```

#### IP REDISTRIBUTION CONFIGURATION - GlobalRouter

```
router isis
redistribute direct
redistribute direct metric 1
redistribute direct enable
exit
```

#### IP REDISTRIBUTE APPLY CONFIGURATIONS

```
isis apply redistribute direct
```

### SwitchD

#### CIRCUITLESS INTERFACE CONFIGURATION - GlobalRouter

```
interface loopback 1
ip address 1 10.0.0.2/255.255.255.255
exit
```

#### ISIS CONFIGURATION

```
router isis
ip-source-address 10.0.0.2
```

#### ISIS SPBM CONFIGURATION

```

spbm 1 ip enable
exit

VLAN CONFIGURATION

vlan create 14 type port-mstprstp 0
vlan member add 14 1/2
interface Vlan 14
ip address 10.0.14.1 255.255.255.0
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router isis
redistribute direct
redistribute direct metric 1
redistribute direct enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

isis apply redistribute direct

```

### Verifying Operation — SwitchC

## Layer 3 VSN Configuration Fundamentals

This section provides fundamental concepts on Layer 3 VSN.

For information about supported service types, see [Fabric Connect Service Types](#) on page 1392.

### SPBM Layer 3 VSN

The SPBM Layer 3 VSN feature is a mechanism to provide IP connectivity over SPBM for VRFs. SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

**Figure 133: SPBM Layer 3 VSN**

In the preceding figure, the BEBs are connected over the SPBM cloud running IS-IS. VRF red and green are configured on the BEBs. VRF red on BEB A has to send and receive routes from VRF red on BEB D. Similar operations are required for VRF green on BEB A and BEB D.

IS-IS TLV 184 is used to advertise SPBM Layer 3 VSN route information across the SPBM cloud. To associate advertised routes with the appropriate VRF, each VRF is associated with an I-SID. All VRFs in the network that share the same I-SID participate in the same VSN.

#### Note

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN coexist and share the same I-SID. You need to configure I-SID only once. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

In this example, I-SID 101 is associated with VRF green and I-SID 102 is associated with VRF red. The I-SID is used to tie the advertised routes to a particular VRF. This identifier has to be the same on all edge nodes for a particular VRF, and has to be unique across all the VRFs on the same node

When IS-IS receives an update from an edge node, it looks for the Layer 3 VSN TLV, and if one exists, it looks at the I-SID identifier. If that identifier is mapped to a local VRF, extracts the IPv4 or IPv6 routes and add them to the RTM of that VRF.

With SPBM Layer 3 VSN, the packet forwarding works in a similar fashion as the IP Shortcuts on the Global Router, with the difference that the encapsulation includes the I-SID to identify the VRF that the packet belongs to. The following figure shows the packet forwarding for VRF red.

**Figure 134: Packet forwarding in SPBM Layer 3 VSN**

When BEB A receives traffic from VRF red that must be forwarded to the far-end location, it performs a lookup and determines that VRF red is associated with I-SID 102 and that BEB D is the destination for I-SID 102. BEB A then encapsulates the IP data into a new B-MAC header, using destination B-MAC: D.

**Note**

With SPBM Layer 3 VSN, the C-MAC header is all null. This header does not have any significance in the backbone. It is included to maintain the same 802.1ah format for ease of implementation.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 102. After identifying the destination as VRF red, the node forwards the packet to the destination VRF.

**Note**

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN coexist and share the same I-SID. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

**IPv6 Layer 3 VSN limitations and considerations**

Consider the following when you configure the IPv6 Layer 3 VSN :

- You can enable IPv6 Layer3 VSN only when `spbm boot` config flag is true.
- IPv4 Shortcuts and IPv6 Shortcuts must be enabled.

### Enable/disable ICMP Response on VRFs/Layer 3 VSNs

This feature supports VRFs/Layer 3 VSNs to operate in stealth mode by disabling ICMP responses on specific VRFs/Layer 3 VSNs.

If the ICMP response is disabled, the switch does not respond to any ICMP requests received on the VRFs/Layer 3 VSNs.

If the ICMP response is enabled, the switch responds to ICMP requests received on the VRF/Layer 3 VSNs.

## Layer 3 VSN configuration using the CLI

This section provides a procedure to configure Layer 3 VSNs using the command line interface (CLI).

### Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

#### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 4185.
- You must create the Customer VLANs and add slots/ports.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable  
  
configure terminal  
  
router vrf WORD<1-16>
```

2. Create an IPv4 VPN instance on the VRF:

```
ipvpn
```

3. Configure SPBM Layer 3 VSN:

```
i-sid <0-16777215>
```

4. Enable IPv4 VPN on the VRF:

```
ipvpn enable
```

By default, a new IPv4 VPN instance is disabled.

5. Display all IPv4 VPNs:  

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
6. Identify routes on the local switch to be announced into the SPBM network:  

```
isis redistribute {direct | bgp | ospf | rip | static}
```
7. Enable routes on the local switch to be announced into the SPBM network:  

```
isis redistribute {direct | bgp | ospf | rip | static} enable
```
8. If you want to delete or disable the configuration, use the no option:  

```
no isis redistribute {direct | bgp | ospf | rip | static}
```

```
no isis redistribute {direct | bgp | ospf | rip | static} enable
```
9. Identify other routing protocols to which to redistribute IS-IS routes:  

```
ip {bgp | ospf | rip} redistribute isis
```
10. Enable IS-IS redistribution to other routing protocols:  

```
ip {bgp | ospf | rip} redistribute isis enable
```
11. Exit Privileged EXEC mode:  

```
exit
```
12. Apply the configured redistribution:  

```
isis apply redistribute {direct | bgp | ospf | rip | static} vrf WORD<1-16>
```

```
ip bgp apply redistribute isis vrf WORD<1-16>
```

```
ip ospf apply redistribute isis vrf WORD<1-16>
```

```
ip rip apply redistribute isis vrf WORD<1-16>
```
13. Display the redistribution configuration:  

```
show ip isis redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

Create the IPv4 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(config)#ipvpn
Switch:1(config)#i-sid 109
Switch:1(config)#ipvpn enable
Switch:1(config)#show ip ipvpn
=====
                        IPv4  IPVPN
=====
VRF Name                VRF ID  IPv4 IPVPN  IPv6 IPVPN  I-SID  I-SID Name
-----
green                    1       enabled  disabled  109       ExtremeServer1
=====
1 out of 1 Total IPv4 L3 VSN, 1 active IPv4 and 0 active IPv6 displayed.
Switch:1(config)#isis redistribute ospf
Switch:1(config)#isis redistribute ospf enable
Switch:1(config)#isis redistribute ospf enable
Switch:1(config)#end
Switch:1(config)#isis apply redistribute ospf vrf vrfred
Switch:1(config)#show ip isis redistribute vrf vrfred
```

```

=====

```

### Variable Definitions

The following table defines parameters for the **show ip ipvpn** command.

| Variable                  | Value                   |
|---------------------------|-------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF ID.   |

The following table defines parameters for the **i-sid** command.

| Variable     | Value                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-16777215> | Assigns an I-SID to the VRF being configured.<br>Use the <b>no</b> or <b>default</b> option to remove the I-SID to VRF allocation for this VRF. |

The following table defines parameters for the **isis redistribute** command.

| Variable                                         | Value                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{direct   bgp   ospf   rip   static}</i>      | Specifies the protocol.                                                                                                                                                                                                                                                                                                       |
| <i>enable</i>                                    | Enables the redistribution of the specified protocol into the SPBM network.<br>The default is disabled. Use the <b>no</b> or <b>default</b> options to disable the redistribution.                                                                                                                                            |
| <i>metric</i> <0-65535>                          | Configures the metric (cost) to apply to redistributed routes.<br>The default is 1.                                                                                                                                                                                                                                           |
| <i>metric-type</i><br><i>{external internal}</i> | Configures the type of route to import into the protocol. The default is internal.                                                                                                                                                                                                                                            |
| <i>route-map</i> WORD<0-64>                      | Configures the route policy to apply to redistributed routes.<br>Specifies a name.                                                                                                                                                                                                                                            |
| <i>subnets</i> <i>{allow suppress}</i>           | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose <b>suppress</b> to advertise subnets aggregated to their classful subnet. Choose <b>allow</b> to advertise the subnets individually with the learned or configured mask of the subnet. The default is <b>allow</b> . |

The following table defines parameters for the **isis apply redistribute** command.

| Variable                                          | Value                                                                    |
|---------------------------------------------------|--------------------------------------------------------------------------|
| <code>{direct   bgp   ospf   rip   static}</code> | Specifies the protocol.                                                  |
| <code>vrf WORD&lt;1-16&gt;</code>                 | Applies IS-IS redistribute for a particular VRF. Specifies the VRF name. |

Configure SPBM IPv6 Layer 3 VSN using CLI

### Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF instance on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 4185.

### About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv6 routes across the SPBM network using the following procedure.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create an IPv6 VPN instance on the VRF:
 

```
ipv6 ipvpn
```
3. Configure SPBM Layer 3 VSN:
 

```
i-sid <0-16777215>
```
4. Enable IPv6 VPN on the VRF:
 

```
ipv6 ipvpn enable
```
5. Display all IPv6 VPNs:
 

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```
6. Identify routes on the local switch to be announced into the SPBM network:
 

```
ipv6 isis redistribute {bgp | direct | ospf | static}
```
7. Enable routes on the local switch to be announced into the SPBM network:
 

```
ipv6 isis redistribute {direct | bgp | ospf | rip | static} enable
```
8. Identify the routing protocol to which to redistribute IS-IS routes:
 

```
ipv6 ospf redistribute isis
```
9. Enable IS-IS redistribution to OSPF:
 

```
ipv6 ospf redistribute isis enable
```
10. Return to Privileged EXEC mode:
 

```
end
```

11. Apply the configured redistribution to a specific VRF:

```
ipv6 isis apply redistribute {direct | bgp | ospf | rip | static} vrf WORD<1-16>
```

12. Apply the OSPF configuration to a specific VRF:

```
ipv6 ospf apply redistribute isis vrf WORD<1-16>
```

13. Display the redistribution configuration:

```
show ipv6 isis redistribute [vrf WORD<1-16> | vrfids WORD<0-512>]
```

14. Verify IPv6 IS-IS routes:

```
show ipv6 route vrf WORD<1-16>
```

**Examples**

Create the IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====

**Variable Definitions**

The following table defines parameters for the **ipv6 ipvpn** command.

| Variable      | Value                                        |
|---------------|----------------------------------------------|
| <i>enable</i> | Enables IPv6 IPVPN. The default is disabled. |

The following table defines parameters for the **show ipv6 ipvpn** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.   |

The following table defines parameters for the **i-sid** command.

| Variable                        | Value                                         |
|---------------------------------|-----------------------------------------------|
| <code>&lt;0-16777215&gt;</code> | Assigns an I-SID to the VRF being configured. |

The following table defines parameters for the **isis redistribute** command.

| Variable                                    | Value                                                                                                |
|---------------------------------------------|------------------------------------------------------------------------------------------------------|
| <code>{bgp   direct   ospf   static}</code> | Specifies the protocol.                                                                              |
| <code>enable</code>                         | Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. |

### Display SPBM IPv6 Unicast Forwarding Information Base

#### About This Task

Perform this procedure to display SPBM IPv6 unicast Forwarding Information Base (FIB).

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display SPBM IPv6 unicast FIB:

```
show isis spbm ipv6-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-
mac] [home|remote]
```

#### Example

```
Switch:1>show isis spbm ipv6-unicast-fib
=====
SPBM IPv6-UNICAST FIB ENTRY INFO

## Variable Definitions

The following table defines parameters for the `show isis spbm ipv6-unicast-fib` command.

| Variable                           | Value                                                                                               |
|------------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>all</code>                   | Displays all IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information for all VRFs.    |
| <code>home</code>                  | Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the home area.   |
| <code>id &lt;1-16777215&gt;</code> | Displays IS-IS SPBM IPv6 unicast FIB information by I-SID ID.                                       |
| <code>remote</code>                | Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area. |
| <code>spbm-nh-as-mac</code>        | Displays the next hop B-MAC of the IPv6 unicast FIB entry.                                          |

### Display IS-IS Link State Database Information

Perform the following procedure to display the IS-IS link state database related information on the switch.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS link state database information:

```
show isis lsdb ipv6-unicast [i-sid <0-16777215>] [lspid
xxxx.xxxx.xxxx.xx-xx] [sysid xxxx.xxxx.xxxx] [home|remote]
```

#### Example

```
Switch:1>show isis lsdb ipv6-unicast

## Layer 3 VSN configuration using EDM

This section provides procedures to configure Layer 3 VSNs using Enterprise Device Manager (EDM).

### Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance on the switch. For more information about how to configure a VRF, see [VRF Lite configuration using Enterprise Device Manager](#) on page 4196.
- You must create the Customer VLANs and add slots/ports.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. To create an IP VPN instance, select **Insert**.
5. Select the ellipsis button (...), select a VRF to associate with the IP VPN, and click **Ok**.
6. Select **Insert**.
7. In the **Enable** column, select **enable** to enable the IP VPN on the VRF.
8. In the **IsidNumber** column, specify an I-SID to associate with the VPN.
9. Select **Apply**.
10. In the navigation pane, expand **Configuration > IP**.
11. Select **Policy**.
12. To identify routes on the local switch to be announced into the SPBM network, select the **Route Redistribution** tab.
13. Select **Insert**.
14. In the **DstVrflid** box, select the ellipsis (...), and then select the destination VRF ID and select **Ok**.
15. In the **Protocol** box, select **isis** as the route destination.
16. In the **SrcVrflid** box, select (...) button, select the source VRF ID and click **Ok**.
17. In the **RouteSource** box, select the source protocol.
18. In the **Enable** box, select **enable**.
19. In the **RoutePolicy** box, select the ellipsis (...), choose the route policy to apply to the redistributed routes and select **Ok**.
20. Configure the other parameters as required.
21. Select **Insert**.
22. To apply the redistribution configuration, select the **Applying Policy** tab.
23. Select **RedistributeApply**, and then select **Apply**.

## Configuring SPBM IPv6 Layer 3 VSN using EDM

### About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv6 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

### Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IPv6 VPN instance on the switch. For more information, see [VRF Lite configuration using Enterprise Device Manager](#) on page 4196.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6-VPN**.
3. Click the **VPN** tab.
4. Click **Insert**.
5. Click the ellipsis [...], and select a VRF.
6. Click **Ok**.
7. Click **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. Click **Apply**.
10. In the **Enable** column, select **true** or **false**.
11. Click **Apply**.
12. In the navigation pane, expand **Configuration > VRF Context View**.
13. Click **Set VRF Context View**.
14. Click the **VRF** tab.
15. Select a context to view.
16. Click **Launch VRF Context view**.  
A new browser tab opens containing the selected VRF view
17. In the navigation pane, expand **Configuration > IPv6**.
18. Click **IS-IS**.
19. Click the **Redistribute** tab.
20. Click **Insert**.
21. Configure the parameters as required.
22. Click **Insert**.
23. Click **Apply**.

## Layer 3 VSN configuration example

The following figure shows a sample Layer 3 VSN deployment.

**Figure 135: Layer 3 VSN**

The following sections show the steps required to configure the Layer 3 VSN parameters in this example.

Note that IP IS-IS redistribution needs to be configured to inject the VRF routes into IS-IS.

You must first configure basic SPBM and IS-IS infrastructure.

### VRF green configuration

The following figure shows the green VRF in this Layer 3 VSN example.

**Figure 136: Layer 3 VSN — VRF green**

The following sections show the steps required to configure the green VRF parameters in this example.

### VRF green – Switch-C

```
VRF CONFIGURATION
ip vrf green vrfid 1
```

```
VLAN CONFIGURATION

vlan create 101 type port-mstprstp 0
vlan mlt 101 1

|                                                                                                      | VSP 8200 Series | Not Supported                                                                      |
|                                                                                                      | VSP 8400 Series | Not Supported                                                                      |
|                                                                                                      | VSP 8600 Series | Not Supported                                                                      |
| XA1400 Series                                                                                        | Not Supported   |                                                                                    |

### Layer 3 Video Surveillance install script

#### Note

The Layer 3 Video Surveillance install script performs the same function as the `run vms endura` script. However, the switch continues to support the `run vms endura` script for backward compatibility.

The `run vms layer-3 switch` command runs the Layer 3 Video Surveillance install script that pre-configures basic and common configuration parameters to deploy a video surveillance network. Use this script to quickly and easily deploy a video surveillance network in accordance with best practices, using networking equipment.

Use this script to use a single command on a switch to configure the core switch where the video surveillance management and operation systems reside. Similarly, using the same command, you can configure each edge switch where the IP cameras connect.

The switch must be in a factory-default state, to ensure correct operation of the configuration.

The Layer 3 Video Surveillance install script performs the following tasks:

- Creates a Shortest Path Bridging (SPB) network core solution with IP Shortcuts to connect IP subnet zones between the core and edge IP subnets.
- Configures all network edge IP subnet areas containing IP cameras with an IP gateway address, that is redistributed over the SPB fabric. This enables the fabric core to act as a single IP routing entity for the solution.
- Relays DHCP services between each IP subnet area and the central server, for IP camera address allocation.
- Enables IP multicast over Fabric Connect virtualization, to support and enable efficient IP multicast communication over the fabric core from IP cameras to central Video Management System (VMS) servers, for viewing and recording video streams.

#### *CLI Command Switch Value*

You must specify a value for the switch in the install script command, and the value must be between 5 and 99. Use the value 5 for a core switch where the VMS core systems are connected.

Use the range 6–99 for switch values when you run the script on edge or access layer switches. Ensure that the switch value is unique for each additional switch that is part of the solution.

For example, the first edge or access switch with the IP Cameras connected would use a value of switch 6. For additional edge or access switches, use switch 7, switch 8, and so on, for each IP subnet and IP camera zone. You can connect up to 48 IP cameras to a switch within an IP subnet zone.

#### *Switch Parameters Configured by the Script*

The following list identifies the major parameters configured by the **run vms layer-3** command:

- SNMP-Server switch hostname
- SPB parameters such as System ID, Nickname, SPB Area ID, Backbone VLAN IDs (4051 and 4052), Multicast virtualization, and Connectivity Fault Management (CFM)
- IP loopback interface addresses
- IP redistribution over IS-IS (IP Shortcuts)
- All SFP ports as SPB NNI ports
- All copper RJ-45 ports as end device ports with Spanning Tree enabled
- Spanning Tree mstprstp mode
- VLAN port memberships
- VLAN IP address (Gateway IP for VLAN)
- DHCP Relay

#### **Note**

DHCP Relay parameters are configured only when you run the script on VSP4900-48P switches.

### Configuration File

After successful completion of the Layer 3 Video Surveillance install script, the switch saves the configuration with a filename based on the switch value provided when you ran the script. The switch updates the primary boot configuration file flags with the new filename.

For example, running the command **run vms layer-3 switch 5** results in a switch configuration filename of `spb-switch-5.cfg`.

### Hardware Considerations

The following list identifies which switches to configure as either a core or edge switch in a VMS solution:

- Core switch:

- VSP 4450GSX-PWR+

Ports 13 to 50 are NNI ports. All other ports are untagged access ports.

- VSP4900-12MXU-12XE

Ports 1 to 12 and the Extreme Integrated Application Hosting (IAH) ports are untagged access ports. Ports 13 to 24, and optional Versatile Interface Module (VIM) ports, are NNI ports.

- VSP4900-24S

Ports 1 to 12 are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.

- VSP4900-24XE

Ports 1 to 12 and the IAH ports are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.

- Edge switch:

- VSP4900-48P

#### Note

To support this feature, VIM installation is mandatory in VSP4900-48P. The VIM ports are configured as NNI ports while all fixed ports are untagged access ports.

### Modes

The **run vms layer-3** command can run in one of two modes:

- Non-verbose mode: This mode is a fully-automated configuration. The command runs the script with all of the variable defined values without user intervention. This mode is the default mode.
- Verbose mode: This mode prompts you to accept or change the default parameters.

#### Note

Product Notice: Verbose mode only applies to VSP 4900 Series.

## Run the Layer 3 Video Surveillance install script

Use the following procedure to run the Layer 3 Video Surveillance install script.

### Note

The **run vms layer-3 switch** command performs the same function as the **run vms endura switch** command. The switch supports the **run vms endura switch** command only for backward compatibility.

### Before You Begin

The switch must be in a factory default state; the switch prompts you to confirm this.

### About This Task

Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers connect. Use a switch value of 6 onwards (until and including 99) for all switches that connect IP Cameras at the network edge/access layer.

For each additional area and switch, increment the switch number by one. For example, use `switch 7` for the second edge switch. The configuration uses the number you specify to customize the IP subnet, loopback addresses, and SPB information.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run the Layer 3 Video Surveillance install script:
 

```
run vms Layer-3 switch <5-99> [syntax | verbose]
```

### Examples

The following example shows the configuration of a switch in the VMS core and shows the configuration file created by the script.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#run vms layer-3 switch 5
Do you want to execute the run vms script? Device needs to be in factory default state.
(y/n) ? y
CP1 [05/05/17 07:48:33.760:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config

successful.

**Previous configurations stored in pre_vms_install.cfg**
**New VMS configurations stored in new primary config file spb-switch-6.cfg**

*** VMS script execution complete ***
Switch:1(config)#exit
Switch:1#
```

### Variable Definitions

The following table defines parameters for the **run vms Layer-3 switch** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <5-99>         | Specifies the numeric switch value used as a common element to configure switch parameters such as name, VLAN ID, SPB, and IP parameters.<br><br><b>Note:</b><br>Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers are connected. Use a value of 6 onwards (until and including 99) for all switches used for connecting IP Cameras at the network edge/access layer. |
| <i>syntax</i>  | Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters.<br><br><b>Note:</b><br>The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch.                                                      |
| <i>verbose</i> | Specifies that the switch prompts you to accept or change the default configuration values. If you do not use this optional parameter, the script runs without user intervention.                                                                                                                                                                                                                                            |

|                                                                                                                | XA1400 Series   | VOSS 8.0.50                        |

Internet Key Exchange (IKE) protocol creates a Security Association (SA) in IPsec. The SA is the relationship between two network devices that define attributes such as authentication mechanism, encryption and hash algorithms, exchange mode, and key length for secured communications. The SA should be agreed by both devices.

The IKE protocol is based on Internet Security Association and Key Management Protocol (ISAKMP) which helps in building a secured connection between two or more hosts using the following concepts:

- authentication
- encryption
- key management
- security association (SA)
- policy

IKE uses a key exchange mechanism based on the Diffie-Hellman encryption key exchange protocol. IKE provides periodic automatic key renegotiation, pre-shared and public key infrastructures, and anti-replay defense. It is layered on top of the UDP protocol and uses UDP port 500 to exchange information between peers.

## IKE Phases

---

A switch negotiates with a peer using IKE in two phases.

- In phase 1, the switch negotiates the IKE SA to protect the negotiations that take place in phase 2. The SAs negotiated in phase 1 are bi-directional, and are applicable to traffic originating in both directions.
- In phase 2, the peers negotiate and establish the SAs for IPsec and session keys through quick mode. A Diffie-Hellman key exchange is done to achieve perfect forward secrecy, which ensures that the compromise of a single key does not permit access to data other than that protected by that compromised key. The SAs in phase 2 are uni-directional. They are used according to the direction of the traffic. The quick mode is initiated by either of the peer endpoints irrespective of who initiated phase 1.

## IKE Modes

---

There are two modes of exchanging messages in Phase 1:

- Main mode

This is a secure mode of exchanging messages. It allows protection of the confidentiality of the peers during negotiation. This mode provides more flexibility in proposals compared to aggressive mode. As the main mode requires a total of 6 messages to be exchanged between peers, it is more time consuming.

- Aggressive mode

This mode is less secure than the main mode. It does not protect the confidentiality of the peers. However, it requires only a total of 3 messages to be exchanged for phase 1, which makes this mode faster than the main mode. The number of total message exchange is reduced in this mode because some messages are embedded in other messages.

The mode of message exchange in phase 2 is called quick mode. In this mode a total of 3 messages are exchanged between the peers. This mode is used to establish IPsec

SA. The negotiations in the quick mode are protected during the phase 1 negotiations in main mode.

## IKE Policies

---

A combination of security parameters used during the IKE SA negotiation is called a policy. The policies must be configured on both the peers and at least one of the policies should match on both ends to have a successful negotiation for. If a policy is not configured on both peers or if a policy does not match on both ends, an SA cannot be setup and data cannot be exchanged.

The following are the attributes of an IKE policy:

- Encryption — This is the cryptographic algorithm that is sent in the proposal by the initiator or responder during the phase 1 negotiation. This cryptographic algorithm is used to encrypt phase 2 negotiation messages. The supported encryption algorithms are:
  - DES
  - 3DES
  - AES
- Hash function — This function is used as part of the authentication mechanism during the authentication of peers in phase 1. It is always used with the authentication algorithm. The supported values are:
  - MD5
  - SHA1
  - SHA256
- Authentication — This process authenticates the peers. Following are the supported authentication modes:
  - Digital Signatures — The digital signatures use digital certificate which is signed by the certificate authority (CA) for authentication.
  - Pre-shared keys (PSK) — The PSKs are shared out-of-band between the peers before hand. Using PSK in main mode exchange limits identifying the peer to an IP address (and not host name).
- Diffie-Hellman (DH) Group — This is an algorithm used by two peers that are unknown to each other to establish a shared secret key. This key that is decided during phase 1 is used to encrypt subsequent message exchanges during phase 2 to establish security associations (SA) and security policies (SP) for IPsec sessions. The supported DH Groups are as follows:
  - Group 1 (MODP768)
  - Group 2 (MODP1024)
  - Group 14 (MODP2048)
- Lifetime — This is a time and data limit agreed by peers to protect an SA from getting compromised. It ensures that the peers renegotiate the SAs just before the lifetime value expires, that is, when the time limit is reached.
- Dead-peer detection – This is a process in which the switch waits for a response from peer for a limited number of seconds before declaring the peer as dead. It is

a keep-alive mechanism required to perform IKE peer fail-over and to reclaim lost resources by freeing up SAs that are no longer in use.

## IKE Authentication

---

The security gateway of a peer must authenticate the security gateway of the peer it intends to communicate with. This ensures that IKE SAs are established between the peers. The switch supports the following two authentication methods:

- Digital certificates (using RSA algorithms)

For digital certificate authentication, the initiator signs the message interchange data using the private key. The responder uses the public key of the initiator to verify the signature. The public key is exchanged by messages containing an X.509v3 certificate. This certificate provides an assurance that the identity of a peer, as represented in the certificate, is associated with a particular public key.

- Pre-shared keys

Pre-shared key authentication, the same secret must be configured on both security gateways before the gateways can authenticate each other.

## Signature Authentication

---

The switch receives the digital signature of its peer in a message exchange. The switch verifies the digital signature by using the public key of the peer. The certificate of the peer, received during the IKE negotiation, contains the public key. To ensure that the peer certificate is valid, the switch verifies its digital signature by using the certificate authority (CA) public key contained in the root CA certificate. The switch and its IKE peer require at least one common trusted root CA for authentication to work.

When IKE is configured to use digital certificates for authentication, the certificates are retrieved from the trusted certificate store in the switch, based on the provided distinguished name. The certificates received from the peer are verified with the public key.

## IKEv2

---

The software supports IKEv2, which is an enhancement of the IKEv1 protocol. All IKEv2 communications consist of pairs of messages: a request and a response. The IKEv2 protocol uses a non-reliable transport protocol (UDP using ports 500). The pairs of exchanges allows ensuring of reliability to the IKEv2 protocol, as there is an expected response for each request.

IKEv2 provides a number of improvements over IKEv1, including the following:

- A simplified initial exchange of messages that reduces latency and increases connection establishment speed.
  - IKEv2 makes use of a single four-message exchange instead of the eight different initial exchanges of IKEv1.
  - It improves upon IKEv1's latency by making the initial exchange to be of two round trips of four messages, and allows the ability to add setup of a child SA on that exchange.
- Improved reliability through the use of sequence numbers, and acknowledgments.
  - IKEv2 reduces the number of possible error states by making the protocol reliable as all messages are acknowledged and sequenced.
- IKE SA integrity algorithms are supported only in IKEv2.
- Traffic Selectors are specified in IKEv2 by their own payloads type and not by overloading ID payloads. This makes the Traffic Selectors more flexible.
- No lifetime negotiations for IKEv2, but in IKEv1 SA lifetimes are negotiated.

## IKEv2 OCSP Validation

Confirmation of certificate reliability is essential to achieve the security assurances public key cryptography provides. One fundamental element of such confirmation is reference to certificate revocation status. IKEv2 enables the use of Online Certificate Status Protocol (OCSP) for in-band signaling of certificate revocation status. The IKEv2 supports the authentication methods as pre shared key and digital certificate. It allows the verification of the digital certificate sent by the peer whether it is revoked or not.

This is done through a method by sending the digital certificate to the OCSP server. The OCSP server in turn verifies the certificate status and sends the response back. Based on the response from OCSP server, the device validates the certificate.

## Using IKE for Secure AAA Server Communication

### Note

Secure AAA server communication is only supported on VSP 8600 Series, and only as a demonstration feature. Demonstration features are for lab use only and are not for use in a production environment.

The VSP 8600 Series supports IP Security (IPsec) for the AAA server communication. IPsec provides the ability to secure RADIUS and TACACS+ servers against unwanted traffic by filtering on specific network adapters, by allowing or blocking specific protocols and enabling the server to selectively allow traffic from specific source IP addresses.

An AAA server program deals with requests for access to computer resources and provides authentication, authorization, and accounting (AAA) services. The switch communicates with AAA servers using Remote Authorization Dial-in User Service (RADIUS) and Terminal Access Controller Access Control System Plus (TACACS+). It is not sufficient to protect authentication information with only RADIUS or TACACS+.

The following diagram shows the communication between AAA client and AAA server. The IPsec module on the client encrypts the packets to the AAA server and decrypts the packets from the AAA server. Similarly, the IPsec module on the server encrypts or decrypts the packets to or from the client.

To implement secure AAA server communication, the VSP 8600 Series software supports the following:

- IPsec with Internet Key Exchange (IKE) protocol for both IPv4 and IPv6.
- IPv4 implementation of IPsec is mainly for protocols involved in communication with AAA servers, that is, RADIUS and TACACS+. However, it supports all UDP and TCP protocols.
- Digital signature as authentication method for IKE, in addition to the pre-shared key authentication method.
- Automatic and manual keying for session establishment. IKE is the default automated key management protocol for IPsec.
- IKEv1 and IKEv2 protocol.

## Restrictions

---

This section describes the restrictions associated with this feature.

- AAA server protection is provided only for SSH/CLI/web/Telnet/Console Access Protection.
- FQDN (Fully Qualified Domain Names) is not supported to identify endpoints. This is because, the user configures the IP address for the AAA servers in the switch.
- XAUTH ( 2-factor authentication ) is not supported.
- Domain of Interpretation is not supported other than for IPsec.
- NAT Traversal is not supported.
- Custom IKE messages and vendor ID for the messages are not supported.
- IKE fragmentation is not supported.
- IKE and IPsec are not supported on the Segmented Management Instance interfaces, or with management applications such as RADIUS and TACACS+. You can configure RADIUS security with RADsec on supported devices.

### Note

Exception: VSP 8600 Series supports IKE on Segmented Management Instance and RADIUS with IPsec as a DEMO FEATURE.

## IKE Configuration using CLI

---

The topics in this section provide the IKE CLI configuration.

### Configure an IKE Phase 1 Profile

#### About This Task

Use the following procedure to configure an IKE Phase 1 profile.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create an IKE phase 1 profile:
 

```
ike profile WORD<1-32>
```
3. Configure the IKE phase 1 profile hash algorithm:
 

```
ike profile WORD<1-32> hash-algo <md5|sha|sha256|any>
```
4. Configure the IKE phase 1 profile encryption algorithm:
 

```
ike profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>
```
5. Configure the IKE phase 1 profile Diffie-Hellman group:
 

```
ike profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any>
```
6. Configure the IKE phase 1 encryption key length:
 

```
ike profile WORD<1-32> encrypt-key-len <128|192|256>
```
7. Configure the IKE phase 1 lifetime, in seconds:
 

```
ike profile WORD<1-32> lifetime-sec <0-4294967295>
```
8. (Optional) Delete the IKE Phase 1 profile:
 

```
no ike profile WORD<1-32>
```

### Variable Definitions

The following table defines parameters for the **ike profile** commands.

| Variable                                        | Value                                                                                                                                                                                                                                        |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>profile</i> WORD<1-32>                       | Specifies the IKE profile name.                                                                                                                                                                                                              |
| <i>hash-algo</i> <md5 sha sha256 any>           | Specifies the type of hash algorithm. The default value is sha256.                                                                                                                                                                           |
| <i>encrypt-algo</i> <desCbc 3DesCbc aesCbc any> | Specifies the type of encryption algorithm. The default value is aesCbc.                                                                                                                                                                     |
| <i>dh-group</i> <modp768 modp1024 modp2048 any> | Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048.                                   |
| <i>encrypt-key-len</i> <128 192 256>            | Specifies the length of the encryption key. The default is 256.                                                                                                                                                                              |
| <i>lifetime-sec</i> <0-4294967295>              | Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. |

## Create an IKE Phase 1 Policy

IKE policy establishes Security Associations (SA) and message exchanges with IKE peers to successfully set up secured channels.

### About This Task

Use the following procedure to create the IKE Phase 1 policy.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create an IKE Phase 1 profile:
 

```
ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
```
3. (Optional) Delete the IKE Phase 1 profile:
 

```
no ike policy WORD<1-32>
```

### Variable Definition

The following table defines parameters for the **ike policy <1-320> laddr** command.

| Variable                 | Value                                         |
|--------------------------|-----------------------------------------------|
| <i>policy</i> WORD<1-32> | Specifies the name of the IKE Phase 1 policy. |
| <i>laddr</i> WORD<1-256> | Specifies the local IPv4 or IPv6 address.     |
| <i>raddr</i> WORD<1-256> | Specifies the remote IPv4 or IPv6 address.    |

## Configuring profile to be used for IKE Phase 1 policy

Use the following procedure to configure the IKE Phase1 profile to be used for the IKE Phase 1 policy.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the profile name to be used for IKE Phase 1 policy:
 

```
ike policy WORD<1-32> profile WORD<1-32>
```

### Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> profile WORD<1-32>** command.

| Variable                              | Value                                                                                                                                                                                                           |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>policy WORD&lt;1-32&gt;</code>  | Specifies the name of the IKE Phase 1 policy.                                                                                                                                                                   |
| <code>profile WORD&lt;1-32&gt;</code> | Specifies the name of the IKE Phase 1 profile to be used for the policy. To set this option to the default value, use the default operator with the command: <b>default ike policy WORD&lt;1-32&gt; profile</b> |

## Configure IKE Phase 2 Perfect Forward Security

Use the following procedure to configure IKE Phase 2 perfect forward security (PFS).

### About This Task

A Diffie-Hellman key exchange is done to achieve perfect forward security. This ensures that the compromise of even a single key does not permit access to data other than that protected by that key.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the IKE Phase 2 perfect forward security:
 

```
ike policy WORD<1-32> p2-pfs <enable|disable> [use-ike-group <enable|
disable>] [dh-group <modp768|modp1024|modp2048|any]
```
3. (Optional) Disable Phase 2 perfect forward security:
 

```
no ike policy <1-32> p2-pfs
```

### Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> p2-pfs** command.

| Variable                             | Value                                         |
|--------------------------------------|-----------------------------------------------|
| <code>policy WORD&lt;1-32&gt;</code> | Specifies the name of the IKE Phase 1 policy. |
| <code>p2-pfs</code>                  | Enables the Phase 2 perfect forward security. |

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dh-group &lt;modp768 modp1024 modp2048 any&gt;</code> | Configures the Diffie-Hellman (DH) group to be used for Phase 2 perfect forward secrecy (PFS). The default value is modp2048. To configure this option to the default value, use the default operator with the command: <b>default ike policy WORD&lt;1-32&gt; p2-pfs dh-group</b> .<br><br><b>Note:</b><br>For Federal Information Processing Standards (FIPS) compliance, only the default value modp2048 is supported. |
| <code>use-ike-group &lt;enable disable&gt;</code>           | Specifies whether to use the IKE Phase 1 DH group for Phase 2 PFS or not to use it. The default is enable. To set this option to the default value, use the default operator with the command: <b>default ike policy WORD&lt;1-32&gt; p2-pfs use-ike-group</b>                                                                                                                                                            |

## Configure the IKE Authentication Method

Use the following procedure to configure the IKE authentication method. The default is pre-shared key.

### About This Task

As part of the IKE protocol, one security gateway must authenticate another security gateway to make sure that IKE SAs are established with the intended party. The switch supports two authentication methods:

- Digital certificates

Configure peer identity name for IKE phase 1 and revocation check method.

- Pre-shared keys

Configure the same secret on both security gateways before the gateways can authenticate each other.

### Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the IKE authentication method using one of the following:

- To use a digital certificate:

```
ike policy WORD<1-32> auth-method digital-certificate [peer-name WORD <1-64> | revocation-check-method <crl|none|ocsp>]
```

- To use a pre-shared key:

```
ike policy WORD<1-32> auth-method pre-shared-key
```

```
ike policy WORD<1-32> pre-shared-key WORD<0-32>
```

### Variable Definitions

The following table defines parameters for the **ike policy WORD<1-32> auth-method** command.

| Variable                                                                      | Value                                                                                                                                                                                         |
|-------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pre-shared-key</code>                                                   | Specifies the authentication method as pre-shared key.                                                                                                                                        |
| <code>digital-certificate peer-name WORD &lt;1-64&gt;</code>                  | Specifies peer identity name for IKE phase 1.                                                                                                                                                 |
| <code>digital-certificate revocation-check-method&lt;crl none ocsp&gt;</code> | Specifies the revocation check method. To set this option to the default value, use the default operator with the command: <b>default ike policy WORD&lt;1-32&gt; revocation-check-method</b> |

The following table defines parameters for the **ike policy WORD<1-32> pre-shared-key** command.

| Variable                                     | Value                                                                                                                              |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>pre-shared-key WORD&lt;0-32&gt;</code> | Specifies the pre-shared key. For Federal Information Processing Standards (FIPS) compliance, the minimum length is 14 characters. |

## Configure Dead-Peer Detection Timeout

Use the following procedure to configure the dead-peer detection (DPD) timeout for the IKE Phase 1 policy.

### About This Task

Dead Peer Detection (DPD) timeout is the interval for which the system sends messages to a peer to confirm its availability.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Configure the DPD timeout:
 

```
ike policy WORD<1-32> dpd-timeout <1-4294967295>
```

### Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> dpd-timeout** command.

| Variable                                      | Value                                                                                                                                                                                                                                                   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>policy WORD&lt;1-32&gt;</code>          | Specifies the name of the IKE Phase 1 policy.                                                                                                                                                                                                           |
| <code>dpd-timeout &lt;1-4294967295&gt;</code> | Specifies the dead peer detection timeout in seconds for the IKE Phase 1 policy. The default is 300 seconds. To set this option to the default value, use the default operator with the command: <b>default ike policy WORD&lt;1-32&gt; dpd-timeout</b> |

## Enable the Admin State of IKE Phase 1 Policy

Use the following procedure to enable admin state of IKE Phase 1 policy.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable admin state of IKE Phase 1 policy:  

```
ike policy WORD<1-32> enable
```
3. (Optional) Disable IKE Phase 1 policy:  

```
no ike policy WORD<1-32> enable
```

## Display IKE Profiles

Use the following procedure to display the configured IKE profiles:

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display all IKE profiles:  

```
show ike profile
```
3. Display a specific ike profile:  

```
show ike profile WORD<1-32>
```

### Example

```
Switch:1#show ike profile
```

```
=====
```

| IKE Profile      |              |                 |                    |             |                  |                     |
|------------------|--------------|-----------------|--------------------|-------------|------------------|---------------------|
| Name             | Hash<br>Algo | Encrypt<br>Algo | Encrypt<br>Key Len | DH<br>Group | Exchange<br>Mode | Lifetime<br>seconds |
| DFLT_IKE_PROFILE | sha256       | aesCbc          | 256                | modp2048    | main             | 86400               |
| ikePRO           | sha256       | aesCbc          | 256                | modp2048    | main             | 180                 |
| test             | sha256       | aesCbc          | 256                | modp2048    | main             | 86400               |

```
=====
```

### Variable Definition

The following table defines parameters for the **show ike profile** command.

| Variable                  | Value                                              |
|---------------------------|----------------------------------------------------|
| <i>profile</i> WORD<1-32> | Specifies the name of the profile to be displayed. |

## Display IKE Policies

Use the following procedure to display the configured IKE policies.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display all IKE policies:  
show ike policy
3. Display a specific IKE policy:  
show ike policy WORD<1-32>
4. Display a specific IKE policy at local address.  
show ike policy WORD<1-32> laddr WORD<1-256>
5. Display a specific IKE policy at remote address.  
show ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>

### Example

```
Switch:1#show ike policy
=====
                        IKE Policy
=====
Policy Name           Addr Type Local Address           Remote Address           Profile Name

vlpol                 300 enable up   disable enable
=====
```

### Variable Definition

The following table defines parameters for the **show ike policy** command.

| Variable                 | Value                                             |
|--------------------------|---------------------------------------------------|
| <i>policy</i> WORD<1-32> | Specifies the name of the policy to be displayed. |
| <i>laddr</i> WORD<1-256> | Specifies the local IPv4 or IPv6 address.         |
| <i>raddr</i> WORD<1-256> | Specifies the remote IPv4 or IPv6 address.        |

## Display IKE Security Association

Use the following procedure to display the configured IKE Phase 1 for version 1 and 2 security associations (SA).

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display all the security associations:  
show ike sa
3. Display security associations for IKE Phase 1 for version 1:  
show ike sa version v1 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
4. Display security associations for IKE Phase 1 for version 2:  
show ike sa version v2 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>

### Example

```
Switch:1(config)#show ike sa version v1

=====
                        IKE V1 Phase 1 Security Association
=====
Policy          Addr
Name            Type Local Address          Remote Address          Initiator/
                                     Responder
-----
ikepsk          IPv4 192.0.2.5                198.51.100.15         Initiator

| v2policy                            | 300         | sha256    | aesCbc       |                | modp2048 | 86400            | active |

### Variable Definition

The following table defines parameters for the **show ike sa** command.

| Variable                                                                                                         | Value                                                                   |
|------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| <i>sa</i>                                                                                                        | Specifies the IKE security association identifier.                      |
| <i>version v1</i><br><i>WORD&lt;1-32&gt; laddr</i><br><i>WORD&lt;1-256&gt; raddr</i><br><i>WORD&lt;1-256&gt;</i> | Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 1 SA. |
| <i>version v2</i><br><i>WORD&lt;1-32&gt; laddr</i><br><i>WORD&lt;1-256&gt; raddr</i><br><i>WORD&lt;1-256&gt;</i> | Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 2 SA. |

## Configure an IKEv2 Profile

### About This Task

Use the following procedure to configure an IKEv2 profile.

### Procedure

- Enter Global Configuration mode:  
`enable`  
`configure terminal`
- Create an IKEv2-profile:  
`ike v2-profile WORD<1-32>`
- Configure the IKEv2 profile hash algorithm:  
`ike v2-profile WORD<1-32> hash-algo <md5|sha|sha256|any>`
- Configure the IKEv2 profile encryption algorithm:  
`ike v2-profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>`
- Configure the IKEv2 profile integrity algorithm  
`ike v2-profile WORD<1-32> integrity-algo <hmac-md5|hmac-sha|hmac-sha256|aes-xcbc|any>`
- Configure the IKEv2 profile dh group  
`ike v2-profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any>`
- Configure the IKEv2 profile encryption key length:  
`ike v2-profile WORD<1-32> encrypt-key-len <128|192|256>`

8. Configure the IKEv2 profile lifetime, in seconds:

```
ike v2-profile WORD<1-32> lifetime-sec <0-4294967295>
```

9. (Optional) Delete the IKEv2 profile:

```
no ike v2-profile WORD<1-32>
```

### Variable Definition

The following table defines parameters for the **ike v2-profile** commands.

| Variable                                           | Value                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>profile</i> WORD<1-32>                          | Specifies the IKE v2-profile name.                                                                                                                                                                                                                                                                                                                                                           |
| <i>hash-algo</i> <md5 sha sha256 any>              | Specifies the type of hash algorithm. The default value is sha256. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; hash-algo</b>                                                                                                                                                                              |
| <i>encrypt-algo</i> <desCbc 3DesCbc aesCbc any>    | Specifies the type of encryption algorithm. The default value is aesCbc. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; encrypt-algo</b>                                                                                                                                                                     |
| <i>integrity-algo</i> <md5 sha-1 sha-256 aes-xcbc> | Specifies the type of integrity algorithm. The default is sha256. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; integrity-algo</b>                                                                                                                                                                          |
| <i>dh-group</i> <modp768 modp1024 modp2048 any>    | Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; dh-group</b>                                       |
| <i>encrypt-key-len</i> <128 192 256>               | Specifies the length of the encryption key. The default is 256. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; encrypt-key-len</b>                                                                                                                                                                           |
| <i>lifetime-sec</i> <0-4294967295>                 | Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. To set this option to the default value, use the default operator with the command: <b>default ike v2-profile WORD&lt;1-32&gt; lifetime-sec</b> |

## Display IKEv2 Profiles

Use the following procedure to display the configured IKEv2 profiles.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display all IKEv2 profiles:  

```
show ike v2-profile
```
3. Display a specific IKEv2 profile:  

```
show ike v2-profile WORD<1-32>
```

### Example

```
Switch:1#show ike v2-profile test
=====
                                IKE2 Profile
=====
Encrypt      Exchange      Hash      Encrypt
Name         Mode          Algo      Algo      Key
Length      Mode
-----
test        main          sha256    aesCbc
256
=====
                                IKE2 Profile
=====
Lifetime     DH      Integrity
Name         Group   Algorithm
seconds
-----
test        modp2048 sha256
180
```

### Variable Definitions

The following table defines parameters for the **show ike v-2profile** command.

| Variable                | Value                             |
|-------------------------|-----------------------------------|
| <i>WORD&lt;1-32&gt;</i> | Specifies the name of the policy. |

## Configure x509 Certificate Identity

### About This Task

Use the following procedure to bind a certificate identity to the IKE certificate store.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the certificate subject name:  

```
ike certificate-identity cert-subject-name WORD<1-45>
```

### Variable Definitions

The following table defines parameters for the **ike certificate-identity** command.

| Variable                                        | Value                                                                                                                                                          |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cert-subject-name WORD&lt;1-45&gt;</code> | Specifies the digital certificate subject name to be used as the identity certificate. If a subject name is not specified, the default subject name is Global. |

## IKE Configuration using EDM

The topics in this section provide the IKE EDM configuration.

### Configure Digital Certificate Subject Name

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IKE**.
3. Select **Globals** tab.
4. In the **CertIdentitySubjectName** field, enter the digital certificate subject name use as identity certificate.

#### **Globals** Field Definitions

Use the data in the following table to use the **Globals** tab.

| Name                           | Description                                                                        |
|--------------------------------|------------------------------------------------------------------------------------|
| <b>CertIdentitySubjectName</b> | Specifies the digital certificate subject name use as identity certificate in IKE. |

### Configure IKE Phase 1 Profile

Use the following procedure to create and configure an IKE Phase 1 profile.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

**Profile** Field Descriptions

Use the data in the following table to use the **Profile** tab.

| Name                       | Description                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                | Specifies the name of the profile.                                                                                                                                                               |
| <b>HashAlgorithm</b>       | Specifies the hash algorithms that can be used during IKE Phase 1 SA negotiation. The default value is sha256.                                                                                   |
| <b>EncryptionAlgorithm</b> | Specifies the encryption algorithms that can be used during IKE Phase 1 SA negotiation. The default value is aesCbc.                                                                             |
| <b>EncryptKeyLen</b>       | Specifies the key length that should be used during IKE Phase 1 SA negotiation. The default value is 256.                                                                                        |
| <b>DHGroup</b>             | Specifies the Diffie-Hellman groups that can be used during IKE Phase 1 SA negotiation. The default value is modp2048.                                                                           |
| <b>ExchangeMode</b>        | Specifies the IKE Phase 1 negotiation mode. The default value is main.                                                                                                                           |
| <b>LifetimeSeconds</b>     | Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid. The default value is 86400 seconds. |

## Configure IKEv2 Profile

Use the following procedure to create and configure an IKEv2 profile.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **V2 Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

**V2 Profile** *Field Descriptions*

Use the data in the following table to use the **V2 Profile** tab.

| Name                       | Description                                                                                                                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                | Specifies the IKE v2 profile name.                                                                                                                                                                                                           |
| <b>HashAlgorithm</b>       | Specifies the type of hash algorithm that can be used during IKE version 2 SA version 2 negotiation. The default value is sha256.                                                                                                            |
| <b>EncryptionAlgorithm</b> | Specifies the encryption algorithms that can be used during IKE version 2 SA version 2 negotiation. The default value is aesCbc.                                                                                                             |
| <b>EncryptKeyLen</b>       | Specifies the type of encryption algorithm. The default value is keylen-256.                                                                                                                                                                 |
| <b>DHGroup</b>             | Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048.                                   |
| <b>ExchangeMode</b>        | Specifies the IKE v2 profile negotiation mode. The default value is main.                                                                                                                                                                    |
| <b>LifetimeSeconds</b>     | Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. |
| <b>IntegrityAlgorithm</b>  | Specifies the type of integrity algorithm. The default value is sha256.                                                                                                                                                                      |

**Configure IKE Phase 1 Policy**

Use the following procedure to create and configure an IKE Phase 1 policy.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **Policy** tab.
4. Click **Insert**.
5. In the **LocalIfIndex** field, click either **Port** or **Vlan**, and then select an interface.
6. In the **LocalAddrType** field, select the type of the local address.
7. In the **LocalAddr** field, type the address of the local peer.
8. In the **RemoteAddrType** field, select the type of the remote address.
9. In the **RemoteAddr** field, type the address of the remote peer.

10. In the **Name** field, type the name for the policy.

Name must be assigned when creating the policy. Once the policy is created, the name cannot be changed.

11. Complete the remaining optional configuration to customize the policy.

12. Click **Insert**.

#### *Policy field descriptions*

Use the data in the following table to use the **Policy** tab.

| Name                        | Description                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalIfIndex</b>         | Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.                                                                                 |
| <b>LocalAddrType</b>        | Specifies whether the local address is an IPv4 or IPv6 address.                                                                                                                  |
| <b>LocalAddr</b>            | Specifies the address of the local peer.                                                                                                                                         |
| <b>RemoteAddrType</b>       | Specifies whether the remote address is an IPv4 or IPv6 address.                                                                                                                 |
| <b>RemoteAddr</b>           | Specifies the address of the remote peer.                                                                                                                                        |
| <b>Name</b>                 | Specifies the name given to the policy. The name should be assigned while creating the policy. You cannot change the name after the policy is created.                           |
| <b>ProfileName</b>          | Specifies the name of the profile that should be used for this policy.                                                                                                           |
| <b>ProfileVersion</b>       | Specifies the profile version used for the policy.                                                                                                                               |
| <b>PeerName</b>             | Specifies the peer name.                                                                                                                                                         |
| <b>AuthenticationMethod</b> | Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key.                                          |
| <b>PSKValue</b>             | Specifies the value of the Pre-Shared Key if the authentication method is set to PSK.                                                                                            |
| <b>DPDTimeout</b>           | Specifies the Dead Peer Detection timeout in seconds. Default value is 300 seconds.                                                                                              |
| <b>P2PFS</b>                | Specifies whether or not the perfect forward secrecy (PFS) is used when refreshing keys. To use PFS, select enable. The default value is disable.                                |
| <b>P2PfsUseIkeGroup</b>     | Specifies whether or not to use the same GroupId (Diffie-Hellman Group) for phase 2 as was used in phase 1. Ignore this entry if P2PFS is disabled. The default value is enable. |

| Name                         | Description                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>P2PfsDHGroup</b>          | Specifies the Diffie-Hellman group to use for phase 2 when P2PFS is enabled and P2PfsUseIkeGroup is disabled. The default value is mod1024. |
| <b>AdminState</b>            | Specifies whether the policy is administratively enabled or disabled. The default value is disable.                                         |
| <b>OperStatus</b>            | Shows is the policy is operationally up or down.                                                                                            |
| <b>RevocationCheckMethod</b> | Specifies the revocation check method as OCSP, CRL or none.                                                                                 |

## Display IKE Phase 1 Security Association

Use the following procedure to view the IKE Phase 1 security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **SA** tab.

### *IKE SA field descriptions*

Use the data in the following table to use the **IKE > SA** tab.

| Name                        | Description                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                   | Specifies the profile ID.                                                                                                               |
| <b>LocalIfIndex</b>         | Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.                                        |
| <b>LocalAddrType</b>        | Specifies whether the local address is an IPv4 or IPv6 address.                                                                         |
| <b>LocalAddr</b>            | Specifies the address of the local peer.                                                                                                |
| <b>RemoteAddrType</b>       | Specifies whether the remote address is an IPv4 or IPv6 address.                                                                        |
| <b>RemoteAddr</b>           | Specifies the address of the remote peer.                                                                                               |
| <b>Name</b>                 | Specifies the name given to the SA.                                                                                                     |
| <b>AuthenticationMethod</b> | Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key. |
| <b>DPDTimeout</b>           | Specifies the Dead Peer Detection timeout in seconds.                                                                                   |

| Name                       | Description                                                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HashAlgorithm</b>       | Specifies the hash algorithm negotiated for this IKE Phase 1 SA.                                                                                             |
| <b>EncryptionAlgorithm</b> | Specifies the encryption algorithm negotiated for this IKE Phase 1 SA.                                                                                       |
| <b>EncryptKeyLen</b>       | Specifies the encryption key length negotiated for this IKE Phase 1 SA.                                                                                      |
| <b>DHGroup</b>             | Specifies the Diffie-Hellman group negotiated for this IKE Phase 1 SA.                                                                                       |
| <b>ExchangeMode</b>        | Specifies the IKE Phase 1 SA mode.                                                                                                                           |
| <b>LifetimeSeconds</b>     | Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid. |
| <b>Status</b>              | Specifies whether the SA is active or inactive.                                                                                                              |
| <b>Initiator</b>           | Specifies whether specifies the whether the SA is created by an initiator or a responder.                                                                    |

## Display IKE V2 Security Association

Use the following procedure to view the IKE version 2 security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **V2 SA** tab.

### V2 SA field descriptions

Use the data in the following table to use the **IKE > V2 SA** tab.

| Name                  | Description                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------|
| <b>Id</b>             | Specifies the profile ID.                                                                        |
| <b>LocalIfIndex</b>   | Specifies the Interface Index of the local address. Only port and vlan interfaces are supported. |
| <b>LocalAddrType</b>  | Specifies whether the local address is an IPv4 or IPv6 address.                                  |
| <b>LocalAddr</b>      | Specifies the address of the local peer.                                                         |
| <b>RemoteAddrType</b> | Specifies whether the remote address is an IPv4 or IPv6 address.                                 |
| <b>RemoteAddr</b>     | Specifies the address of the remote peer.                                                        |
| <b>Name</b>           | Specifies the name given to the SA.                                                              |

| Name                        | Description                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthenticationMethod</b> | Specifies the proposed authentication method for theVersion 2 security association. The default authentication method is pre-shared key.                         |
| <b>DPDTimeout</b>           | Specifies the Dead Peer Detection timeout in seconds.                                                                                                            |
| <b>HashAlgorithm</b>        | Specifies the hash algorithm negotiated for this IKE Version 2 SA.                                                                                               |
| <b>EncryptionAlgorithm</b>  | Specifies the encryption algorithm negotiated for this IKE Version 2 SA.                                                                                         |
| <b>EncryptKeyLen</b>        | Specifies the encryption key length negotiated for this IKE Version 2 SA.                                                                                        |
| <b>DHGroup</b>              | Specifies the Diffie-Hellman group negotiated for this IKE Version 2 SA.                                                                                         |
| <b>ExchangeMode</b>         | Specifies the IKE Version 2 SA mode.                                                                                                                             |
| <b>LifetimeSeconds</b>      | Specifies the amount of time for which an IKE Version 2 SA can remain valid during IKE Version 2 negotiation. A value of 0 means no the SA always remains valid. |
| <b>Status</b>               | Specifies whether the SA is active or inactive.                                                                                                                  |
| <b>Initiator</b>            | Specifies whether specifies the whether the SA is created by an initiator or a responder.                                                                        |
| <b>IntegrityAlgorithm</b>   | Specifies the type of integrity algorithm.                                                                                                                       |

This section describes how to administer and configure IP Multicast Routing protocols.

The topics in this section provide conceptual background, as well as CLI and EDM configuration procedures.

## IP multicast fundamentals

---

IP multicast extends the benefits of Layer 2 multicasting on LANs to WANs. Use multicasting techniques on LANs to help clients and servers find each other. With IP multicast, a source can send information to multiple destinations in a WAN with a single transmission. IP multicast results in efficiency at the source and saves a significant amount of bandwidth.

### Enabling multicast on the switch

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, use the boot flag called **spbm-config-mode**:

- The **spbm-config-mode** boot flag is enabled by default. This configuration enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.

- If you disable the boot flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you plan to disable the boot flag, remove all SPB configurations first.
- If you plan to use the default (enabled) setting, remove all PIM configurations first.

*Simplified Virtual-IST*

Simplified Virtual-IST (vIST) is for conventional network deployments that use SMLT and not SPB. The Simplified vIST feature provides a single CLI command to enable the virtual IST for SMLT deployments.

- Simplified vIST is available **ONLY** for conventional multicast deployments with PIM and IGMP when the boot flag (**spbm-config-mode**) is disabled.
- When the boot flag is enabled (default setting), Simplified vIST is not available. This means that you continue to configure SPB/IS-IS for vIST.
- Simplified vIST requires that the two vIST devices be directly connected.

**Note**

- PIM is supported with Simplified vIST only, not SPB vIST. However, you do not have to configure Simplified vIST to run PIM or IGMP Snooping in a **non-SMLT** topology.
- Do not configure LACP on SPB NNI MLT links or on the Simplified Virtual IST.
- Do not configure ECMP in PIM Simplified vIST scenarios. Running PIM in a Simplified vIST environment with ECMP enabled may lead to incorrect behavior since there are multiple options in terms of choosing the upstream node towards a host or source. For example, since the path chosen cannot be predicted (it is determined by the downstream PIM neighbor), we may end up not adding the Virtual IST MLT port in the PIM mroute's outgoing port list on the joined interface if the PIM Join Prune Message was received on an alternative path, different from the interface the local router considers to be the correct upstream to the source.

Traffic loss can occur in such an environment. Do not enable ECMP in PIM vIST scenarios.

After you disable the **spbm-config-mode** boot flag, you can configure PIM or IGMP Snooping on any VLAN including the vIST VLAN.

To configure the boot flag and Simplified vIST, see [Configuring IP multicast in SMLT topologies](#) on page 1663 or [Configuring multicast on the switch](#) on page 1686.

### *vIST VLAN IP addresses*

Do not configure an RP or BSR on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the **ip pim enable** command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and
RP related configurations, as unicast packets to virtual IST vlan
IP address from outside of virtual IST vlan subnet will be dropped.
Use Loopback or CLIP interface IP address for BSR and RP related
configurations.
```

## Overview of IP multicast

IP multicast transmits messages to multiple recipients at the same time. This one-to-many delivery mechanism is similar to broadcasting, except that multicasting transmits to specific groups and broadcasting transmits to all receivers on a network. Because IP multicast transmits only one stream of data to the network where it replicates to many receivers, multicasting saves a considerable amount of bandwidth.

IP multicast services benefit applications such as video conferencing, dissemination of datagram information, and dissemination of mail or news to a large number of recipients.

Multicast protocols use different techniques to discover delivery paths.

A distribution tree is a set of multicast routers and subnetworks that permit the members of a group to receive traffic from a source. The source of the tree depends on the algorithm used by the multicast protocol. The following diagram is an example of a simple distribution tree where S is the multicast source and the arrows indicate the multicast broadcast procedure.

**Figure 138: Multicast distribution tree and broadcasting**

Broadcast and prune methods use multicast traffic to build the distribution tree. Periodically, the source sends or broadcasts data to the extremities of the internetwork to search for active group members. If no local members of the group exist, the router sends a message to the host, removing itself from the distribution tree, and thus pruning the router.

The following diagram illustrates how the host prunes routers from the distribution tree. First, the router sends a message to the source, after which the pruned routers do not receive multicast data.

**Figure 139: Pruning routers from a distribution tree**

Reverse path multicast is based on the concept that a multicast distribution tree is built on the shortest path from the source to each subnetwork that contains active receivers. After a datagram arrives on an interface, the router determines the reverse path to the source of the datagram by examining the routing table of known network sources. If the datagram is not on the optimal delivery tree, the router discards it.

Multicast host groups and their group members enable the IP multicast router to transmit just to those groups interested in receiving the traffic. The switch uses the Internet Group Membership Protocol (IGMP) to learn the existence of host group members on their directly attached subnets. A router communicates with the hosts on a local network by sending IGMP queries. Hosts respond by issuing IGMP reports. For more information about host groups, see [Multicast host groups](#) and [Multicast addresses](#) on page 1591. For more information about IGMP, see [Internet Group Management Protocol](#).

Multicast traffic forwarding transmits frames to all interfaces or subnets for which it receives IGMP reports for the multicast group indicated in the destination IP address. Multicast packets forwarded within the same virtual LAN (VLAN) remain unchanged. The switch does not forward packets to networks that do not use members of the multicast group indicated in the destination IP address.

#### *Multicast host groups*

IP multicast is a method for addressing, routing, and delivering a datagram to a collection of receivers called a host group.

Host groups are permanent or transient, with the following characteristics:

- A permanent host group uses a well-known, administratively assigned IP multicast group address. This address is permanent and defines the group. A permanent host group can consist of zero or more members.

- A transient host group exists only as long as members need its services. IP addresses in the multicast range that are not reserved for permanent groups are available for dynamic assignment to transient host groups.

A host system on an IP network sends a message to a multicast group by using the IP multicast address for the group. To receive a message addressed to a multicast group, however, the host must be a member of the group and must reside on a network where that group is registered with a local multicast router.

An IP multicast host group can consist of zero or more members and places no restrictions on its membership. Host members can reside anywhere, they can join and leave the group at any time, and they can be members of more than one group at the same time.

In general, hosts that are members of the same group reside on different networks. However, a range of multicast addresses (224.0.0.x) is reserved for locally-scoped groups. All message traffic for these hosts typically remains on the local network. Hosts that belong to a group in this address range and that reside in different networks do not receive message traffic for each other.

### Important

You can apply a special set of filters (global filters) to multicast packets. You can also create, deny, or accept filters to configure the sources that can receive and send data. For more information about how to configure filters, see [Traffic filtering fundamentals](#) on page 3695.

### *Multicast addresses*

Each host group uses a unique multicast address. To reach all members of the group, a sender uses the multicast address as the destination address of the datagram.

An IP version 4 multicast address is a Class D address (the high-order bits are 1110) from 224.0.0.0 to 239.255.255.255. These addresses are assigned statically for use by permanent groups and dynamically for use by transient groups.

The block of addresses from 224.0.0.1 to 224.0.0.255 is reserved for routing protocols and other low-level protocols. Multicast routers do not forward datagrams with addresses in this range because the time-to-live (TTL) value for the packet is usually 1.

### *Multicast protocols*

You can use the following protocols to enable multicast routing on a switch:

- Internet Group Management Protocol (IGMP)—learns the existence of host group members on directly attached subnets.
- Multicast Router Discovery (MRDISC) protocol—discovers multicast routers in a Layer 2 bridged domain configured for IGMP snoop.
- Protocol Independent Multicast (PIM)
  - Sparse Mode (PIM-SM) protocol—suitable for implementation on networks sparsely populated by receivers.

- Source Specific Multicast (PIM-SSM) protocol—uses a one-to-many model where members can receive traffic from one or more specific sources. This protocol is suitable for television channels and other content-distribution applications.

### *Static source groups*

Use static source groups to configure static source-group entries in the PIM-SM, or PIM-SSM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers for the group exist, the multicast stream for a static source-group entry stays active. PIM never prunes static forwarding entries. If you no longer need the entries, you must manually delete them.

To configure static source groups, you must first globally enable PIM. If you disable PIM, the switch saves all of the configured static source-group entries and deactivates them. After you re-enable PIM, the switch reactivates the static source groups.

Static source groups ensure that the multicast route (mroute) records remain in the distribution tree. After receivers join the group, they do not experience a delay in receiving multicast data because they do not need to graft onto the group, or start a join process in the case of PIM. This timing is essential for applications where the multicast data must send to a receiver as soon as the receiver joins the group, for example, when a switch delivers television channels to receivers. After the receiver turns the channel, which is equivalent to joining a group, the receiver can view the channel immediately.

Static entries result in continuous traffic if the source is active, even if no receivers exist. However, the system does not forward traffic with a static entry if no receivers exist, but forwards it continuously to the switch where the entry is programmed and crosses intermediate switches on the path.

You can configure static source-group entries for a specific source or subnet. If several sources on the same subnet send traffic to the same group, traffic for all these sources flows continuously when using the subnet configuration.

After you configure static source groups, keep the following points in mind:

- If you disable PIM, the switch deactivates all of the static source groups. After you re-enable PIM, the switch activates the static source groups.
- In PIM-SM configuration, the static source-group feature works for both specific source addresses and subnet addresses by using the SrcSubnetMask field.

When the network mask is 255.255.255.255, the full source address is used to match the (S,G) which is the specific source case. When the network mask field is a subnet mask for the source, only the source subnet is used to match (S,G)s.

- In PIM-SSM configurations, static source groups have the following limitations:
  - Subnets: SSM static source groups work only with specific IP addresses. Static source groups cannot work with source subnets, so the mask must use a full 32-bit mask, 255.255.255.255, and the source must use a host address.

### IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. These extensions, combined with the use of IGMP snooping and querier functions at the edge of the SPBM cloud, efficiently transport IP multicast data by using sub-trees of the VSN shortest path tree per IP multicast group.

## Internet Group Management Protocol

**Table 125: Internet Group Management Protocol product support**

| Feature                                                             | Product         | Release introduced |
|---------------------------------------------------------------------|-----------------|--------------------|
| Internet Group Management Protocol (IGMP), including virtualization | 5320 Series     | Fabric Engine 8.6  |
|                                                                     | 5420 Series     | VOSS 8.4           |
|                                                                     | 5520 Series     | VOSS 8.2.5         |
|                                                                     | 5720 Series     | Fabric Engine 8.7  |
|                                                                     | 7520 Series     | Fabric Engine 8.10 |
|                                                                     | 7720 Series     | Fabric Engine 8.10 |
|                                                                     | VSP 4450 Series | VSP 4000 4.0       |
|                                                                     | VSP 4900 Series | VOSS 8.1           |
|                                                                     | VSP 7200 Series | VOSS 4.2.1         |
|                                                                     | VSP 7400 Series | VOSS 8.0           |
|                                                                     | VSP 8200 Series | VSP 8200 4.0.1     |
|                                                                     | VSP 8400 Series | VOSS 4.2           |
|                                                                     | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                                                       | Not Supported   |                    |

A host uses IGMP to register group memberships with the local querier router to receive datagrams sent to this router targeted to a group with a specific IP multicast address.

A router uses IGMP to learn the existence of group members on networks to which it directly attaches. The router periodically sends a general query message to each of its local networks. A host that is a member of a multicasting group identifies itself by sending a response.

### IGMP queries

When multiple IGMP routers operate on a network, one router is elected to send queries. This elected querier periodically sends host membership queries (also known as general queries) to the attached local subnets. The switch supports queries from all three versions of IGMP.

### *IGMP host reports*

A host that receives a membership query from a local router can respond with a host membership report, one for each multicast group that joins. A host that receives a query delays its reply by a random interval and listens for a reply from other hosts in the same host group. For example, consider a network that includes two host members—host A and host B—of the same multicast group. The router sends out a host membership query on the local network. Both host A and host B receive the query and listen on the network for a host membership report. The delay timer for host B expires first, so it responds to the query with a membership report. Hearing the response, host A does not send a report of its own for the same group.

Each query from a router to a host includes a maximum response time field. IGMP inserts a value  $n$  into this field specifying the maximum time in tenths of a second within which the host must issue a reply. The host uses this value to calculate a random value between 0 and  $n$  tenths of a second for the period that it waits before sending a response. This calculation is true for IGMP versions 2 and 3. For IGMP version 1, this field is 0 but defaults to a value of 100, that is, 10 seconds.

If at least one host on the local network specifies that it is a member of a group, the router forwards to that network all datagrams that bear the multicast address for the group.

Upon initialization, the host can immediately issue a report for each of its supported multicast groups. The router accepts and processes these asynchronous reports the same as requested reports.

After hosts and routers are in a steady state, they communicate in a way that minimizes the exchange of queries and reports. The designated routers establish a path between the IP multicast stream source and the end stations and periodically query the end stations about whether to continue participation. As long as a client continues to participate, all clients, including nonparticipating end stations on the switch port, receive the IP multicast stream.

### *Host leave messages*

If an IGMPv2 host leaves a group and it is the host that issues the most recent report, it also issues a leave group message. The multicast router on the network issues a group-specific query to determine whether other group members exist on the network. If no host responds to the query, the router assumes that no members belonging to that group exist on that interface.

### *Fast leave feature*

The switch supports a fast leave feature that is useful for multicast-based television distribution applications. Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Fast leave alleviates the network from additional bandwidth demand after a customer changes television channels.

The switch provides several fast leave processes for IP multicast:

- immediate leave with one user for each interface
- immediate leave with several users for each interface
- standard IGMP leave based on a Last Member Query Interval (LMQI), which you can configure in tenths of seconds

Fast leave modifies the IGMP leave processing mechanism on an IGMP interface. After the system receives an IGMP leave message on a fast leave enabled interface, the switch does not send a group-specific query and immediately stops sending traffic to the leaving member (IGMP host) port. Without fast leave, traffic continues to forward until the group times out. This situation wastes bandwidth if no receiver that requires the group traffic exists.

Fast leave mode provides two options of the fast leave mechanism—single-user mode and multiple-users mode:

- **Single-user mode:** In this mode, the port stops receiving traffic immediately after a group member on that port sends a leave message. Use the single-user mode if each interface port connects to only one IGMP host.
- **Multiple-users mode:** Use this mode if the interface port connects to multiple IGMP hosts. In this case, the port stops receiving traffic after all members leave the IGMP group. The switch removes the leaving IGMP member and, if more group members exist on that port, the switch continues sending traffic to the port.

When operating in multiple-users mode, the switch must use the correct membership information. To support multiple-users mode, multicast receivers on the same interface cannot use IGMP report suppression. If you must use IGMP report suppression, do not use this mode. Instead, use the LMQI (configurable in units of 1/10ths of seconds) to provide a faster leave process while still sending group-specific queries after the interface receives a leave message.

Fast leave mode applies to all fast-leave enabled IGMP interfaces.

### *IGMP snoop*

The switch provides IP multicast capability and can support all three versions of IGMP to prune group membership for each port within a VLAN. This feature is IGMP snoop.

#### **Important**

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

Use the IGMP snoop feature to optimize the multicast data flow, for a group within a VLAN, to only those ports that are members of the group. The switch builds a database of group members by listening to IGMP reports from each port. The switch suppresses the reports heard by not forwarding them to ports other than the one receiving the report, thus forcing the members to continuously send their own reports. The switch relays group membership from the hosts to the multicast routers and forwards queries

from multicast routers to all port members of the VLAN. Furthermore, the switch forwards multicast data only to the participating group members and to the multicast routers within the VLAN.

The multicast routing functionality can coexist with IGMP snoop on the same switch, but you can configure only one of IGMP snoop or an IP multicast routing protocol, excluding IGMP, on the same VLAN.

#### *Multicast group trace for IGMP snoop*

Use this feature to monitor the multicast group trace for an IGMP snoop-enabled switch. You can view the multicast group trace from CLI.

Multicast group trace tracks the data flow path of the multicast streams. Group trace tracks information such as the multicast group address, the source address, ingress VLAN and port, and egress VLAN and port.

#### *IGMP proxy*

If a switch receives multiple reports for the same multicast group, it does not transmit each report to the multicast upstream router. Instead, the switch consolidates the reports into a single report and forwards the one report. If you add another multicast group or the system receives a query since it last transmitted the report upstream, the system forwards the report onto the multicast router ports. This feature is IGMP proxy.

#### *IGMP versions*

The switch supports IGMPv1, IGMPv2, and IGMPv3. IGMPv1 and IGMPv2 are backward compatible and can exist together on a multicast network. The following list describes the purpose for each version:

- IGMPv1 provides the support for IP multicast routing. IGMPv1 specifies the mechanism to communicate IP multicast group membership requests from a host to its locally attached routers. For more information, see RFC1112.
- IGMPv2 extends the features in IGMPv1 by quickly reporting group membership termination to the routing protocol. This feature is important for multicast groups with highly volatile group membership. For more information, see RFC2236.
- IGMPv3 supports the PIM Source Specific Multicast (SSM) protocol, PIM-SM, and snooping. A host can selectively request or filter traffic from individual sources within a multicast group or from specific source addresses sent to a particular multicast group. Multicast routing protocols use this information to avoid delivering multicast packets from specific sources to networks where there are no interested receivers. For more information, see RFC3376.

For the switch implementation of PIM-SSM, each group can use multiple sources.

The following list identifies group records that a report message includes:

- current-state record
- source-list-change record
- filter-mode-change record

A current-state record is sent by a system in response to a query received on an interface. It reports the current reception state of that interface, with respect to a single multicast address.

The Record Type of a current-state record has one of the following two values:

- `MODE_IS_INCLUDE` — Indicates that the interface has a filter mode of include for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.
- `MODE_IS_EXCLUDE` — Indicates that the interface has a filter mode of exclude for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.

**Source-List Change Record** — The system sends a source-list-change record after a change of source list occurs that does not coincide with a filter-mode change on the interface for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a source-list-change record can be one of the following two values:

- `ALLOW_NEW_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the additional sources that the system wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were added to the list. If the change was to an exclude source list, these are the addresses that were deleted from the list.
- `BLOCK_OLD_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the sources that the system no longer wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were deleted from the list; if the change was to an exclude source list, these are the addresses that were added to the list.

If a change of source list results in both allowing new sources and blocking old sources, then two group records are sent for the same multicast address, one of type `ALLOW_NEW_SOURCES` and one of type `BLOCK_OLD_SOURCES`.

**Filter Mode** — The switch implements the filter-mode-change record. The system sends a filter-mode-change record whenever the filter mode changes (during a change from include to exclude, or from exclude to include) for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a filter-mode-change record can be one of the following two values:

- `CHANGE_TO_INCLUDE_MODE` — Indicates that the interface has changed to include filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.
- `CHANGE_TO_EXCLUDE_MODE` — Indicates that the interface has changed to exclude filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.

After you enable IGMPv3, the following actions occur:

- After you change the version on an interface to or from IGMPv3, the switch experiences a disruption to existing multicast traffic on that interface but traffic does recover. Do not make this change when the system passes multicast traffic.

#### *IGMP states*

Multicast routers implementing IGMPv3 keep one state for each group for every port in every attached network. This group state consists of a filter-mode, a list of sources, and various timers. For each attached network running IGMP, a multicast router records the desired reception state for that network. This state consists of a set of records of the following form:

- multicast address
- group timer
- filter mode (source records)

Each source record is of the form source address or source timer. If all sources within a given group are desired, an empty source record list is kept with filter-mode set to EXCLUDE. This means hosts on this network want all sources for this group to be forwarded. This is the IGMPv3 equivalent to a IGMPv1 or IGMPv2 group join.

#### *Group timer*

A group timer represents the time for the filter-mode to expire and switch to INCLUDE mode and is used only when a group is in EXCLUDE mode.

Group timers are updated according to the types of group records received. If a group timer is expiring when a router filter-mode for the group is EXCLUDE means, there are no listeners on the attached network in EXCLUDE mode. At this point, a router will transition to INCLUDE filter-mode.

#### *Source timer*

A source timer is maintained for every source record. Source timers are updated according to:

- the type and filter-mode of the group record received
- whenever the source is present in a received record for that group.

If a source timer expires with a router filter-mode for the group of INCLUDE, the router concludes that traffic from this particular source is no longer desired on the attached network, and deletes the associated source record.

If a source record has a running timer with a router filter-mode for the group of EXCLUDE, it means that at least one system desires the source. It should therefore be forwarded by a router on the network. If a source timer expires with a router filter-mode for the group of EXCLUDE, the router informs the routing protocol that there is no receiver on the network interested in traffic from this source. The records are deleted when the group timer expires in the EXCLUDE router filter-mode.

### Processing IGMP messages for groups in SSM range

IGMP messages are processed for groups in SSM range in the following scenarios:

1. IGMPv3 interface enabled; PIM-sparse or snooping enabled
  - IGMPv3 reports that contain group records with groups within SSM range are processed with no restrictions.
  - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type IS\_EXCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
  - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type TO\_INCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
2. IGMPv3 interface enabled; PIM-SSM or ssm-snooping enabled
  - IGMPv3 reports that contain group records with groups within SSM range received from members in the EXCLUDE mode are discarded (eg. IS\_EXCLUDE and TO\_EXCLUDE messages).
  - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type ALLOW{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.
  - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type BLOCK{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.

#### Note

In order to accept v2 messages, you must enable the compatibility mode on the IGMPv3 interface.

### IGMPv3 source-specific forwarding rules

After a multicast router receives a datagram from a source destined to a particular group, the router must decide to forward the datagram to the attached network. The multicast routing protocol uses IGMPv3 information to forward datagrams to all required sources or groups on a subnetwork.

The following table describes the forwarding suggestions that IGMPv3 makes to the routing protocol. The table also identifies the action taken after the source timer expires, based on the filter mode of the group.

| Group filter-mode | Source-timer value | Action                                                                                                                                             |
|-------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| INCLUDE           | TIMER > 0          | Forward the traffic from the source.                                                                                                               |
| INCLUDE           | TIMER = 0          | Stop forwarding the traffic from the source, and remove the source record. If no more source records exist for the group, delete the group record. |
| INCLUDE           | No source elements | Do not forward the source.                                                                                                                         |

| Group filter-mode | Source-timer value | Action                                                                                                              |
|-------------------|--------------------|---------------------------------------------------------------------------------------------------------------------|
| EXCLUDE           | TIMER > 0          | Forward the traffic from the source.                                                                                |
| EXCLUDE           | TIMER = 0          | Do not forward the traffic from the source. If no more source records exist for the group, delete the group record. |
| EXCLUDE           | No source elements | Forward the traffic from the source.                                                                                |

### *IGMPv3 explicit host tracking*

IGMPv3 explicit host tracking enables the IGMP to track all the source and group members. To track all the source and group members, the sources that are in the include mode hold a list of members who want to receive traffic from that source.

The members that are in the exclude mode are on hold on the reporter list under the port data. By default, IGMPv3 explicit host tracking is disabled.

#### **Important**

If explicit host tracking is enabled, you cannot downgrade the IGMPv3 interface to IGMPv1 or IGMPv2.

### *IGMPv3 fast leave*

When a BLOCK message is received for a source, you must check if the member that sent this message is the last reporter for the source. If it is the last reporter, delete the source. Else, delete the member. No group and source specific queries are sent.

When a LEAVE message is received, you must check if the member that sent this message is the last reporter for the group. If it is the last reporter, switch to INCLUDE mode if sources are available (if no sources are available the port is deleted). Else, delete the member. No group and source specific queries or group specific queries are sent.

#### **Important**

To use the IGMPv3 fast leave feature, you must first enable the explicit host tracking feature.

### *Synchronization of IGMPv3 over SMLT*

The implementation of IGMPv3 offers support for IGMPv3 over SMLT. The Virtual-IST (vIST) peers must be in sync with the IGMPv3 reports received over SMLT links to ensure effective performance. The vIST protocol ensures the infrastructure to send such information from one vIST peer to the other.

The synchronization of IGMPv3 members and their advertised sources is different from IGMPv1 and IGMPv2. Because of IGMPv3 compatibility mode, you must consider the IGMP member version. If you have version 1 or 2 members, you must synchronize the IGMP information as IGMPv1 or IGMPv2 reports, so the peer can build an accurate database. In particular, if members with version 1 or 2 exist, the group filter mode is exclude and the exclude source list is empty. Also no v1 or v2 member will be present on any source from include list.

Each member sends IGMP reports in the same manner for all IGMP versions. The sending mechanism depends on the SMLT state.

After a vIST peer receives an IGMPv3 report over an SMLT link, it must pass the message to its peer. If the SMLT state is up, the vIST peer sends the message encapsulated in an vIST IGMPv3 message. If the SMLT state is down, the vIST peer sends the message as a plain IGMPv3 report.

In both cases the IGMPv3 message is not altered and the receiving vIST peer processes it as expected in SMLT conditions (translating the receiving port to SMLT port if applicable).

**Note**

If you enable compatibility mode and the member sends an IGMPv1 or IGMPv2 report, the message is either a vIST IGMPv1 or v2 encapsulated Message or a plain IGMPv1 or IGMPv2 report.

After SMLT up or down events occur, the vIST peer must synchronize its IGMPv3 database to its peer, taking into account the new state of the SMLT link.

If you enable IGMP explicit host tracking, each include source stores information for each member that advertises that particular source in an include list. This information is synchronized with the vIST peer.

If you do not enable explicit host tracking, each source from include list contains only information related to the last member that sent an IGMPv3 report. Only this information is synchronized with the vIST peer.

*Backward compatibility*

IGMPv3 for PIM-SSM is backward compatible with IGMPv2. You can configure the switch to operate in v3-only mode or in v2-v3 compatibility mode. If you configure the switch to use v3-only mode, it ignores all v2 and v1 messages except the query message.

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv1, v2, and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message; if it is a v2 message, PIM-SM or IGMP snoop processes handle the message.

After the switch receives an IGMPv2 leave message and the group address in it is within SSM range, the switch sends the group-and-source specific query. If the group address is not within the SSM range, the switch sends the group specific query.

According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2 hears an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure if the switch dynamically downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

In v2-v3 compatibility mode, an IGMPv2 host can only join if you configure a static entry in SSM map and if the interface operates in PIM-SSM mode or IGMP SSM-Snoop mode.

You can use the compatibility mode with Split MultiLink Trunking (SMLT). One core switch sends an SMLT message to the other core switch after it receives an IGMPv3 message. This action synchronizes the IGMP host information.

#### *Implementation of IGMP*

You can enable and disable multicast routing on an interface basis. If you disable multicast routing on an interface, the interface does not generate IGMP queries. If the switch or interface is in IGMP router behavior mode, for example, PIM enabled, you cannot configure IGMP snoop. The switch still learns the group membership and snoops multicast receivers on the switch VLAN or ports.

## IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

#### *Overview*

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

#### *IGMP Snooping*

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

- Generate the Layer 2 MAC forwarding tables used for further switching sessions
- Regulate the multicast traffic to prevent it from flooding the Layer 2 segment of the network

#### *IGMP Layer 2 Querier and IGMP interaction*

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

#### **Note**

Group Specific When Leave does not apply to IGMPv1.

#### *IGMP Layer 2 Querier limitations*

The following limitations apply to IGMP Layer 2 Querier.

- IGMP Layer 2 Querier is based on IGMP Snoop. If you disable IGMP Snoop, IGMP Layer 2 Querier does not work until you enable IGMP Snoop and IGMP Layer 2 Querier.
- After you enable IGMP Snoop and IGMP Layer 2 Querier on an interface, if the system receives no IGMP query messages, it becomes the querier.

#### **IGMP Layer 2 Querier limitations and DvR**

The following limitations apply when you configure IGMP Layer 2 Querier on DvR enabled nodes.

- You can configure IGMP Layer 2 Querier only on the DvR Controllers in a DvR domain. When you configure the following parameters on the Controllers, the configuration is automatically pushed to the DvR Leaf nodes within the domain.
  - IGMP version
  - IGMP query interval
  - IGMP query maximum response time
  - IGMP robustness value
  - IGMP last member query interval
  - IGMP compatibility mode
- You cannot configure IGMP snooping on DvR enabled Layer 2 VSNs.

For more information on DvR, see [Distributed Virtual Routing Fundamentals](#) on page 743.

## Multicast access control

Multicast access control is a set of features that operate with standard existing multicast protocols. You can configure multicast access control for an IP multicast-enabled port or VLAN with an access control policy that consists of several IP multicast groups.

You can use this feature to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams). For example, in a television distribution application, instead of applying a filter to each channel (multicast group), you can apply a multicast access policy to a range of channels (groups), thereby reducing the total number of filters and providing a more efficient and scalable configuration. Also, if you want to add or remove television channels from a package, you can modify the multicast access policy; you do not need to change filters for individual VLANs or ports. Multicast access policies contain an ID and a name (for example, PremiumChannels), the list of IP multicast addresses, and the subnet mask.

Multicast access control is not a regular filtering configuration. Multicast access control is for multicast streams and relies on handling multicast control and initial data to prevent hosts from sending or receiving specified multicast streams; it does not use filters. Also, multicast access control provides a list of multicast groups in one configuration using the same routing policy prefix list configuration. For information about prefix lists, see [Configuring prefix lists](#) on page 3174. You can configure multicast access control and change it dynamically to support changes in the configuration without restarting the protocol. You can change the access capabilities of a user or service subscriber without loss of service.

The following paragraph describes a typical application.

The local cable television company offers three packages; each one includes 35 channels (35 multicast groups). The company configures each package in an access control policy. This policy applies to a set of VLANs or ports to prevent users from viewing the channels on those VLANs. Use the same policy to prevent users from sending traffic to those groups (also known as spoofing) by specifying the deny-tx option for that port. After you define the packages, you can use them for access policy configuration. You can easily change the package by changing the group range, without changing all the port configurations.

The multicast access control functionality applies to an IP multicast application where you must control user access. You can use it in financial-type applications and other enterprise applications, such as multicast-based video conferencing.

Six types of multicast access control policies exist:

- deny-tx
- deny-rx
- deny-both

- allow-only-tx
- allow-only-rx
- allow-only-both

The tx policies control the sender and ingress interface for a group; the rx policies control the receivers and egress interface for a group.

#### *deny-tx*

Use the deny-tx access policy to prevent a matching source from sending multicast traffic to the matching group on the interface where you configure the deny-tx access policy. Configure this policy on the ingress interface to the multicast source. The deny-tx access policy performs the opposite function of the allow-only-tx access policy. Therefore, the deny-tx access policy and the allow-only-tx access policy cannot exist on the same interface at the same time.

For example, in [Figure 140](#), a VLAN 1, the ingress VLAN, uses a deny-tx access policy. This policy prevents multicast traffic sent by Sender from forwarding from VLAN 1 to a receiver, consequently preventing Receiver 1 and Receiver 2 from receiving data from the multicast group. You can create receive-only VLANs, such as VLAN 1, with the deny-tx policy.

**Figure 140: Data flow using deny-tx policy**

#### *deny-rx*

Use the deny-rx access policy to prevent a matching group from receiving IGMP reports from the matching receiver on the interface where you configure the deny-rx access policy. The deny-rx access policy performs the opposite function of the allow-only-rx access policy. Therefore, the deny-rx access policy and the allow-only-rx access policy cannot exist on the same interface at the same time.

For example, in [Figure 141](#), a VLAN 2 uses a deny-rx access policy, preventing IGMP reports sent by Receiver 1 from receiving on VLAN 2. You can deny a multicast group access to a specific VLAN or receiver using the deny-rx policy.

**Figure 141: Data flow using deny-rx policy**

*deny-both*

Use the deny-both access policy to prevent a matching IP address from both sending multicast traffic to, and receiving IGMP reports from, a matching receiver on an interface where you configure the deny-both policy. You can use this policy to eliminate all multicast activity for a receiver or source in a specific multicast group. The deny-both access policy performs the opposite function of the allow-only-both access policy. Therefore, the deny-both access policy and the allow-only-both access policy cannot exist on the same interface at the same time.

For example, in [Figure 142](#), a VLAN 2 uses a deny-both access policy, preventing VLAN 2 from receiving IGMP reports sent by Receiver 2, and preventing multicast traffic sent by Sender 2 from forwarding from VLAN 2. You can prevent certain VLANs from participating in an activity involving the specified multicast groups with the deny-both policy.

**Figure 142: Data flow using deny-both policy**

*allow-only-tx*

Use the allow-only-tx policy to allow only the matching source to send multicast traffic to the matching group on the interface where you configure the allow-only-tx policy. The interface discards all other multicast data it receives. The allow-only-tx access policy performs the opposite function of the deny-tx access policy. Therefore, the allow-only-tx access policy and the deny-tx access policy cannot exist on the same interface at the same time.

*allow-only-rx*

Use the allow-only-rx policy to allow only the matching group to receive IGMP reports from the matching receiver on the interface where you configure the allow-only-rx access policy. The interface discards all other multicast data it receives. The allow-only-rx access policy performs the opposite function of the deny-rx access policy. Therefore,

the allow-only-rx access policy and the deny-rx access policy cannot exist on the same interface at the same time.

#### *allow-only-both*

Use the allow-only-both policy to allow only the matching IP address to both send multicast traffic to, and receive IGMP reports from, the matching receiver on the interface where you configure the allow-only-both access policy. The interface discards all other multicast data and IGMP reports. The allow-only-both access policy performs the opposite function of the deny-both access policy. Therefore, the allow-only-both access policy and the deny-both access policy cannot exist on the same interface at the same time.

#### *Host addresses and masks*

When you configure multicast access policies, you must specify the host (IP) address and host (subnet) mask of the host to filter (the host that sends multicast traffic).

You can use the host subnet mask to restrict access to a portion of the host network. For example, if you configure the host subnet mask as 255.255.255.255, you use the full host address. To restrict access to a portion of the network of a host, use a subnet mask such as 255.255.255.0. Access control applies to the specified subnet only.

## Multicast stream limitation feature

You can configure the multicast stream limitation feature to limit the number of multicast groups that can join a VLAN. By limiting the number of concurrent multicast streams, a service provider can, for example, protect the bandwidth on a specific interface and control access to multicast streams.

Use multicast stream limitation in an environment where you want to limit users to a certain number of multicast streams simultaneously. For example, a television service provider can limit the number of television channels a user can watch at a time. (To a television service provider, a multicast stream is synonymous with a television channel.) If a user purchases a service contract for two single-tuner television receivers, they can use two channels flowing at the same time, but not a third. The service provider can control the bandwidth usage in addition to preventing users from watching more than the allowed number of channels at a point in time.

You can enable the multicast stream limitation feature on the switch by using one of the following methods:

- for each interface—This limitation controls the total number of streams for all clients on this router port.
- for each VLAN—This limitation controls the total number of streams for all clients on this VLAN. This method is equivalent to the interface stream limitation.
- for each VLAN port—This limitation controls the number of streams for all clients on this VLAN port. This method is equivalent to the interface port stream limitation.

You can configure the maximum number of streams for each limit independently. After the number of streams meets the limit, the interface drops additional join reports for

new streams. The maximum number of streams for each limit is 65535 and the default is 4.

## Multicast Router Discovery protocol

The Multicast Router Discovery (MRDISC) protocol can automatically discover multicast-capable routers. By listening to multicast router discovery messages, Layer 2 devices can determine where to send multicast source data and IGMP host membership reports. This feature is useful in a Layer 2 bridging domain that you configure for IGMP snoop.

IGMP multicast router discovery consists of three message types that discover multicast routers on the network:

- Multicast router advertisements: routers advertise that IP multicast forwarding is enabled on an interface.
- Multicast router solicitations: routers solicit a response of multicast router advertisements from all multicast routers on a subnet.
- Multicast router termination messages: a router terminates its multicast routing functions.

Multicast routers send multicast router advertisements periodically on all interfaces where you enable multicast forwarding. Multicast routers also send advertisements in response to multicast router solicitations.

Multicast router solicitations transmit to the IGMP-MRDISC all-routers multicast group that uses a multicast address of 224.0.0.2. Multicast router solicitations do not transmit if a router needs to discover multicast routers on a directly attached subnet.

Multicast router termination messages transmit after a router terminates its multicast routing functions. Other non-IP forwarding devices, such as Layer 2 switches, can send multicast router solicitations to solicit multicast router advertisements.

To function MRDISC on IGMP snoop interface, you must explicitly enable MRDISC. The Solicitation messages are sent only if IGMP snoop and MRDISC are enabled on the switch.

## Multicast flow distribution over MLT

MultiLink Trunking (MLT) is a mechanism to distribute multicast streams over a multilink trunk and achieve an even distribution of the streams. The distribution is based on source-subnet and group addresses. In applications like television distribution, multicast traffic distribution is particularly important because the bandwidth requirements are substantial when you use a large number of television streams.

The switch enables this feature by default and you can not change the configuration.

### *Traffic distribution*

Traffic distribution distributes the streams on the multilink trunk links if an MLT configuration change occurs. For example, you can add or delete ports.

This feature distributes active streams according to the distribution algorithm on the multilink trunk links. This distribution can cause minor traffic interruptions. To minimize the effect of distribution of multicast traffic on the multilink trunks, the implementation does not move the streams to the appropriate links at the same time. Instead, it distributes a few streams at every time tick of the system.

To that end, after a multilink trunk port becomes inactive, this feature distributes all the streams on the multilink trunk ports based on the assignment provided by the distribution algorithm.

By default, distribution is enabled and you can not change the configuration.

For more information about MLT, see [MultiLink Trunking](#) on page 2575 .

## Multicast virtualization

Multicast provides simplified extension of internal video and data delivery to remote locations.

Virtualized multicast enables multiple VPN routing instances on devices and supports various unicast routing protocols so that you can provide the services of many virtual routers from one physical device.

You can configure multicast routing support with the Virtual Routing and Forwarding (VRF) Lite feature and you can use VRF Lite to emulate many virtual routers with one router.

Multicast virtualization support includes:

- IGMP snooping
- IGMP in Layer 2 virtual services networks (VSN)
- IGMP in Layer 3 VSNs

To implement multicast virtualization, you must perform the following tasks:

1. Create a VRF. For more information about how to create and configure a VRF, see [Create a VRF Instance](#) on page 4186.
2. Create a VLAN and associate it with the VRF.
3. Enable one of the following: IGMP snooping on the VLAN, Layer 2 VSN, or Layer 3 VSN.

If you use IGMP snooping on the VLAN, ensure the IGMP version on the multicast hosts or other network devices is either the same as the version on the VLAN, or enable compatibility mode.

Multicast virtualization does not support PIM. The switch supports IGMP with PIM only in the Global Router.

*VRF Lite background*

VRF Lite provides independent IPv4 forwarding instances and independent routing instances (contexts), which can reside on the same or different VLANs and ports.

While forwarding and routing instances are mapped to IP interfaces, incoming traffic is classified into a VLAN and IP interface and, depending on the IP interface, routed context traffic is forwarded.

## Protocol Independent Multicast-Sparse Mode

**Table 126: Protocol Independent Multicast - Sparse Mode product support**

| Feature                                                      | Product         | Release introduced |
|--------------------------------------------------------------|-----------------|--------------------|
| Protocol Independent Multicast-Sparse Mode (PIM-SM) for IPv4 | 5320 Series     | Fabric Engine 8.6  |
|                                                              | 5420 Series     | VOSS 8.4           |
|                                                              | 5520 Series     | VOSS 8.2.5         |
|                                                              | 5720 Series     | Fabric Engine 8.7  |
|                                                              | 7520 Series     | Fabric Engine 8.10 |
|                                                              | 7720 Series     | Fabric Engine 8.10 |
|                                                              | VSP 4450 Series | VOSS 4.1           |
|                                                              | VSP 4900 Series | VOSS 8.1           |
|                                                              | VSP 7200 Series | VOSS 4.2.1         |
|                                                              | VSP 7400 Series | VOSS 8.0           |
|                                                              | VSP 8200 Series | VOSS 4.0.1         |
|                                                              | VSP 8400 Series | VOSS 4.2           |
|                                                              | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                                                | Not Supported   |                    |

**Table 126: Protocol Independent Multicast - Sparse Mode product support (continued)**

| Feature                                  | Product         | Release introduced |
|------------------------------------------|-----------------|--------------------|
| PIM Infinite Threshold for IPv4 and IPv6 | 5320 Series     | Fabric Engine 8.6  |
|                                          | 5420 Series     | VOSS 8.5           |
|                                          | 5520 Series     | VOSS 8.5           |
|                                          | 5720 Series     | Fabric Engine 8.7  |
|                                          | 7520 Series     | Fabric Engine 8.10 |
|                                          | 7720 Series     | Fabric Engine 8.10 |
|                                          | VSP 4450 Series | VOSS 8.5           |
|                                          | VSP 4900 Series | VOSS 8.5           |
|                                          | VSP 7200 Series | VOSS 8.5           |
|                                          | VSP 7400 Series | VOSS 8.5           |
|                                          | VSP 8200 Series | VOSS 8.5           |
|                                          | VSP 8400 Series | VOSS 8.5           |
|                                          | VSP 8600 Series | Not Supported      |
|                                          | XA1400 Series   | Not Supported      |

**Note**

PIM is supported in Global Routing Table (GRT) only.

PIM-SM, as defined in RFC2362, supports multicast groups spread out across large areas of a company or the Internet. PIM-SM sends multicast traffic only to routers that specifically join a multicast group. This technique reduces traffic flow over WAN links and overhead costs for processing unwanted multicast packets.

Dense-mode protocols use a flood-and-prune technique, which is efficient with densely-populated receivers. However, for sparsely populated networks, PIM-SM is more efficient because it sends multicast traffic only to those routers that belong to a specific multicast group and that choose to receive the traffic.

PIM-SM is independent of a specific unicast routing protocol, but it does require the presence of a unicast routing protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). PIM-SM uses the information from the unicast routing table to create and maintain multicast trees that enable PIM-enabled routers to communicate.

Typically, a PIM-SM network consists of several multipoint data streams, each targeted to a small number of LANs in the internetwork. For example, customers whose

networks consist of multiple hosts on different LANs can use PIM-SM to simultaneously access a video data stream, such as video conferencing, on a different subnet.

**Important**

In some cases, PIM stream initialization can take several seconds.

*Hosts*

A host is a source, a receiver, or both:

- A source, also known as a sender, sends multicast data to a multicast group.
- A receiver receives multicast data from one or several sources that sends data to a multicast group.

*PIM-SM domain*

PIM-SM operates in a domain of contiguous routers on which PIM-SM is enabled.

Each PIM-SM domain requires the following routers:

- designated router (DR)
- rendezvous point (RP) router
- bootstrap router (BSR)

Although a PIM-SM domain can use only one active RP router and one active BSR, you can configure additional routers as a candidate RP (C-RP) router and as a candidate BSR (C-BSR). Candidate routers provide backup protection in case the primary RP router or BSR fails.

As a redundancy option, you can configure several RPs for the same group in a PIM domain. As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

*Designated router*

The designated router (DR), the router with the highest IP address on a LAN, performs the following tasks:

- sends register messages to the RP router on behalf of directly connected sources
- sends join and prune messages to the RP router on behalf of directly connected receivers
- maintains information about the status of the active RP router for local sources in each multicast group

**Important**

The DR is not a required configuration. Switches act automatically as the DR for directly attached sources and receivers.

*Rendezvous point router*

PIM-SM builds a shared multicast distribution tree within each domain, and the RP router is at the root of this shared tree. Although you can physically locate the RP

anywhere on the network, it must be as close to the source as possible. Only one active RP router exists for a multicast group.

At the RP router, receivers meet new sources. Sources use the RP to identify themselves to other routers on the network; receivers use the RP to learn about new sources.

The RP performs the following tasks:

- registers a source that wants to announce itself and send data to group members
- joins a receiver that wants to receive data for the group
- forwards data to group

#### **Candidate rendezvous point router**

You can configure a set of routers as C-RP routers that serve as backup to the RP router. If an RP fails, all the routers in the domain apply the same algorithm to elect a new RP from the group of C-RP routers. To make sure that the routers use a complete list of C-RP routers, the C-RP router periodically sends unicast advertisement messages to the BSR. The most common implementation is to configure a PIM-SM router as both a C-RP router and a C-BSR.

The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

#### **Static rendezvous point router**

You can configure a static entry for an RP router with static RP. This feature avoids the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. Static RP-enabled switches cannot learn about RPs through the BSR because the switch loses all dynamically learned BSR information and ignores BSR messages. After you configure static RP entries, the switch adds them to the RP set as if they were learned through the BSR.

#### **Important**

In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.

When you configure a PIM static RP in a switch, the next hop of the unicast route toward the PIM static RP must be a PIM neighbor. The PIM protocol fails to work, due to a route change, if the next hop toward an already configured static RP becomes a non-PIM neighbor. If a PIM neighbor cannot reach the configured RP, the RP does not activate and its state remains invalid.

A static RP-enabled switch can communicate with switches from other vendors that do not use the BSR mechanism. Some vendors use either early implementations of PIM-SM v1 that do not support the BSR or proprietary mechanisms like the Cisco Auto-RP. For a network to work properly with static RP, you must map all the switches in the network (including switches from other vendors) to the same RP or RPs, if several RPs exist in the network.

To avoid a single point of failure, you can also configure redundant static RPs.

Use the static RP feature when you do not need dynamic learning mode, typically in small networks, or for security reasons, where RPs are forced to devices in the network so that they do not learn other RPs.

### Static RP configuration considerations

Before you can configure a static RP, you must enable PIM-SM and enable static RP.

After you meet these prerequisites, keep in mind the following configuration considerations:

- You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.
- All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.
- Static RPs do not age, that is, they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP.
- In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interfaces configured as an RP.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, you must ensure that all switches and routers use the same active RP because other vendors can use different algorithms to elect the active RP. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.

#### Important

To reduce convergence times, create only one static RP for each group. The more static RPs you configure for redundancy, the more time PIM requires to rebuild the mroute table and associate RPs.

- Static RP configured on the switch is active as long as the switch uses a unicast route to the static RP network. If the switch loses this route, the static RP is invalidated and the hash algorithm remaps all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm remaps the affected groups.

### *Bootstrap router*

The BSR receives RP router advertisement messages from the candidate RPs. The BSR adds the RP router with its group prefix to the RP set. Only one BSR exists for each PIM-SM domain.

The BSR periodically sends bootstrap messages containing the complete RP set to all routers in the domain. The BSR ensures that all PIM-SM routers send join, prune, and register packets.

Within a PIM-SM domain, you can configure a small set of routers as C-BSRs. The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

**Important**

Configure C-BSRs on routers that are central to all candidate RPs.

*Shared trees and shortest-path trees*

A PIM-SM domain uses shared trees and shortest-path trees to deliver data packets to group members. This section describes both trees.

**Shared trees**

Group members in a PIM-SM domain receive the first packet of data from sources across a shared tree. A shared tree consists of a set of paths that connect all members of a multicast group to the RP. PIM creates a shared tree when sources and receivers send messages toward the RP.

**Shortest-path trees**

After receiving a certain number of packets from the RP, the DR changes from a shared tree to an SPT. Switching to an SPT creates a direct route between the receiver and the source. The switch changes to the SPT after it receives the first packet from the RP.

[Figure 143](#) shows a shared tree and an SPT.

**Figure 143: Shared tree and shortest-path tree**

#### *Receiver Joining a Group*

The following steps describe how a receiver joins a multicast group:

1. A receiver multicasts an IGMP host membership message to the group that it wants to join.
2. After the last-hop router (the DR), normally the PIM router with the highest IP address for that VLAN, receives the IGMP message for a new group join, the router looks up the associated elected RP with responsibility for the group.
3. After it determines the RP router for the group, the last-hop router creates a (\*,G) route entry in the multicast forwarding table and sends a (\*,G) join message to the RP. After the last-hop router receives data packets from the RP, if the multicast packet arrival rate exceeds the DR threshold, the last-hop router switches to the SPT by sending an (S,G) join message to the source. (S denotes the source unicast IP address, and G denotes the multicast group address.)
4. If the last-hop router switches to the SPT, the following actions occur:
  - All intermediate PIM routers along the path to the source create the (S,G) entry.
  - To trim the shared tree, the router sends an (S,G) prune message to the RP.

You can enable the PIM Infinite Threshold Policy feature to prevent the SPT switchover. Multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of switching over to SPT.

**Note**

PIM Infinite Threshold Policy for IPv4 and IPv6 is not supported on VSP 8600 Series or XA1400 Series.

*Receiver leaving a group*

Before it leaves a multicast group, a receiver sends an IGMP leave message to the DR. If all directly connected members of a multicast group leave or time out, and no downstream members remain, the DR sends a prune message upstream and PIM-SM deletes the route entry after that entry times out.

When the system ages PIM mroutes, it does not clear the (S,G) entry for an inactive route immediately after the expiration period. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.

*Source sending packets to a group*

The following steps describe how a source sends multicast packets to a group:

1. A source directly attached to a VLAN bridges the multicast data to the DR. The DR for the VLAN (the router with the highest IP address) encapsulates each packet in a register message and sends a unicast message directly to the RP router to distribute to the multicast group.
2. If a downstream group member chooses to receive multicast traffic, the RP router sends a join or prune message toward the source DR and forwards the data down the RP tree after it obtains the data natively.
3. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.
4. If no downstream members want to receive multicast traffic, the RP router sends a register-stop message (for the source) to the DR.

The DR starts the register suppression timer after it receives the first register-stop message. During the register suppression timeout period (the default is 60 seconds), the following events occur:

- The DR for the source sends a probe packet to the RP router before the register suppression timer expires. The probe packet prompts the RP router to determine whether new downstream receivers joined the group.
- If no new receivers joined the group, the RP router sends another register-stop message to the DR for the source, and its register suppression timer restarts.
- After the RP router no longer responds with a register-stop message to the source DR probe message, the register suppression timer expires and the DR sends encapsulated multicast packets to the RP router. The RP router uses this method to tell the DR that new members joined the group.

The RP sends a register-stop message to the DR immediately after it receives the first multicast data packet.

*Required elements for PIM-SM operation*

For PIM-SM to operate, the following elements must exist in the PIM-SM domain:

- You must enable an underlying unicast routing protocol for the switch to provide routing table information to PIM-SM.
- You must configure an active BSR to send bootstrap messages to all PIM-v2 configured switches and routers to enable them to learn group-to-RP mapping. If you configure several BSRs in a network, an active BSR is elected based on priority and IP address (if priority is equal, the BSR with the higher IP address is elected).
- You must include an RP to perform the following tasks:
  - manage one or several IP multicast groups
  - become the root for the shared tree to these groups
  - accept join messages from receiver switches for groups that it manages
  - elect an active RP based on priority and IP address (if priority is equal, the RP with the higher IP address is elected)

*PIM-SM simplified example*

Figure 144 shows a simplified example of a PIM-SM configuration.

**Figure 144: PIM-SM simplified example**

In the sample configuration, the following events occur:

1. The BSR distributes RP information to all switches in the network.
2. R sends an IGMP membership report to S4.
3. Acting on this report, S4 sends a (\*,G) join message to RP.
4. S sends data to G.

5. The DR (S1 in this example) encapsulates the data that it unicasts to RP (S2) in register messages.
6. S2 decapsulates the data, which it forwards to S4.
7. S4 forwards the data to R.
8. If the packet rate exceeds the DR threshold, S4 sends S1 an (S,G) join message.
9. S1 forwards data to S4. After S4 receives data from S1, it prunes the stream from the RP.

**Important**

[Figure 144](#) on page 1618 is a simplified example and is not the best design for a network if you locate the source and receiver as shown. In general, place RPs as close as possible to sources.

### *PIM-SM Static Source Groups*

You can configure static source groups as static source-group entries in the PIM-SM multicast routing table. PIM-SM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1592.

## Join and prune messages

The DR sends join and prune messages from a receiver toward an RP for the group to either join the shared tree or remove (prune) a branch from it. A single message contains both a join and a prune list. This list includes a set of source addresses that indicate the shortest-path trees or the shared trees that the host wants to join. The DR sends join and prune messages hop-by-hop to each PIM router on the path to the source or the RP.

## Register and register-stop messages

The DR sends register messages to the RP for a directly connected source. The register message informs the RP of a new source, causing the RP to send join or prune messages back toward the DR of the source, which forwards the data down the RP tree after it obtains the data natively. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.

The DR stops sending encapsulated packets to the RP after it receives a register-stop message. This traffic stops without delay because the RP sends a register-stop message immediately after it receives the first multicast data packet, and joins the shortest-path tree.

## PIM-SMLT

IP multicast routing support with Split MultiLink Trunking (SMLT) builds a virtual switch that represents the two switches of the split multilink trunk core.

When switches use PIM in the core, they need to exchange protocol-related updates as part of the interswitch trunking (IST) protocol. IST hides the fact that the edge switch attaches to two physical switches.

PIM-SMLT can work in triangular, square, and full mesh configurations with Layer 3 IP multicast. However, PIM-SSM in square or full mesh SMLT topologies is not supported.

The following rules apply:

- If a VLAN receives traffic from the IST link, it cannot forward on the split multilink trunk link or the edge for the same VLAN.
- If one side of the SMLT link toward the receiver is down, such that the traffic cannot be forwarded directly down the SMLT link from the router on which traffic is ingressing, the IST Peer MUST forward that traffic it receives over the IST link down its side of the SMLT toward the receiver. The decision of whether the IST Peer needs to forward traffic received over the IST to SMLT receivers is made in the datapath, which has full knowledge of the remote SMLT link state.
- Traffic can use the IST to route between VLANs if the forwarding decision for the multicast protocol requires that the other side of the core forwards the multicast traffic (follow the IP multicast routing and forwarding rules for routed traffic). Other VLANs that are not part of SMLT continue to behave in the same way.
- To create a temporary default route pointing to a peer IST, you must enable PIM on the IST VLAN.
- In a scaled multicast environment, if you must reconfigure the members of an MLT link, either SMLT or IST, by removing the ports from the MLT membership list, you must first shutdown the port by using the **shutdown** command at the port configuration level. Let the unicast and multicast traffic subside, and then remove the port from the MLT membership list. If you reconfigure the MLT without first shutting down the port, it can lead to excessive hardware updates to multicast forwarding records and can result in high utilization of the CPU.

#### Note

In a scaled PIM over Simplified vIST deployment, disabling all the PIM interfaces (**no ip routing**) causes the VLACP ports to bounce. With no user intervention, the packets start getting processed again in approximately 10 seconds. VLACP enables the ports and full functionality is restored.

SMLT provides for fast failover in all cases, but does not provide a functionality similar to Routed SMLT (RSMLT).

#### Important

You must enable square SMLT globally before you configure square or full-mesh configurations.

#### *Traffic delay with PIM while restarting peer SMLT switches*

If you restart peer SMLT switches, you can lose, or experience a delay in, PIM traffic. The local and remote SMLT links must be up to forward traffic. If a remote SMLT link is down, you can experience a traffic delay.

PIM uses a DR to forward data to receivers on a VLAN. If you restart the DR in an SMLT VLAN, you can lose data because of the following actions:

- If the DR is down, the non-DR switch assumes the role and starts forwarding data.
- After the DR comes back up, it takes priority (higher IP address) to forward data so the non-DR switch stops forwarding data.
- The DR is not ready to forward traffic due to protocol convergence and because it takes time to learn the RP set and create the forwarding path. This situation can result in a traffic delay of 2 to 3 minutes because the DR learns the RP set after Open Shortest Path First (OSPF) converges.

A workaround to this delay is to configure the static RP router on the peer SMLT switches. This feature avoids the process of selecting an active RP router from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. After the DR comes back up, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay to approximately 15 to 65 seconds.

## Protocol Independent Multicast-Source Specific Multicast

**Table 127: Protocol Independent Multicast-Source Specific Mode product support**

| Feature                                     | Product         | Release introduced |
|---------------------------------------------|-----------------|--------------------|
| PIM-Source Specific Mode (PIM-SSM) for IPv4 | 5320 Series     | Fabric Engine 8.6  |
|                                             | 5420 Series     | VOSS 8.4           |
|                                             | 5520 Series     | VOSS 8.2.5         |
|                                             | 5720 Series     | Fabric Engine 8.7  |
|                                             | 7520 Series     | Fabric Engine 8.10 |
|                                             | 7720 Series     | Fabric Engine 8.10 |
|                                             | VSP 4450 Series | VOSS 4.1           |
|                                             | VSP 4900 Series | VOSS 8.1           |
|                                             | VSP 7200 Series | VOSS 4.2.1         |
|                                             | VSP 7400 Series | VOSS 8.0           |
|                                             | VSP 8200 Series | VOSS 4.0.1         |
|                                             | VSP 8400 Series | VOSS 4.2           |
|                                             | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                               | Not Supported   |                    |

### Note

PIM is supported in Global Routing Table (GRT) only.

Source Specific Multicast optimizes PIM-SM by simplifying the many-to-many model. Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM only builds source-based SPTs. Whereas PIM-SM always joins a shared tree first, and then switches to the source tree, SSM eliminates the need to start with a shared tree by immediately joining a source through the SPT. SSM avoids using an RP and RP-based shared trees, which can be a potential problem.

You can configure multiple channels for the SSM group members in the SSM map table.

This configuration is ideal for applications like television channel distribution and other content-distribution businesses. Banking and trade applications can also use SSM as it provides more control over the hosts receiving and sending data over their networks.

When a v2 report in SSM range is received it is translated to an igmpv3 report message with one group record with type ALLOW and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. When a v2 leave in SSM range is received it is translated to an igmpv3 report message with one group record with type BLOCK and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. This behaviour is displayed only when PIM-SSM mode is enabled.

SSM applications use IP addresses reserved by the Internet Assigned Numbers Authority (IANA) in the 232/8 range (232.0.0.0 to 232.255.255.255). SSM recognizes packets in this range and controls the behavior of multicast routing devices and hosts that use these addresses. When a source (S) transmits IP datagrams to an SSM destination address (G), a receiver can receive these datagrams by subscribing to the (S,G) channel.

A channel is a source-group (S,G) pair where S is the source that sends to the multicast group and G is an SSM group address. SSM defines channels on an individual or multiple source basis, which enforces the one-to-many concept of SSM applications. In an SSM channel, each group is associated with multiple sources.

### *SSM features*

PIM-SM requires a unicast protocol to forward multicast traffic within the network to perform the Reverse Path Forwarding (RPF) check. PIM-SM uses the information from the unicast routing table to create and maintain the shared and shortest multicast tree that PIM-enabled routers use to communicate. The unicast routing table must contain a route to every multicast source in the network as well as routes to PIM entities like the RPs and BSR.

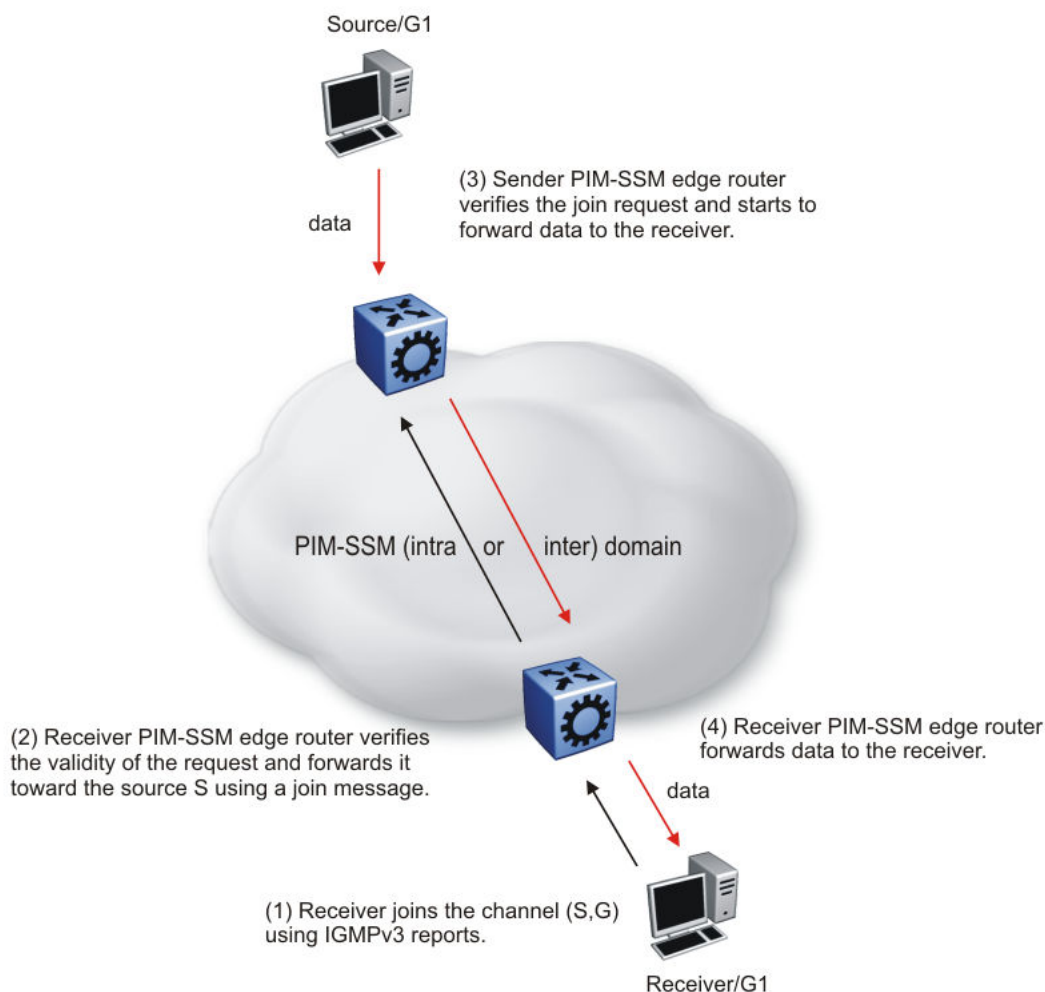

SSM uses only a subset of the PIM-SM features such as the SPT, DR, and some messages (hello, join, prune, and assert). However, some features are unique to SSM. These features, described in the following sections, are extensions of the IGMP and PIM protocols.

### *PIM-SSM architecture*

The following diagram illustrates how the PIM-SSM architecture requires routers to perform the following actions:

- support IGMPv3 source-specific host membership reports and queries at the edge routers

- initiate PIM-SSM (S,G) joins directly and immediately after receiving an IGMPv3 join report from the designated router
- restrict forwarding to SPTs within the SSM address range by all PIM-SSM routers

**Figure 145: PIM-SSM architecture**

The following rules apply to Layer 3 devices with SSM enabled:

- Receive IGMPv3 membership join reports in the SSM range and, if no entry (S,G) exists in the SSM channel table, create one.
- Receive IGMPv2 membership join reports, but only for groups that already use a static (S,G) entry in the SSM channel table.
- Send periodic join messages to maintain a steady SSM tree state.
- Use standard PIM-SM SPT procedures for unicast routing changes, but ignore rules associated with the SPT for the (S,G) route entry.
- Receive prune messages and use standard PIM-SM procedures to remove interfaces from the source tree.

- Forward data packets to interfaces from the downstream neighbors that sent an SSM join, or to interfaces with locally attached SSM group members.
- Drop data packets that do not use an exact-match lookup (S,G) in their forwarding database for S and G.

### *PIM-SSM Static Source Groups*

You can configure static source group entries in the PIM-SSM multicast routing table with static source groups. PIM-SSM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1592.

### *Implementation of SSM and IGMP*

The following sections describe how the switch implements PIM-SSM and IGMP.

#### **SSM range**

The standard SSM range is 232/8, but you can extend the range to include an IP multicast address. Although you can configure the SSM range, you cannot configure it for all multicast groups (224/4 or 224.0.0.0/240.0.0.0 or 224.0.0.0/255.0.0.0).

You can extend the SSM range to configure existing applications without changing their group configurations.

#### **SSM channel table**

You can use the SSM channel to manually configure (S,G) entries that map existing groups to their sending source. These table entries apply to the whole switch, not for each interface, and both IGMPv2 and IGMPv3 hosts use the SSM channel table.

The following rule applies to an SSM channel table for an individual switch:

- You can map one source to multiple groups.
- You can allow multiple sources to the same group.

#### **Important**

Different switches can use different mappings for groups to sources, for example, different channels map differently even if they are on the same network.

#### **SSM and IGMPv2**

SSM-configured switches can accept reports from IGMPv2 hosts on IGMPv2 interfaces if the group uses an SSM channel table entry. However, the IGMPv2 host groups must exist in the SSM range defined on the switch, which is 232/8 by default.

- After the SSM switch receives an IGMPv2 report for a group that is in the SSM channel table, it joins the specified source immediately.
- After the SSM switch receives an IGMPv2 report for a group that uses an enabled static SSM channel table entry, it triggers PIM-SSM processing as if it received an equivalent IGMPv3 report.

- After the SSM switch receives an IGMPv2 report for a group out of the SSM range, it processes the report as if it is in PIM-SM mode.

#### Deleting or Disabling an ssm-map with IGMPv1 or IGMPv2

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate using IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

Consider the following configuration scenario:

- A device is PIM-enabled, running in SSM mode, with IGMPv1 or IGMPv2 configured on the interface.
- IGMPv1 and IGMPv2 hosts send IGMPv1 or IGMPv2 reports for groups in SSM range.

The following table identifies the expected behaviors in this scenario.

**Table 128: Expected behaviors for ssm-map configuration**

| Action                                                      | Expected behavior                                                              |
|-------------------------------------------------------------|--------------------------------------------------------------------------------|
| You do not configure an ssm-map for the group in SSM range. | IGMPv1 and IGMPv2 reports are not processed.                                   |
| You do configure an ssm-map for the group in SSM range.     | IGMPv1 and IGMPv2 reports are processed and the group in SSM range is learned. |

#### SSM and IGMPv3

The switch supports IGMPv3 for SSM. With IGMPv3, a host can selectively request or filter traffic from sources within the multicast group. IGMPv3 is an interface-level configuration.

#### Important

IGMPv3 works without PIM-SSM or SSM-snoop enabled on the interface.

The following rules apply to IGMPv3-enabled interfaces:

- Send only IGMPv3 (source-specific) reports for addresses in the SSM range.
- Accept IGMPv3 reports.
- Drop IGMPv2 reports.

The IGMPv2 report mentioned in [SSM and IGMPv2](#) on page 1624 is processed because it is an IGMPv2 report received on an IGMPv2 interface. If an IGMPv2 interface receives an IGMPv3 report, it drops the report even if PIM-SSM is enabled and the entry is in the SSM channel table. The IGMP versions must match.

- Discard IGMP packets with a group address out of the SSM range.

The switch implements IGMPv3 in one of two modes: dynamic and static.

In dynamic mode, the switch learns about new (S,G) pairs from IGMPv3 reports and adds them to the SSM channel table. If you do not enable dynamic mode and an

IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report.

In static mode, you can statically configure (S,G) entries in the SSM channel table. If an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report. The interface also ignores the report if the group is in the table, but the source or mask does not match what is in the table.

**Important**

After you enable IGMPv3, changes to the query interval and robustness values on the querier switch propagate to other switches on the same VLAN through IGMP query.

Both IGMPv2 and IGMPv3 hosts use the SSM channel table:

- An IGMPv2 host (with an IGMPv2 VLAN) must use an existing SSM channel entry if the group is in the SSM range.
- If you enable dynamic learning for an IGMPv3 host, the SSM channel automatically learns the group. Otherwise, the SSM channel also needs a static entry.

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you disable IGMPv3 compatibility. In the following table, references to matching a static SSM channel entry assumes that the entry is enabled. If an entry is disabled, it is treated as though it is disallowed.

**Table 129: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility disabled**

| Host        | VLAN        | SSM range          | Action                                                                                                                                                   |
|-------------|-------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMPv2 host | IGMPv3 VLAN | In or out of range | Drop report.                                                                                                                                             |
| IGMPv3 host | IGMPv2 VLAN | In or out of range | Drop report.                                                                                                                                             |
| IGMPv2 host | IGMPv2 VLAN | In range           | If the report matches an existing static SSM channel entry, create (S,G).<br>If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 host | IGMPv2 VLAN | Out of range       | Ignore the SSM channel table and process the report as if it is in PIM-SM mode.                                                                          |
| IGMPv3 host | IGMPv3 VLAN | Out of range       | Process the report.                                                                                                                                      |
| IGMPv3 host | IGMPv3 VLAN | In range           | Dynamic enabled. Create (S,G).                                                                                                                           |

**Table 129: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility disabled (continued)**

| Host        | VLAN        | SSM range | Action                                                                          |
|-------------|-------------|-----------|---------------------------------------------------------------------------------|
| IGMPv3 host | IGMPv3 VLAN | In range  | Dynamic disabled and matches an existing SSM channel entry. Create (S,G).       |
| IGMPv3 host | IGMPv3 VLAN | In range  | Dynamic disabled and does not match an existing SSM channel entry. Drop report. |

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you enable IGMPv3 compatibility.

**Table 130: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility enabled**

| Host        | VLAN        | SSM range    | Action                                                                                                                                                |
|-------------|-------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMPv2 Host | IGMPv3 VLAN | In range     | If the report matches an existing static SSM channel entry, create (S,G). If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 Host | IGMPv3 VLAN | Out of range | Process the report as in PIM-SM mode.                                                                                                                 |

If an IGMPv3 group report enters the VLAN port and the port must discard one or more of the groups in that packet after the application of IGMP access controls, the port drops the entire packet and does not forward it on to other ports of the VLAN.

If an IGMPv3 interface receives an IGMPv2 or v1 query, the interface backs down to IGMPv2 or v1. As a result, the interface flushes all senders and receivers on the interface.

### Configuration limitations

Run PIM-SSM on either all switches in the domain or only on the edge routers. If you use a mix of PIM-SSM and PIM-SM switches in the domain, run PIM-SSM on all the edge routers and run PIM-SM on all the core routers.

#### Important

A PIM domain with edge routers running PIM-SM and core routers running PIM-SSM does not operate properly. If you prefer or require a mixed PIM-SM and PIM-SSM topology, run PIM-SSM on the edge switches and PIM-SM in the core. Ensure a valid RP configuration exists for groups that exist outside of the SSM range. If a valid RP configuration exists, the SSM switches process the joins in SM mode. If no RP exists, the SSM switches drop the reports.

Static source groups cannot conflict with SSM channels. If you configure a static source group or an SSM channel, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple groups to a single source for both static source group and an SSM channel.

## PIM passive interfaces

You can configure the PIM interface as active or passive. The default is active. With an active interface, you can configure transmit and receive PIM control traffic. A passive interface drops all PIM control traffic, thereby reducing the load on the system. This feature is useful when you use a high number of PIM interfaces and these interfaces connect to end users, not to other switches.

A PIM passive interface does not transmit and drops messages of the following type:

- hello
- join
- prune
- register
- register-stop
- assert
- candidate-RP-advertisement
- bootstrap

If a PIM passive interface receives these types of messages, it drops them and the switch logs a message, detailing the type of protocol message and the IP address of the sending device. These log messages help to identify the device that performs routing on the interface, which is useful if you must disable a device that does not operate correctly.

### Important

A device can send register and register-stop messages to a PIM passive interface, but these messages cannot be sent out of that interface.

The PIM passive interface maintains information about hosts, through IGMP, that are related to senders and receivers, but the interface does not maintain information about PIM neighbors. You can configure a BSR or an RP on a PIM passive interface.

You can also use the PIM passive interface feature as a security measure to prevent routing devices from becoming attached and participating in the multicast routing of the network.

### Important

Before you change the state (active or passive) of a PIM interface, disable PIM on that interface. This action prevents instability in the PIM operations, especially when neighbors exist or the interface receives streams. After you disable PIM, the switch loses traffic for approximately 80 seconds.

## Multicast route statistics

**Table 131: Mroute statistics product support**

| Feature                                               | Product         | Release introduced |
|-------------------------------------------------------|-----------------|--------------------|
| Multicast route (mroute) statistics for IPv4 and IPv6 | 5320 Series     | Fabric Engine 8.6  |
|                                                       | 5420 Series     | VOSS 8.4           |
|                                                       | 5520 Series     | VOSS 8.2.5         |
|                                                       | 5720 Series     | Fabric Engine 8.7  |
|                                                       | 7520 Series     | Fabric Engine 8.10 |
|                                                       | 7720 Series     | Fabric Engine 8.10 |
|                                                       | VSP 4450 Series | Not Supported      |
|                                                       | VSP 4900 Series | VOSS 8.1           |
|                                                       | VSP 7200 Series | VOSS 5.1           |
|                                                       | VSP 7400 Series | VOSS 8.0           |
|                                                       | VSP 8200 Series | VOSS 5.1           |
|                                                       | VSP 8400 Series | VOSS 5.1           |
|                                                       | VSP 8600 Series | Not Supported      |
|                                                       | XA1400 Series   | Not Supported      |

The multicast route statistics feature provides statistics for multicast streams through the switch. Using the Command Line Interface (CLI), Simple Network Management Protocol (SNMP) or Enterprise Device Manager (EDM), you can track the number of senders sending multicast streams to a particular group address. You can also obtain a count of the packets or bytes being received for a particular multicast group address and the average size of the frames. Multicast route statistics are supported for both IPv4 and IPv6 group addresses.

Determining the route statistics is especially useful when debugging a multicast network and also when administering the network.

### *Multicast route statistics and DvR*

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing Fundamentals](#) on page 743.

## IP multicast network design

Use multicast routing protocols to efficiently distribute a single data source among multiple users in the network. This section provides information about how to design networks that support IP multicast routing.

For more design guidelines, conceptual, and configuration information about IP Multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1593.

### *Multicast scalability design rules*

The following section lists the design rules to increase multicast route scaling.

#### **Important**

The switch software supports the following:

- Protocol-Independent Multicast (PIM)
- Split MultiLink Trunking (SMLT) and Routed-SMLT (RSMLT)

#### **Multicast scalability design rules**

1. Whenever possible, use simple network designs that do not use VLANs that span several switches. Instead, use routed links to connect switches.
2. Whenever possible, group sources sending to the same group in the same subnet. The switch uses a single egress forwarding pointer for all sources in the same subnet sending to the same group. Be aware that these streams have separate hardware forwarding records on the ingress side.
3. Do not configure multicast routing on edge switch interfaces that do not contain multicast senders or receivers. By following this rule, you:
  - Provide secure control over multicast traffic that enters or exits the interface.
  - Reduce the load on the switch, as well as the number of routes. This improves overall performance and scalability.
4. Avoid initializing many (several hundred) multicast streams simultaneously. Initial stream setup is a resource-intensive task, and initializing a large number can increase the setup time. In some cases, this delay can result in stream loss.
5. Whenever possible, do not connect IP multicast sources and receivers by using VLANs that interconnect switches (see the following figure). In some cases, this can result in excessive hardware record use. By placing the source on the interconnected VLAN, traffic takes two paths to the destination, depending on the reverse path forwarding (RPF) checks and the shortest path to the source.

For example, if a receiver is on VLAN 1 on switch S1 and another receiver is on VLAN 2 on switch S1, traffic can be received from two different paths to the two receivers, which results in the use of two forwarding records. If the source on switch S2 is on a different VLAN than VLAN 3, traffic takes a single path to switch S1 where the receivers are located.

**Figure 146: IP multicast sources and receivers on interconnected VLANs**

#### *IP multicast address range restrictions*

IP multicast routers use D class addresses, which range from 224.0.0.0 to 239.255.255.255. Although you can use subnet masks to configure IP multicast address ranges, the concept of subnets does not exist for multicast group addresses. Consequently, the usual unicast conventions—where you reserve the all 0s subnets, all 1s subnets, all 0s host addresses, and all 1s host addresses—do not apply.

Internet Assigned Numbers Authority (IANA) reserves addresses from 224.0.0.0 through 224.0.0.255 for link-local network applications. Multicast-capable routers do not forward packets with an address in this range. For example, Open Shortest Path First (OSPF) uses 224.0.0.5 and 224.0.0.6, and Virtual Router Redundancy Protocol (VRRP) uses 224.0.0.18 to communicate across local broadcast network segments.

IANA also reserves the range of 224.0.1.0 through 224.0.1.255 for well-known applications. IANA assigns these addresses to specific network applications. For example, the Network Time Protocol (NTP) uses 224.0.1.1, and Mtrace uses 224.0.1.32. RFC1700 contains a complete list of these reserved addresses.

Multicast addresses in the 232.0.0.0/8 (232.0.0.0 to 232.255.255.255) range are reserved only for source-specific multicast (SSM) applications, such as one-to-many applications. While this range is the publicly reserved range for SSM applications, private networks can use other address ranges for SSM.

Finally, addresses in the range 239.0.0.0/8 (239.0.0.0 to 239.255.255.255) are administratively scoped addresses; they are reserved for use in private domains. Do not advertise these addresses outside the private domain. This multicast range is analogous to the 10.0.0.0/8, 172.16.0.0/20, and 192.168.0.0/16 private address ranges in the unicast IP space.

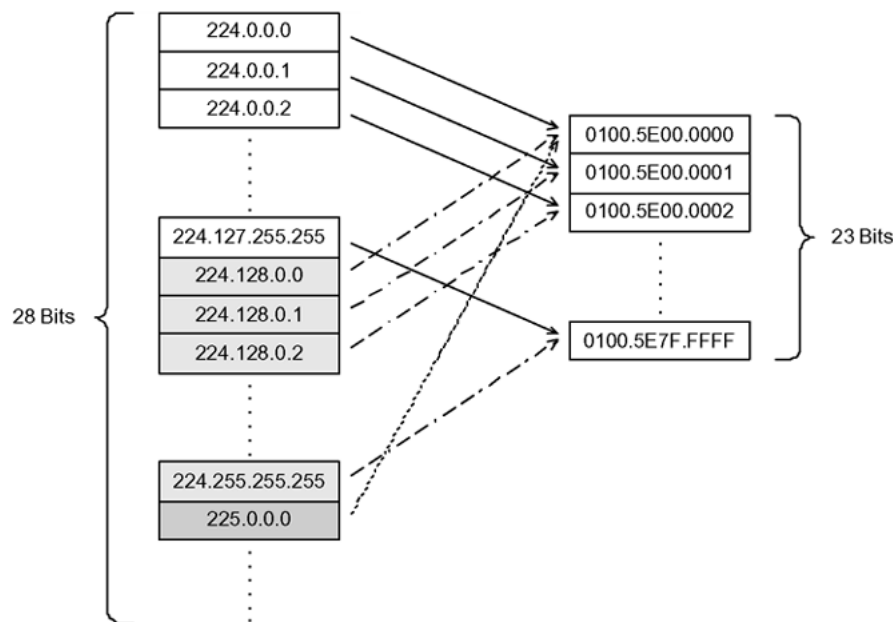

In a private network, only assign multicast addresses from 224.0.2.0 through 238.255.255.255 to applications that are publicly accessible on the Internet. Assign addresses in the 239.0.0.0/8 range to multicast applications that are not publicly accessible.

Although you can use a multicast address you choose on your own private network, it is generally not good design practice to allocate public addresses to private network entities. Do not use public addresses for unicast host or multicast group addresses on private networks.

#### *Multicast MAC Address Mapping Considerations*

Like IP, Ethernet has a range of multicast MAC addresses that natively support Layer 2 multicast capabilities. While IP has a total of 28 addressing bits available for multicast addresses, Ethernet has only 23 addressing bits assigned to IP multicast. The Ethernet multicast MAC address space is much larger than 23 bits, but only a subrange of that larger space is allocated to IP multicast. Because of this difference, 32 IP multicast addresses map to one Ethernet multicast MAC address.

IP multicast addresses map to Ethernet multicast MAC addresses by placing the low-order 23 bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01:00:5E:00:00:00. Thus, more than one multicast address maps to the same Ethernet address (see the following figure). For example, all 32 addresses 224.1.1.1, 224.129.1.1, 225.1.1.1, 225.129.1.1, 239.1.1.1, 239.129.1.1 map to the same 01:00:5E:01:01:01 multicast MAC address.

**Figure 147: Multicast IP address to MAC address mapping**

Most Ethernet switches handle Ethernet multicast by mapping a multicast MAC address to multiple switch ports in the MAC address table. Therefore, when you design the group addresses for multicast applications, take care to efficiently distribute streams only to hosts that are receivers.

The VSP 4450 Series devices switch IP multicast data based on the IP multicast address, not the MAC address, and thus, do not have this issue.

As an example, consider two active multicast streams using addresses 239.1.1.1 and 239.129.1.1. Suppose that two Ethernet hosts, receiver A and receiver B, connect to ports on the same switch and only want the stream addressed to 239.1.1.1. Suppose also

that two other Ethernet hosts, receiver C and receiver D, also connect to the ports on the same switch as receiver A and B, and want to receive the stream addressed to 239.129.1.1. If the switch uses the Ethernet multicast MAC address to make forwarding decisions, then all four receivers receive both streams—even though each host only wants one stream. This transmission increases the load on both the hosts and the switch. To avoid this extra load, ensure that you manage the IP multicast group addresses used on the network.

The VSP 4450 Series devices do not forward IP multicast packets based on multicast MAC addresses—even when bridging VLANs at Layer 2. Thus, the platform does not encounter this problem. Instead, the platform internally maps IP multicast group addresses to the ports that contain group members.

When an IP multicast packet is received, the lookup is based on the IP group address, regardless of whether the VLAN is bridged or routed. While the problem described in the previous example does not affect the VSP 4450 Series devices, other switches in the network can be affected. This problem is particularly true of pure Layer 2 switches.

In a network that includes multiple hardware platforms, the easiest way to ensure that this issue does not arise is to use only a consecutive range of IP multicast addresses that correspond to the lower-order 23 bits of that range. For example, use an address range from 239.0.0.0 through 239.127.255.255. A group address range of this size can still easily accommodate the needs of even the largest private enterprise.

#### *Dynamic multicast configuration changes*

You must not perform dynamic multicast configuration changes when multicast streams flow in a network. For example, do not change the routing protocol that runs on an interface, or the IP address, or the subnet mask for an interface until multicast traffic ceases.

For such changes, ensure that you temporarily stop all multicast traffic. If the changes are necessary and you have no control over the applications that send multicast data, you can disable the multicast routing protocols before you perform the change. For example, consider disabling multicast routing before making interface address changes. In all cases, these changes result in traffic interruptions because they affect neighbor-state machines and stream-state machines.

In addition, when removing port members of an MLT group you must first disable the ports. Changing the group set without first shutting the ports down can result in high-CPU utilization and processing in a scaled multicast environment due to the necessary hardware reprogramming on the multicast records.

#### *IGMPv3 backward compatibility*

IGMPv3 for PIM is backward compatible with IGMPv1/v2. According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.

- If a router that is not explicitly configured to use IGMPv1 or IGMPv2, detects an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure the IGMP version of an interface to version 3 regardless of the PIM or snooping mode.

You can configure whether the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

**Note**

If you enable the explicit host tracking option on an IGMPv3 interface, you cannot downgrade to IGMPv1 or IGMPv2. You must disable explicit host tracking to downgrade the IGMP version.

### *TTL in IP multicast packets*

The switch treats multicast data packets with a time-to-live (TTL) of 1 as expired packets and sends them to the CPU before dropping them. To avoid this issue, ensure that the originating application uses a hop count large enough to enable the multicast stream to traverse the network and reach all destinations without reaching a TTL of 1. Ensure that you use a TTL value of 33 or 34 to minimize the effect of looping in an unstable network.

### *Multicast MAC filtering*

Certain network applications require multiple hosts to share a multicast MAC address. Instead of flooding all ports in the VLAN with this multicast traffic, you can use Multicast MAC filtering to forward traffic to a configured subset of the ports in the VLAN. This multicast MAC address is not an IP multicast MAC address.

At a minimum, map the multicast MAC address to a set of ports within the VLAN. In addition, if traffic is routed on the local host, you must configure an Address Resolution Protocol (ARP) entry to map the shared unicast IP address to the shared multicast MAC address. You must configure an ARP entry because the hosts can also share a virtual IP address, and packets addressed to the virtual IP address need to reach each host.

Ensure that you limit the number of such configured multicast MAC addresses to a maximum of 100. This number is related to the maximum number of possible VLANs you can configure, because for every multicast MAC filter that you configure the maximum number of configurable VLANs reduces by one. Similarly, configuring large numbers of VLANs reduces the maximum number of configurable multicast MAC filters downward from 100.

Although you can configure addresses starting with 01.00.5E, which are reserved for IP multicast address mapping, do not enable IP multicast with streams that match the configured addresses. This configuration can result in incorrect IP multicast forwarding and incorrect multicast MAC filtering.

### *Guidelines for multicast access policies*

Use the following guidelines when you configure multicast access policies:

- Use masks to specify a range of hosts. For example, 10.177.10.8 with a mask of 255.255.255.248 matches hosts addresses 10.177.10.8 through 10.177.10.15. The host subnet address and the host mask must be equal to the host subnet address. An easy way to determine this is to ensure that the mask has an equal or fewer number of trailing zeros than the host subnet address. For example, 3.3.0.0/255.255.0.0 and 3.3.0.0/255.255.255.0 are valid. However, 3.3.0.0/255.0.0.0 is not.
- Apply receive-access policies to all eligible receivers on a segment. Otherwise, one host joining a group makes that multicast stream available to all.
- Receive access policies are initiated after the switch receives reports with addresses that match the filter criteria.
- Transmit access policies apply after the switch receives the first packet of a multicast stream.

Multicast access policies can apply to a routed PIM interface if Internet Group Management Protocol (IGMP) reports the reception of multicast traffic.

The following rules and limitations apply to IGMP access policy parameters when you use them with IGMP instead of PIM:

- The static member parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- The Static Not Allowed to Join parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- For multicast access control, the denyRx parameter applies to IGMP snooping and PIM. The DenyTx and DenyBoth parameters apply only to IGMP snooping.

### *Split-subnet and multicast*

The split-subnet issue arises when you divide a subnet into two unconnected sections in a network. This division results in the production of erroneous routing information about how to reach the hosts on that subnet. The split-subnet problem applies to all types of traffic, but it has a larger impact on a PIM-SM network.

To avoid the split-subnet problem in PIM networks, ensure that the RP router is not in a subnet that can become a split subnet. Also, avoid having receivers on this subnet. Because the RP is an entity that must be reached by all PIM-enabled switches with receivers in a network, placing the RP on a split-subnet can impact the whole multicast traffic flow. Traffic can be affected even for receivers and senders that are not part of the split-subnet.

### *Protocol Independent Multicast-Sparse Mode guidelines*

Protocol Independent Multicast-Sparse Mode (PIM-SM) uses an underlying unicast routing information base to perform multicast routing. PIM-SM builds unidirectional shared trees rooted at a RP router for each group and can also create shortest-path trees for each source.

## PIM-SM and PIM-SSM Scalability

For more information on interface scaling, see the [VOSS Release Notes](#).

The software does not support virtualized PIM. PIM is supported in the Global Routing Table only.

Interfaces that run PIM must also use a unicast routing protocol (PIM uses the unicast routing table), which puts stringent requirements on the system. With a high number of interfaces, take special care to reduce the load on the system.

Use few active IP routed interfaces. You can use IP forwarding without a routing protocol enabled on the interfaces, and enable only one or two with a routing protocol. You can configure proper routing by using IP routing policies to announce and accept routes on the switch. Use PIM passive interfaces on the majority of interfaces.

### Important

For information on the maximum values for total PIM interfaces and active interfaces, see the [VOSS Release Notes](#). If you configure the maximum number of active interfaces, all remaining interfaces must be passive.

When you use PIM-SM, the number of routes can scale up to the unicast route limit because PIM uses the unicast routing table to make forwarding decisions. For higher route scaling, use OSPF instead of Routing Information Protocol (RIP).

As a general rule, a well-designed network does not have many routes in the routing table. For PIM to work properly, ensure that all subnets configured with PIM are reachable and that PIM uses the information in the unicast routing table. For the RPF check, to correctly reach the source of any multicast traffic, PIM requires the unicast routing table.

## PIM General Requirements

Design simple PIM networks where VLANs do not span several switches.

PIM relies on unicast routing protocols to perform its multicast forwarding. As a result, include in your PIM network design, a unicast design where the unicast routing table has a route to every source and receiver of multicast traffic, as well as a route to the RP router and Bootstrap router (BSR) in the network. Ensure that the path between a sender and receiver contains PIM-enabled interfaces. Receiver subnets are not always required in the routing table.

Use the following guidelines:

- Ensure that every PIM-SM domain is configured with an RP, either by static definition or via BSR.
- Ensure that every group address used in multicast applications has an RP in the network.
- As a redundancy option, you can configure several RPs for the same group in a PIM domain.
- As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups.

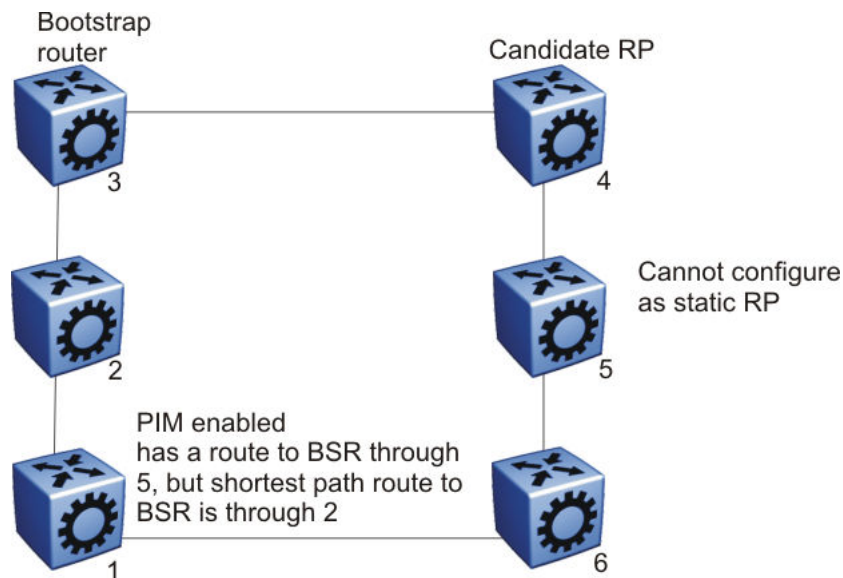

- In order to configure an RP to cover the entire multicast range, configure an RP to use the IP address of 224.0.0.0 and the mask of 240.0.0.0.
- Configure an RP to handle a range of multicast groups by using the mask parameter. For example, an entry for group value of 224.1.1.0 with a mask of 255.255.255.192 covers groups 224.1.1.0 to 224.1.1.63.
- In a PIM domain with both static and dynamic RP switches, you cannot configure one of the (local) interfaces for the static RP switches as the RP. For example, in the following scenario:

(static RP switch) Sw1 ----- Sw2 (BSR/Cand-RP1) -----Sw3

You cannot configure one of the interfaces on switch Sw1 as static RP because the BSR cannot learn this information and propagate it to Sw2 and Sw3. PIM requires that you consistently configure RP on all the routers of the PIM domain, so you can only add the remote interface Candidate-RP1 (Cand-RP) to the static RP table on Sw1.

- If a switch needs to learn an RP-set, and has a unicast route to reach the BSR through this switch, you cannot enable or configure static RP on a switch in a mixed mode of candidate RP and static RP switches. For examples, see the following two figures.

### PIM and Shared Tree to Shortest Path Tree Switchover

When an IGMP receiver joins a multicast group, PIM on the leaf router first joins the shared tree. After the first packet is received on the shared tree, the router uses the source address information in the packet to immediately switch over to the shortest path tree (SPT). If you enable PIM Infinite Threshold Policy for IPv4 and IPv6, multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of switching immediately over to the SPT.

#### Note

PIM Infinite Threshold Policy for IPv4 and IPv6 is not supported on VSP 8600 Series or XA1400 Series.

### PIM Traffic Delay and SMLT Peer Reboot

PIM uses a designated router (DR) to forward data to receivers on the DR VLAN. The DR is the router with the highest IP address on a LAN. If this router is down, the router with the next highest IP address becomes the DR. However, if the VLAN is an SMLT VLAN, the DR is not a factor in determining which switch forwards the data down to the receiver. Either aggregate switch can forward data to the receiver, because the switches act as one. The switch that forwards depends on where the source is located (on another SMLT/VIST link or on a non-SMLT/non-VIST link) and whether either side of the receiver SMLT link is up or down. If the forwarder switch is rebooted, traffic loss occurs until protocol convergence is completed.

Consider the following cases:

- If the source is on an SMLT link that is not the receiver SMLT, the switch that directly received the data on its side of the source SMLT link forwards it down to the receiver on the receiver SMLT regardless of which switch is the DR for the receiver VLAN. The forwarding switch sends a copy of the data over the VIST link to the peer switch, which drops the data because it knows that the remote SMLT is up and therefore the remote peer has already forwarded the data. If the forwarding switch goes down, the other switch receives the data directly over its source SMLT link and takes over

forwarding to the receivers. After the original switch comes back up, the original switch again receives the data directly over its source SMLT. The original switch may not be ready to forward the data because of the protocol reconvergence, so the original switch loses traffic until reconvergence is complete.

- If the source is not learned on another SMLT link or the vIST link on each aggregate switch; they have a route to the source which is not on an SMLT or across the vIST. The switches must choose which one forwards the data down the receiver SMLT link; which one is the designated forwarder, so that duplicate data does not occur. The highest IP address is the designated forwarder. If the designated forwarder becomes disabled, the other takes over. When it is reenabled, the other switch sees that it is no longer the highest IP address and it sees that the remote SMLT link comes up. The other switch then assumes that the vIST peer is capable of being the designated forwarder and it stops forwarding down to the receivers. If the original switch is not ready to forward the data due to reconvergence, traffic loss occurs.

In either case, configuring a static RP helps the situation. To avoid this traffic delay, a workaround is to configure a static RP on the peer SMLT switches. This configuration avoids the process of selecting an active RP router from the list of candidate RPs, and also of dynamically learning about RPs through the BSR mechanism. Then, when the DR comes back, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay.

### Circuitless IP for PIM-SM

Use CLIP to configure a resilient RP and BSR for a PIM network. When you configure an RP or BSR on a regular interface, if it becomes nonoperational, the RP and BSR also become nonoperational. This status results in the election of other redundant RPs and BSRs, and can disrupt IP multicast traffic flow in the network. As a best practice for multicast networks design, always configure the RP and BSR on a CLIP interface to prevent a single interface failure from causing these entities to fail.

Also, configure redundant RPs and BSRs on different switches such that these entities are on CLIP interfaces. For the successful setup of multicast streams, ensure that a unicast route exists to all CLIP interfaces from all locations in the network. A unicast route is mandatory because, for proper RP learning and stream setup on the shared RP tree, every switch in the network needs to reach the RP and BSR. You can use PIM-SM CLIP interfaces only for RP and BSR configurations, and are not intended for other purposes.

Do not configure non-SMLT IGMP leaf ports on a router to be one of the redundant RP CLIP devices. It is possible that these IGMP hosts can become isolated from the multicast data stream(s).

If you configure dual-redundant RPs (vIST peers with the same CLIP interface IP address used for the RP), the topology in the following figure does not work in link-failure scenarios. Use caution if you design a network with this topology where the vIST peers are PIM enabled, and the source and receiver edges are Layer 2.

Consider an example where one of the peers, vIST-A, is the PIM DR for the source VLAN, and the source data is hashed to vIST-A from the Layer 2 source edge. vIST-A forwards traffic to the receiver edge using the SMLT link from vIST-A to the receiver edge. If the SMLT link fails, vIST-A does not forward traffic over the vIST link to vIST-B, and the receiver edge does not receive the data.

In this topology, the receiver edge sends an IGMP membership report for a group, which is recorded on both vIST peers as an IGMP LEAF on the receiver SMLT port on the receiver VLAN.

Because both of the vIST peers are the RP for the group, they do not send a (\*,g) PIM JOIN message toward the other RP. The (\*,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (\*,g) mroute records only a LEAF on the SMLT receiver port.

Because the source is local (Layer 2 edge), there is no PIM (s,g) JOIN message toward the source and the (s,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (s,g) mroute records only a LEAF on the SMLT receiver port.

If the source is hashed to vIST-A, the PIM DR for the incoming VLAN, traffic is forwarded to the receiver correctly. vIST-A does not forward traffic over the vIST to vIST-B, because no JOIN exists on the vIST port. If the receiver SMLT link from the vIST-A peer is down, the traffic is not forwarded to vIST-B, and is not received by the receiver edge. Traffic resumes after the link is restored. If the source data hashes to the non-DR peer, vIST-B, no problem occurs because the non-DR always forwards traffic to the DR.

A similar situation exists in this topology when vIST-A is both the RP and the DR for the Layer 2 receiver edge. The vIST port is not in the outgoing port list because there is no JOIN message from the peer toward the source (which is not PIM enabled). Therefore, if the SMLT link from vIST-A to the receiver edge is down, the system does not forward traffic to the peer vIST-B and down to the receiver.

You can avoid the preceding problems with this topology by performing one of the following actions:

- Enable PIM on the source edge.

The vIST peers send PIM joins toward the source and the JOIN is recorded on the vIST port for the (s,g). Data is forwarded to the peer.

- Do not configure dual redundant RPs.

One vIST peer is the RP for a group.

- Do not configure one vIST peer as both the DR for the source VLAN and the RP for the receiver group.

The system forwards the traffic to the RP or to the DR, depending on which peer receives the source, and, if the SMLT link to the receiver goes down there will be no data loss.

### PIM-SM and Static RP

Use static RP to provide security, interoperability, and redundancy for PIM-SM multicast networks. Consider if the administrative ease derived from using dynamic RP assignment is worth the security risks involved. For example, if an unauthorized user connects a PIM-SM router that advertises itself as a candidate RP (C-RP), it can possibly take over new multicast streams that otherwise distribute through an authorized RP. If security is important, use static RP assignment.

You can use the static RP feature in a PIM environment with devices that run legacy PIM-SMv1 and Cisco Auto-RP. For faster convergence, you can also use static RP in a PIM-SMv2 environment. If you configure static RP with PIM-SMv2, the BSR is not active.

### Static RP and Auto-RP

Some legacy PIM-SMv1 networks use the auto-RP protocol. Auto-RP is a Cisco proprietary protocol that provides equivalent functionality to the legacy platform supported PIM-SM RP and BSR. You can use the static RP feature to interoperate in this environment. For example, in a mixed-vendor network, you can use auto-RP among routers that support the protocol, while other routers use static RP. In such a network, ensure that the static RP configuration mimics the information that is dynamically distributed to guarantee that multicast traffic is delivered to all parts of the network.

In a mixed auto-RP and static RP network, ensure that the legacy platform does not serve as an RP because it does not support the auto-RP protocol. In this type of network, the RP must support the auto-RP protocol.

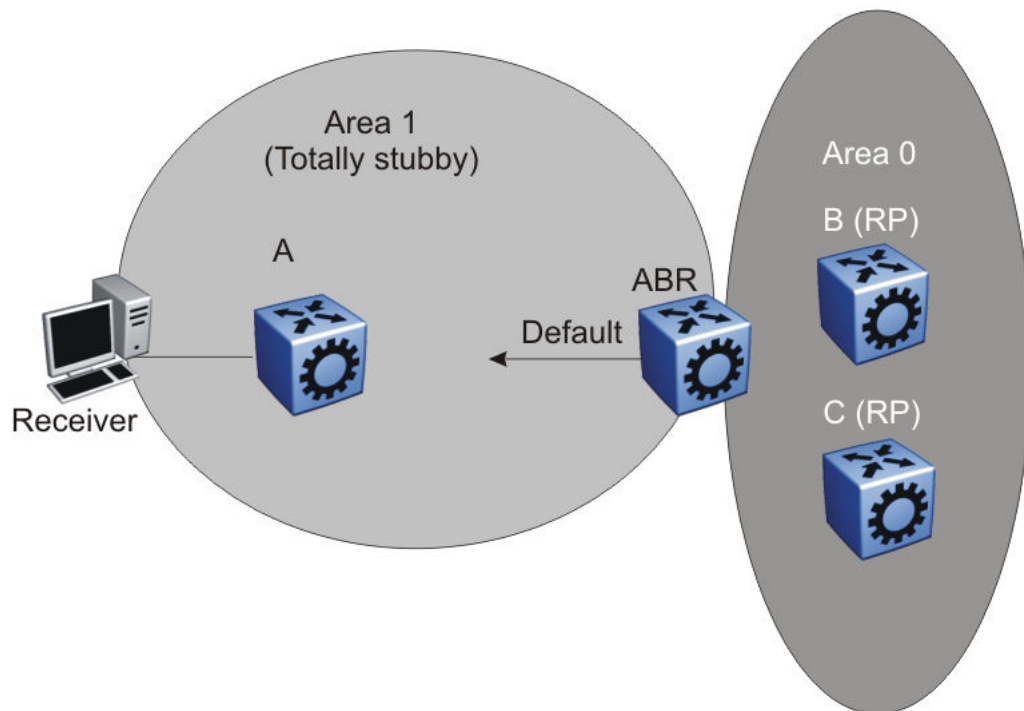

### Static RP and RP Redundancy

You can provide RP redundancy through static RPs. To ensure consistency of RP selection, implement the same static RP configuration on all PIM-SM routers in the network. In a mixed vendor network, ensure that the same RP selection criteria is used among all routers. For example, to select the active RP for each group address, the switch uses a hash algorithm defined in the PIM-SMv2 standard. If a router from another vendor selects the active RP based on the lowest IP address, then the inconsistency prevents stream delivery to certain routers in the network.

If a group address-to-RP discrepancy occurs among PIM-SM routers, network outages occur. Routers that are unaware of the true RP cannot join the shared tree and cannot receive the multicast stream.

Failure detection of the active RP is determined by the unicast routing table. As long as the RP is considered reachable from a unicast routing perspective, the local router assumes that the RP is fully functional and attempts to join the shared tree of that RP.

The following figure shows a hierarchical OSPF network where a receiver is in a totally stubby area. If RP B fails, PIM-SM router A does not switch over to RP C because the injected default route in the unicast routing table indicates that RP B is still reachable.

Because failover is determined by unicast routing behavior, carefully consider the unicast routing design, as well as the IP address you select for the RP. Static RP failover performance depends on the convergence time of the unicast routing protocol. For quick convergence, ensure that you use a link state protocol, such as OSPF. For example, if you use RIP as the routing protocol, an RP failure can take minutes to detect. Depending on the application, this situation can be unacceptable.

Static RP failover time does not affect routers that have already switched over to the SPT; failover time only affects newly-joining routers.

### Unsupported Static RP Configurations

If you use static RP, you disable dynamic RP learning. The following figure shows an unsupported configuration for static RP. In this example because of inter-operation between static RP and dynamic RP, no RP exists at switch 2. However, (S,G) creation and deletion occurs every 210 seconds at switch 16.

Switches 10, 15, and 16 use static RP, whereas switch 2 uses dynamic RP. The source is at switch 10, and the receivers are switches 15 and 16. The RP is at switch 15 locally. The receiver on switch 16 cannot receive packets because its SPT goes through switch 2.

Switch 2 is in a dynamic RP domain, so it cannot learn about the RP on switch 15. However, (S, G) records are created and deleted on switch 16 every 210 seconds.

### Rendezvous Point Router Considerations

You can place an RP on a switch when VLANs extend over several switches. However, when you use PIM-SM, ensure that you do not span VLANs on more than two switches.

Use static group-range-to-RP mappings in an SMLT topology as opposed to RP set learning using the Bootstrap Router (BSR) mechanism. Static RP allows for faster convergence in box failure and reset, whereas there are inherent delays in the BSR mechanism as follows:

- When a router comes back up after a failover or reset, to accept and propagate (\*,g) join requests from surrounding routers (either PIM join messages or local IGMP membership reports) to the RP, a PIM router must determine the address of the RP for each group for which they desire (\*,g) state. The PIM router must know the unicast route to the RP address. The route to the RP address is learned by using a unicast routing protocol such as OSPF, and the RP address is either statically configured or dynamically learned using the BSR mechanism.
- When a box comes up after a reset, if the RP is not statically configured, it must wait for the BSR to select the RP from candidate RP routers, and then propagate the RP set hop-by-hop to all PIM routers. This must be done before a join message can be processed. If the PIM router receives a join message before it learns the RP set, it drops the join message, and the router waits for another join or prune message to arrive before it creates the multicast route and propagates the join message to the RP. The default Join/Prune timer is 60 seconds, and because of this and the delays inherent in BSR RP-set learning, significant multicast traffic interruptions can

occur. If the RP is statically configured, the only delay is in the unicast routing table convergence and the arrival of the Join/Prune messages from surrounding boxes.

### Layer 3 Multicast Extended VLANS

Avoid using a Layer 3 multicast extended VLAN topology without SMLT.

Do not connect non-SMLT PIM routers in a linear fashion on the same VLAN. This topology is called an extended VLAN. Unlike a shared VLAN topology where all routers on the same VLAN are physically one hop away from each other, a VLAN router at one end of the extended VLAN has one or more routers in between it and the router at the far end of the extended VLAN. The following figure shows an extended VLAN.

In the preceding figure, all routers use PIM-SSM. The source connects to Router A on VLAN 10. All routers and receiver hosts connect on the same extended VLAN, VLAN 20. All routers have a receiver in VLAN 20. Router D is the PIM DR for VLAN 20 and the source host is not on VLAN 20. PIM-SSM does not require a Rendezvous Point (RP).

In this topology, each router receives an IGMP membership report from its local receiver host, and then sends a PIM SG join message towards the source on VLAN 20. VLAN flooding propagates the PIM SG join message through to Router A, the PIM DR for the source VLAN 10. Each router from Router D to Router A records a PIM join on the port on which the join message was received, and then sends out its own join message toward the source. Data then flows from the source to the receiver, as long as a join exists on those ports.

Because all routers are in the same VLAN 20, they receive joins from one another due to flooding in the VLAN. For example, Router D receives join messages from Router C on its port 'b', and Router C receives join messages from Router B on its port toward Router B. In accordance with the PIM protocol rules, suppression causes Router D to stop sending a join towards the source because it receives a join for the same group and same RP on the port (port b) of the upstream neighbor (the router towards the source). Router D does not need to send a redundant join on the same VLAN. Router D stops sending a join, and the join that is recorded on port c of Router C eventually times out and is removed from the egress list of the (s,g) multicast route entry on Router C. This removal causes Router C to stop forwarding multicast traffic to Router D, and to the receiver (R1).

The purpose of join suppression is to suppress joins on a shared VLAN, such that if all routers on the shared VLAN want to receive data from the same RP and group, then only one of them needs to send the join on the VLAN. One join is enough to pull the data from the source router to the shared VLAN for all routers to receive. The other routers can suppress sending their own joins when they see such a join on the port toward the upstream router. In this way, less protocol message congestion exists in the shared VLAN. In the following figure, Router D sends the initial join message, which is seen by Router B and Router C. Router B and Router C suppress their own join messages. Router A (the PIM DR for the source VLAN 10) sends the data to VLAN 20, which is received by Routers B, C, and D due to the shared (non-extended) VLAN topology, and traffic is forwarded to all receiver hosts.

The extended VLAN topology looks exactly like the non-extended shared VLAN topology to the router, which cannot distinguish between the two.

In the current release, you cannot disable join suppression on a router. This enhancement will be added in a future release. Until this enhancement is included, you can perform the following actions:

1. Avoid this type of extended VLAN topology, and instead use Layer 3 routing between the routers. Do not extend VLAN 20 throughout, but rather, create a different VLAN between each router.
2. Configure the PIM DR for VLAN 20 to be the router closer to the source (Router B) so that any join received on the VLAN 20 DR (Router B) will be recorded as an IGMP local leaf on VLAN 20 as opposed to a PIM join, which does not time out until the receiver host stops sending IGMP membership reports.

### PIM-SM Design and the BSR Hash Algorithm

To optimize the flow of traffic down the shared trees in a network that uses a BSR to dynamically advertise candidate RPs, consider the hash function. The BSR uses the hash function to assign multicast group addresses to each C-RP.

The BSR distributes the hash mask used to compute the RP assignment. For example, if two RPs are candidates for the range 239.0.0.0 through 239.0.0.127, and the hash mask is 255.255.255.252, that range of addresses is divided into groups of four consecutive addresses and assigned to one or the other C-RP.

The following figure illustrates a suboptimal design where Router A sends traffic to a group address assigned to RP D. Router B sends traffic assigned to RP C. RP C and RP D serve as backups for each other for those group addresses. To distribute traffic, it is desirable that traffic from Router A use RP C and that traffic from Router B use RP D.

While still providing redundancy in the case of an RP failure, you can ensure that the optimal shared tree is used by using the following methods.

1. Use the hash algorithm to proactively plan the group-address-to-RP assignment.

Use this information to select the multicast group address for each multicast sender on the network and to ensure optimal traffic flows. This method is helpful for modeling more complex redundancy and failure scenarios, where each group address has three or more C-RPs.

2. Allow the hash algorithm to assign the blocks of addresses on the network, and then view the results using the command `show ip pim active-rp`.

Use the command output to assign multicast group addresses to senders that are located near the indicated RP. The limitation to this approach is that while you can easily determine the current RP for a group address, the backup RP is not shown. If more than one backup for a group address exists, the secondary RP is not obvious. In this case, use the hash algorithm to reveal which of the remaining C-RPs take over for a particular group address in the event of primary RP failure.

The hash algorithm works as follows:

1. For each C-RP router with matching group address ranges, a hash value is calculated according to the formula:

$$\text{Hash value [G, M, C(i)]} = \{ [1\ 03\ 515\ 245 * [(1\ 103\ 515245 * (G\&M) + 12\ 345) \text{ XOR } C(i)] + 12\ 345] \text{ mod } 2^{31}$$

The hash value is a function of the group address (G), the hash mask (M), and the IP address of the C-RP C(i). The expression (G&M) guarantees that blocks of group addresses hash to the same value for each C-RP, and that the size of the block is determined by the hash mask.

For example, if the hash mask is 255.255.255.248, the group addresses 239.0.0.0 through 239.0.0.7 yield the same hash value for a given C-RP. Thus, the block of eight addresses are assigned to the same RP.

2. The C-RP with the highest resulting hash value is chosen as the RP for the group. In the event of a tie, the C-RP with the highest IP address is chosen.

This algorithm runs independently on all PIM-SM routers so that every router has a consistent view of the group-to-RP mappings.

### Candidate RP Considerations

The C-RP priority parameter determines an active RP for a group. The hash values for different RPs are only compared for RPs with the highest priority. Among the RPs with the highest priority value and the same hash value, the C-RP with the highest RP IP address is chosen as the active RP.

You cannot configure the C-RP priority. Each RP has a default C-RP priority value of 0, and the algorithm uses the RP if the group address maps to the grp-prefix that you configure for that RP. If a different router in the network has a C-RP priority value greater than 0, the switch uses this part of the algorithm in the RP election process.

Currently, you cannot configure the hash mask used in the hash algorithm. Unless you configure a different PIM BSR in the network with a nondefault hash mask value, the default hash mask of 255.255.255.252 is used. Static RP configurations do not use the BSR hash mask; they use the default hash mask.

For example:

RP1 = 128.10.0.54 and RP2 = 128.10.0.56. The group prefix for both RPs is 238.0.0.0/255.0.0.0. Hash mask = 255.255.255.252.

The hash function assigns the groups to RPs in the following manner:

The group range 238.1.1.40 to 238.1.1.51 (12 consecutive groups) maps to 128.10.0.56. The group range 238.1.1.52 to 238.1.1.55 (4 consecutive groups) maps to 128.10.0.54. The group range 238.1.1.56 to 238.1.1.63 (8 consecutive groups) maps to 128.10.0.56.

### PIM-SM Receivers and VLANs

Some designs cause unnecessary traffic flow on links in a PIM-SM domain. In these cases, traffic is not duplicated to the receivers, but wastes bandwidth.

The following figure shows such a situation. Switch B is the DR between switches A and B. Switch C is the RP. A receiver R is on the VLAN (V1) that connects switches A and B. A source sends multicast data to the receiver.

IGMP reports that the messages that the receiver sends are forwarded to the DR, and both A and B create (\*,G) records. Switch A receives duplicate data through the path

from C to A, and through the second path from C to B to A. Switch A discards the data on the second path (assuming the upstream source is A to C).

To avoid this waste of resources, do not place receivers on V1. This configuration guarantees that no traffic flows between B and A for receivers attached to A. In this case, the existence of the receivers is only learned through PIM join messages to the RP [for (\*,G)] and of the source through SPT joins.

### **PIM Network with Non-PIM Interfaces**

For proper multicast traffic flow in a PIM-SM domain, as a general rule, enable PIM-SM on all interfaces in the network (even if paths exist between all PIM interfaces). Enable PIM on all interfaces because PIM-SM relies on the unicast routing table to determine the path to the RP, BSR, and multicast sources. Ensure that all routers on these paths have PIM-SM enabled interfaces.

The following figure provides an example of this situation. If A is the RP, then initially the receiver receives data from the shared tree path (that is, through switch A).

If the shortest path from C to the source is through switch B, and the interface between C and B does not have PIM-SM enabled, then C cannot switch to the SPT. C discards data that comes through the shared path tree (that is, through A). The simple workaround is to enable PIM on VLAN1 between C and B.

### Source Filtering

The system can report interest in receiving packets from only a specific source address (INCLUDE), from all but specific source addresses (EXCLUDE), or sent to specific multicast addresses. IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

#### *Protocol Independent Multicast-Source Specific Multicast guidelines*

PIM-Source Specific Multicast (SSM) is a one-to-many model that uses a subset of the PIM-SM features. In this model, members of an SSM group can only receive multicast traffic from a specific source or sources, which is more efficient and puts less load on multicast routing devices.

IGMPv3 supports PIM-SSM by enabling a host to selectively request traffic from individual sources within a multicast group. The system can report interest in receiving packets from only specific source addresses (INCLUDE). IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

### IGMPv2 SSM extensions

VSP 4450 Series processes messages according to the following rules:

- After IGMPv3 receives an IGMPv2 report in the SSM range, the system translates the report to an IGMPv3 report message.
- After an IGMPv2 router sends queries on an IGMPv3 interface, the switch downgrades this interface to IGMPv2 (backward compatibility).

This can cause traffic interruption, but the switch recovers quickly.

### PIM-SSM design considerations

Use the following information when you design an SSM network:

- If you configure SSM, it affects SSM groups only. The switch handles other groups in sparse mode (SM) if a valid RP exists on the network.
- You can configure PIM-SSM only on switches at the edge of the network. Core switches use PIM-SM if they do not have receivers for SSM groups.
- For networks where group addresses are already in use, you can change the SSM range to match the groups.
- One switch has a single SSM range.
- You can have different SSM ranges on different switches.

Configure the core switches that relay multicast traffic so that they cover all of these groups in their SSM range, or use PIM-SM.

- One group in the SSM range can have multiple sources for a given SSM group.

### *Multicast for Multimedia*

The switch provides a flexible and scalable multicast implementation for multimedia applications. Several features are dedicated to multimedia applications and in particular to television distribution.

#### Join and leave performance

For TV applications, you can attach several TVs directly to the switch, or through an IGMP-capable Ethernet switch. Base this implementation on IGMP; the set-top boxes use IGMP reports to join a TV channel and IGMP leaves to exit the channel. After a viewer changes channels, the switch issues an IGMPv2 leave for the old channel (multicast group), and sends a membership report for the new channel. If viewers change channels continuously, the number of joins and leaves can become large, particularly if many viewers attach to the switch.

The switch supports more than a thousand joins and leaves per second, which is well adapted to TV applications.

#### **Important**

For IGMPv3, ensure a join rate of 1000 per second or less. This ensures the timely processing of join requests.

If you use the IGMP proxy functionality at the receiver edge, you reduce the number of IGMP reports received by switch. This provides better overall performance and scalability.

### **Fast Leave**

IGMP Fast Leave supports two modes of operation: single-user mode and multiple-user mode.

In single-user mode, if more than one member of a group is on the port and one of the group members leaves the group, everyone stops receiving traffic for this group. Single-user mode does not send a group-specific query before the effective leave takes place.

Multiple-user mode allows several users on the same port or VLAN. If one user leaves the group and other receivers exist for the same stream, the stream continues. The switch tracks the number of receivers that join a given group. For multiple-user mode to operate properly, do not suppress reports. This ensures that the switch properly tracks the correct number of receivers on an interface.

The Fast Leave feature is particularly useful in IGMP-based TV distribution where only one receiver of a TV channel connects to a port. If a viewer changes channels quickly, you create considerable bandwidth savings if you use Fast Leave.

You can implement Fast Leave on a VLAN and port combination; a port that belongs to two different VLANs can have Fast Leave enabled on one VLAN (but not on the other). Thus, with the Fast Leave feature enabled, you can connect several devices on different VLANs to the same port. This strategy does not affect traffic after one device leaves a group to which another device subscribes. For example, you can use this feature when two TVs connect to a port through two set-top boxes, even if you use the single-user mode.

To use Fast Leave, you must first enable explicit host tracking. IGMP uses explicit host tracking to track all source and group members. Explicit host tracking is disabled by default. For configuration information, see [Configuring Fast Leave Mode](#) on page 1770.

### **Last member query interval tuning**

If an IGMPv2 host leaves a group, it notifies the router by using a leave message. Because of the IGMPv2 report suppression mechanism, the router cannot access information of other hosts that require the stream. Thus, the router broadcasts a group-specific query message with a maximum response time equal to the last member query interval (LMQI).

Because this timer affects the latency between the time that the last member leaves and the time the stream actually stops, you must properly tune this parameter. This timer can especially affect TV delivery or other large-scale, high-bandwidth multimedia applications. For instance, if you assign a value that is too low, this can lead to a storm of membership reports if a large number of hosts are subscribed. Similarly, assigning a value that is too high can cause unwanted high-bandwidth stream propagation across the network if users change channels rapidly. Leave latency also depends on the robustness value, so a value of 2 equates to a leave latency of twice the LMQI.

Determine the proper LMQI value for your particular network through testing. If a very large number of users connect to a port, assigning a value of 3 can lead to a storm of report messages after a group-specific query is sent. Conversely, if streams frequently start and stop in short intervals, as in a TV delivery network, assigning a value of 10 can lead to frequent congestion in the core network.

Another performance-affecting factor that you need to be aware of is the error rate of the physical medium. For links that have high packet loss, you can find it necessary to adjust the robustness variable to a higher value to compensate for the possible loss of IGMP queries and reports.

In such cases, leave latency is adversely affected as numerous group-specific queries are unanswered before the stream is pruned. The number of unanswered queries is equal to the robustness variable (default 2). The assignment of a lower LMQI can counterbalance this effect. However, if you configure the LMQI too low, it can actually exacerbate the problem by inducing storms of reports on the network. LMQI values of 3 and 10, with a robustness value of 2, translate to leave latencies of 6/10 of a second and 2 seconds, respectively.

When you choose an LMQI, consider all of these factors to determine the best configuration for the given application and network. Test that value to ensure that it provides the best performance.

#### **Important**

In networks that have only one user connected to each port, use the Fast Leave feature instead of LMQI, because no wait is required before the stream stops. Similarly, the robustness variable does not affect the Fast Leave feature, which is an additional benefit for links with high loss.

### *Layer 3 switch clustering and multicast SMLT*

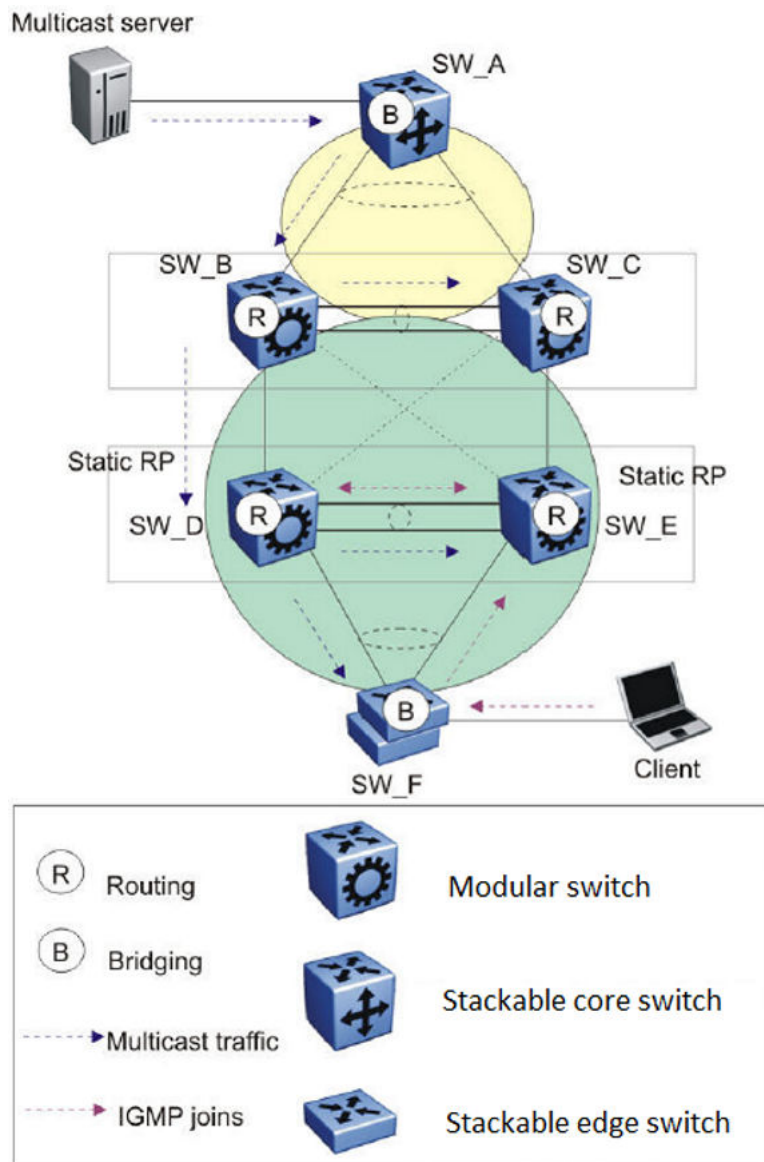

Switch clustering is the logical aggregation of two nodes to form one logical entity known as the switch cluster. The two peer nodes in a switch cluster connect using a virtual interswitch trunk (vIST). The vIST exchanges forwarding and routing information between the two peer nodes in the cluster. This section provides guidelines for switch clusters that use multicast and Split Multilink Trunking (SMLT).

#### **General guidelines**

The following list identifies general guidelines to follow if you use multicast and switch clustering:

- Enable Protocol Independent Multicast - Sparse Mode (PIM-SM) on the vIST VLAN for fast recovery of multicast. A unicast routing protocol is not required.
- Enable Internet Group Management Protocol (IGMP) snooping and proxy on the edge switches.

The following figure shows multicast behavior in an SMLT environment. The configuration in the following figure provides fast failover if the switch or rendezvous point (RP) fails.

**Figure 148: Multicast behavior in SMLT environment**

In Multicast behavior in SMLT environment the following actions occur:

1. The multicast server sends multicast data towards the source designated router (DR).
2. The source DR sends register messages with encapsulated multicast data towards the RP.
3. After the client sends IGMP membership reports towards the multicast router, the router creates a (\*,G) entry.
4. The RP sends join messages towards the source DR on the reverse path.
5. After the source DR receives the join messages, it sends native multicast traffic.
6. After SW\_B or SW\_D receives multicast traffic from upstream, it forwards the traffic on the vIST as well as on the SMLT link. Other aggregation switches drop multicast

traffic received over the vIST at egress. This action provides fast failover for multicast traffic. Both SW\_D and SW\_E (Aggregation switches) have similar (S,G) records.

7. In case of SW\_D or RP failure, SW\_B changes only the next-hop interface towards SW\_E. Because the circuitless IP (CLIP) RP address is the same, SW\_B does not flush (S,G) entries and achieves fast failover.

### Multicast triangle topology

A triangle design is an SMLT configuration that connects edge switches or SMLT clients to two aggregation switches. Connect the aggregation switches together with a vIST that carries all the SMLT trunks configured on the switches.

The switch supports the following triangle configurations:

- a configuration with Layer 3 PIM-SM routing on both the edge and aggregation switches
- a configuration with Layer 2 snooping on the client switches and Layer 3 routing with PIM-SM on the aggregation switches

To avoid using an external query device to provide correct handling and routing of multicast traffic to the rest of the network, use the triangle design with IGMP Snoop at the client switches. Use multicast routing at the aggregation switches as shown in the following figure.

**Figure 149: Multicast routing using PIM-SM**

Client switches run IGMP Snoop or PIM-SM, and the aggregation switches run PIM-SM. This design is simple and, for the rest of the network, PIM-SM performs IP multicast routing. The aggregation switches are the query devices for IGMP, so an external query device is not required to activate IGMP membership. These switches also act as redundant switches for IP multicast.

Multicast data flows through the vIST link when receivers are learned on the client switch and senders are located on the aggregation switches, or when sourced data

comes through the aggregation switches. This data is destined for potential receivers attached to the other side of the vIST. The data does not reach the client switches through the two aggregation switches because only the originating switch forwards the data to the client switch receivers.

#### Note

Always place multicast receivers and senders on the core switches on VLANs different from those that span the vIST.

The following figure shows a switch clustering configuration with a single switch cluster core and dual-connected edge devices. This topology represents different VLANs spanning from each edge device and those VLANs routed at the switch cluster core. You can configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster core.

**Figure 150: Multicast SMLT triangle**

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either Virtual Router Redundancy Protocol (VRRP) BackupMaster or Routed SMLT (RSMLT) Layer 2 Edge on the switch cluster core.

#### Square and full-mesh topology multicast guidelines

A square design connects a pair of aggregation switches to another pair of aggregation switches. A square design becomes a full-mesh design if the aggregation switches are connected in a full-mesh. The switch supports Layer 3 IP multicast (PIM-SM only) over a full-mesh SMLT or RSMLT configuration.

In a square design, configure all switches with PIM-SM. Place the bootstrap router (BSR) and RP in one of the four core switches; and place the RP closest to the source. If using PIM-SM over a square or full-mesh configuration, enable the `multicast smlt-square` flag.

The following three figures show switch clustering configurations with two-switch cluster cores and dual-connected edge devices.

**Figure 151: Multicast SMLT square 1**

In the preceding figure, only one of the switch cluster cores performs Layer 3 multicast routing while the other is strictly Layer 2. Configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster cores.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster core.

**Figure 152: Multicast SMLT square 2**

In the preceding figure, both of the switch cluster cores performs Layer 3 multicast routing, while the edge devices are Layer 2 IGMP.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

**Figure 153: Multicast SMLT square 3**

In the preceding figure, both of the switch cluster cores and the edge devices perform Layer 3 multicast routing.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

#### SMLT and multicast traffic issues

If PIM-SM or other multicast protocols are used in an SMLT environment, enable the protocol on the vIST. Routing protocols in general are not run over an vIST but multicast routing protocols are an exception. When using PIM-SM and a unicast routing protocol, ensure the unicast route to the BSR and RP has PIM-SM active and enabled. If multiple OSPF paths exist and PIM-SM is not active on each pair, the BSR is learned on a path that does not have PIM-SM active. The following figure demonstrates this issue.

**Figure 154: Unicast route example**

The network configuration in the preceding figure is as follows:

- 5510A is on VLAN 101.
- 5510B is on VLAN 102.
- Switch B is the BSR.
- Switch A and Switch B have OSPF enabled.
- PIM is enabled and active on VLAN 101.
- PIM is either disabled or passive on VLAN 102.

In this example, the unicast route table on Switch A learns the BSR on Switch B through VLAN 102 using OSPF. The BSR is either not learned or does not provide the RP to Switch A.

## Protocol Independent Multicast over IPv6

**Table 132: PIM over IPv6 product support**

| Feature       | Product         | Release introduced |
|---------------|-----------------|--------------------|
| PIM over IPv6 | 5320 Series     | Fabric Engine 8.6  |
|               | 5420 Series     | VOSS 8.4           |
|               | 5520 Series     | VOSS 8.2.5         |
|               | 5720 Series     | Fabric Engine 8.7  |
|               | 7520 Series     | Fabric Engine 8.10 |
|               | 7720 Series     | Fabric Engine 8.10 |
|               | VSP 4450 Series | VOSS 5.1           |
|               | VSP 4900 Series | VOSS 8.1           |
|               | VSP 7200 Series | VOSS 5.1           |
|               | VSP 7400 Series | VOSS 8.0           |
|               | VSP 8200 Series | VOSS 5.1           |
|               | VSP 8400 Series | VOSS 5.1           |
|               | VSP 8600 Series | Not Supported      |
|               | XA1400 Series   | Not Supported      |

**Note**

PIM is supported in Global Routing Table (GRT) only.

Several multicast protocols are used to enable IP multicast.

Hosts use the Internet Group Management Protocol (IGMP) for IPv4 and Multicast Listener Discovery (MLD v1/v2) for IPv6 to report multicast group memberships of directly attached multicast listeners to neighboring multicast routers. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4.

Routers use Protocol Independent Multicast-Sparse Mode (PIM-SM) and PIM source Specific Mode (SSM) to exchange multicast routing information. The PIM-SM protocol is the multicast routing protocol that uses the underlying unicast routing information base to build unidirectional shared trees to group members rooted at the RP per group, and creates shortest-path trees (SPT) per source. The router forwards multicast packets along these trees. PIM-SSM does not require RP and only supports SPT.

PIM over IPv6 uses the IPv6 unicast routing table for reverse path information about source and RP.

**Note**

IPv4 and IPv6 multicast streams cannot interact. To configure an end-to-end PIM IPv6 network, all nodes from sender to receiver must support PIM IPv6.

### *PIM-SM over IPv6 features*

The following are features of PIM-SM over IPv6:

- Compliant with RFC 4601
- Multicast networks built by PIM IPv4 and PIM IPv6 do not overlap
- IPv4 receiver hosts cannot receive data from IPv6 source hosts and vice versa
- IPv4 and IPv6 multicast protocols can be enabled at the same time on the same VLAN
- PIM IPv4 and PIM IPv6 can be configured on the same VLAN
- PIM IPv4 and PIM IPv6 must be configured separately
- Supports sparse and ssm modes

### *Operational note for PIM-SM over IPv6*

The following are operational considerations when deploying PIM-SM over IPv6:

- You can only configure PIM-SM if you configure the `spbm_config_mode` boot flag to false.
- The following HELLO messages options are not supported:
  - GENid
  - DR priority
  - LAN-PRUNE delay
  - T-bit
- IPv6 multicast is not supported over SPBM
- IPv6 multicast routing is not virtualized, it is supported only on GRT
- IPv6 multicast configuration on SMLT VLAN is not supported. vIST peers cannot form PIM-SM over IPv6 neighbor adjacencies. Senders and receivers on the vIST peers (SMLT and non-SMLT) cannot communicate. MLT and LACP is supported.
- The switch does not support the following features:
  - Static entries
  - Bootstrap message (BSR)
  - Anycast RP
  - Virtual PIM neighbors
  - Fast join prune
  - Software forwarding
  - Passive PIM interfaces
  - IP mroute stream limit
  - Bidirectional PIM
  - Multicast Border Router (PMBR)
  - VRF support for PIM (GRT only)
  - IGMP and PIM mtrace capability

### *IPv6 interface multiple addresses*

IPv6 interfaces can have multiple addresses associated with them. A router running PIM for IPv6 has a network unique domain-wide reachable IPv6 VLAN address used

for multiple hop messages. A link local address is associated with the VLAN. The link local address is a non-routable unicast IPv6 address used as source address (primary interface address) for transmitting different types of PIM messages.

## IP multicast configuration and DvR

Configuration of IPv4 multicast is supported only on the Controller nodes of a DvR domain. You cannot configure IP multicast on the DvR Leaf nodes. The following sections detail IP multicast configuration support on DvR enabled nodes (Controllers or Leaf nodes).

For more information on DvR, see [Distributed Virtual Routing Fundamentals](#) on page 743.

### *Multicast configuration that is pushed from DvR Controllers to DvR Leaf nodes*

When you perform the following multicast configuration on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- IP multicast over Fabric Connect
- IGMP Layer 2 Querier parameters, such as the IGMP Layer 2 Querier version, query interval, query maximum response time, robustness value, last member query interval and compatibility mode
- Enabling and clearing of multicast route statistics

### *Multicast configuration that is not supported on DvR enabled Layer 2 VSNs*

- IGMP Snooping on DvR enabled Layer 2 VSNs
- SPB-PIM Gateway

For more information on SPB-PIM Gateway, see [SPB-PIM Gateway configuration](#) on page 3473.

## IP multicast basic configuration using CLI

---

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts subscribe to multicast services using a host membership protocol. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

## Configuring IP multicast in SMLT topologies

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then

configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

### Before You Begin

SPBM must not be enabled on the vIST peers or any router that participates in the PIM network.

### About This Task

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable the boot flag:

```
no boot config flags spbm-config-mode
```

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this  
to take effect.
```

```
Warning: Please carefully save your configuration file before  
rebooting the switch. Saving configuration file when spbm-config-  
mode is changed to disable, removes SPBM configurations from the  
configuration file.
```

3. Save the configuration and, then reboot the switch.

#### Important

Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.

4. Create the vIST VLAN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

```
interface vlan <1-4059>
```

```
ip address <A.B.C.D/X>
```

5. Configure the vIST peer address and VLAN:

```
virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
```

6. Configure the SMLT MLT:

```
mlt <1-512> enable
```

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

```
interface mlt <1-512>
```

```
smlt
```

7. Configure the vIST MLT:

```
mlt <1-512> enable
```

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

```
mlt <1-512> encapsulation dot1q
```

```
interface mlt <1-512>
```

```
virtual-ist enable
```

#### Note

The **virtual-ist enable** command enables Simplified vIST and is only available when the **spbm-config-mode** boot flag is disabled.

8. Create a customer VLAN and assign the SMLT MLT ID:

```
vlan create <2-4059>
```

```
vlan mlt <1-4059> <1-512>
```

```
interface vlan <1-4059>
```

```
ip address <A.B.C.D/X>
```

9. Configure PIM or IGMP Snooping on the SMLT VLAN:

```
interface vlan <1-4059>
```

```
ip pim enable or ip igmp snooping
```

10. Configure PIM on the vIST VLAN:

```
interface vlan <1-4059>
```

```
ip pim enable
```

## 11. Enable PIM globally:

```
ip pim enable
```

### Note

You can also configure other global PIM attributes such as **ip pim join-prune-interval**.

## Example

```
enable
configure terminal
no boot config flags spbm-config-mode
```

Save the configuration and reboot the switch.

```
virtual-ist peer-ip 198.51.100.0 vlan 50

mlt 3 enable
mlt 3 member 1/35,1/36
interface mlt 3
smlt
exit
mlt 5 enable
mlt 5 member 2/15,2/17
mlt 5 encapsulation dot1q
interface mlt 5
virtual-ist enable
exit
vlan create 50 type port-mstprstp 0
interface vlan 50
ip address 198.51.100.0 255.255.255.0 1
exit
vlan create 100
vlan mlt 100 3
interface vlan 100
ip address 192.0.2.0 255.255.255.0 2
exit
interface vlan 100
ip pim enable (or ip igmp snooping)
exit
interface vlan 50
ip pim enable
exit
ip pim enable
```

## Configure PIM-SM Globally

Configure PIM-SM to enable or disable PIM-SM globally on the switch and change default global parameters.

## Before You Begin

### Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

## About This Task

PIM-SM is the default mode so you do not need to configure the PIM mode.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable PIM-SM:  
`ip pim enable`
3. Configure the time between bootstrap messages:  
`ip pim bootstrap-period <5-32757>`
4. Configure the timeout to discard data:  
`ip pim disc-data-timeout <5-65535>`
5. Enable the fast join prune interval:  
`ip pim fast-joinprune`
6. Configure the forward cache timeout:  
`ip pim fwd-cache-timeout <10-86400>`
7. Configure the interval for join and prune messages:  
`ip pim join-prune-interval <1-18724>`
8. Specify how long to suppress register messages:  
`ip pim register-suppression-timeout <6-65535>`
9. Specify how often the candidate-redirect point (C-RP) sends advertisements:  
`ip pim rp-c-adv-timeout <5-26214>`
10. Configure PIM Infinite Threshold Policy:
  - a. Disable PIM-SM.  
`no pim enable`
  - b. Enable PIM Infinite Threshold Policy:  
`ip pim spt-infinite-threshold`
  - c. Enable PIM-SM:  
`ip pim enable`
11. Configure the polling interval for the routing table manager (RTM):  
`ip pim unicast-route-change-timeout <2-65535>`

## 12. Verify the configuration changes:

```
show ip pim
```

**Example**

Verify the configuration changes:

```
Switch:1(config)#show ip pim
```

```
Switch:1#show ip pim
=====
                          Pim General Group - GlobalRouter
=====
PimStat           : disabled
Mode              : sparse
StaticRP          : disabled
FastJoinPrune    : disabled
SptInfiniteThreshold : enabled
BootstrapPeriod   : 60
CRPAdvTimeout    : 60
DiscDataTimeout  : 60
FwdCacheTimeout  : 210
RegSupprTimeout  : 60
UniRouteChangeTimeout : 5
JoinPruneInt     : 60
```

*Variable Definitions*

The following table describes the variables for the **ip pim** command.

| Variable                      | Value                                                                                                                                                                                                                                                                                              |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disc-data-timeout <5-65535>   | Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message.<br>The default value is 60. |
| bootstrap-period              | Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages. The range is from 5–32757 and the default is 60 seconds.                                                                                                                                    |
| enable                        | Enables PIM globally on the switch.<br>The default is disabled.                                                                                                                                                                                                                                    |
| fast-joinprune                | Enables or disables the PIM fast join prune feature.                                                                                                                                                                                                                                               |
| fwd-cache-timeout <10-86400>  | Specifies the forward cache timeout value.<br>The default value is 120.                                                                                                                                                                                                                            |
| join-prune-interval <1-18724> | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The default value is 60.                                                                                                                                            |

| Variable                                | Value                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode <sparse> <ssm>                     | Configures PIM mode on the switch. The default value is sparse.                                                                                                                                                                                                                                           |
| register-suppression-timeout <10-65535> | Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP. The default value is 60.                                                                                                 |
| rp-c-adv-timeout                        | Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR). The range is from 5–26214 and the default is 60 seconds. |
| spt-infinite-threshold                  | Enables PIM Infinite Threshold Policy for IPv4, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT). The default is disabled.                                                                      |
| static-rp                               | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.                                                                                             |
| unicast-route-change-timeout <2-65535>  | Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM. The default value is 5.                                                                                                                                                                       |
| virtual-neighbor                        | Specifies to enter virtual neighbor IP to an interface globally.                                                                                                                                                                                                                                          |

## Enable IPv6 PIM-SM Globally

### About This Task

Use this procedure to enable IPv6 PIM-SM globally. By default, IPv6 PIM-SM is disabled.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable IPv6 PIM-SM:

```
ipv6 pim enable
```

## Configure Global IPv6 PIM-SM Properties

### Before You Begin

#### Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM

### About This Task

Use this procedure to configure the global IPv6 PIM-SM parameters on the switch.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the timeout to discard data:  
`ipv6 pim disc-data-timeout <5-65535>`
3. Configure the forward cache timeout:  
`ipv6 pim fwd-cache-timeout <10-86400>`
4. Configure the interval for join and prune messages:  
`ipv6 pim join-prune-interval <1-18724>`
5. Specify how long to suppress register messages:  
`ipv6 pim register-suppression-timeout <10-65535>`
6. Configure PIM Infinite Threshold Policy:  
`ipv6 pim spt-infinite-threshold`
7. Configure the polling interval for the routing table manager (RTM):  
`ipv6 pim unicast-route-change-timeout <2-65535>`
8. Configure the PIM mode:  
`ipv6 pim mode <sparse> <ssm>`
9. Verify the configuration changes:  
`show ipv6 pim`

### Example

Verify the configuration changes:

```
Switch:1#show ipv6 pim
=====
                          Pim General Group - GlobalRouter
=====
PimStat                   : enabled
Mode                      : sparse
StaticRP                  : disabled
SptInfiniteThreshold     : enabled
```

```

FwdCacheTimeout      : 210
DiscDataTimeout      : 60
RegSupprTimeout      : 60
UniRouteChangeTimeout : 5
JoinPruneInt         : 60

```

### Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

| Variable                                | Value                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disc-data-timeout <5-65535>             | Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message.<br>The default value is 60. |
| enable                                  | Enables PIM globally on the switch.<br>The default is disabled.                                                                                                                                                                                                                                    |
| fwd-cache-timeout <10-86400>            | Specifies the forward cache timeout value.<br>The default value is 120.                                                                                                                                                                                                                            |
| join-prune-interval <1-18724>           | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The default value is 60.                                                                                                                                            |
| mode <sparse> <ssm>                     | Configures PIM mode on the switch.<br>The default value is sparse.                                                                                                                                                                                                                                 |
| register-suppression-timeout <10-65535> | Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP.<br>The default value is 60.                                                                                       |
| spt-infinite-threshold                  | Enables PIM Infinite Threshold Policy for IPv6, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT).<br>The default is disabled.                                                            |
| static-rp                               | Add new static-rp entries and enable static-rp.                                                                                                                                                                                                                                                    |
| unicast-route-change-timeout <2-65535>  | Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM.<br>The default value is 5.                                                                                                                                                             |

## Configure PIM on a VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you configure PIM on a VLAN.
- The interface uses a valid IP address.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Create a PIM interface on a VLAN:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

5. Verify the configuration:

```
show ip pim interface vlan [<1-4059>]
```

### Example

Configure the interval for join and prune messages, the time between hello messages, and then verify the configuration.

```
Switch:1(config-if)#ip pim join-prune-interval 60
Switch:1(config-if)#ip pim hello-interval 30
Switch:1>show ip pim interface vlan 10
=====
                        Vlan Ip Pim
=====
VLAN-ID   PIM-ENABLE MODE   HELLOINT  JPINT   CBSRPREF   INTF TYPE
-----
10        enable   sparse  30      60      -1 (disabled) active
```

## Configuring PIM on a port

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you configure it on an interface.

- The interface uses a valid IP address.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

### Example

Configure the interval for join and prune messages and the time between hello messages:

```
Switch(config-if)#ip pim join-prune-interval 60  
Switch(config-if)#ip pim hello-interval 30
```

## Configuring IPv6 PIM on a port or VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- Enable IPv6 interface.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port or VLAN:

```
ipv6 pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ipv6 pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ipv6 pim hello-interval <0-18724>
```

## Example

```
Switch:1(config-if)#ipv6 pim join-prune-interval 60
Switch:1(config-if)#ipv6 pim hello-interval 30
```

## Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

| Variable                             | Value                                                                                                                                                        |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hello-interval</i> <0-18724>      | Specifies the duration in seconds before the PIM router sends out the next hello message to neighboring switches. The default value is 30 seconds.           |
| <i>join-prune-interval</i> <1-18724> | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors. The default value is 60 seconds. |

## Configuring SSM globally

Configure SSM to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Before You Begin

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using CLI](#) on

page 3063. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2685.

- Enable PIM globally.

### About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure PIM-SSM:

```
ip pim mode ssm
```

## Configuring IPv6 SSM globally

Configure IPv6 SSM to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 3073.

For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2730.

- Enable IPv6 PIM globally.

### About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model which requires only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure IPv6 PIM-SSM:

```
ipv6 pim mode ssm
```

## Configuring IGMP on a VLAN

Configure IGMP for each interface to change default multicasting operations.

### Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

For more information on DvR, see .

### Before You Begin

- For PIM interfaces, you must enable PIM globally and on the VLAN. For snooping interfaces, do not enable PIM.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable IGMP v2-v3 compatibility mode:

```
ip igmp compatibility-mode
```

3. Configure the system to downgrade the version of IGMP:

```
ip igmp dynamic-downgrade-version
```

4. Configure message intervals and response times:

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]  
[query-max-response <0-255>]
```

5. Configure expected packet loss and IGMP version:

```
ip igmp robust-value <2-255> [version <1-3>]
```

6. Add multicast router ports:

```
ip igmp mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. Enable proxy-snoop:

```
ip igmp proxy
```

8. Enable router alert:

```
ip igmp router-alert
```

9. Enable snooping:

```
ip igmp snooping
```

10. Enable SSM-snooping:

```
ip igmp ssm-snoop
```

## Example

Enter VLAN Interface Configuration Mode for VLAN 10:

```
Switch:1(config)# interface vlan 10
```

Configure the last member query interval to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp last-member-query-interval 15
```

Configure the query interval to 100 seconds.

```
Switch:1(config-if)# ip igmp query-interval 100
```

Configure the query maximum response time to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp query-max-response 15
```

Configure the robustness value to 4 seconds.

```
Switch:1(config-if)# ip igmp robust-value 4
```

Enable proxy snoop for the VLAN.

```
Switch:1(config-if)# ip igmp proxy
```

Enable snoop for the VLAN.

```
Switch:1(config-if)# ip igmp snooping
```

Enable support for SSM on the snoop interface.

```
Switch:1(config-if)# ip igmp ssm-snoop
```

Enable IGMPV3.

```
Switch:1(config-if)# ip igmp version 3
```

## Variable Definitions

Use the definitions in the following table to use the `ip igmp` command.

| Variable                                                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>access-list WORD&lt;1-64&gt; {A.B.C.D/X} &lt;eny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both&gt;</code> | Specifies the name of the access list from 1–64 characters.<br>Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.<br>Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                                    |
| <code>compatibility-mode</code>                                                                                                    | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br><code>default ip igmp compatibility-mode</code><br>, or use the no option to disable compatibility mode:<br><code>no ip igmp compatibility-mode</code>                                                                                                                                                                                                                                    |
| <code>dynamic-downgrade-version</code>                                                                                             | Configures the version of IGMP to handle older query messages if the system downgrades. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br><code>default ip igmp dynamic-downgrade-version</code><br>or use the no option to disable downgrade:<br><code>no ip igmp dynamic-downgrade-version</code> |
| <code>igmpv3-explicit-host-tracking</code>                                                                                         | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>snoop-querier-addr {A.B.C.D}</code>                                                                                | Specifies the IGMP Layer 2 Querier source IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>snooping</code>                                                                                                    | Activates the snoop option for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>ssm-snoop</code>                                                                                                   | Activates support for PIM-SSM on the snoop interface.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>static-group {A.B.C.D} {A.B.C.D} {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static blocked]</code>     | Configures IGMP static members to add members to a snoop group. <code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group. <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry. <code>[static blocked]</code> configures the route to static or blocked.                                                                                                                                           |
| <code>stream-limit stream-limit-max-streams &lt;0-65535&gt;</code>                                                       | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |
| <code>stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams &lt;0-65535&gt;</code> | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4.                                                                                                                                                                                                                                                                                                  |
| <code>version &lt;1-3&gt;</code>                                                                                         | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).                                                                                                                                                                                                                                                                                                                        |

## Configure IGMP Ports

Configure IGMP for each interface to change default multicasting operations.

### Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- `ip igmp version`
- `ip igmp query-interval`
- `ip igmp query-max-response`
- `ip igmp robust-value`
- `ip igmp last-member-query-interval`
- `ip igmp compatibility-mode`

For more information on DvR, see [Distributed Virtual Routing](#) on page 738.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IGMP v2-v3 compatibility mode:

```
ip igmp compatibility-mode
```

3. Configure the system to downgrade the version of IGMP:

```
ip igmp dynamic-downgrade-version
```

4. Configure message intervals and response times:

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]
[query-max-response <0-255>]
```

5. Configure expected packet loss and IGMP version:

```
ip igmp robust-value <2-255> [version <1-3>]
```

6. Configure IGMP for a specific port:

```
ip igmp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. Enable router alert:

```
ip igmp router-alert
```

## Example

Configure message intervals and response times:

```
Switch(config-if)#ip igmp last-member-query-interval 30 query-interval 60 query-max-response 90
```

Configure expected packet loss and IGMP version:

```
Switch(config-if)#ip igmp robust-value 2 version 3
```

Configure IGMP for a specific port:

```
Switch(config-if)#ip igmp port 1/4
```

Enable router alert:

```
Switch(config-if)#ip igmp router-alert
```

## Variable definitions

Use the definitions in the following table to use the **ip igmp** command.

| Variable                                                                                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list WORD&lt;1-64&gt; {A.B.C.D/X} &lt;deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both&gt;</i> | Specifies the name of the access list from 1–64 characters.<br>Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.<br>Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                          |
| <i>compatibility-mode</i>                                                                                                     | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br>default ip igmp compatibility-mode<br>, or use the no option to disable compatibility mode:<br>no ip igmp compatibility-mode                                                                                                                                                                                                                                    |
| <i>dynamic-downgrade-version</i>                                                                                              | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br>default ip igmp dynamic-downgrade-version<br>or use the no option to disable downgrade:<br>no ip igmp dynamic-downgrade-version |

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>igmpv3-explicit-host-tracking</code>                              | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>immediate-leave</code>                                            | Enables fast leave on a port.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>last-member-query-interval &lt;0-255&gt;</code>                   | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3–10 (equal to 0.3 – 1.0 seconds). |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Configures IGMP for a specific port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                     |
| <code>query-interval &lt;1-65535&gt;</code>                             | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.                                                                                                                                                                                                                                                                                                                                                |
| <code>query-max-response &lt;0-255&gt;</code>                           | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the query-interval.                                                                                          |
| <code>robust-value &lt;2-255&gt;</code>                                 | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.                                                                                                                                                                                                                                                                                                              |

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>router-alert</code>                                          | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <code>stream-limit stream-limit-max-streams &lt;0-65535&gt;</code> | Configures multicast stream limitation on a port to limit the number of concurrent multicast streams on the port. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |
| <code>version &lt;1-3&gt;</code>                                   | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).                                                                                                                                                                                                                                                                                                                        |

## Configuring IGMP on a VRF

You configure IGMP on a VRF instance the same way you configure IGMP for the Global Router, except that you must use VRF Router Configuration mode.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Enable SSM dynamic learning:

```
ip igmp ssm dynamic-learning
```

3. Configure the range group:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter *y* to continue.

4. Enable the SSM map table for all static entries:

```
ip igmp ssm-map all
```

## 5. Create a static entry for a specific group:

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

## 6. Enable the generation of IGMP traps:

```
ip igmp generate-trap
```

## 7. Enable the generation of IGMP log messages:

```
ip igmp generate-log
```

## 8. Configure the fast leave mode:

```
ip igmp immediate-leave-mode {multiple-user|one-user}
```

### Example

For the VRF Red context, configure a new IP multicast group address and create an SSM map table entry for the multicast group and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ip igmp ssm group-range 232.1.1.10/32

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(router-vrf)#ip igmp ssm-map 232.1.1.10 192.32.99.151
Switch:1(router-vrf)#ip igmp ssm-map all
```

### Variable definitions

Use the definitions in the following table to use the **ip igmp** command on a VRF.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>generate-log</i>                                            | Enables the generation of IGMP log messages. The default is disabled.                                                                                                                                                                                                                                              |
| <i>generate-trap</i>                                           | Enables the generation of IGMP traps. The default is disabled.                                                                                                                                                                                                                                                     |
| <i>immediate-leave-mode</i><br><i>{multiple-user one-user}</i> | <ul style="list-style-type: none"> <li>• multiple-user: Removes (from the group) the IGMP member who sent the leave message. The default is multiple-user.</li> <li>• one-user: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member.</li> </ul> |
| <i>ssm dynamic-learning</i>                                    | Enables dynamic learning from IGMPv3 reports. The default is enabled.                                                                                                                                                                                                                                              |

| Variable                                                                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ssm group-range</code><br><code>{A.B.C.D/X}</code>                                                  | Changes the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0.                                                                                                                       |
| <code>ssm-map &lt;all</code><br><code>  {A.B.C.D}</code><br><code>{A.B.C.D}</code><br><code>enable</code> | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group. Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

## View IP Multicast Threshold Exceeded Statistics

This procedure does not apply to XA1400 Series or VSP 8600 Series.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

```
show sys stats ipmc-threshold-exceeded-cnt
```

### Example

```
Switch:1>show sys stats ipmc-threshold-exceeded-cnt
SourceGroupThresholdExceeded : 7372
EgressStreamThresholdExceeded : 7331
```

## IP multicast basic configuration using EDM

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts use a host membership protocol to subscribe to multicast services. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

## Configuring multicast on the switch

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then

configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

### Before You Begin

SPBM must not be enabled on the vIST peers or any router participating in the PIM network.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit > Chassis** folders.
2. Click the **Boot Config** tab.
3. Clear the **EnableSpbmConfigMode** to disable the boot flag.

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-
mode is changed to disable, removes SPBM configurations from the
configuration file.
```

4. Click **Apply**.
5. Save the configuration, and then reboot the switch.

#### Important

Any change to the **EnableSpbmConfigMode** boot flag requires a reboot for the change to take effect.

6. Configure the *SMLT*MLT:
  - a. Expand the following folders: **Configuration > VLAN > MLT/LACP**.
  - b. Click the **MultiLink/LACP Trunks** tab.
  - c. Click **Insert**.
  - d. In the **Id** box, type the ID number of the MLT.
  - e. In the **PortMembers** box, click the (...) button.
  - f. In the **Port Editor: PortMembers** dialog box, select the desired ports.
  - g. Click **Ok**
  - h. Click **Insert**.

The switch adds the SMLT MLT to the MultiLink/LACP Trunks tab in the MLT\_LACP box.

7. Configure the *vIST*MLT:
  - a. Repeat steps 6a to 6g to configure the MLT.

- b. Click **MltVistEnable** to enable Simplified vIST.

#### Note

The **MltVistEnable** field enables Simplified vIST and is only available when the **EnableSpbmConfigMode** boot flag is disabled.

- c. Click **Insert**.
8. Create the *vIST*VLAN:
  - a. Expand the following folders: **Configuration > VLAN > VLANs**
  - b. In the **Basic** tab, click **Insert**.
  - c. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
  - d. In the **MstpInstance** box, click the down arrow, and then choose an MSTI instance from the list.
  - e. In the **Type** box, select **byPort**.
  - f. Click **OK**.
  - g. Click **Insert**.
  - h. Select the vIST VLAN from the list of VLANs, and then click **IP**.
  - i. Click **Insert**.
  - j. Configure the IP address for the vIST VLAN.
9. Repeat Step 8 to create an *SMLT*VLAN and assign the SMLT MLT ID to it. Do not use the vIST MLT ID.
10. Configure PIM or IGMP Snooping on the *SMLT*VLAN:
  - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
  - b. To enable IGMP Snooping, select the SMLT VLAN from the list of VLANs and click **IP > IGMP**. Select **SnoopEnable** and click **Apply**.
11. Configure PIM on the *SMLT*VLAN:
  - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
12. Click **IP > PIM > Globals** to enable PIM globally.
13. Select the **Enable** check box, and then click **Apply**.

## Enable IPv4 PIM-SM Globally

Enable PIM-SM to offer multicasting services. After you enable PIM-SM globally and on a particular interface, the IGMP parameters take effect.

### Before You Begin

#### Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Select **PIM**.
3. Select the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select the **Enable** check box.
6. Select **Apply**.
7. Configure PIM Infinite Threshold Policy:
  - a. To disable PIM, clear the **Enable** check box, and then click **Apply**.
  - b. Select **enable**, and then click **Apply**
  - c. To enable PIM, select the **Enable** check box, and then click **Apply**.

## *Globals* field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mode</b>               | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).                                                                                                                                                                                                                                                                                                                                       |
| <b>Enable</b>             | Enables or disables PIM.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>JoinPruneInterval</b>  | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The range is from 1–18724 and the default is 60 seconds.                                                                                                                                                                                                                                         |
| <b>RegisterSuppTimer</b>  | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP.<br>The range is from 6–65535 and the default is 60 seconds.                                                                                                                                                               |
| <b>UniRouteChgTimeOut</b> | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM.<br>The range is from 2–65535 and the default is 5 seconds.<br><br><b>Important:</b><br>If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| <b>DiscardDataTimeOut</b> | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message.<br>The range is from 5–65535 and the default is 60 seconds.                                                                                                                           |

| Name                                                                       | Description                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CRPADVTimeOut</b>                                                       | Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR).<br>The range is from 5–26214 and the default is 60 seconds.               |
| <b>BootStrapPeriod</b>                                                     | Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages.<br>The range is from 5–32757 and the default is 60 seconds.                                                                                                                                                         |
| <b>StaticRP</b>                                                            | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.                                                                                                              |
| <b>FwdCacheTimeOut</b>                                                     | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.                                  |
| <b>FastJoinPrune</b>                                                       | Enables or disables the PIM fast join prune feature.                                                                                                                                                                                                                                                                       |
| <b>SptInfiniteThreshold</b>                                                | Enables or disables PIM Infinite Threshold Policy, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT).<br>The default value is disabled, which means that multicast traffic is automatically switched over to SPT. |
| <b>Note:</b> Exception: not supported on XA1400 Series or VSP 8600 Series. |                                                                                                                                                                                                                                                                                                                            |

## Enable IPv6 PIM-SM Globally

Enable IPv6 PIM-SM to offer multicasting services. After you enable IPv6 PIM-SM globally and on a particular interface, the MLD parameters take effect.

### Before You Begin

#### Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Select **IPv6 PIM**.
3. Select the **Globals** tab.
4. Select the **Enable** check box.
5. Select **sm** (sparse mode).

6. Select **Apply**.
7. Configure PIM Infinite Threshold Policy:
  - a. To disable PIM, clear the **Enable** check box, and then click **Apply**.
  - b. Select **enable**, and then click **Apply**
  - c. To enable PIM, select the **Enable** check box, and then click **Apply**.

### *Globals* field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>             | Enables or disables PIM.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Mode</b>               | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).                                                                                                                                                                                                                                                                                                                                    |
| <b>RegisterSuppTimer</b>  | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 10–65535 and the default is 60 seconds.                                                                                                                                                              |
| <b>UniRouteChgTimeOut</b> | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds.<br><br><b>Important:</b><br>If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| <b>DiscardDataTimeOut</b> | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds.                                                                                                                           |
| <b>StaticRP</b>           | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.                                                                                                                                                                                                                      |
| <b>FwdCacheTimeOut</b>    | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.                                                                                                                                          |

| Name                                                                                                      | Description                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>JoinPruneInterval</b>                                                                                  | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The range is from 1–18724 and the default is 60 seconds.                                                                                                                              |
| <b>SptInfiniteThreshold</b><br><b>Note:</b> Exception: not supported on XA1400 Series or VSP 8600 Series. | Enables or disables PIM Infinite Threshold Policy, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT).<br>The default value is disabled, which means that multicast traffic is automatically switched over to SPT. |

## Enabling PIM on a port

Enable PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you enable it on an interface.
- The interface uses a valid IP address.

### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Select the **Enable** check box.
6. Click **Apply**.

### *PIM* field descriptions

Use the data in the following table to use the **PIM** tab.

| Name                 | Description                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enables (true) or disables (false) PIM for the specified port.                                                                                                                  |
| <b>Mode</b>          | Displays the mode currently running on the routing switch.                                                                                                                      |
| <b>IntfType</b>      | Indicates the interface type as active or passive.                                                                                                                              |
| <b>HelloInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds. |

| Name                     | Description                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds.                                                                         |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a candidate BSR (C-BSR). The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

## Enabling IPv6 PIM on a port

Enable IPv6 PIM for each interface to enable the interface to perform multicasting operations.

### About This Task

You can also right-click the port and use the **Edit IPv6** shortcut menu to reach this same tab.

### Before You Begin

- You must enable IPv6 interface before you enable PIM on a port.

### Procedure

- On the Device Physical View tab, select a port.
- In the navigation pane, expand the **Configuration > Edit > Port** folders.
- Click **IPv6**.
- Click the **PIM** tab.
- Select **Enable**.
- Click **Apply**.

### *PIM* field descriptions

Use the data in the following table to use the **PIM** tab.

| Name           | Description                                                           |
|----------------|-----------------------------------------------------------------------|
| <b>Address</b> | Specifies the IPv6 address of the PIM interface.                      |
| <b>NetMask</b> | Specifies the network mask for the IPv6 address of the PIM interface. |
| <b>Enable</b>  | Enables (true) or disables (false) PIM for the specified port.        |
| <b>Mode</b>    | Displays the mode currently running on the routing switch.            |
| <b>DR</b>      | Specifies the designated router on this PIM interface.                |

| Name                     | Description                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds.            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds. |
| <b>OperState</b>         | Specifies the current operational state of this PIM interface.                                                                                                                             |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                           |

## Enable SSM Globally

Enable Source Specific Multicast (SSM) to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

### Before You Begin

- Configure a unicast protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using EDM](#) on page 3078. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2760.
- Enable PIM globally.

#### Important

After you enable PIM in SSM mode, the IGMP parameters take effect. To take full advantage of SSM, enable IGMPv3 if hosts that attach to the switch run IGMPv3 or configure the SSM table.

### About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Select **PIM**.
3. Select the **Globals** tab.
4. Select **ssm** (source specific multicast).
5. Select the **Enable** check box.

6. Select **Apply**.

The system displays the following message:

```
Are you sure you want to change the PIM mode? The traffic will not be
stopped immediately. All Static Source Group entries in the SSM range
will be deleted. Do you wish to continue?
```

7. Select **Yes**.

## Enable IPv6 SSM globally

Enable Source Specific Multicast (SSM) to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the IPv6 PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

### Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using EDM](#) on page 3089. For more information about OSPFv3, [OSPFv3 Configuration using EDM](#) on page 2800.

- Enable PIM globally.

#### Important

After you enable IPv6 PIM in SSM mode, the MLD parameters take effect. To take full advantage of SSM, enable MLDv2 if hosts that attach to the switch run MLDv2.

### About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Select **IPv6 PIM**.
3. Select the **Globals** tab.
4. Select the **Enable** check box.
5. Select **ssm** (source specific multicast).
6. Select **Apply**.

The system displays the following message:

```
Warning: RP entries in the SSM range will be deleted
```

```
Do you wish to continue? (y/n)?
```

- Click **Yes**.

## Enabling PIM on a VLAN interface

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you enable it on an interface.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANS**.
- Click the **Basic** tab.
- Select the VLAN ID that you want to configure with PIM.
- Click **IP**.
- Click the **PIM** tab.
- Select the **Enable** check box.
- Click **Apply**.

### *PIM field descriptions*

Use the descriptions in the following table to use the **PIM** tab.

| Name                     | Description                                                                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>            | Enables (true) or disables (false) PIM.                                                                                                                                                                                                            |
| <b>Mode</b>              | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field.                                                                                                                       |
| <b>IntfType</b>          | Specifies the type of interface: active or passive.                                                                                                                                                                                                |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724.                                                                            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724.                                                                 |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

## Enabling IPv6 PIM on a VLAN interface

Configure IPv6 PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable IPv6 PIM globally before you enable it on an interface.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Basic** tab.
- Select the VLAN ID that you want to configure with PIM.
- Click **IPv6**.
- Click the **PIM** tab.
- Select the **Enable** check box.
- Click **Apply**.

### *PIM field descriptions*

Use the descriptions in the following table to use the **PIM** tab.

| Name                     | Description                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>           | Specifies the interface index for PIM.                                                                                                                                             |
| <b>Address</b>           | Specifies the IPv6 address of the PIM interface.                                                                                                                                   |
| <b>Netmask</b>           | Specifies the network mask for the IPv6 address of the PIM interface.                                                                                                              |
| <b>Enable</b>            | Enables (true) or disables (false) PIM.                                                                                                                                            |
| <b>Mode</b>              | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field.                                                       |
| <b>DR</b>                | Specifies the designated router on this PIM interface.                                                                                                                             |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724.            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724. |
| <b>OperState</b>         | Specifies the current operational state of this PIM interface.                                                                                                                     |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                   |

## Configuring IGMP parameters on a port

Configure IGMP for each interface to enable the interface to perform multicasting operations.

### Procedure

- On the Device Physical View tab, select a port.

2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **IGMP** tab.
5. Edit the appropriate values.

**Note**

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

For information on DvR, see .

**Note**

To use the fast leave feature on IGMP, enable explicit-host-tracking.

6. Click **Apply**.

**IGMP** field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The range is from 1–65535 and the default is 125.                                                                                                                                                                                                                                                       |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval. |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Robustness</b>               | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                      |
| <b>LastMembQueryIntvl</b>       | Configures the maximum response time (in 1/10 seconds) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, Use values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>SnoopEnable</b>              | Enables snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SsmSnoopEnable</b>           | Enables SSM snoop. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ProxySnoopEnable</b>         | Enables proxy snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Version</b>                  | Configures the version of IGMP (1, 2 or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>FastLeaveEnable</b>          | Enables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams this port permits. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Current Number Of Stream</b> | Displays the current number of streams. This variable is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FastLeavePortMembers</b>     | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopMRouterPorts</b>        | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.                                                                                                          |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RouterAlertEnable</b>          | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p>To maximize network performance, configure this parameter according to the version of IGMP currently in use:</p> <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <b>DynamicDowngradeEnable</b>     | <p>Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.</p>                                                                                       |
| <b>CompatibilityModeEnable</b>    | <p>Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.</p>                                                                                                                                                                                                                                                                                                                                               |
| <b>ExplicitHostTrackingEnable</b> | <p>Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.</p>                                                                                                                                                                                                                                                                                                                        |

## Configuring IGMP parameters on a VLAN

Configure IGMP for each interface to enable the interface to perform multicasting operations.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Select **IGMP**.

## 7. Configure the relevant variables.

**Note**

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

Configuration of IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

8. Click **Apply**.**IGMP** field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1–65535 and the default is 125.                                                                                                                                                                                                                                                                                 |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval.                                 |
| <b>Robustness</b>           | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastMembQueryIntvl</b>       | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |
| <b>SnoopEnable</b>              | Enables snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SsmSnoopEnable</b>           | Enables SSM snoop. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ProxySnoopEnable</b>         | Enables proxy snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Version</b>                  | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>FastLeaveEnable</b>          | Enables or disables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Current Number Of Stream</b> | Displays the current number of streams. This value is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>FastLeavePortMembers</b>     | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SnoopMRouterPorts</b>        | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this field only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.                                                                                                                       |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RouterAlertEnable</b>          | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p>To maximize network performance, configure this parameter according to the version of IGMP currently in use:</p> <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <b>DynamicDowngradeEnable</b>     | <p>Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.</p>                                                                                       |
| <b>CompatibilityModeEnable</b>    | <p>Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.</p>                                                                                                                                                                                                                                                                                                                                               |
| <b>ExplicitHostTrackingEnable</b> | <p>Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.</p>                                                                                                                                                                                                                                                                                                                        |
| <b>SnoopQuerierEnable</b>         | <p>Enables snoop querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.</p> <p>Enable Layer 2 Querier on only one node in the VLAN.</p>       |
| <b>SnoopQuerierAddr</b>           | <p>Specifies the pseudo IP address of the IGMP snoop querier. The default IP address is 0.0.0.0.</p>                                                                                                                                                                                                                                                                                                                                                                                        |

## Multicast Listener Discovery

**Table 133: Multicast Listener Discovery product support**

| Feature                            | Product         | Release introduced |
|------------------------------------|-----------------|--------------------|
| Multicast Listener Discovery (MLD) | 5320 Series     | Fabric Engine 8.6  |
|                                    | 5420 Series     | VOSS 8.4           |
|                                    | 5520 Series     | VOSS 8.2.5         |
|                                    | 5720 Series     | Fabric Engine 8.7  |
|                                    | 7520 Series     | Fabric Engine 8.10 |
|                                    | 7720 Series     | Fabric Engine 8.10 |
|                                    | VSP 4450 Series | VOSS 5.1           |
|                                    | VSP 4900 Series | VOSS 8.1           |
|                                    | VSP 7200 Series | VOSS 5.1           |
|                                    | VSP 7400 Series | VOSS 8.0           |
|                                    | VSP 8200 Series | VOSS 5.1           |
|                                    | VSP 8400 Series | VOSS 5.1           |
|                                    | VSP 8600 Series | Not Supported      |
|                                    | XA1400 Series   | Not Supported      |

### MLD Fundamentals

MLD is an asymmetric protocol. It specifies separate behaviors for multicast address listeners (that is, hosts or routers that listen to multicast packets) and multicast routers. Each multicast router learns, for each directly attached link, which multicast addresses and which sources have listeners on that link. The information that MLD gathers is provided to the multicast routing protocols that the router uses. This information ensures that multicast packets arrive at all links where listeners require such packets.

A multicast router can itself be a listener of one or more multicast addresses; that is, the router performs both the multicast router role and the multicast address listener part of the protocol. The router collects the multicast listener information needed by the multicast routing protocol and informs itself and other neighboring multicast routers of the listening state.

IPv6 routers use MLD to discover:

- The presence of multicast listeners on directly attached links
- Multicast addresses required by neighboring nodes

#### *MLD versions*

The purpose of the MLD protocol in the IPv6 multicast architecture is to allow an IPv6 router to discover the presence of multicast listeners on directly-attached links and to discover which multicast addresses are of interest to neighboring nodes. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4. The MLD implementation

described in this document is based on the MLDv2 standard, which is a backward-compatible update to the MLDv1 standard.

There are three versions of IGMP, and two versions of MLD. IGMPv2 is equivalent in function to MLDv1 and IGMPv3 is equivalent to MLDv2.

### *MLD Querier*

MLD Querier is similar to IGMP querier. A multicast query router communicates with hosts on a local network by sending MLD queries. This router periodically sends a general query message to each local network of the router. This is standard multicast behavior.

#### **Note**

Queries are sent only if PIM is enabled globally and on the interface. PIM and snooping cannot be enabled at the same time.

Each VLAN using MLD multicast must have a router performing multicast queries. Networks with no stand-alone devices currently have no capability for implementing the pruning of multicast traffic. A dedicated querier must be available on the network.

There are several behavioral differences between a traditional query router and a switch or stack using the MLD Querier functionality. The following are the differences:

- There is no election process. When a switch or stack restarts, queries are sent as part of MLD startup. This process stops other devices from sending queries while they detect the new device starting up. The last active device sending queries on the network is the active one. This is not the case with Layer 3 MLD behavior.
- If the current active device stops sending queries, a timeout period must elapse before another device takes over. This can result in an ageout of groups, and subsequent flooding, before a new query is sent and the pruning process restarts. This occurs only during the transition between active query devices. Once the new device is established, queries are sent as configured in the Query Interval and Robust Values fields.
- Multiple active query devices are not supported. Enabling multiple devices establishes one active device and other devices listening to take over should the active device fail.

The querier version is determined by the received query version and establishes the interface operational version. By default, the interface operational version is MLDv1. If the interface operational version is downgraded from MLDv2 to MLDv1 (when operational version is MLDv2 and a MLDv1 query is received), then all MLDv2 listeners (registered by MLDv2 reports) are removed and all incoming MLDv2 reports are dropped.

### *MLD snooping*

MLD snooping is an IPv6 multicast constraining mechanism running on Layer 2 devices. When MLD snooping is enabled on a VLAN, the switch examines the MLD messages between hosts and multicast routers and learns which hosts are interested in receiving traffic for a multicast group. Based on the learning, the switch forwards

multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

The following figure shows an example of this scenario. On the left side of the figure, IPv6 multicast packets are transmitted when MLD snooping is not enabled. All the hosts that are interested and not interested receive the IP Multicast traffic consuming bandwidth. Whereas, on the right side of the figure, when MLD snooping is enabled and IPv6 multicast packets are transmitted, only the interested hosts receive the IP multicast packets.

**Figure 155: IPv6 multicast packet transmission when MLD snooping is enabled and not enabled**

The following figure shows IPv6 multicast packets transmitted when MLD v2 snooping is enabled and not enabled.

**Figure 156: IPv6 multicast packet transmission when MLD v2 snooping is enabled and not enabled**

#### MLD snooping configuration guidelines and restrictions

You can perform the following configurations to manage and control IPv6 multicast groups using the MLD snooping feature:

- Enable or disable MLD snooping on each VLAN. MLD snooping can be enabled on a maximum of 512 VLANs.
- Enable IGMP snooping and MLD snooping on the same VLAN.

#### Limitations

Following are the limitations for MLD snooping configuration:

- The maximum (S,G,V) entries supported in the IPv6 multicast routing table (L3\_ENTRY\_IPV6\_MULTICAST) is 512.

MLD snooping shares the (S,G,V) entries with IGMP snooping, where the (S,G,V) entries number = (G,V) MLD\_V1 type entries number + (S,G,V) MLD\_V2 type entries number + (\*,G,V) MLD\_V2 type entries number + number of groups without (\*,G,V) registered listeners.

- IPv6 MLD proxy functionality is not supported.

- Multicast Flood Control (MFC) is not supported.
- Static mrouter ports cannot be configured.
- IPv6 MLD send query functionality is not supported.
- Configure static router ports is not supported.
- Multicast Listener Discovery (MLDv1/v2) is not supported with vIST/SMLT.
- Multicast Listener Discovery (MLDv1/v2) is not supported with Fabric Connect.
- Protocol Independent Multicast (PIM) with IPv6 is not supported vIST/SMLT.
- Protocol Independent Multicast (PIM) with IPv6 is not supported with Fabric Connect (SPBM).

## MLD Configuration Using the CLI

This section provides procedures to configure Multicast Listener Discovery (MLD) using the command line interface (CLI).

### *Configuring MLD trap generation*

#### **About This Task**

Use this procedure to enable MLD traps.

#### **Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MLD trap generation:  
`ipv6 mld generate-trap`
3. Disable MLD trap generation:  
`no ipv6 mld generate-trap`
4. Set MLD trap enable status to default:  
`default ipv6 mld generate-trap`

### *Configuring MLD log status*

#### **About This Task**

Use this procedure to enable MLD traps.

#### **Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MLD log status:  
`ipv6 mld generate-log`

3. Disable MLD log status:  

```
no ipv6 mld generate-log
```
4. Set MLD log enable status to default:  

```
default ipv6 mld generate-log
```

### Configuring MLD version

#### About This Task

Use this procedure to configure MLD version.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MLD version:

```
ipv6 mld version <1-2>
```

#### Note

For MLD to function correctly, the MLD version must be the same on all routers in the network.

3. Set MLD version to default:

```
default ipv6 mld version
```

#### Variable Definitions

The following table describes the variables for the **ipv6 mld version** command.

| Variable | Value                                                     |
|----------|-----------------------------------------------------------|
| <1-2>    | Indicates the version of MLD that runs on this interface. |

### Configuring the MLD last listener query interval

#### About This Task

Use this procedure to configure the last listener query interval in seconds for the MLD interface.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the last listener query interval:

```
ipv6 mld last-listener-query-interval <0-60>
```

3. Set the last listener query interval to its default value:

```
default ipv6 mld last-listener-query-interval
```

## Variable Definitions

The following table describes the variables for the **ipv6 mld last-listener-query-interval** command.

| Variable | Value                                                  |
|----------|--------------------------------------------------------|
| <0-60>   | Indicates the last listener query interval in seconds. |

## Configuring the MLD query interval

### About This Task

Use this procedure to configure the query interval for the MLD interface.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query interval for the MLD interface:

```
ipv6 mld query-interval <1-65535>
```

3. Set the query interval to its default value:

```
default ipv6 mld query-interval
```

### Variable Definitions

The following table describes the variables for the **ipv6 mld query-interval** command.

| Variable  | Value                                                                               |
|-----------|-------------------------------------------------------------------------------------|
| <1-65535> | Indicates the frequency at which MLD host query packets transmit on this interface. |

### Configuring the MLD query maximum response time

#### About This Task

Use this procedure to configure the query maximum response time for mld interface.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query maximum response time for mld interface:

```
ipv6 mld query-max-response-time <0-60>
```

3. Set the query maximum response time to its default value:

```
default ipv6 mld query-max-response-time
```

### Variable Definitions

The following table describes the variables for the **ipv6 mld query-max-response-time** command.

| Variable | Value                                                          |
|----------|----------------------------------------------------------------|
| <0-60>   | Indicates the query maximum response interval time in seconds. |

### Configuring the MLD robustness

## About This Task

The robustness value allows the tuning for the expected packet loss on a link. If a link expects packet loss, increase the robustness variable value.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the MLD robustness:

```
ipv6 mld robust-value <2-255>
```

3. Set the MLD robustness to its default value:

```
default ipv6 mld robust-value
```

## Variable Definitions

The following table describes the variables for the **ipv6 mld robust-value** command.

| Variable | Value                                                    |
|----------|----------------------------------------------------------|
| <2-255>  | Specifies a numerical value for MLD snooping robustness. |

## Enabling MLD snooping on a VLAN

### About This Task

Use this procedure to enable MLD snooping on a VLAN.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable MLD snooping:

```
ipv6 mld snooping
```

3. Set the MLD snooping to its default value:

```
default ipv6 mld snooping
```

*Enabling MLD ssm-snooping on a VLAN***About This Task**

Use this procedure to enable IPv6 MLD ssm-snooping on a VLAN.

**Procedure**

1. Enter VLAN Interface Configuration mode:
 

```
enable
configure terminal
interface vlan <1-4059>
```
2. Enable MLD snooping:
 

```
ipv6 mld ssm-snoop
```
3. Set the MLD snooping to its default value:
 

```
default ipv6 mld ssm-snoop
```

*Display MLD Snooping Configuration Status***About This Task**

Use this procedure to display information about the MLD snooping configuration for the switch.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display the switch MLD snooping configuration status:
 

```
show ipv6 mld snooping
```

**Example**

```
Switch:1#show ipv6 mld snooping
=====
                        Mld Snooping - GlobalRouter
=====
IFINDEX SNOOP   SSM   ACTIVE   MROUTER
          ENABLE SNOOP  MROUTER  EXPIRATION
          ENABLE  PORTS   TIME
-----
V666   False   False  NONE     0
1 out of 1 entries displayed
```

*Display MLD Snooping Tracing Information***About This Task**

Use this procedure to display MLD snooping tracing information.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the MLD snooping tracing information:  
show ipv6 mld snoop-trace

## Example

```
Switch:1#show ipv6 mld snoop-trace
=====
                        Mld Snoop Trace - GlobalRouter
=====
GROUP/
SOURCE                IN    IN  OUT  OUT    TYPE
ADDRESS              VLAN  PORT VLAN  PORT
-----
ff10:0:0:0:0:0:1/    10   2/15 10   3/16   ACCESS
5051:0:0:0:0:1:84:51
```

## Display MLD Interface Information

### About This Task

Use this procedure to display MLD snooping interface parameters.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display MLD interface information:  
show ipv6 mld interface [gigabitethernet {slot/port[/sub-port]}] [vlan <1-4059>]

### Examples

```
Switch:1#show ipv6 mld interface
=====
                        Mld Interface - GlobalRouter
=====

```

### Variable Definitions

The following table describes the variables for the **show ipv6 mld interface** command.

| Variable                               | Value                                                       |
|----------------------------------------|-------------------------------------------------------------|
| vlan <1-4059>                          | Displays MLD snooping information for the configured VLANs. |
| gigabitEthernet {slot/port[/sub-port]} | Displays MLD snooping information on a specific interface.  |

### Displaying MLD system parameters

#### About This Task

Use this procedure to display information about the MLD traps and logs.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the system parameters:  
show ipv6 mld sys

#### Example

```

Switch:1#show ipv6 mld sys
=====
Mld System Parameters - GlobalRouter
=====
generate-trap : disable
generate-log  : disable

```

### Display MLD Cache Information

#### About This Task

Use this procedure to display the learned multicast groups in the cache.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the learned multicast groups in the cache:  
show ipv6 mld cache

**Example**

```
Switch:1#show ipv6 mld cache
=====
                        MLD Cache Information
=====

1 out of 1 entries displayed
```

*Display the MLD Group Information*

**About This Task**

Use this procedure to display the MLD group information to show the learned multicast groups and the attached ports.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display the MLD group information:  
show ipv6 mld group [count] [group] [member-subnet]

**Examples**

```
Switch:1#show ipv6 mld group
=====
                        Mld Group - GlobalRouter
=====

```

*View IPv6 MLD Host Cache*

View the learned multicast group addresses in the host cache.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View IPv6 MLD host cache:

```
show ipv6 mld-host-cache
```

**MLD Configuration Using EDM**

This section provides procedures to configure Multicast Listener Discovery (MLD) using Enterprise Device Manager (EDM).

*Configuring MLD globally***About This Task**

Use the following procedure to configure MLD parameters for the switch.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Globals** tab.
4. Configure the MLD global parameters as required.
5. On the toolbar, click **Apply** to save the changes.
6. On the toolbar, click **Refresh** to update the changes.

**Globals field description**

Use the data in the following table to use the **Globals** tab.

| Field        | Description                    |
|--------------|--------------------------------|
| GenerateTrap | Enables MLD to generate traps. |
| GenerateLog  | Enables MLD to generate logs.  |

*Viewing the MLD SSM global information***Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Ssm Globals** tab.

### Ssm Globals field description

Use the data in the following table to use the **Ssm Globals** tab.

| Field      | Description                   |
|------------|-------------------------------|
| RangeGroup | Specifies the ssm range.      |
| RangeMask  | Specifies the ssm range mask. |

### MLD interface configuration

Configure the interfaces so that the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

### Configuring an MLD interface

Perform this procedure to change the configuration of existing MLD interfaces.

#### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Interfaces** tab.
4. On the toolbar, click **Insert**.
5. Configure the MLD interface parameters.
6. Click **Insert**.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

### MLD interfaces field description

Use the data in the following table to use the **Interfaces** tab.

| Field                 | Description                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|
| IfIndex               | Specifies the internetwork layer interface value of the interface for which MLD is enabled.                              |
| QueryInterval         | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version               | Indicates the MLD version.                                                                                               |
| Querier               | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                         |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.        |
| Joins                 | Specifies the number of times a group membership has been added on this interface.                                       |

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Groups                 | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                   |
| Robustness             | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                             |
| LastListenQueryIntvl   | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable            | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                |
| FlushAction            | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>• flushGrpMember</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                        |
| SsmEnable              | Indicates if ssm is enabled.                                                                                                                                                                                                                                                                                                                                                                     |
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                                                                                                                                                                                                               |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                                                                                                                                                                                                       |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                                                                                                                                                                                                          |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>• snoop</li> <li>• pim</li> <li>• snoopSpb</li> <li>• routerSpb</li> <li>• dvmrp</li> <li>• none</li> </ul>                                                                                                                                                                                     |

### Configuring MLD on a port

Configure the MLD on a port.

#### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.

3. Click **IPv6**.
4. Click the **MLD** tab.
5. Configure the MLD interface parameters.
6. On the toolbar, click **Apply** to save the changes.
7. On the toolbar, click **Refresh** to update the changes.

#### MLD field description

Use the data in the following table to use the **MLD** tab.

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QueryInterval         | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535.                                                                                                                                                                                                                                                                         |
| Version               | Indicates the MLD version.                                                                                                                                                                                                                                                                                                                                                                       |
| Querier               | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                 |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.                                                                                                                                                                                                                                                                                |
| Joins                 | Specifies the number of times a group membership has been added on this interface.                                                                                                                                                                                                                                                                                                               |
| Groups                | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                   |
| Robustness            | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                             |
| LastListenQueryIntvl  | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable           | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                |
| FlushAction           | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>• flushGrpMember</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                        |
| SsmEnable             | Indicates if ssm is enabled.                                                                                                                                                                                                                                                                                                                                                                     |

| Field                  | Description                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                           |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                   |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                      |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>• snoop</li> <li>• pim</li> <li>• snoopSpb</li> <li>• routerSpb</li> <li>• dvmrp</li> <li>• none</li> </ul> |

### Configuring MLD on a VLAN

#### About This Task

Configure MLD on a VLAN.

#### Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Click **VLANS**.
3. Select a VLAN from the list.
4. Click the **IPv6** tab.
5. Click the **MLD** tab.
6. Configure the MLD interface parameters.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

#### MLD field description

Use the data in the following table to use the **MLD** tab.

| Field         | Description                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| QueryInterval | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version       | Indicates the MLD version.                                                                                               |
| Querier       | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                         |

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QueryMaxResponseDelay  | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.                                                                                                                                                                                                                                                                                |
| Joins                  | Specifies the number of times a group membership has been added on this interface.                                                                                                                                                                                                                                                                                                               |
| Groups                 | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                   |
| Robustness             | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                             |
| LastListenQueryIntvl   | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable            | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                |
| FlushAction            | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>• flushGrpMember</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                        |
| SsmEnable              | Indicates if ssm is enabled.                                                                                                                                                                                                                                                                                                                                                                     |
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                                                                                                                                                                                                               |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                                                                                                                                                                                                       |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                                                                                                                                                                                                          |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>• snoop</li> <li>• pim</li> <li>• snoopSpb</li> <li>• routerSpb</li> <li>• dvmrp</li> <li>• none</li> </ul>                                                                                                                                                                                     |

*Configuring MLD snooping***About This Task**

Use the following procedure to enable MLD snooping on the switch.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click **Snooping** tab.
4. Select a value, double-click the cell in **SnoopEnable** column, select **True** or **False**.
5. Select a value, double-click the cell in **SsmEnable** column, select **True** or **False**.
6. Click **Apply**.

**Snooping field description**

Use the data in the following table to use the **Snooping** tab.

| Field       | Description                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IfIndex     | Specifies the interface on which you enabled MLD snooping. It specifies the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.                       |
| SnoopEnable | Indicates the status of MLD snooping on the specified interface: <ul style="list-style-type: none"> <li>• True – MLD snooping is enabled</li> <li>• False – MLD snooping is disabled</li> </ul> |
| SsmEnable   | Indicates the status of SSM on the specified interface: <ul style="list-style-type: none"> <li>• True – SSM is enabled</li> <li>• False – SSM is disabled</li> </ul>                            |

*Viewing the MLD snoop trace information***About This Task**

Use this procedure to display information about the multicast groups traversing the snoop enabled router.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Snoop Trace** tab.

**Snoop Trace field description**

Use the data in the following table to use the **Snoop Trace** tab.

| Field   | Description                                                            |
|---------|------------------------------------------------------------------------|
| GrpAddr | Specifies the IP multicast address of the group traversing the router. |
| SrcAddr | Specifies the IP source address of the multicast group address.        |
| OutVlan | Specifies the egress VLAN ID for the multicast group.                  |
| OutPort | Specifies the egress port of the multicast group.                      |
| InVlan  | Specifies the ingress VLAN ID for the multicast source.                |
| InPort  | Specifies the ingress port for the multicast group.                    |
| Type    | Specifies the port type on which the snoop entry is learnt.            |

*Viewing the MLD cache information***About This Task**

Use this procedure to display information about the learned multicast groups in the cache.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Cache** tab.

**MLD cache field description**

Use the data in the following table to use the **Cache** tab.

| Field        | Description                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address      | The IPv6 multicast group address for which this entry contains information.                                                                                                               |
| IfIndex      | Indicates the internetwork-layer interface for which this entry contains information for an IPv6 multicast group address.                                                                 |
| LastReporter | Indicates the source IPv6 address of the last membership report received for this IPv6 Multicast group address on this interface. If membership report is not received, the value is 0::0 |
| ExpiryTime   | Indicates the minimum amount of time remaining before the entry ages out.                                                                                                                 |

*Viewing the MLD V2 cache information***About This Task**

Use this procedure to display information about the MLDv2 corresponding to each interface, port and multicast group paired on a router.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **V2 Cache** tab.

**V2 Cache field description**

Use the data in the following table to use the **V2 Cache** tab.

| Field             | Description                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupAddress      | Specifies the multicast group address that others want to join. A group address can be the same for many incoming ports.                                                                                                                                                 |
| Ifindex           | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.                                                                                                                                                    |
| InPort            | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.                                                                                                                                                    |
| Version1HostTimer | Specifies the time remaining until the local router assumes that there are no more MLDv1 members on the IP subnet attached to the interface. This is applicable only for MLDv1 hosts. Upon receiving an MLDv1 report, this value is reset to the group membership timer. |
| SourceFilterMode  | Specifies the current group state applicable on MLDv2 compatible nodes.                                                                                                                                                                                                  |

*Viewing IPv6 MLD host cache*

View the learned multicast group addresses in the host cache.

**Procedure**

1. In the navigation tree, expand the **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Host Cache** tab.

### MLD host cache field descriptions

Use the data in the following table to use the **Host Cache** tab.

| Name                        | Description                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the index value that uniquely identifies the interface to which this entry applies. |
| <b>GrpAddress</b>           | Shows the IP address for the multicast group.                                             |
| <b>GrpLocallyRegistered</b> | Shows the Group Locally Registered for an IPv6 MLD host-cache entry.                      |
| <b>GrpLastReporter</b>      | Shows the Group Last Reporter address for an IPv6 MLD host-cache entry.                   |
| <b>GrpUpTime</b>            | Shows the Group Uptime for an IPv6 MLD host-cache entry.                                  |
| <b>GrpExpiryTime</b>        | Shows the Group Expiry Time for an IPv6 MLD host-cache entry.                             |
| <b>GrpFilterMode</b>        | Shows the Group Filter Mode for an IPv6 MLD host-cache entry.                             |

### Viewing the MLD source information

#### About This Task

Use this procedure to display information about the MLD source.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Source** tab.

### Source field description

Use the data in the following table to use the **Source** tab.

| Field        | Description                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------|
| GroupAddress | Specifies the IPv6 multicast group address for which this entry contains information.                          |
| Ifindex      | Specifies the interface for which this entry contains information for an IP multicast group address.           |
| InPort       | Identifies a physical interface or logical interface (VLAN), which has received group reports for this source. |
| HostAddress  | Specifies the host address to which this entry corresponds.                                                    |

| Field         | Description                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------|
| MemberAddress | Specifies the IPv6 address of a member that has sent source specific report wishing to join this source. |
| Expire        | Specifies the state of this entry.                                                                       |
| Mode          | Specifies the current member state. This is applicable to MLDv2 compatible nodes.                        |
| MemberExpire  | Specifies the time until the member for this source expires.                                             |

### Viewing the MLD sender information

#### About This Task

Use this procedure to display information about the multicast senders.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Sender** tab.

#### Source field description

Use the data in the following table to use the **Sender** tab.

| Field      | Description                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| GrpAddr    | Specifies the IPv6 multicast group address.                                                                                                          |
| Ifindex    | Specifies the interface index of the sender.                                                                                                         |
| MemberAddr | Specifies the IPv6 host address.                                                                                                                     |
| Action     | Specifies the MLD action as one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushEntry</li> <li>• flushGrp</li> </ul> |
| Port       | Specifies the MLD sender port.                                                                                                                       |

### Viewing the MLD group information

#### About This Task

Use this procedure to display information about the groups configured in this device.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Group** tab.

### Group field description

Use the data in the following table to use the **Group** tab.

| Field       | Description                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| IPv6Address | Specifies the multicast group address that others want to join to. A group address can be the same for many incoming ports. |
| Members     | Specifies the IP address of a source that has sent group report wishing to join this group.                                 |
| InPort      | Identifies a physical interface or a logical interface which has received group reports from various sources.               |
| Expiration  | Specifies the time left before group report expires on this port. This is updated upon receiving a group report.            |
| IfIndex     | Identifies a physical interface or a logical interface which has received group reports from various sources.               |

## PIM Configuration Using the CLI

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### Before You Begin

For an IPv4 PIM configuration using the CLI:

- Configure an IPv4 interface.

For more information, see [IP routing configuration using the CLI](#) on page 2026.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using CLI](#) on page 3063. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2685.

- Enable PIM-SM globally.

- Enable PIM-SM on individual interfaces.
- You must first configure and enable PIM on an IP interface, which can be circuitless, before you can utilize that interface as a candidate rendezvous point (RP). To configure PIM-SM RP for an IP interface, see [Configuring a candidate rendezvous point](#) on page 1733.
- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using the CLI:

- Configure an IPv6 interface.

For more information, see [Configure an IPv6 Interface](#) on page 2112.

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 3073. For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2730.

- Enable IPv6 PIM-SM globally
- Enable IPv6 PIM-SM on individual interfaces.

## Changing the interface status to passive

Change the PIM interface status to passive to deny PIM control traffic on the interface.

### Before You Begin

- The PIM interface is disabled.

### About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a passive interface and enable it simultaneously:

```
ip pim passive
```

3. Create a passive interface in the disabled state:

```
ip pim interface-type passive
```

You must manually enable the interface.

4. Enable a disabled interface:

```
ip pim enable
```

### Variable definitions

Use the data in the following table to use the **ip pim** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>active</i>  | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |
| <i>passive</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Changing the interface status to active

Change the PIM interface status to active to allow PIM control traffic on the interface.

### Before You Begin

- The PIM interface is disabled.

## About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an active interface in the disabled state:

```
ip pim interface-type active
```

You must manually enable the interface.

3. Create an active interface and enable it simultaneously:

```
ip pim active
```

OR

```
ip pim enable
```

The second command enables an active interface only if this is the first PIM interface you create on the port or VLAN or you created an active interface in the disabled state. If you already created a passive interface in the disabled state, the second command enables that passive interface.

*Variable definitions*

Use the data in the following table to use the **ip pim** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>active</i>  | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control traffic transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the PIM virtual neighbor:
 

```
ip pim virtual-neighbor <A.B.C.D> <A.B.C.D>
```

## Example

Configure the PIM virtual neighbor:

```
Switch:1(config)#ip pim virtual-neighbor 192.0.2.0 198.51.100.0
```

### Variable definitions

Use the definitions in the following table to use the **ip pim virtual-neighbor** command.

| Variable            | Value                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} {A.B.C.D} | The first IP address indicates the IP address of the selected interface. The second IP address indicates the IP address of the neighbor. |

## Configuring a candidate rendezvous point

Configure a candidate rendezvous point (C-RP) to serve as backup to the RP router.

### About This Task

You can configure only one interface on the switch for multiple groups. You cannot configure multiple interfaces for multiple groups.

With the mask value, you can configure a C-RP router for several groups in one configuration.

For example, if you use a C-RP configuration with a group address of 224.0.0.0 and a group mask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Add a candidate rendezvous point:
 

```
ip pim rp-candidate group <A.B.C.D> <A.B.C.D> rp <A.B.C.D>
```
3. Remove a candidate rendezvous point:
 

```
no ip pim rp-candidate group <A.B.C.D> <A.B.C.D>
```
4. Display information about the candidate rendezvous points for the PIM-SM domain:
 

```
show ip pim rp-candidate
```

### Example

Add a candidate rendezvous point:

```
Switch:1(config)#ip pim rp-candidate group 224.1.1.0 255.255.255.0 rp 198.51.100.0
```

### Variable definitions

Use the definitions in the following table to use the `ip pim rp-candidate` command.

| Variable                                               | Value                                                                                                                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>group {A.B.C.D}</code><br><code>{A.B.C.D}</code> | Specifies the IP address and the address mask of the multicast group. After the IP address and group mask are combined, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <code>rp {A.B.C.D}</code>                              | Specifies the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.                                                                                                     |

## Configuring static RP

Configure a static RP to ignore the bootstrap router (BSR) mechanism and use the statically configured RPs.

### Before You Begin

- Enable PIM-SM globally.

### About This Task

Static RP-enabled switches use this feature to communicate with switches from other vendors that do not use the BSR.

### Important

You cannot configure a static RP-enabled switch as a BSR or as a C-RP router. All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable static RP:

```
ip pim static-rp
```

The system displays the following message:

```
WARNING: RP information learnt dynamically through BSR functionality will be lost.
Do you wish to enable Static RP? (y/n) ?
```

3. Enter `y`.
4. Configure a static RP entry:
 

```
ip pim static-rp {A.B.C.D/X} {A.B.C.D}
```
5. Configure all the switches in the network (including switches from other vendors) to map to the same RP.

6. Display information about the candidate rendezvous points for the PIM-SM domain:

```
show ip pim static-rp
```

### Example

Configure a static RP:

```
Switch:1(config)# ip pim static-rp 239.255.0.0/255.255.0.0 198.51.100.0
```

### Variable definitions

Use the definitions in the following table to use the **ip pim static-rp** command.

| Variable    | Value                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Specifies the IP address and address mask of the multicast group. When combined, the IP address and address mask identify the range of the multicast addresses that the RP handles. |
| {A.B.C.D}   | Specifies the IP address of the static RP.                                                                                                                                          |

## Configuring IPv6 PIM static RP

On IPv6 PIM BSR mechanism is not supported so static RP must be configured.

### Before You Begin

Enable IPv6 PIM-SM globally.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable static RP:
 

```
ipv6 pim static-rp
```
3. Configure an IPv6 static RP entry:
 

```
ipv6 pim static-rp WORD<0-255> WORD<0-255>
```
4. Configure all the switches in the network (including switches from other vendors) to map to the same RP.
5. Display information about the candidate rendezvous points for the PIM-SM domain:
 

```
show ipv6 pim static-rp
```

### Variable Definitions

The following table describes the variables for the **ipv6 pim static-rp** command.

| Variable    | Value                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<0-255> | Specifies the IPv6 address and address mask of the multicast group. When combined, the IPv6 address and address mask identify the range of the multicast addresses that the RP handles. |
| WORD<0-255> | Specifies the IPv6 address of the static RP.                                                                                                                                            |

## Configuring a candidate BSR on a port

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

### Before You Begin

- Static RP is disabled.

### About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a candidate BSR:

```
ip pim bsr-candidate preference <0-255>
```

### Example

Configure a candidate BSR:

```
Switch:1(config-if)#ip pim bsr-candidate preference 2
```

*Variable definitions*

Use the definitions in the following table to use the `ip pim bsr-candidate` command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference &lt;0-255&gt;</code> | Activates the C-BSR on this interface and configures its preference value, from 0–255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. To set this option to the default value, use the <b>default</b> operator with the command. |

## Configuring a candidate BSR on a VLAN

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

### Before You Begin

- Static RP is disabled.

### About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

### Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable
configure terminal
interface vlan <1-4059>
```
2. Configure a candidate BSR on a VLAN:
 

```
ip pim bsr-candidate preference <0-255>
```

### Example

Configure a candidate BSR on a VLAN:

```
Switch:1(config-if)#ip pim bsr-candidate preference 5
```

### Variable definitions

Use the definitions in the following table to use the `ip pim bsr-candidate` command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference &lt;0-255&gt;</code> | Activates the C-BSR on this interface and configures its preference value, from 0–255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

### About This Task

#### Important

The following command also activates full-mesh configurations.

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable square-SMLT:

```
multicast smlt-square
```

## PIM Configuration Using EDM

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.

- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

**Important**

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

**Before You Begin**

For an IPv4 PIM configuration using EDM:

- Configure an IP interface.

For more information, see [IP routing configuration using Enterprise Device Manager](#) on page 2055.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using EDM](#) on page 3078. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2760.

- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- Configure one or more rendezvous points (RP) for the groups that multicast applications use in the network.

**Important**

If you configure the rendezvous point (RP) to be the address of a circuitless IP (CLIP) interface, then you must first configure and enable PIM on the CLIP interface before you can utilize that interface as a candidate RP. To configure a PIM-SM RP for a circuitless IP interface, see [Configuring a candidate RP](#) on page 1750.

- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using EDM:

- Configure an IPv6 interface. For more information, see [Configure an IPv6 Interface](#) on page 2145.
- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM. For more information about RIPng, see [RIPng Configuration using EDM](#) on page 3089. For more information about OSPFv3, see [OSPFv3 Configuration using EDM](#) on page 2800.
- Enable IPv6 PIM-SM globally.
- Enable IPv6 PIM-SM on individual interfaces.

## Enabling static RP

Enable static RP to avoid the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.

The system displays the following message:

```
RP information learnt dynamically through BSR functionality will be
lost. Do you wish to enable Static RP?
```

8. Click **Yes**.

## Enabling IPv6 static RP

Use this procedure to enable IPv6 static RP.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.
8. Click **Yes**.

## Configuring a static RP

Configure a static RP to ignore the BSR mechanism and use the statically configured RPs only. A static RP-enabled switch uses this feature to communicate with switches from other vendors that do not use the BSR mechanism.

### Before You Begin

- Before you can configure a static RP, you must enable the following:
  - PIM-SM
  - static RP

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.

2. Click **PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

### **Static RP** field descriptions

Use the descriptions in the following table to use the **Static RP** tab.

| Name                | Description                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.      |
| <b>GroupMask</b>    | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| <b>Address</b>      | Configures the IP address of the static RP.                                                                                                                               |
| <b>Status</b>       | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP and is invalid otherwise.        |

### *Job aid*

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

## Configuring an IPv6 static RP entry

Configure an IPv6 static RP to use the statically configured RPs. A static RP-enabled switch uses this feature to elect the active RP only from the statistically configured switches, without any relation to the RP information of other switches.

### Before You Begin

- Before you can configure a static RP, you must enable the following:
  - IPv6 PIM-SM
  - IPv6 static RP

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

### *Static RP field descriptions*

Use the descriptions in the following table to use the **Static RP** tab.

| Name                | Description                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Configures the IPv6 address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.    |
| <b>GroupMask</b>    | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| <b>Address</b>      | Configures the global IPv6 address of the static RP.                                                                                                                      |
| <b>Status</b>       | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP.                                 |

### *Job aid*

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different

algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.

- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

## Viewing the active RP

Perform this procedure to show information about the active RP for all the running multicast groups on the switch.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Active RP** tab.

#### *Active RP field descriptions*

Use the data in the following table to use the **Active RP** tab.

| Name                | Description                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IP address of the multicast group.                                                            |
| <b>Address</b>      | Shows the IP address of the RP router. This address must be one of the local PIM-SM enabled interfaces. |
| <b>Priority</b>     | Shows the priority of the RP.                                                                           |

## Viewing the IPv6 active RP

Perform this procedure to show information about the IPv6 active RP for all the running multicast groups on the switch.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Active RP** tab.

#### *Active RP field descriptions*

Use the data in the following table to use the **Active RP** tab.

| Name                | Description                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IPv6 address of the multicast group.                                                                                                                                                                                                                                              |
| <b>Address</b>      | Shows the IPv6 address of the RP router. This address can be one of the local PIM-SM enabled interfaces or any reachable global IPv6 address configured using the <b>static-rp</b> CLI command.<br><br><b>Note:</b><br>IPv6 link local address is always used as the PIM interface address. |
| <b>Priority</b>     | Shows the priority of the RP.                                                                                                                                                                                                                                                               |

## Configuring a candidate bootstrap router

Configure routers as candidate bootstrap routers (C-BSR) to provide backup protection in case the primary BSR fails. PIM-SM cannot operate without a BSR. A PIM-SM domain can use only one active BSR.

### About This Task

The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Click **Enable**.
6. In the **CBSRPreference** box, type the preference.

The C-BSR with the highest BSR-preference and address becomes the active BSR. The default is -1, which indicates that the current interface is not a C-BSR.

7. Click **Apply**.

## Viewing current BSR information

View the current BSR information to review the configuration.

### Before You Begin

- You must disable static RP.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Current BSR** tab.

### *Current BSR field descriptions*

Use the descriptions in the following table to use the **Current BSR** tab.

| Name                  | Description                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>        | Shows the IP address of the current BSR for the local PIM domain.                                                                                                                            |
| <b>FragmentTag</b>    | Shows a randomly generated number that distinguishes fragments that belong to different bootstrap messages. Fragments that belong to the same bootstrap message carry the same fragment tag. |
| <b>HashMask</b>       | Shows the mask used in the hash function to map a group to one of the C-RPs from the RP set. The hashmask allows a small number of consecutive groups to always hash to the same RP.         |
| <b>Priority</b>       | Shows the priority of the current BSR. The C-BSR with the highest BSR priority and address (referred to as the preferred BSR) is elected as the BSR for the domain.                          |
| <b>BootStrapTimer</b> | Shows the bootstrap timer. After the bootstrap timer expires, the BSR sends out bootstrap messages.                                                                                          |

## Changing VLAN interface type

Change the state (active or passive) of PIM on a VLAN interface.

### Before You Begin

- Before you change the state of PIM on a VLAN interface, you must first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Clear the **Enable** check box.
8. Click **Apply**.
9. Select **active** or **passive**.
10. Reenable PIM on the VLAN interface.
11. Click **Apply**.

## Editing PIM interface parameters

Edit PIM parameters for an interface to customize the PIM configuration.

### Before You Begin

- Before you change the state (active or passive) of a PIM interface, first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                     | Description                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>           | Shows the interface Index. This variable is a read-only field.                                                                                                                                                                |
| <b>Address</b>           | Shows the IP address of the PIM interface. This variable is a read-only field.                                                                                                                                                |
| <b>NetMask</b>           | Shows the network mask for the IP address of the PIM interface. This variable is a read-only field.                                                                                                                           |
| <b>Mode</b>              | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field.                                                                                                          |
| <b>InterfaceType</b>     | Specifies if the interface is active or passive.                                                                                                                                                                              |
| <b>DR</b>                | Shows the router with the highest IP address on a LAN designated to perform these tasks.                                                                                                                                      |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.                                                                            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds.                                                                  |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. |
| <b>OperState</b>         | Indicates the status of PIM on this interface: Up or Down.                                                                                                                                                                    |

## Editing IPv6 PIM interface parameters

Edit the IPv6 PIM parameters for an interface to customize the IPv6 PIM configuration.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                     | Description                                                                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>           | Shows the interface Index. This variable is a read-only field.                                                                                               |
| <b>Address</b>           | Shows the IPv6 address of the PIM interface. This variable is a read-only field.                                                                             |
| <b>NetMask</b>           | Shows the network mask for the IPv6 address of the PIM interface. This variable is a read-only field.                                                        |
| <b>Enable</b>            | Shows the configured mode of this PIM interface. sparseDense mode is valid only for PIMv1.                                                                   |
| <b>Mode</b>              | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field.                                         |
| <b>DR</b>                | Shows the router with the highest IPv6 address on a LAN designated to perform these tasks.                                                                   |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.           |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. |
| <b>OperState</b>         | Indicates the status of PIM on this interface: Up or Down.                                                                                                   |
| <b>Type</b>              | Specifies the interface type.                                                                                                                                |

## Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Virtual Neighbors** tab.
4. Click **Insert**.
5. Specify the IP address of the virtual neighbor.
6. Specify the interface index for the PIM interface.
7. Click **Insert**.

**Virtual Neighbors** field descriptions

Use the descriptions in the following table to use the **Virtual Neighbors** tab.

| Name           | Description                                    |
|----------------|------------------------------------------------|
| <b>Address</b> | Specifies the IP address of the neighbor.      |
| <b>IfIndex</b> | Specifies the IP address of the PIM interface. |

## Viewing PIM-SM neighbor parameters

View PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Neighbors** tab.

**Neighbors** field descriptions

Use the descriptions in the following table to use the **Neighbors** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Address</b>    | Shows the IP address of the PIM neighbor.                                                   |
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>UpTime</b>     | Shows the time since this neighbor became a neighbor of the local router.                   |
| <b>ExpiryTime</b> | Shows the time remaining before the neighbor expires.                                       |

## Viewing IPv6 PIM-SM neighbor parameters

View IPv6 PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbors** tab.

**Neighbors** *field descriptions*

Use the descriptions in the following table to use the **Neighbors** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Address</b>    | Shows the IPv6 address of the PIM neighbor.                                                 |
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>UpTime</b>     | Shows the time since this neighbor became a neighbor of the local router.                   |
| <b>ExpiryTime</b> | Shows the time remaining before the neighbor expires.                                       |

## Viewing IPv6 Neighbor Secondary Address

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbor Secondary Address** tab.

**Neighbor Secondary Address** *field descriptions*

Use the descriptions in the following table to use the **Neighbor Secondary Address** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>Type</b>       | Shows the address type of this PIM neighbor.                                                |
| <b>Primary</b>    | The primary IPv6 address of this PIM neighbor.                                              |
| <b>SecAddress</b> | The secondary IPv6 address of this PIM neighbor.                                            |

## Viewing RP set parameters

View the RP set to see a list of rendezvous point addresses. The BSR constructs this list from C-RP advertisements, and then distributes it to all PIM routers in the PIM domain for the BSR. View the parameters for troubleshooting purposes.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **RP Set** tab.

**RP Set** field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name                | Description                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.                                                                                |
| <b>GroupMask</b>    | Shows the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.                                                                           |
| <b>Address</b>      | Shows the IP address of the C-RP router.                                                                                                                                                                                                                         |
| <b>HoldTime</b>     | Shows the time specified in a C-RP advertisement that the BSR uses to time out the RP. After the BSR receives an advertisement for the RP, it restarts the timer. If no advertisement arrives before the timer expires, the BSR removes that RP from the RP set. |
| <b>ExpiryTime</b>   | Shows the time remaining before this C-RP router times out.                                                                                                                                                                                                      |

## Configuring a candidate RP

Configure a C-RP router to add it to the RP Set.

**About This Task**

You can configure only one interface on a switch for multiple groups; that is, you cannot configure multiple interfaces for multiple groups.

Using the GroupMask value, you can configure a candidate RP for several groups in one configuration. For example, if you use a C-RP configuration with a GroupAddress value of 224.0.0.0 and a GroupMask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Candidate RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

### Candidate RP field descriptions

Use the descriptions in the following table to use the **Candidate RP** tab.

| Name                    | Description                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>     | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.      |
| <b>GroupMask</b>        | Configures the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <b>InterfaceAddress</b> | Configures the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.                                                                              |

### Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

#### About This Task

#### Important

The following configuration also activates full-mesh configurations.

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select **MulticastSquareSmltEnable**.  
Clear this check box if you want to disable square-SMLT globally.
5. Click **Apply**.

### Viewing IPv6 RP set parameters

View the IPv6 RP set to see a list of rendezvous point addresses. View the parameters for troubleshooting purposes.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **RP Set** tab.

**RP Set** field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name                | Description                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Specifies the IPv6 address of the multicast group. When combined with the group mask, this value identifies a group prefix for which the address is a static RP.    |
| <b>GroupMask</b>    | Specifies the address mask of the multicast group. When combined with the group address, this value identifies a group prefix for which the address is a static RP. |
| <b>Address</b>      | Specifies the IPv6 address of the static RP.                                                                                                                        |
| <b>HoldTime</b>     | Specifies the hold time of the static RP. The value is 0.                                                                                                           |
| <b>ExpiryTime</b>   | Specifies the minimum time remaining before the static RP is down. The value is 0.                                                                                  |

## Viewing IPv6 Mroute interface information

Use the following procedure to view IPv6 Mroute information for an interface.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Interfaces** tab.

**Interfaces** field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>  | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                                                                                                                          |
| <b>Ttl</b>      | Displays the datagram time-to-live (TTL) threshold for the interface. IPv6 multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.                                                                                |
| <b>Protocol</b> | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## Viewing IPv6 Mroute next hop information

Use the following procedure to view IPv6 Mroute next hop information.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Next Hop** tab.

### **Next Hop** field descriptions

Use the data in the following table to use the **Next Hop** tab.

| Name              | Description                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>      | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                       |
| <b>Source</b>     | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                |
| <b>SourceMask</b> | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                       |
| <b>IfIndex</b>    | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                               |
| <b>Address</b>    | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface. |
| <b>State</b>      | Displays whether the outgoing interface and next hop represented by this entry currently forward IPv6 datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.                                       |
| <b>ExpiryTime</b> | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                 |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ClosestMemberHops</b> | Displays the minimum number of hops between this router and members of the IPv6 multicast group reached through the next hop on this outgoing interface. IPv6 multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop.                                                              |
| <b>Protocol</b>          | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## Configuring resource usage counter for IPv6 Mroute

Configure the resource usage counters to query the number of ingress and egress IPv6 multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

### Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

### **Resource Usage** field descriptions

Use the data in the following table to use the **Resource Usage** tab.

| Name                          | Description                                                                     |
|-------------------------------|---------------------------------------------------------------------------------|
| <b>Ingress Records In-Use</b> | Displays the number of ingress records (source or group) traversing the switch. |
| <b>Egress Records In-Use</b>  | Displays the number of egress records traversing the switch.                    |
| <b>Ingress Threshold</b>      | Configures the ingress threshold level (0–32767).                               |
| <b>Egress Threshold</b>       | Configures the egress threshold level (0–32767).                                |

| Name                  | Description                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SendTrapAndLog</b> | Sends both trap and log notification messages after the number of streams exceeds a threshold level.                                       |
| <b>SendTrapOnly</b>   | Sends only trap notification messages after the number of streams exceeds a threshold level. You can configure only one notification type. |
| <b>LogMsgOnly</b>     | Sends only log notification messages after the number of streams exceeds a threshold level.                                                |

## Viewing IPv6 multicast route information

Use the following procedure to view IPv6 Mroute route information.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Route** tab.

### *IPv6 Multicast Route* field descriptions

Use the data in the following table to use the **Route** tab.

| Name                    | Description                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>            | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                        |
| <b>Source</b>           | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| <b>SourceMask</b>       | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.        |
| <b>UpStreamNeighbor</b> | Shows the address of the upstream neighbor from which the IPv6 datagrams from these sources are received.                                                                                   |
| <b>IfIndex</b>          | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                |

| Name              | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ExpiryTime</b> | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                            |
| <b>Protocol</b>   | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## IGMP Configuration Using the CLI

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

### Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### Before You Begin

- Complete one of the following tasks:
  - Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
  - Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

### Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Configuring IGMP on a VRF](#) on page 1684.

## Configuring multicast stream limitation on an Ethernet port

Configure multicast stream limitation on an Ethernet port to limit the number of concurrent multicast streams on the port. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

## About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the port drops joins to new streams. A service provider uses this feature to control the overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

### Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

3. If stream-limit is already enabled on the interface, change the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

4. Display multicast stream limitation information for the ports on a specific interface:

```
show ip igmp stream-limit interface
```

## Example

Enable multicast stream limitation on the Ethernet port and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit  
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

*Variable definitions*

Use the data in the following table to use the `ip igmp stream-limit-max-streams` command.

| Variable  | Value                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------|
| <0-65535> | Configures the maximum number of allowed streams on this port. The range is from 0-65535 and the default is 4. |

## Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops joins to new streams. A service provider uses this feature to control the overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

#### Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

3. If stream-limit is already enabled on the VLAN, change the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

4. Display multicast stream limitation information for the ports on a specific interface:

```
show ip igmp stream-limit port
```

## Example

Enable multicast stream limitation and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

### Variable definitions

Use the data in the following table to use the **ip igmp stream-limit** command.

| Variable  | Value                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------|
| <0-65535> | Configures the maximum number of allowed streams on this VLAN. The range is from 0-65535 and the default is 4. |

## Configuring VLAN multicast stream limitation members

Configure multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Configure multicast stream limitation members on a VLAN:

```
ip igmp stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams <0-65535>
```

### Example

Enable multicast stream limitation on ports 2/3 to 2/8 and configure the maximum allowed number of streams to 6 for this interface.

```
Switch:1(config-if)# ip igmp stream-limit-group 2/3-2/8 max-streams 6
```

*Variable definitions*

Use the data in the following table to use the `ip igmp stream-limit-group` command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-65535>                                            | Configures the maximum number of allowed streams for the specified ports on this VLAN. The range is from 0-65535 and the default is 4.                                                                                                                                                                                                                        |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring multicast router discovery options

Configure the multicast router discovery options to enable the automatic discovery of multicast-capable routers.

### About This Task

#### Important

The switch does not support the Multicast Router Discovery (MRDISC) protocol on brouter ports.

### Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable multicast router discovery:
 

```
ip igmp mrdisc
```
3. Configure the maximum advertisement intervals between successive advertisements:
 

```
ip igmp mrdisc maxadvertinterval <2-180> maxinitadvertinterval <2-180>
```
4. Configure the maximum advertisements after initialization:
 

```
ip igmp mrdisc maxinitadvertisements <2-15>
```
5. Configure the minimum advertisement interval between successive advertisements:
 

```
ip igmp mrdisc minadvertinterval <3-180>
```
6. Configure the time allowed before a neighbor is declared dead:
 

```
ip igmp mrdisc neighdeadinterval <2-180>
```

## Example

Configure the maximum advertisement intervals between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc maxadvertinterval 30 maxinitadvertinterval 5
```

Configure the maximum advertisements after initialization:

```
Switch:1(config-if)#ip igmp mrdisc maxinitadvertisements 8
```

Configure the minimum advertisement interval between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc minadvertinterval 30
```

Configure the time allowed before a neighbor is declared dead:

```
Switch:1(config-if)#ip igmp mrdisc neighdeadinterval 60
```

## Variable definitions

Use the data in the following table to use the **ip igmp mrdisc** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>maxadvertinterval</i> <2-180>     | Configures the maximum number (in seconds) between successive advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the <b>default</b> operator with the command. The default is 20.          |
| <i>maxinitadvertinterval</i> <2-180> | Configures the maximum number (in seconds) between successive initial advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the <b>default</b> operator with the command. The default is 2.   |
| <i>maxinitadvertisements</i> <2-15>  | Configures the maximum number of initial multicast advertisements after initialization. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the <b>default</b> operator with the command. The default is 3. |

| Variable                                     | Value                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>minadvertinterval &lt;3-180&gt;</code> | Configures the minimum number (in seconds) between successive advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the <b>default</b> operator with the command. The default is 15.               |
| <code>neighdeadinterval &lt;2-180&gt;</code> | Configures the multicast router discovery dead interval—the number of seconds the multicast route neighbors for the switch must wait before assuming that the multicast router is down. To configure this option to the default value, use the <b>default</b> operator with the command. The default is 60. |

## Configure Explicit Host Tracking

Configure explicit host tracking to track all the source and group members.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure explicit host tracking:

```
ip igmp igmpv3-explicit-host-tracking
```

3. Display all the tracked members for a specific group:

```
show ip igmp group group <A.B.C.D> tracked-members [member-subnet
<A.B.C.D/X>] [source-subnet <A.B.C.D/X>] [port {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}] [vlan <1-4059>]
```

4. Display the IGMPv3 specific data:

```
show ip igmp group group <A.B.C.D> detail port {{slot/port[/sub-port]
[-slot/port[/sub-port]] [,...]} vlan <1-4059>
```

### Examples

Configure explicit host tracking:

```
Switch:1(config-if)#ip igmp igmpv3-explicit-host-tracking
```

Display all the tracked members:

```
Switch:1#show ip igmp group

=====
                        Igmp Group - GlobalRouter
=====
GRPADDR      INPORT      MEMBER      EXPIRATION  TYPE      L2ISID
-----
224.5.2.1    V701-1/4    62.0.1.1    214         Dynamic   40400
224.5.2.2    V702-1/4    62.0.2.1    221         Dynamic   40400
224.5.2.3    V703-1/4    62.0.3.1    217         Dynamic   40400
224.5.2.4    V704-1/4    62.0.4.1    223         Dynamic   40400

4 out of 4 group Receivers displayed

Total number of unique groups 2
```

Display all the tracked members for a specific group:

```
Switch:1(config-if)#show ip igmp group group 232.1.1.1 tracked-members

=====
                        Members of Channels/Groups - GlobalRouter
=====
INTERFACE    CHANNEL/GROUP  MEMBER      MEMBER_MODE  EXP
-----
Vlan333-2/30  */232.1.1.1    133.133.133.200  IS_EXCLUDE  205

Note:
The "*" attached to the interface (if any) indicates that the interface has explicit host tracking disabled.
```

Display IGMPv3 specific data:

```
Switch:1(config-if)#show ip igmp group group 232.32.32.10 detail

=====
                        Igmp Group Detail - GlobalRouter
=====
Interface:                Vlan222-1/10
IGMPv3 Group:             232.32.32.10

Interface Compatibility Mode: IGMP_V3
V2 Host Timer:            Not Running
V1 Host Timer:            Not Running
Interface Group Include Source List:
    Source Address  Expires
    133.133.133.200  114
```

#### Variable definitions

Use the data in the following table to use the `ip igmp igmpv3-explicit-host-tracking` command.

| Variable                            | Value                                                                   |
|-------------------------------------|-------------------------------------------------------------------------|
| <code>explicit-host-tracking</code> | Enables explicit host tracking on IGMPv3. The default state is disable. |
| <code>&lt;A.B.C.D&gt;</code>        | Specifies the IP address of the group of the tracked member.            |

## Configuring IGMP static members

Configure IGMP static members to add members to a snoop group. You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams are always forwarded to the multicast router within the VLAN, in addition to the ports in this static entry.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Configure interface static members:

```
ip igmp static-group {A.B.C.D} {A.B.C.D} {port {slot/port[/sub-port] [-
slot/port[/sub-port]] [, ...]} [static|blocked]
```

### Example

Configure interface static members:

```
Switch:1(config-if)#ip igmp static-group 239.1.1.1 239.1.2.1 port 2/1 static
```

### Variable definitions

Use the data in the following table to use the **ip igmp static-group** command.

| Variable                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D} {A.B.C.D}</i>                                    | Indicates the IP address range of the selected multicast group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>port</i>                                                   | Adds ports to a static group entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i> | Creates a static group entry. Specifies the port or list of ports that is a member of the VLAN interface being configured to which you want to redirect the multicast stream for this multicast group. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>&lt;static blocked&gt;</i>                                 | Configures the route to static or blocked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring SSM dynamic learning and range group

Configure SSM dynamic learning and a range group to enable the IGMPv3 dynamic learning feature and to extend the default SSM range of 232/8 to include an IP multicast address. As new SSM channels are learned, the system displays them in the SSM channel table.

### Before You Begin

- To define the range group, you must first disable PIM.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

- Enter Global Configuration mode:  
enable  
  
configure terminal
- Enable SSM dynamic learning:  
ip igmp ssm dynamic-learning
- Configure the range group:  
ip igmp ssm group-range <A.B.C.D/X>

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter *y* to continue.

### Example

Define the SSM range group address (234.0.0.0) and mask (255.0.0.0). Enable dynamic learning from IGMPv3 reports.

```
Switch:1(config)#ip igmp ssm group-range 234.0.0.0/255.0.0.0

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(config)#ip igmp ssm dynamic-learning
```

### Variable definitions

Use the data in the following table to use the **ip igmp ssm** command.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

## Changing the SSM range group

Change the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address.

### Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

### About This Task

#### Important

This procedure reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), it also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable PIM:

```
no ip pim enable
```

If you forget to disable PIM, the system displays the following error message:

```
Error: PIM is enabled in SSM mode, disable PIM
```

3. Delete each entry in the SSM channel table:

```
no ip igmp ssm-map [all] [{A.B.C.D} enable]
```

If you forget to delete the SSM channels, the system displays the following error message:

```
Error: SSM source group table not empty
```

4. Configure the new IP multicast group address:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)?
```

Enter *y* to continue.

## 5. Enable PIM:

```
ip pim enable
```

**Example**

Configure the new IP multicast group address:

```
Switch:1(config)#ip igmp ssm group-range 232.0.0.0/16
```

```
WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
```

*Variable definitions*

Use the data in the following table to use the **ip igmp ssm group-range** and **ip igmp ssm** commands.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

**Configuring the SSM map table**

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple sources to the same group for both static source group and an SSM map.

**About This Task**

The consistency check applies to all SSM map entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenabling it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the SSM map table for all static entries:  

```
ip igmp ssm-map all
```
3. Create a static entry for a specific group:  

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

### Example

Create an SSM map table entry for the multicast group 234.0.1.0 and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1(config)#ip igmp ssm-map 234.0.1.0 192.32.99.151
Switch:1(config)#ip igmp ssm-map all
```

### Variable definitions

Use the data in the following table to use the **ip igmp ssm-map** command.

| Variable                         | Value                                                                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{A.B.C.D} {A.B.C.D}</code> | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group.                         |
| <code>{A.B.C.D} enable</code>    | Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

## Configuring multicast access control for an IGMP Ethernet port

Configure multicast access control for an IGMP Ethernet port to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> {A.B.C.D/X} <deny-tx|deny-rx|deny-both|
allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64>> {A.B.C.D/X} mode <deny-tx|deny-rx|
deny-both|allow-only-tx|allow-only-rx|allow-only-both>
```

## Variable definitions

Use the data in the following table to use the **ip igmp access-list** command

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D/X}</i>                                                           | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| <i>deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both</i> | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                                                                                                     |
| <i>mode</i>                                                                  | Changes the access control group configuration.                                                                                                                                                                                                                                              |
| <i>WORD&lt;1-64&gt;</i>                                                      | Specifies the name of the access list from 1–64 characters.                                                                                                                                                                                                                                  |

## Configuring multicast access control for a VLAN

Configure multicast access control for an IGMP VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

## Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] <deny-tx|deny-rx|deny-both|
allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] mode <deny-tx|deny-rx|deny-
both|allow-only-tx|allow-only-rx|allow-only-both>
```

### Variable definitions

Use the data in the following table to use the **ip igmp access-list** command.

| Variable                                                                       | Value                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D/X}</i>                                                             | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| <i>deny-tx deny-rx deny-both  allow-only-tx allow-only-rx  allow-only-both</i> | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                                                                                                     |
| <i>mode</i>                                                                    | Changes the access control group configuration.                                                                                                                                                                                                                                              |
| <i>WORD&lt;1-64&gt;</i>                                                        | Specifies the name of the access list from 1-64 characters.                                                                                                                                                                                                                                  |

## Configuring Fast Leave Mode

Configure fast (immediate) leave mode to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces. Normal IGMP behavior is skipped. Fast leave mode provides one command that controls all IGMP fast leave enabled interfaces.

### Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode for IGMPv3. For more information on enabling explicit-host-tracking, see [Configure Explicit Host Tracking](#) on page 1762.

## About This Task

If a single user connects to an interface, you do not need to track if other users exist on the interface to perform the fast leave. In cases like this, you must change the mode to one-user.

### Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. View the current fast leave mode:

```
show ip igmp sys
```

### Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

3. Configure fast leave mode:

```
ip igmp immediate-leave-mode <multiple-user|one-user>
```

## Example

Change the mode to one-user.

```
Switch:1(config)#ip igmp immediate-leave-mode one-user
```

### Variable definitions

Use the data in the following table to use the **ip igmp immediate-leave-mode** command.

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>multiple-user one-user</i> | <p><i>multiple-user</i> removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This configuration is the default.</p> <p><i>one-user</i> removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process.</p> |

## Enabling fast leave mode on a port

Enable fast (immediate) leave mode to specify if a port receives a leave message from a member of a group. If you enable fast leave mode on a port, it uses the global fast leave mode configuration.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable fast leave:

```
ip igmp immediate-leave
```

## Configuring IGMP fast leave members on a VLAN

Configure IGMP fast leave members on a VLAN to specify fast leave capable ports.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable fast leave on the VLAN:

```
ip igmp immediate-leave
```

3. Configure fast leave members on a VLAN:

```
ip igmp immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]}
```

*Variable definitions*

Use the data in the following table to use the `ip igmp immediate-leave-members` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Enable IGMP Layer 2 Querier

When no multicast router exists in your network, you can use IGMP Layer 2 Querier to allow the Layer 2 switch to act as a multicast router so that the system can participate in multicast environments where multicast routing is not required.

### Before You Begin

- You must enable IGMP snooping.

### About This Task

When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.

By default, IGMP Layer 2 Querier is disabled.

Enable Layer 2 Querier on only one node in the VLAN.

On Shortest Path Bridging (SPB) Customer VLANs (CVLAN), IGMP Querier is enabled automatically when you enable snooping on the VLAN.

### Procedure

- Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Enable IGMP Layer 2 Querier:

```
ip igmp snoop-querier
```

## What to Do Next

You must enable the IGMP Layer 2 Querier address. See [EnablingIGMPLayer2QuerierAddress](#)

## Enable IGMP Layer 2 Querier Address

To use the IGMP Layer 2 Querier feature you must designate the IGMP Layer 2 Querier source IP address, the address the system uses in the query message.

### Before You Begin

- Enable IGMP Layer 2 Querier.

### About This Task

You must configure the IGMP Layer 2 Querier address to an IP address in the IP subnet that IGMP hosts, and to which IGMP snoopers in the VLAN belong.

The default IP address is 0.0.0.0 when the IGMP Layer 2 Querier is disabled.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```

3. Verify the configuration:

```
show ip igmp snooping [vrf WORD<1-16>] [vrffids WORD<0-512>]
```

### Example

Enable the IGMP Layer 2 Querier feature for VLAN 4, and configure the querier address. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 4
Switch:1(config-if)#ip igmp snoop-querier
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1#show ip igmp snooping
```

```

## IGMP configuration using EDM

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

### Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

### Before You Begin

- Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
- Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM), or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

### Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Select and Launch a VRF Context View](#) on page 4203.

## Enabling IGMP snoop on a VLAN

Enable IGMP snooping on a VLAN to optimize the multicast data flow for a group within a VLAN to only those that are members of the group that uses IGMP snoop.

### About This Task

The switch listens to group reports from each port and builds a database of multicast group members for each port. The switch suppresses the reports heard by not forwarding them to other hosts, forcing the members to continuously send their own reports.

The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. The switch

multicasts data only to the participating group members and to the multicast routers within the VLAN.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. Select the **ProxySnoopEnable** check box.
9. For SteamLimtEnable, select **enable**.
10. Click **Apply**.

## Configuring IGMP interface static members

Configure IGMP interface static members to add members to a snoop group.

### About This Task

You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams always forward to the multicast router within the VLAN, in addition to the ports in this static entry.

#### Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Static** tab.
4. Click **Insert**.
5. Type the appropriate information.
6. Click **Insert**.

**Static** field descriptions

Use the data in the following table to use the **Static** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>          | Shows the interface where the IGMP entry is enabled.                                                                                                                                                                                                                                                                                        |
| <b>GrpAddr</b>          | Indicates the start of the IP multicast address range of the multicast stream.<br>Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message. |
| <b>ToGrpAddr</b>        | Indicates the end of the IP multicast address range of the multicast stream. If an address is not entered, the IP address in the GrpAddr field is the single address.                                                                                                                                                                       |
| <b>MemberPorts</b>      | Specifies the ports to which you want to redirect the multicast stream for this multicast group. The ports must be member ports of the VLAN.                                                                                                                                                                                                |
| <b>NotAllowedToJoin</b> | Specifies the ports that do not receive the multicast stream for this multicast group.                                                                                                                                                                                                                                                      |

## Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) or multiple groups to different sources for both static source group and an SSM channel.

### Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

### About This Task

The consistency check applies to all SSM channel entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenoble it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Map** tab.
4. Select **Insert**.
5. Type the IP address for the multicast group and source.
6. Select **Insert**.

You can change the default status of an SSM map from enable to disable in the **AdminState** field.

### *Ssm Map* field descriptions

Use the data in the following table to use the **Ssm Map** tab.

| Name                  | Description                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpMulticastGrp</b> | Specifies an IP multicast address that is within the SSM range.                                                                                                                                                                   |
| <b>IpSource</b>       | Specifies the IP address of the source that sends traffic to the group.                                                                                                                                                           |
| <b>LearningMode</b>   | Displays whether the entry is statically configured (Static) or dynamically-learned from IGMPv3 (Dynamic). This variable a read-only field.                                                                                       |
| <b>Activity</b>       | Displays the current activity of the selected (S,G) entry. True indicates that traffic is flowing to the switch, otherwise, the system displays it false. This variable a read-only field.                                        |
| <b>AdminState</b>     | Configures the administrative state for the selected static entry. This state determines whether the switch uses the static entries. Configure this field to enable (default) to use the entry or disable to save for future use. |

## Configure SSM Range and Global Parameters

Configure the SSM range parameter to extend the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without changing their group configurations.

### Before You Begin

- To change the RangeGroup configuration, you must first disable PIM.
- To change the RangeGroup configuration, you must delete all entries in the SSM channel table before you configure the new IP multicast group address.

## About This Task

The other global parameters enable the IGMPv3 dynamic learning feature and configure the administrative state for all the entries in the SSM channel table.

### Important

If you change the RangeGroup configuration, the switch reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), this procedure also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Global** tab.
4. Configure the appropriate fields.
5. Select **Apply**.

### *Ssm Global* field descriptions

Use the data in the following table to use the **SsmGlobal** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DynamicLearning</b>   | Activates the dynamic learning of SSM channel (S,G) pairs from IGMPv3 reports. As new SSM channels are learned, the system displays them in the SSM channel table.                                                                                                                                                                                                                                                                                     |
| <b>RangeGroup</b>        | Configures the IP multicast group address. The lowest group address is 224.0.0.0 and the highest is 239.255.255.255. The default is 232.0.0.0.                                                                                                                                                                                                                                                                                                         |
| <b>RangeMask</b>         | Configures the address mask of the multicast group. The default is 255.0.0.0.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SsmMapAdminAction</b> | Configures the administrative state, which determines whether the switch uses the table entries: <ul style="list-style-type: none"> <li>• enableAll—Globally activates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries.</li> <li>• disableAll—Globally inactivates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries.</li> </ul> |

## Configuring multicast stream limitation on an interface

Configure multicast stream limitation to limit the number of concurrent multicast streams on the interface. By limiting the number of concurrent multicast streams,

you can protect the bandwidth on a specific interface and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the interface drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit** tab.
4. To change the status of an interface, double-click on the **StreamLimitEnable** field for the interface, and then select **enable** or **disable** from the menu. If the interface is enabled, you can edit the **Maximum Number of Stream** field.
5. Click **Apply**.

### **StreamLimit** field descriptions

Use the data in the following tab to use the **StreamLimit** tab.

| Name                            | Description                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>                | Displays the slot and port number or VLAN ID for this interface.                                                     |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this interface.                                                             |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams allowed on this interface. The range is from 0–65535, and the default is 4. |
| <b>Current Number Of Stream</b> | Displays the current number of streams received on this interface. This value is a read-only value.                  |

## Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific VLAN and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. For StreamLimitEnable, select **enable**.
8. Configure the maximum number of streams.
9. Click **Apply**.

## Configuring multicast stream limitation on a port

Configure multicast stream limitation to limit the number of concurrent multicast streams on the port. Limit the number of streams to protect the bandwidth on a specific port and control access to multicast streams.

### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **IGMP** tab.
5. In the StreamLimitEnable field, select the **Enable** option button.
6. Configure the maximum number of streams.
7. Click **Apply**.

## Configuring multicast stream limitation members

Configure multicast stream limitation members on ports of the specified interface to configure the maximum number of streams on the interface.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click **Insert**.
5. Type the number of the VLAN to which you want to add a member or click **Vlan** to select an ID from the list.

6. Type the number of the slot and port that you want to add as a member or click **Port**, and then select one from the graphic display. If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

#### Important

You must select one of the ports in the VLAN that you selected in step 4.

7. Type a maximum number of streams or accept the default of 4.
8. Click **Insert**.

### **StreamLimit Members** field descriptions

Use the data in the following table to use the **StreamLimit Members** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Displays the ID of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Port</b>       | Lists each slot and port number for this interface with stream limitation enabled. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <b>MaxStreams</b> | Configures the maximum number of allowed streams for this specific port. The number of allowed streams cannot exceed the maximum number for the interface. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                       |
| <b>NumStreams</b> | Displays the current number of streams received on this interface. This value is a read-only value.                                                                                                                                                                                                                                                                                                                                              |

## Deleting multicast stream limitation member

Delete a multicast stream limitation member from an interface to remove it from the configuration.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click on the row that lists the member you want to delete.
5. Click **Delete**.

## Configuring the IGMP interface

Configure the IGMP interface to change global IGMP values for the interface. Use the Interface tab to view or edit the IGMP interface table.

### About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but PIM-SM is not enabled, the system displays the interface as notInService in the Status field.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **IGMP**.
3. Click the **Interface** tab.
4. Edit the appropriate information.
5. Click **Apply**.

### Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                 | Description                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>       | Shows the interface where IGMP is enabled.                                                                                                                                                          |
| <b>QueryInterval</b> | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                 |
| <b>Status</b>        | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                           |
| <b>Version</b>       | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. |
| <b>OperVersion</b>   | Shows the version of IGMP that currently runs on this interface.                                                                                                                                    |
| <b>Querier</b>       | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                            |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryMaxResponseTime</b>        | <p>Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)</p> <p><b>Important:</b><br/>You must configure this value lower than the QueryInterval.</p>                                                                                                                                                                                                                                                                          |
| <b>WrongVersionQueries</b>         | <p>Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Joins</b>                       | <p>Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Robustness</b>                  | <p>Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.</p> <p>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.</p>                                                                                                                                                                                                                                                                                    |
| <b>LastMembQueryIntvl</b>          | <p>Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.</p> <p>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)</p> |
| <b>OtherQuerierPresent Timeout</b> | <p>Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>FlushAction</b>                 | <p>Configures the flush action to one of the following:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RouterAlertEnable</b>          | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <b>SsmSnoopEnable</b>             | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SnoopQuerierEnable</b>         | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SnoopQuerierAddr</b>           | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                        |
| <b>McastMode</b>                  | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>• snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>• snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>• pim — Indicates PIM is enabled.</li> <li>• routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul>                                       |
| <b>ExtnUpnpFilterEnable</b>       | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ExtnUpnpFilterAddress</b>      | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ExtnUpnpFilterAddressMask</b>  | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SnoopOrigin</b>                | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                                                                    |
| <b>ExtnRoutedSpbQuerierAddr</b>   | Specifies the IP address of the SPB querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Configuring IGMP sender entries

Configure IGMP sender entries to identify a source that sends multicast data to a multicast group.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Sender** tab.
4. Change the appropriate options.
5. Select **Apply**.

### *Sender* field descriptions

Use the data in the following table to use the **Sender** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Specifies the interface where you enabled the IGMP entry.                                                                                                                                                                                                                                                                 |
| <b>GrpAddr</b>    | Specifies the multicast group address of the multicast stream.<br>Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an error message. |
| <b>MemberAddr</b> | Specifies the IP address of a host.                                                                                                                                                                                                                                                                                       |
| <b>Action</b>     | Flushes an entry or a group.                                                                                                                                                                                                                                                                                              |
| <b>TPort</b>      | Identifies the T port.                                                                                                                                                                                                                                                                                                    |
| <b>State</b>      | Indicates whether a sender exists because of an IGMP access filter. The options are filtered and not filtered.                                                                                                                                                                                                            |
| <b>L2Isid</b>     | Specifies the Layer 2 I-SID of the C-VLAN.                                                                                                                                                                                                                                                                                |
| <b>Scopelsid</b>  | Indicates the scope I-SID of SPB routed multicast sender. If the sender does not support an SPB scope I-SID, the field displays an invalid value of 0xFFFFFFFF.                                                                                                                                                           |
| <b>Datalsid</b>   | Indicates the data I-SID of SPB routed multicast sender. If the sender does not support an SPB data I-SID, the field displays an invalid value of 0xFFFFFFFF.                                                                                                                                                             |

## Configuring Fast Leave Mode

Configure fast leave mode to control all IGMP fast leave enabled interfaces.

### Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode. To enable explicit-host-tracking, see [Configuring IGMP parameters on a port](#) on page 1697 and [Configuring IGMP parameters on a VLAN](#) on page 1700.

### About This Task

Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Use this global parameter to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces.

#### Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > IP**.
- Click **IGMP**.
- Click the **Global** tab.
- Select the mode.
- Click **Apply**.

### *Global* field descriptions

Use the data in the following table to use the **Global** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FastLeaveMode</b> | Configures the mode to one of the following values: <ul style="list-style-type: none"> <li>multipleUser: Removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This value is the default.</li> <li>oneUser: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process.</li> </ul> |
| <b>GenerateTrap</b>  | Generates a trap. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>GenerateLog</b>   | Generates a log message. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring multicast access control for an interface

Configure multicast access control for a selected IGMP interface or VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

## About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Access Control** tab.
4. Click **Insert**.
5. Type the number of the slot and port or VLAN ID that you want to add as a member or click the appropriate button, and then select one from the graphic display.
6. Click the ellipsis button (...) next to **PrefixListId**.
7. Select a prefix list ID.
8. Click **OK**.
9. Type the host address and host mask.
10. Select the action mode that you want for the specified host.
11. Click **Insert**.

### *Access Control* field descriptions

Use the data in the following table to use the **Access Control** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Specifies the interface where the IGMP entry is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>PrefixListId</b>   | Specifies a numeric string that identifies the prefix list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>HostAddr</b>       | Specifies the IP address of the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>HostMask</b>       | Specifies the subnet mask that determines the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>PrefixListName</b> | Specifies the name of the prefix list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ActionMode</b>     | Specifies the action for the host identified by HostAddr. The options include the following: <ul style="list-style-type: none"> <li>• denied IP multicast transmitted traffic (deny-tx).</li> <li>• denied IP multicast received traffic (deny-rx).</li> <li>• denied both IP multicast transmitted and received traffic (deny-both).</li> <li>• allowed IP multicast transmitted traffic (allow-only-tx).</li> <li>• allowed IP multicast received traffic (allow-only-rx).</li> <li>• allowed both IP multicast transmitted and received traffic (allow-only-both).</li> </ul> |

## Viewing IGMP cache information

View IGMP cache information to view the group for which members exist on a specific interface.

### About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**
3. Click the **Cache** tab.

### Cache field descriptions

Use the data in the following table to use the **Cache** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>           | Shows the IP multicast group address for this entry that contains this information.                                                                                                                                                                                                                                                                                  |
| <b>IfIndex</b>           | Shows the interface from which the corresponding multicast group address is heard.                                                                                                                                                                                                                                                                                   |
| <b>LastReporter</b>      | Shows the IP address of the source of the last membership report received for this IP multicast group address on this interface. If no membership report is received, the object uses the value 0.0.0.0.                                                                                                                                                             |
| <b>ExpiryTime</b>        | Shows the amount of time (in seconds) that remain before this entry ages out.                                                                                                                                                                                                                                                                                        |
| <b>Version1HostTimer</b> | Shows the time that remains until the local router assumes that no IGMPv1 members exist on the IP subnet attached to the interface. Upon hearing IGMPv1 membership report, this value resets to the group membership timer. When the time that remains is nonzero, the local router ignores IGMPv2 leave messages for this group that it receives on this interface. |
| <b>Type</b>              | Shows the type of IGMP entry.                                                                                                                                                                                                                                                                                                                                        |
| <b>StaticPorts</b>       | Shows the static ports associated with the entry.                                                                                                                                                                                                                                                                                                                    |

## Viewing IGMPv3 cache

View the IGMPv3 specific data corresponding to each interface, port, and multicast group pair on a router.

### About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **IGMPv3 Cache** tab to view the IGMPv3 cache information.

**IGMPv3 Cache** field descriptions

Use the data in the following table to use the **IGMPv3 Cache** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>      | Specifies the Multicast group Address (Class D) that others want to join. A group address can be the same for many incoming ports.                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b>           | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.                                                                                                                                                                                                                                                                                                |
| <b>InPort</b>            | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.                                                                                                                                                                                                                                                                                                |
| <b>ModeExpiryTimer</b>   | Represents the time remaining before the interface EXCLUDE state expires and the interface state transitions to INCLUDE mode. This value is applicable only to IGMPv3-compatible nodes.                                                                                                                                                                                                                                               |
| <b>Version1HostTimer</b> | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 1 members on the IP subnet attached to this interface. This entry only applies to IGMPv1 hosts. Upon hearing any IGMPv1 report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 Leave messages for this group that it receives on this interface. |
| <b>Version2HostTimer</b> | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 membership report, this value is reset to the group membership timer. Assuming no IGMPv1 hosts have been detected, the local router does not ignore any IGMPv2 Leave messages for this group that it receives on this interface.                 |
| <b>SourceFilterMode</b>  | Specifies the current group state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.                                                                                                                                                                                                                                                                                                |

## Viewing and editing multicast router discovery information

View multicast router discovery information to view the current configuration.

## About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Multicast Router Discovery** tab.
4. To edit the current configuration, double-click the value, make the change, and then click **Apply**.

### *Multicast Router Discovery* field descriptions

Use the data in the following table to use the **Multicast Router Discovery** tab.

| Name                               | Description                                                                                                                                                                                                                                              |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>                   | Shows the interface where IGMP is enabled.                                                                                                                                                                                                               |
| <b>MrdiscEnable</b>                | Enables (true) or disables (false) the router interface to listen for multicast router discovery messages to determine where to send multicast source data and IGMPv2 reports. If you enable snoop, you automatically enable multicast router discovery. |
| <b>DiscoveredRouterPorts</b>       | Lists ports that the Multicast Router Discovery (MRDISC) protocol discovers.<br><br><b>Important:</b><br>The switch does not support the MRDISC protocol on brouter ports.                                                                               |
| <b>MaxAdvertiseInterval</b>        | Shows the maximum time allowed between sending router advertisements from the interface, in seconds. The range is from 2–180 seconds. The default is 20 seconds.                                                                                         |
| <b>MinAdvertiseInterval</b>        | Shows the minimum time allowed between sending unsolicited router advertisements from the interface, in seconds. This value must be more than 3 seconds but no greater than the value assigned to the MaxAdvertiseInterval value.                        |
| <b>MaxInitialAdvertiseInterval</b> | Configures the maximum number (in seconds) of multicast advertisement intervals that you can configure on the switch.                                                                                                                                    |
| <b>MaxInitialAdvertisements</b>    | Configures the maximum number of initial multicast advertisements that you can configure on the switch.                                                                                                                                                  |
| <b>NeighborDeadInterval</b>        | Shows the time interval (in seconds) before the router interface drops traffic after a user leaves the multicast group.                                                                                                                                  |

## Viewing the IGMP router source list

View the source list entries corresponding to each interface and multicast group pair on a router.

### About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Igmp Router Source List** tab to view the IGMPv3 cache information.

### *Igmp router source list* field descriptions

Use the data in the following table to use the **Igmp Router Source List** tab.

| Name                 | Description                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>  | Specifies the IP multicast group address for which this entry contains information.                                                                                                         |
| <b>IfIndex</b>       | Specifies the interface for which this entry contains information for an IP multicast group address.                                                                                        |
| <b>InPort</b>        | Specifies a unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports for this source.                                                  |
| <b>HostAddress</b>   | Specifies the host address to which this entry corresponds.                                                                                                                                 |
| <b>MemberAddress</b> | Specifies the IP Address of a member that has sent source specific report wishing to join this source.                                                                                      |
| <b>Expire</b>        | This value indicates the relevance of the source list entry, where a non-zero value indicates this is an INCLUDE state value, and a zero value indicates this to be an EXCLUDE state value. |
| <b>Mode</b>          | Specifies the current member state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.                                                     |
| <b>MemberExpire</b>  | This value indicates the time until the member for this source expires.                                                                                                                     |

## Viewing IGMP snoop information

View information about IGMP snoop to see the current configuration.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop** tab.

### *Snoop field descriptions*

Use the data in the following table to use the **Snoop** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>               | Shows the VLAN ID for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SnoopEnable</b>             | Shows the status of IGMP snoop. IGMP snoop works only if a multicast router exists in the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SsmSnoopEnable</b>          | Shows the status of SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ProxySnoopEnable</b>        | Indicates whether the IGMP report proxy feature is enabled. If you enable this feature, the switch forwards reports from hosts to the multicast router once for each group for each query interval, or after new group information is available. If you disable this feature, the switch forwards all reports from different hosts to multicast routers, and can forward more than one group report for the same multicast group for each query interval. The default is enabled.                   |
| <b>FastLeaveEnable</b>         | Shows the status of fast leave for this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>FastLeavePortMembers</b>    | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SnoopMRouterPorts</b>       | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| <b>SnoopActiveMRouterPorts</b> | Shows the active multicast router ports. Active multicast router ports are ports that directly attach to a multicast router. These ports include the querier port and all ports in the forwarding state that you configure as well as those that were dynamically learned through receiving queries.                                                                                                                                                                                                |
| <b>SnoopMRouterExpiration</b>  | Indicates the time that remains before the multicast router ages out. If the switch does not receive queries before this time expires, it flushes out all group memberships known to the VLAN. The query maximum response interval (obtained from the queries received) is used as the timer resolution.                                                                                                                                                                                            |

## View IGMP Snoop Trace Information

View the multicast group trace to track the data flow path of multicast streams.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop Trace** tab.

### **Snoop Trace** Field Descriptions

Use the data in the following table to use the **Snoop Trace** tab.

| Name           | Description                                                           |
|----------------|-----------------------------------------------------------------------|
| <b>GrpAddr</b> | Displays the IP multicast address of the group traversing the router. |
| <b>SrcAddr</b> | Displays the IP source address of the multicast group.                |
| <b>OutVlan</b> | Displays the egress VLAN ID for the multicast group.                  |
| <b>InPort</b>  | Displays the ingress port for the multicast group.                    |
| <b>InVlan</b>  | Displays the ingress VLAN ID for the multicast group.                 |
| <b>OutPort</b> | Displays the egress port of the multicast group.                      |
| <b>Type</b>    | Displays the port type on which the snoop entry is learned.           |

## View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

### About This Task

#### Note

The following procedure displays the dynamically learned IGMP groups. **IP > IGMP > Static** displays statically configured IGMP groups. This is in contrast to the CLI command **show ip igmp group**, which displays both dynamically learned and statically configured IGMP groups, and the CLI command **show ip igmp static**, which displays only the statically configured groups.

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Groups** tab.

**Groups** *Field Descriptions*

Use the data in the following table to use the **Groups** tab.

| Name              | Description                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddress</b>  | Shows the multicast group address (Class D). A group address can be the same for many incoming ports.                              |
| <b>Members</b>    | Shows the IP address of the host that issues the membership report to this group.                                                  |
| <b>InPort</b>     | Shows the port that receives the group membership report.                                                                          |
| <b>IfIndex</b>    | Shows a unique value that identifies a physical interface or a logical interface (VLAN) that receives the membership report.       |
| <b>Expiration</b> | Shows the time left before the group report expires on this port. This variable is updated after the port receives a group report. |

## Route management using the CLI

With multicast route commands, you can configure and view IP multicast routing parameters on the switch.

### Configuring multicast stream limits

Limit the number of multicast streams to protect the CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

#### About This Task

You can enable or disable the mroute stream limit for the entire device or for individual ports when the switch is operating. If you enable the mroute stream limit for the device and for an individual port, only the periodic check is performed for that port.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable stream limitation globally:
 

```
ip mroute stream-limit
```
3. Enter GigabitEthernet Interface Configuration mode.
 

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

## 4. Enable stream limits:

```
ip mroute stream-limit
```

## 5. For Gigabit Ethernet interfaces, configure the maximum number of streams and the interval at which to sample:

```
ip mroute max-allowed-streams <1-32768> max-allowed-streams-timer-check <1-3600>
```

## 6. Show the mroute stream limit configuration:

```
show ip mroute interface gigabitethernet [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

**Example**

```
Switch:1(config)#ip mroute stream-limit
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#ip mroute stream-limit
Switch:1(config-if)#ip mroute max-allowed streams 1000 max-allowed-streams-timer-check 20
```

*Variable definitions*

Use the data in the following table to use the **interface** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...] | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

Use the data in the following table to use the **ip mroute** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max-allowed-streams &lt;1-32768&gt;</code>            | Configures the maximum number of streams on the specified port. The port is shut down if the number of streams exceeds this limit. The value is a number between 1–32768. The default value is 1984 streams. To configure this option to the default value, use the <b>default</b> operator with the command.                      |
| <code>max-allowed-streams-timer-check &lt;1-3600&gt;</code> | Configures the sampling interval, which checks if the number of ingress multicast streams to the CPU is under a configured limit or if the port needs to shut down. The range is between 1–3600. The default value is 10 seconds. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configuring multicast static source groups

Configure static source group entries in the Protocol Independent Multicast (PIM) multicast routing table. The PIM cannot prune these entries from the distribution tree.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

### About This Task

Even if no receivers exist in the group, the multicast stream for a static source group entry remains active.

The maximum number of static source groups must not exceed 1024.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Configure a static source group entry:
 

```
ip mroute static-source-group <A.B.C.D> <A.B.C.D/X>
```

## Example

Create a static source group for two multicast groups: 224.32.2.1 and 226.50.2.2. The static source group for group 224.32.2.1 is for a source subnet 10.10.10.0/24. The static source group for group 226.50.2.2 is for the host 20.20.20.100/32.

```
Switch:1(config)# ip mroute static-source-group 224.32.2.1 10.10.10.0/24
Switch:1(config)# ip mroute static-source-group 226.50.2.2 20.20.20.100/32
```

### Variable definitions

Use the definitions in the following table to use the **ip mroute static-source-group** command.

| Variable         | Value                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A.B.C.D</i>   | Specifies the IP address of the multicast group. Use the <b>no</b> operator to later remove this configuration.                                                                                                                                                                |
| <i>A.B.C.D/X</i> | Specifies the multicast source IP address and subnet mask for the static source group entry. You cannot create duplicate groups. How you configure the source address depends on the protocol and mode you use. Use the <b>no</b> operator to later remove this configuration. |

## Configuring IP multicast software forwarding

When you use the IP multicast software forwarding feature you can avoid initial data loss experienced by multicast applications; this is suitable for low bandwidth conditions.

When you configure the IP multicast software forwarding feature the system forwards the initial packets of an IP multicast data stream it receives and creates a corresponding hardware record for subsequent packets.

By default, multicast software forwarding is disabled.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware continues to forward IP multicast traffic. The software only forwards initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only.

If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding and packet suppression by the hardware is disabled.

If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

### Important

To avoid overloading the CPU, ensure that you do not use the IP multicast software forwarding feature for video multicast applications.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable software forwarding:  
`mcast software-forwarding`
3. Show the software forwarding configuration:  
`show mcast software-forwarding`

### Example

```
Switch:1#show mcast software-forwarding
=====
                        Mcast Software Forwarding - GlobalRouter
=====
McastSoftwareForwarding      :enabled
```

## Configuring the resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

After you configure the counter thresholds for ingress and egress records, if the record usage exceeds the threshold, you receive notification by a trap on the console, a logged message, or both.

If you do not configure the thresholds, the system displays only the ingress and egress records currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the thresholds:

```
ip mroute resource-usage egress-threshold <0-32767> ingress-threshold <0-32767>
```

3. Configure one of the following notification methods:

- Configure a log-only notification method:

```
ip mroute resource-usage log-msg
```

- Configure a trap-only notification method:

```
ip mroute resource-usage trap-msg
```

- Configure both notification methods:

```
ip mroute resource-usage log-msg trap-msg
```

### Example

Configure the egress threshold to 200.

```
Switch:1(config)# ip mroute resource-usage egress-threshold 200
```

Configure the ingress threshold to 100.

```
Switch:1(config)# ip mroute resource-usage ingress-threshold 100
```

Enable the log message notification method.

```
Switch:1(config)# ip mroute resource-usage log-msg
```

### Variable definitions

Use the data in the following table to use the `ip mroute resource-usage` command.

| Variable                                       | Value                                                                                                                                                                                                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>egress-threshold &lt;0-32767&gt;</code>  | Configures the egress record threshold (S,G). The system sends a notification message after the number of streams exceeds a threshold level.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 0. |
| <code>ingress-threshold &lt;0-32767&gt;</code> | Configures the ingress record threshold. The system sends a notification message after the number of streams exceeds a threshold level.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 0.      |

## Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

### About This Task

#### Important

When you configure a prefix list for a route policy, add the prefix as `a.b.c.d/32`. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a prefix list:

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [le <0-32>]
```

3. (Optional) Rename an existing prefix list:

```
ip prefix-list WORD<1-64> name WORD<1-64>
```

4. Display the prefix list:

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids  
WORD<0-512>] [WORD <1-64>]
```

## Example

Configure a prefix-list. Display the prefix list.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list LIST1 47.17.121.50/255.255.255.0
Switch:1(config)#show ip prefix-list LIST1
=====
                          Prefix List - GlobalRouter
=====
-----
      PREFIX                MASKLEN FROM TO
-----
List 1      LIST1:
      47.17.121.50      24      24  24
1 Total Prefix List entries configured
-----
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range
```

### Variable definitions

The following table defines parameters for the **ip prefix-list** command.

| Variable        | Value                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X}     | Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d/x</li> <li>• a.b.c.d/x.x.x.x</li> <li>• default</li> </ul> |
| ge <0-32>       | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                          |
| le <0-32>       | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                          |
| name WORD<1-64> | Renames the specified prefix list. The name length is 1-64 characters.                                                                                                             |
| WORD<1-64>      | Specifies the name for a new prefix list.                                                                                                                                          |

The following table defines parameters for the **show ip prefix-list** command.

| Variable       | Value                                                  |
|----------------|--------------------------------------------------------|
| {A.B.C.D}      | Specifies the prefix to include in the command output. |
| vrf WORD<1-16> | Specifies the name of the VRF.                         |

| Variable                              | Value                                                                |
|---------------------------------------|----------------------------------------------------------------------|
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF and is an integer in the range of 0–512. |
| <code>WORD&lt;1-64&gt;</code>         | Specifies a prefix list, by name, to use for the command output.     |

The following table defines parameters for the **show ip prefix-list** command output.

| Variable | Value                                             |
|----------|---------------------------------------------------|
| PREFIX   | Indicates the member of a specific prefix list.   |
| MASKLEN  | Indicates the prefix mask length in bits.         |
| FROM     | Indicates the prefix mask starting point in bits. |
| TO       | Indicates the prefix mask endpoint in bits.       |

## Route management using EDM

View or edit interface configuration information for Layer 3 IP multicast protocols on the switch.

### View Multicast Route Information

View multicast route information for troubleshooting purposes.

This tab shows multicast routing information for IP datagrams from a particular source and addressed to a particular IP multicast group address.

#### About This Task

#### Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

#### Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Select the **Routes** tab.

**Routes** field descriptions

Use the data in the following table to use the **Routes** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>            | Displays the IP multicast group address for this entry that contains multicast routing information.                                                                                                                                                                                                                                                                                |
| <b>Source</b>           | Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.                                                                                                                                                                                                                 |
| <b>SourceMask</b>       | Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.                                                                                                                                                                                                                                                          |
| <b>UpstreamNeighbor</b> | Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.                                                                                                                                                                                                                            |
| <b>Interface</b>        | Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.                                                                                                                                                                                                                                 |
| <b>ExpiryTime</b>       | Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                                                                 |
| <b>Protocol</b>         | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb (12)</li> <li>• spbpimgw(13)</li> </ul> |

## View Multicast Next-Hop Information

View all multicast next-hop information.

This tab shows information about the next hops used by outgoing interfaces to route IP multicast datagrams. Each entry is one in a list of next hops on outgoing interfaces for particular sources that send to a particular multicast group address.

**About This Task**

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.

2. Select **Multicast**.
3. Select the **Next Hops** tab.

### **Next Hops** field descriptions

Use the data in the following table to use the **Next Hops** tab.

| Name                     | Description                                                                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>             | Displays the IP multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                                                   |
| <b>Source</b>            | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                                          |
| <b>SourceMask</b>        | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                                                 |
| <b>ReceiverPort</b>      | Displays the receiver port for this next hop.                                                                                                                                                                                                                                        |
| <b>OutInterface</b>      | Displays the interface slot and portnumber or VLAN ID for the outgoing interface for this next hop.                                                                                                                                                                                  |
| <b>Address</b>           | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface.                           |
| <b>State</b>             | Displays whether the outgoing interface and next hop represented by this entry currently forward IP datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.                                                                   |
| <b>UpTime</b>            | Displays the up time for this entry.                                                                                                                                                                                                                                                 |
| <b>ExpiryTime</b>        | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                           |
| <b>ClosestMemberHops</b> | Displays the minimum number of hops between this router and members of the IP multicast group reached through the next hop on this outgoing interface. IP multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop. |

| Name            | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Protocol</b> | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |
| <b>Pkts</b>     | Displays the number of next hop packets.                                                                                                                                                                                                                                                                                                              |

## View Multicast Interface Information

View multicast interface information to verify the multicast configuration.

This tab shows multicast routing information specific to interfaces.

### About This Task

You can view multicast interface information for a Layer 3 VSN the same way you view the Global Router except that you must first launch the appropriate VRF context.

#### Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Interfaces** tab.

**Interfaces** field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                                                                                                                          |
| <b>Ttl</b>       | Displays the datagram time-to-live (TTL) threshold for the interface. IP multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.                                                                                  |
| <b>Protocol</b>  | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## Adding new static source groups

Add a new static source group to create an entry that the switch cannot prune from the distribution tree. An attempt to add a duplicate of an existing source-group entry results in an error message.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-SM
  - PIM-SSM

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Click **Insert**.
5. Complete the information in the dialog box.
6. Click **Insert**.

## Editing static source groups

Configure static source-group entries in the PIM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers exist in the group, the multicast stream for a static source-group entry stays active.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The maximum number of static source groups must not exceed 1024.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Edit the required information.
5. Click **Apply**.

### **Static Source Group** field descriptions

Use the data in the following table to use the **Static Source Group** tab.

| Name                 | Description                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>  | Configures the multicast group IP address for this static source-group entry.                                                                                 |
| <b>SourceSubnet</b>  | Configures the multicast source address for this static source-group entry.<br>How you configure the source address depends on the protocol and mode you use. |
| <b>SrcSubnetMask</b> | Configures the subnet mask of the source for this static source-group entry.                                                                                  |

## Configuring IP multicast software forwarding

Configure IP multicast software forwarding to enable the system to initially forward IP multicast data until a hardware record is created. The system forwards the initial packets of a stream it receives and creates a corresponding hardware record for

subsequent packets. The advantage of this feature is that it avoids initial data loss experienced by multicast applications and is most suited for low bandwidth.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware still forwards IP multicast traffic. The software forwards only initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only. If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding. If you enable software forwarding, packet suppression by the hardware is disabled. If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

By default, the feature is disabled.

#### Important

To avoid overloading the CPU, do not use the IP multicast software forwarding feature for video multicast applications.

If you configure multicast software forwarding from within a VRF context, the configuration applies to the Global Router and all VRF contexts. You cannot change the multicast software forwarding configuration for individual VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select the **SWForwardingEnable** check box.
5. Click **Apply**.

**Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>SWForwardingEnable</b> | Enables the system to initially forward IP multicast data until a hardware record is created. The default is disabled. |
| <b>StatsEnabled</b>       | Enables or disables multicast route statistics. The default is disabled.                                               |
| <b>StatsClear</b>         | Clears multicast route statistics.                                                                                     |

## Configuring mroute stream limit

Limit the number of multicast streams to protect a CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

**Procedure**

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Select the **Mroute Stream Limit** tab.
5. Select the **StreamLimitEnable** box.
6. Edit other fields as required.
7. Click **Apply**.

**Mroute Stream Limit** field descriptions

Use the data in the following table to use the **Mroute Stream Limit** tab.

| Name                     | Description                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>StreamLimitEnable</b> | Enables or disables mroute stream limit on the port.                                                                      |
| <b>StreamLimit</b>       | Specifies the maximum number of multicast streams allowed to enter the CPU through this port.                             |
| <b>StreamTimerCheck</b>  | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through this port. |

## Configuring Mroute Stream Limit on an Extreme Integrated Application Hosting Port

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### About This Task

Perform this procedure to limit the number of multicast streams to protect a Central Processing Unit (CPU) from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization, or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the Extreme Integrated Application Hosting (IAH) port you want to configure.
3. Select the **Mroute Stream Limit** tab.
4. Select **StreamLimitEnable**.
5. Configure other fields as required.
6. Select **Apply**.

### *Mroute Stream Limit* Field Descriptions

Use data in the following table to configure the **Mroute Stream Limit** tab.

| Name                     | Description                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>StreamLimitEnable</b> | Enables or disables mroute stream limit on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.                              |
| <b>StreamLimit</b>       | Specifies the maximum number of multicast streams allowed to enter the CPU through the IAH port. The default value is 1984.                             |
| <b>StreamTimerCheck</b>  | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through the IAH port. The default is 10 seconds. |

## Configuring resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

### About This Task

**Note**

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

**Important**

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Select the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

### *Resource Usage field descriptions*

Use the data in the following table to use the **Resource Usage** tab.

| Name                          | Description                                                                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Egress Records In-Use</b>  | Displays the number of egress records traversing the switch.                                                                                                                                           |
| <b>Ingress Records In-Use</b> | Displays the number of ingress records (source or group) traversing the switch.                                                                                                                        |
| <b>Egress Threshold</b>       | Configures the egress threshold level (0–32767).                                                                                                                                                       |
| <b>Ingress Threshold</b>      | Configures the ingress threshold level (0–32767).                                                                                                                                                      |
| <b>SendTrapOnly</b>           | Sends only trap notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. You can configure only one notification type. |
| <b>SendTrapAndLog</b>         | Sends both trap and log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.                                       |
| <b>LogMsgOnly</b>             | Sends only log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.                                                |

## Multicast route statistics configuration using the CLI

The following sections provide procedural information you can use to configure multicast route statistics using the Command Line Interface (CLI).

### Enabling IP multicast route statistics

Enable the collection and display of IP multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

#### Note

When you enable IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable the collection of IP multicast route statistics.
 

```
ip mroute stats enable
```
3. (Optional) Set the IP multicast route statistics to default.
 

```
default ip mroute stats enable
```
4. (Optional) Disable the collection of IP multicast route statistics.
 

```
no ip mroute stats enable
```
5. View the IP multicast route statistics.
 

```
show ip mroute stats [WORD<3-160> {A.B.C.D[,E.F.G.H][,...]}]
```

#### Note

The maximum number of multicast group IP addresses is 10.

#### Example

Enable the collection of IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip mroute stats enable
```

View the IP multicast route statistics:

```
Switch:1#show ip mroute stats
```

```
=====
                          Multicast Stats
```

```

=====
-----
Statistics : Enabled
-----

```

View the statistics for the multicast group IP address 225.0.0.1:

```

Switch:1#show ip mroute stats 225.0.0.1

=====
Multicast Stats - GlobalRouter
=====
GroupAddress      SourceCounter      IngressPackets      IngressBytes      AverageSize
-----
225.0.0.1         1                  30452198            3897881344       128

```

View the statistics for multiple (up to a maximum of 10) group IP addresses.

```

Switch:1#show ip mroute stats
225.0.0.1,225.0.0.2,225.0.0.3,225.0.0.4,225.0.0.5,225.0.0.6,225.0.0.7,225.0.0.8,225.0.0.9,
225.0.0.10

=====
Multicast Stats - GlobalRouter
=====
GroupAddress      SourceCounter      IngressPackets      IngressBytes      AverageSize
-----
225.0.0.1         1                  32446194            4153112832       128
225.0.0.2         1                  32446196            4153112960       127
225.0.0.3         1                  32446197            4153113088       127
225.0.0.4         1                  32446198            4153113216       127
225.0.0.5         1                  32446199            4153113472       128
225.0.0.6         1                  32446200            4153113600       128
225.0.0.7         1                  32446201            4153113728       128

225.0.0.9         1                  32446203            4153113856       127
225.0.0.10        1                  32446203            4153113984       128

```

*Variable definitions*

Use the data in the following table to use the **show ip mroute stats** command.

| Variable                                 | Definition                                                                                                                                                                                                                        |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<3-160><br>{A.B.C.D[,E.F.G.H][,...]} | Specifies the multicast group IP address for which to display statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses.<br>You can specify a maximum of 10 groups. |

## Clearing IP multicast route statistics

Use this procedure to clear the IP multicast route statistics. This resets the IP multicast statistics counters.

### Note

When you clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the IP multicast route statistics:  
clear ip mroute stats

*Example:*

Clear the IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ip mroute stats
```

## Monitor IP Multicast Route Statistics

Use this procedure to monitor the IP multicast route statistics at regular intervals.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Monitor the IP multicast route statistics:  
monitor ip mroute stats WORD<7-160> {A.B.C.D[,E.F.G.H][,...]} [vrf WORD<1-32>] [vrfid <0-255>]

### Note

You can monitor a maximum of 10 group IP addresses.

*Examples*

Monitor the IP multicast route statistics for the group IP address 225.0.0.1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds. The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>en
Switch:1#monitor ip mroute stats 225.0.0.1

MULTICAST STATISTIC

### Variable definitions

The following table defines parameters for the **monitor ip mroute stats** command.

| Variable                                                                  | Definition                                                                                                                                                                                                    |
|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-32&gt;</code>                                         | Specifies a VRF name.                                                                                                                                                                                         |
| <code>vrfid &lt;0-255&gt;</code>                                          | Specifies a VRF ID.                                                                                                                                                                                           |
| <code>WORD&lt;7-160&gt;</code><br><code>{A.B.C.D[,E.F.G.H][, ...]}</code> | Specifies the multicast group IP address for which to monitor statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

## Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

## Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable the collection of IPv6 multicast route statistics.  
ipv6 mroute stats enable
3. (Optional) Set the IPv6 multicast route statistics to default:  
default ipv6 mroute stats
4. (Optional) Disable the collection of IPv6 multicast route statistics.  
no ipv6 mroute stats
5. View the IPv6 multicast route statistics.  
show ipv6 mroute stats [WORD<7-400> {Ipv6address[,Ipv6address][,...]}]

### Note

The maximum number of multicast group IP addresses is 10.

*Example:*

Enable collection of IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ipv6 mroute stats enable
```

View the IPv6 multicast route statistics:

```
Switch:1#show ipv6 mroute stats

=====
                          Multicast Stats
=====
-----
                          Statistics : Enabled
```

View the statistics for the multicast group IP address FF05::1:

```
Switch#show ipv6 mroute stats FF05::1

=====
                          Multicast Stats - GlobalRouter

### Variable definitions

Use the data in the following table to use the **show ipv6 mroute stats** command

| Variable                                                  | Definition                                                                                                                                                                                                                        |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<7-400><br>{Ipv6address [, Ipv6address]<br>[ , ... ]} | Specifies the multicast group IP address for which to display statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses.<br>You can specify a maximum of 10 groups. |

## Clearing IPv6 multicast route statistics

Use this procedure to clear the IPv6 multicast route statistics. This resets the IP multicast statistics counters.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the IPv6 multicast route statistics:  
clear ipv6 mroute stats

### Example:

Clear the IPv6 multicast route statistics:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ipv6 mroute stats

```

## Monitoring IPv6 multicast route statistics

Use this procedure to monitor IPv6 multicast route statistics at regular intervals.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Monitor IPv6 multicast route statistics:

```
monitor ipv6 mroute stats WORD<7-400> {Ipv6address[,Ipv6address]
[,...]}
```

### Note

You can monitor a maximum of 10 group IP addresses.

### Example:

Monitor the IPv6 multicast route statistics for the group IPv6 address FF05::1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>enable
Switch:1#monitor IPv6 mroute stats FF05::1

                          MULTICAST STATISTIC

### Variable definitions

Use the data in the following table to use the `monitor ipv6 mroute stats` command:

| Variable                                               | Definition                                                                                                                                                                                                    |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<7-400><br>{Ipv6address[, Ipv6address]<br>[, ...]} | Specifies the multicast group IP address for which to monitor statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

## Multicast route statistics configuration using EDM

The following sections provide procedural information you can use to configure multicast route statistics using the Enterprise Device Manager (EDM).

### Enabling IP multicast route statistics

Use this procedure to enable IP multicast route statistics.

#### Note

When you enable or clear IP multicast route statistics on the Controller node of a DVR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **Multicast**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

**Globals** *Field Definitions*

Use the data in the following table to use the **Globals** tab.

| Field        | Description                                                 |
|--------------|-------------------------------------------------------------|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear   | Clears the multicast route statistics.                      |

## Viewing IP multicast route statistics

Use this procedure to view IP multicast route statistics.

**Before You Begin**

- You must enable the collection of multicast statistics.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Stats** tab to view the statistics.

**Stats** *Field Definitions*

Use the data in the following table to use the **Stats** tab.

| Field             | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupAddress      | Specifies the multicast group IP address for which to show statistics.                                                                                                                                         |
| SourceCounter     | Specifies the number of sources associated with the multicast route record.                                                                                                                                    |
| Pkts              | Specifies the number of packets received for the associated IP address.                                                                                                                                        |
| Bytes             | Specifies the number of bytes received for the associated IP address.                                                                                                                                          |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

## Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.

3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

#### **Globals** Field Definitions

Use the data in the following table to use the **Globals** tab.

| Field        | Description                                                 |
|--------------|-------------------------------------------------------------|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear   | Clears the multicast route statistics.                      |

## Viewing IPv6 multicast route statistics

Use this procedure to view IPv6 multicast route statistics.

#### **Before You Begin**

- You must enable the collection of multicast statistics.

#### **Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Stats** tab to view the statistics.

#### **Stats** Field Definitions

Use the data in the following table to use the **Stats** tab.

| Field             | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupAddress      | Specifies the multicast group IP address for which to show statistics.                                                                                                                                         |
| SourceCounter     | Specifies the number of sources associated with the multicast route record.                                                                                                                                    |
| Pkts              | Specifies the number of packets received for the associated IP address.                                                                                                                                        |
| Bytes             | Specifies the number of bytes received for the associated IP address.                                                                                                                                          |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

# IP Multicast over Fabric Connect

---

[IP Multicast over Fabric Connect basic configuration](#) on page 1826

[IP Multicast over Fabric Connect Services Configuration](#) on page 1859

[IP SPB Multicast Policy Configuration](#) on page 1916

The topics in this section provide conceptual and procedural information about IP Multicast over Fabric Connect:

- Basic configuration including IP Multicast config-lite for Fabric Connect
- Services configuration such as IP Shortcuts, Layer 2 VSN, and Layer 3 VSN
- IP SPB Multicast Policy configuration

## IP Multicast over Fabric Connect basic configuration

**Table 134: IP Multicast over Fabric Connect product support**

| Feature                                                                                                 | Product         | Release introduced                                                                                                       |

## IP Multicast over Fabric Connect Fundamentals

This section provides information about IP Multicast over Fabric Connect.

### *IP Multicast over Fabric Connect*

Extreme Networks is leading the industry with a new approach to transporting IP multicast using IP Multicast over Fabric Connect. IP Multicast over Fabric Connect

greatly simplifies multicast deployment, with no need for any multicast routing protocols such as Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM). A BEB can forward a multicast stream anywhere in an SPBM network where IS-IS advertises the stream to the rest of the fabric.

The advantage of this solution over traditional approaches is the simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

You can compare the quick convergence times for IP Multicast over Fabric Connect to Interior Gateway Protocols like Open Shortest Path First (OSPF) combined with PIM-SM or PIM-SSM. OSPF combined with PIM-SM or PIM-SSM can have recovery times that are sub optimal with convergence times that take tens of seconds. PIM experiences longer convergence times, in part, because unicast IP routing protocols must converge before PIM can converge. PIM also maintains the network state for every multicast group and uses a mechanism based on each hop to update the network about state changes, which affects scalability.

IP Multicast over Fabric Connect is extremely scalable because you only apply the multicast bridging and routing functionality at the SPBM fabric edge, with the streams mapped to SPBM multicast trees in the fabric.

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

### IP Multicast over Fabric Connect and Universal Plug and Play Filtering

When multicast packets are received on IGMP-enabled interfaces and the multicast group matches the range of groups to be filtered, Universal Plug and Play (uPnP) Filtering drops them.

For more information, see [Universal Plug and Play Filtering](#) on page 1838.

### How IP Multicast over Fabric Connect works

The BEBs act as the boundary between the multicast domain (currently only IGMP dynamic or static) and the SPBM domain. Multicast senders (sources) and receivers connect directly or indirectly (using Layer 2 switches) to the BEBs. You can enable IP Multicast over Fabric Connect services at the Layer 2 VSN level or the Layer 3 VSN level (including the GRT).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

**Figure 157: IP Multicast over Fabric Connect streams**

The following list describes how multicast senders and receivers connect to the SPBM cloud using BEBs in the preceding diagram:

1. The sender transmits multicast traffic with group IP address 233.252.0.1.
2. After the BEB receives the IP multicast stream from the sender, the BEB allocates data I-SID 16000001 for the S,G multicast stream. The BEB sends an LSP with the TLV 185 (for Layer 2 VSN multicast and Layer 3 VSN multicast) or TLV 186 (for IP Shortcuts multicast) with the transmit bit set. The BEB also sends an IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the I-SID is the Data I-SID).
3. The receiver sends a join request to Group 233.252.0.1.
4. The BEB (acting as the IGMP Querier) queries the IS-IS database to find all senders for group 233.252.0.1. If the group exists, the BEB sends an LSP with the IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast

bit set and the nickname is the stream transmitter BEB and the I-SID is the data I-SID).

5. The multicast tree is calculated for the data I-SID and the data starts flowing from the sender.

### Scope level

IP Multicast over Fabric Connect constrains all multicast streams within the level in which they originate, which is called the scope level. In other words, if a sender transmits a multicast stream to a BEB on a C-VLAN (a VLAN that is mapped to an I-SID, for instance, a Layer 2 VSN) with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream. Similarly, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT or a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 instance (GRT or L3 VSN) can receive that stream.

### Note

In the context of IP Multicast over Fabric Connect, scope is either the Global Routing Table or the I-SID value of the Layer 2 or Layer 3 VSN associated with the local VLAN on which the IP multicast data was received.

### Data I-SID

After the BEB receives the IP multicast stream from the sender, a BEB allocates a data Service Identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the S,G, V tuple, which is the source IP address, the group IP address, and the local VLAN the multicast stream is received on.

The BEB propagates this information through the SPBM cloud by using IS-IS TLV updates in LSPs, which results in the creation of a multicast tree for that stream. All BEBs now know what data I-SID to use for that stream and its scope. The data I-SID is a child of the scope or VSN I-SID. If no receiver requests the IP multicast stream, the ingress BEB does not forward the multicast stream.

### IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver, and this information is propagated through the SPBM cloud.

IS-IS acts dynamically using the TLV information it receives from BEBs that connect to the sender and the receivers to create a multicast tree between them. IS-IS creates very efficient multicast trees for the data I-SID allocated at the sender edge of the SPBM cloud to transport data between the sender and the receivers. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID. After IS-IS creates the multicast tree, the sender transports data to the receiver across the SPBM cloud using the data I-SID.

The trigger to send IS-IS updates to announce a multicast stream into the SPBM cloud is the multicast traffic arriving at the BEB. Because the BEB only interacts with IGMP and not PIM, all multicast traffic must be drawn towards the BEB for the stream to be announced, which SPBM accomplishes by making the BEB an IGMP Querier. In a VLAN, the IGMP Querier sends out periodic IGMP queries.

**Note**

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, it causes unexpected behavior, including traffic loss.

### *IP Multicast config-lite for Fabric Connect*

With IP Multicast config-lite for Fabric Connect you can configure Layer 3 IP Multicast routing over Fabric Connect using a Layer 2 edge node without associating an IP address on the VLAN. When you configure an MVPN I-SID on a VLAN, a dynamic VRF named **l3vsn** is created, and **ipvpn** is configured. **isid 1000** is added to the new VRF and **mvpn** is enabled.

**Note**

**ipvpn enable** is not configured on this VRF.

Dynamic VRFs are not present in the running config and are not saved.

You can convert a dynamic VRF to a static VRF by using typical VRF creation with the VRF name. For more information, see [Create a VRF Instance](#) on page 4186.

**Note**

If a VRF with the same I-SID already exists on the device, the VLAN is associated with the existing VRF when you enter **mvpn-isid** on the VLAN.

Configure **ip spb-multicast enable** on a VLAN interface without an IP address to avoid depleting the IP address pool of the network. IP Multicast config-lite for Fabric Connect requires no additional licensing.

**Note**

Manually configuring Layer 3 VSNs is not available.

### *BEB as IGMP Querier*

The BEB acts as the IGMP Querier and creates tables for links that need IP multicast streams. IGMP and IGMP Snooping cannot work without an IGMP Querier that sends out periodic IGMP queries.

The BEB only interacts with IGMP messages and not PIM. All multicast traffic must enter the BEB for the data stream to be announced.

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, unexpected behavior results, including traffic loss.

The IGMP query message is an IP packet and requires a source IP address. However, Layer 2 IGMP Snooping with SPBM by default turns on the service without the configuration of an IP address on the VLAN. By default, the BEB sends an IGMP query message with an IP source address of 0.0.0.0. If there are interoperability issues with third party vendors as a result of the 0.0.0.0 IP address, then you can configure the querier address under IGMP, without having to configure an IP address for the Layer 2 VSN VLAN.

IGMP Snooping, operating on the Layer 2 VSN, listens to conversations between hosts and routers, and maintains a table for links that need IP multicast streams.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

For more conceptual and configuration information on IGMP, see [IP Multicast](#) on page 1586.

### *Switch Clustering at the Edge of the SPBM Network*

Typical customer deployments require redundancy all the way to the access side of the network. IP Multicast over Fabric Connect supports switch clustering, Split Multilink Trunking (SMLT) technology, at the edge of the SPBM fabric, providing redundancy to the access Layer 2 switch where you can attach multicast senders and receivers. Typical SPBM fabric deployments use two or more B-VLANs for Equal Cost Multipath (ECMP) and resiliency. For simplicity in understanding how the SPBM network works, assume that there are two B-VLANs (primary and secondary).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

**Figure 158: IP Multicast over Fabric Connect streams in an SMLT configuration**

The following list describes the preceding diagram:

1. The edge switch hashes the sender multicast data to a specific MLT link.
2. A multicast stream received at the edge of the SPBM fabric is mapped to a dedicated multicast data I-SID.
3. For the non-SMLT attached sender 2, the stream is hashed to the primary or secondary B-VLAN based on whether the data I-SID is even or odd numbered. For the SMLT attached to sender 1, IS-IS advertises the stream to the rest of the fabric on the primary B-VLAN and synchronizes information to the vIST peer.
4. The edge switch hashes the receiver IGMP join to a specific MLT link.
5. Both BEBs on both B-VIDs advertise the IGMP join.
6. The multicast tree is built for (S1,G1), which is rooted in the primary sender BEB. The multicast tree is built for (S1,G1), which is rooted in the secondary sender BEB.

IGMP Snooping is widely used on Layer 2 access switches to prune multicast traffic. In IP Multicast over Fabric Connect, BEBs are the IGMP Queriers, therefore access switches forward multicast data from the senders as well as IGMP control messages from receivers to the BEBs.

When a sender transmits multicast data to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB allocates a data I-SID and sends a TLV update on either the primary B-VLAN or the secondary B-VLAN, depending on whether the BEB is the primary or secondary switch. The primary switch uses the primary B-VLAN, whereas, the secondary switch uses the secondary B-VLAN. This information is propagated through the SPBM fabric so all BEBs are aware of this stream availability.

The sender information is also synchronized over the vIST to the peer switch. Then the peer switch allocates a data I-SID for the multicast stream and sends a TLV update on the appropriate B-VLAN to announce the availability of the stream. The data I-SIDs allocated by the primary and secondary switch cluster peers may be the same or different, as they are allocated independently by each switch.

**Note**

If a sender attaches to only one BEB in a switch cluster, the sender information is not synchronized over the vIST because it is not SMLT attached. The sender information is advertised, and data is sent on either the primary or secondary B-VLAN. The odd-numbered data I-SIDs use the primary B-VLAN, and the even-numbered data I-SIDs use the secondary B-VLAN. The same hashing rules apply to the forwarding of multicast data.

When a receiver sends an IGMP join message to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB queries the IS-IS Link State Database (LSDB) to check if a sender exists for the requested stream within the scope of the receiver.

If the requested stream does not exist, the BEB keeps the IGMP information but no further action is taken. If the requested stream exists, the BEB sends an IS-IS Link State Packet (LSP), with TLV update information, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of a receiver. The BEB propagates this information through LSPs through the SPBM cloud. The receiver information is also synchronized over the vIST to the peer switch. The peer switch then queries its IS-IS Link State Database (LSDB) and, if the requested stream exists, it sends an IS-IS LSP, with a TLV update, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of the receiver.

IS-IS uses these TLV updates in LSPs to create multicast shortest path first trees in the SPBM fabric. IS-IS creates a shortest path first tree for the primary and secondary B-VLANs, but only one of the B-VLANs transports multicast data with the other in active standby in case of failures at the SPBM edge. After IS-IS creates the trees, multicast data flows between senders and receivers.

**IP Multicast over Fabric Connect and SMLT**

The following section summarizes the IP Multicast over Fabric Connect actions in an SMLT environment. The BEBs on the sender side behave as follows:

- Primary SMLT peer BEB always advertises the streams it receives, and sends data for them on the primary B-VLAN.
- Secondary SMLT peer BEB always advertises the streams it receives, and sends data for them on the secondary B-VLAN.
- Non-SMLT BEBs or SMLT BEBs with single attached senders advertise streams, and send data on the primary or secondary B-VLAN based on hash criteria (odd-numbered data I-SIDs use primary B-VLAN; even-numbered data I-SIDs use secondary B-VLAN).

The BEBs on the receiver side behave as follows:

- The primary SMLT peer BEB that receives multicast data on the primary B-VLAN sends it to both SMLT and non-SMLT SPBM access (UNI) links.
- The primary SMLT peer BEB that receives multicast data on the secondary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.
- The secondary SMLT peer BEB that receives multicast data on primary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.
- The secondary SMLT peer BEB that receives multicast data on secondary B-VLAN sends data to both SMLT and non-SMLT SPBM access (UNI) links.
- The non-SMLT BEB that receives multicast data on primary or secondary B-VLAN sends data to all SPBM access (UNI) links.

#### Layer 2 Querier behavior for a switch cluster

For C-VLANs in an SMLT environment, the vIST ports are not part of the VLAN.

IGMP on a C-VLAN behaves as follows to account for the fact that vIST peers do not see the membership queries of each other:

- The vIST peer with the higher IP address sends the queries out all SMLT and non-SMLT ports on SPBM access links.
- The vIST peer with the lower IP address only sends out queries on its non-SMLT ports. This includes SMLT ports whose remote ports are down (SMLT state of 'norm').
- With the existence of an vIST peer with a higher IP address and an vIST peer with a lower IP address, it means two queriers exist within the C-VLAN. Having two queriers poses no problems in this SPB environment, as all SMLT access devices see the vIST peer with the higher IP address as the querier, and non-SMLT access devices see the directly connected vIST peer as the querier. Non-SMLT access devices that connect on either side of the vIST peers can talk to each other using the SPBM cloud.

#### *Considerations when you connect an IP Multicast over Fabric Connect network to a PIM network*

IP Multicast over Fabric Connect does not integrate PIM functionality. Apply the following considerations when you connect to a PIM network:

- You must configure static IGMP receivers on the BEB access interface that faces the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network.

#### **Note**

The PIM router must have a configuration option to accept streams with non-local sources or the router drops the packets. The switch does not support a configuration option to accept streams with non-local sources.

You must configure static IGMP receivers on the PIM interface that face the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.

**Note**

For security reasons and to limit unnecessary multicast streams from being injected into the SPBM domain, you should configure ACLs on the BEB facing the PIM network.

### *IP Multicast over Fabric Connect restrictions*

Review the following restrictions for the IP Multicast over Fabric Connect feature.

**IGMP**

The BEB must be the only IGMP querier in the network. If the BEB receives an IGMP query from any other device, it causes unpredictable behavior, including traffic loss.

SPBM supports IGMP Snooping on a C-VLAN, but it does not support PIM on a C-VLAN. If you enable IGMP Snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IP Multicast over Fabric Connect.

SPBM supports Network Load Balancing (NLB) unicast and multicast modes. SPBM does not support NLB Multicast operation with IGMP.

**Note**

The NLB Multicast operation feature is not supported on all hardware platforms. For more information about feature support, see [VLAN Feature Support](#) on page 4093.

You must enable SSM snoop before you configure IGMP version 3, and you must enable both `ssm-snoop` and `snooping` for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is either the same as the IGMP version configured on the IGMP Snooping VLAN, or that compatibility mode is enabled.

**SSM**

If you delete any `ssm-map` in a static range group, the switch deletes the entire static range group. For example, create an `ssm-map` for 232.122.122.122 to 232.122.122.128 and after that configure this same range in a static group. If you delete any `ssm-map` between 232.122.122.122. to 232.122.122.128, the switch deletes the entire static range group.

**PIM**

There can be no interaction with PIM and multicast routers on the access.

The BEB only interacts with IGMP messages and not PIM, so all multicast traffic must be drawn towards the BEB, which acts as the IGMP querier, for the stream to be announced.

IP Multicast over Fabric Connect does not integrate PIM functionality so the following considerations apply when connecting to a PIM network:

- You must configure static IGMP receivers on the BEB access interface facing the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network. Static IGMP receivers make the PIM router accept streams and avoid a Reverse Path Forwarding (RPF) check that can change the source of the stream.
- You must configure static IGMP receivers on the PIM interface facing the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.
- You must configure Access Control Lists (ACLs) on the BEB facing the PIM network for security.

### Data I-SID

The BEB matches a single multicast stream to a particular data I-SID. As a result there is a one-to-one mapping between the S,G to data I-SID for each BEB.

### VLAN

The SPBM network does not support multiple multicast streams with the same source address and group address (S,G) learned on a VSP 8600 Series source BEB on multiple VLANs in the same VRF.

### Supported services

The switch does not support IP Multicast over Fabric Connect routing on inter-VSN routing interfaces.

The switch supports the following modes of IP Multicast over Fabric Connect:

- Layer 2 VSN multicast service — Multicast traffic remains within the same Layer 2 VSN across the SPBM cloud.
- Layer 3 VSN multicast service — Multicast traffic remains within the same Layer 3 VSN across the SPBM cloud.
- IP Shortcuts multicast service — Multicast traffic can cross VLAN boundaries but remains confined to the subset of VLANs with the Global Routing Table that have IP Multicast over Fabric Connect enabled.

## SPBM Multicast FIB

### Multicast FIB

SPBM runs all pair Dijkstras to produce the multicast FIB. The computing node loops through each node to run Dijkstra using that node as the root, and then prunes paths to only keep the shortest paths. The computing node then computes the intersection of the set of I-SIDs for which the root node transmits, with the set of I-SIDs for which the path endpoints receive.

The multicast addresses are built out of two pieces: the SPBM Node Nickname and the I-SID ID converted to hexadecimal format to form the multicast MAC address.

|                 |                   |
|-----------------|-------------------|
| ----- -----     | ----- -----       |
| nickname 0x3000 | hexadecimal I-SID |

For example, if the nickname is 0.00.10 and the I-SID is 100 (0x64), the multicast address is 03:00:10:00:00:64.

The following text shows an example of the multicast FIB.

```
Switch:1(config)#show isis spbm multicast-fib
```

```

### Universal Plug and Play Filtering

The switch can filter multicast packets destined for the Universal Plug and Play (uPnP) multicast IP address with a Universal Plug and Play (uPnP) Filtering option. uPnP Filtering drops all incoming multicast packets received by a switch on an IGMP-enabled interface if the destination multicast IP address matches the configured range.

uPnP Filtering applies to both multicast receivers and multicast senders. If you want to use the uPnP Filtering address range for actual multicast streaming, you must disable uPnP Filtering on the IGMP interface.

uPnP Filtering is disabled by default. If you create a new IGMP interface, uPnP Filtering is enabled automatically on the interface for the destination multicast IP address range 239.255.255.250/32. If you enable uPnP Filtering on an existing IGMP-enabled interface with senders and receivers already present, the filter does not delete the existing senders or receivers; the filter begins to drop packets from that point forward. Existing senders and receivers eventually expire and senders are not relearned.

You can use CLI or EDM to configure a different destination multicast IP address range.

uPnP Filtering functions in the following scenarios:

- IGMP snooping is enabled on a VLAN and IP Multicast over Fabric Connect on Layer 2 VSN is configured.
- IP Multicast over Fabric Connect within the Global Routing Table (GRT) is configured.
- IP Multicast over Fabric Connect on a Layer 3 VSN is configured.

## IP Multicast over Fabric Connect Configuration using the CLI

This section provides procedures to configure IP Multicast over Fabric Connect using the command line interface (CLI).

### Enabling IP Multicast over Fabric Connect globally

Use this procedure to enable IP Multicast over Fabric Connect globally on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose.

**Note**

IP Multicast over Fabric Connect uses I-SIDs starting at 16,000,000 and above. If Layer 2 or Layer 3 I-SIDs are in this range, the system displays an error message and the switch does not enable IP Multicast over Fabric Connect.

**Note**

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must add IST slot/ports to the C-VLAN for an SMLT topology.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify no I-SIDs exist in the default reserved range:
  - a. For Layer 2 use the following command:

```
show vlan i-sid
```
  - b. For Layer 3 use the following command:

```
show ip ipvpn vrf WORD<1-16>
```
3. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```
4. Enable IP Multicast over Fabric Connect globally:

```
spbm <1-100> multicast enable
```

**Note**

The switch only supports one SPBM instance.

5. (Optional) Disable IP Multicast over Fabric Connect globally:

```
no spbm <1-100> multicast enable

default spbm <1-100> multicast enable
```

**Example**

Enable IP Multicast over Fabric Connect globally:

```
Switch:1>show vlan i-sid
=====
                        Vlan I-SID
=====
VLAN_ID      I-SID      I-SID NAME
-----
1
10           100        Hospital-Server-10
90           1000       ISID-1000

3 out of 3 Total Num of Vlans displayed
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast enable
```

**Variable definitions**

The following table defines parameters for the **spbm** command.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-100>  | Enables IP Multicast over Fabric Connect globally. The default is disabled. Specifies the SPBM instance. The switch only supports one instance. |

*Display IP Multicast over Fabric Connect information*

Use this procedure to display IP Multicast over Fabric Connect summary information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the status of the global IP Multicast over Fabric Connect configuration:
 

```
show isis spbm multicast
```
3. Display IP Multicast over Fabric Connect summary information for each S, G, V tuple:
 

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```
4. Display information about the multicast routes on the switch:
 

```
show ip mroute route [vrf WORD<1-32>] [vrfigs WORD<0-255>]
```

**Example**

Display IP Multicast over Fabric Connect global configuration information:

```
Switch:1>enable
Switch:1#show isis spbm multicast
```

```

multicast : enable
fwd-cache-timeout(seconds) : 210

Switch:1#show isis spb-mcast-summary

=====

### Variable Definitions

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                               | Value                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i>                           | Displays the total number of SPB multicast entries.                                                                                             |
| <i>host-name WORD&lt;0-255&gt;</i>     | Displays the IP Multicast over Fabric Connect summary information for a specific host-name.                                                     |
| <i>lspid &lt;xxx.xxx.xxx.xx-xx&gt;</i> | Displays the IP Multicast over Fabric Connect summary information for the specified LSP ID that you enter in xxx.xxx.xxx.xx-xx — 8 byte format. |

The following table defines parameters for the **show ip mroute route** command.

| Variable                        | Value                |
|---------------------------------|----------------------|
| <i>vrf WORD&lt;1-32&gt;</i>     | Specifies a VRF.     |
| <i>vrfids WORD&lt;0-255&gt;</i> | Specifies the VRF ID |

### Configure IP Multicast config-lite for Fabric Connect

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

### Before You Begin

Create a VLAN. For more information see, [VLAN Configuration](#) on page 4082

## About This Task

Use **mvpn-isid** to dynamically create a VRF on one of the reserved Layer 3 VSN VLANs. The dynamically created VRF, **13vsn-*<isid\_number>***, obtains the **<isid\_number>** from the **mvpn-isid *<isid\_number>*** command.

### Note

If you are using a DvR leaf instance, the VRF name is **13vsn-*<13isid>***.

You can now use the **ip spb-multicast enable** command on that VLAN without configuring an IP address.

### Note

If a VRF with the same I-SID already exists on the device, the VLAN is associated with the existing VRF when you enter **mvpn-isid** on the VLAN.

### Note

You cannot have an IP address and **mvpn-isid** configured on the same VLAN at the same time.

## Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure an MVPN I-SID on the VLAN:

```
mvpn-isid <0-15999999>[0-511]
```

3. (Optional) Configure a routed SPB querier source IP address:

```
ip igmp routed-spb-querier-addr {A.B.C.D}
```

4. Enable SPB Multicast on the VLAN:

```
ip spb-multicast enable
```

## Example

To enable SPB Multicast for a VLAN in VRF use **mvpn-isid 100**.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 10
Switch:1(config-if)#mvpn-isid 100
Switch:1(config-if)#ip igmp routed-spb-querier-addr 192.0.2.1
Switch:1(config-if)#ip spb-multicast enable
```

## Variable Definitions

The following table defines parameters for the **mvpn-isid** command.

| Variable                               | Definition                                                                                                                                                              |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;0-15999999&gt;[0-511]</code> | Specifies the I-SID. The MAC offset value is optional.<br><br><b>Note:</b> Use <code>mvpn-isid 0</code> to enable spb-multicast for a VLAN in the Global Routing Table. |

The following table defines parameters for the **ip igmp routed-spb-querier-addr** command.

| Variable               | Definition                                       |
|------------------------|--------------------------------------------------|
| <code>{A.B.C.D}</code> | The SPB querier address. The default is 0.0.0.0. |

*Display the Multicast FIB*

### About This Task

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display the SPBM multicast FIB:  
`show isis spbm multicast-fib [vlan <1-4059>] [i-sid <1-16777215>]  
[nick-name <x.xx.xx>] [summary]`

### Example

```
Switch#show isis spbm multicast-fib
```

```
=====
                        SPBM MULTICAST FIB ENTRY INFO
=====
```

## Configure Universal Plug and Play (uPnP) Filtering

### Before You Begin

Create a port-based VLAN.

### About This Task

Use the following procedure to enable Universal Plug and Play (uPnP) Filtering on an IGMP-enabled interface. uPnP Filtering is disabled by default.

The default uPnP Filtering multicast group address range is 239.255.255.250/32. If you do not configure the multicast group range, uPnP Filtering filters multicast packets destined for the default multicast group range.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...] } Or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## 2. Enable uPnP Filtering:

```
ip igmp upnp-filter [ip {A.B.C.D/X}]
```

**Example**

Enable uPnP Filtering on a VLAN using the default multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter
```

Enable uPnP Filtering on a VLAN with configured multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter ip 233.252.0.0/24
```

**Variable Definitions**

The following table defines parameters for the **ip igmp upnp-filter** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>ip {A.B.C.D/X}</i>                                                        | Configures the multicast destination IP address range to filter for an IGMP interface. The default multicast group address is 239.255.255.250/32.                                                                                                                                                                                                             |
| <i>vlan &lt;1-4059&gt;</i>                                                   | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |

*View uPnP Filtering information on an IGMP-enabled interface*

Use the following command to display uPnP Filtering information on an IGMP-enabled interface.

**Procedure**

## 1. Enter Privileged EXEC mode:

```
enable
```

## 2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

View the default uPnP Filtering information on an IGMP-enabled interface:

```
Switch:1#show ip igmp interface vlan 2
=====
Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST PROXY SNOOP SNOOP SSM UPnP FAST FAST
ID INTVL MAX MEMB SNOOP ENABLE ORIGIN SNOOP FILTER LEAVE LEAVE
```

```

-----
                RESP                QUERY ENABLE                ENABLE ENABLE ENABLE PORTS
-----
2  125  100  2    2    10  false  false  RADIUS  false  false
false

VLAN SNOOP   SNOOP           DYNAMIC  COMPATIBILITY  EXPLICIT  UPnP
ID   QUERIER QUERIER        DOWNGRADE  MODE          HOSTS     FILTER
     ENABLE  ADDRESS        VERSION    TRACKING      ADDRESS
-----
2   false  0.0.0.0        enable    disable       disable  239.255.255.250/32

```

View uPnP Filtering information on an IGMP-enabled interface when uPnP Filtering is enabled and a non-default multicast group address is configured:

```

Switch:1(config)#show ip igmp interface vlan 2
=====
                        Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST  PROXY  SNOOP  SNOOP  SSM  UPnP  FAST  FAST
ID   INTVL MAX    RESP          QUERY  MEMB  SNOOP  ENABLE ORIGIN SNOOP  FILTER  LEAVE  LEAVE
-----
2   125  100  2    2    10  false  false  RADIUS  false  true  false

VLAN SNOOP   SNOOP           DYNAMIC  COMPATIBILITY  EXPLICIT  UPnP
ID   QUERIER QUERIER        DOWNGRADE  MODE          HOSTS     FILTER
     ENABLE  ADDRESS        VERSION    TRACKING      ADDRESS
-----
2   false  0.0.0.0        enable    disable       disable  233.252.0.0/24

```

**Variable Definitions**

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

**IP Multicast over Fabric Connect configuration using EDM**

This section provides procedures to configure IP Multicast over Fabric Connect using Enterprise Device Manager (EDM).

*Configure IP Multicast over Fabric Connect Globally*

Use this procedure to globally enable IP Multicast over Fabric Connect on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches)

connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose. IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

### Important

IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

### Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

## Procedure

1. In the navigation pane, expand **Configuration > Fabric > SPBM** to determine if any I-SIDs are within the default range reserved for multicast..
2. Select the **I-SID** tab to determine if the I-SIDs are within the default range reserved for multicast.
3. In the navigation pane, expand **Configuration > Fabric > SPBM**.
4. Select the **SPBM** tab.
5. If you want to enable multicast on an SPBM instance that already exists, in the **Mcast** column in the table, select **enable**.
6. If you want to enable multicast on an SPBM instance that does not yet exist, select **Insert**.
7. In the **Mcast** box, select **enable** to enable IP Multicast over Fabric Connect globally.
8. Select **Insert**.
9. Select **Apply**.

## SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

| Name                                                                             | Description                                                                                                                                                                                       |
|----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                        | Specifies the SPBM instance ID. Only one SPBM instance is supported.                                                                                                                              |
| <b>NodeNickName</b>                                                              | Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.                                                                                            |
| <b>PrimaryVlan</b>                                                               | Specifies the primary SPBM B-VLANs to add to the SPBM instance.                                                                                                                                   |
| <b>Vlans</b>                                                                     | Specifies the SPBM B-VLANs to add to the SPBM instance.                                                                                                                                           |
| <b>LsdbTrap</b>                                                                  | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.                                                                                                |
| <b>IpShortcut</b>                                                                | Enables or disables SPBM IP shortcut state. The default is disable.                                                                                                                               |
| <b>SmltSplitBEB</b>                                                              | Specifies whether the switch is the primary or secondary vIST peer. The default is primary.                                                                                                       |
| <b>SmltVirtualBmac</b>                                                           | Specifies a virtual MAC address that can be used by both peers.                                                                                                                                   |
| <b>SmltPeerSysId</b>                                                             | Specifies the system ID of the SPBM SMLT for this SPBM instance.                                                                                                                                  |
| <b>Mcast</b>                                                                     | Specifies if IP multicast over SPBM is enabled. The default is disabled.                                                                                                                          |
| <b>McastFwdCacheTimeout</b>                                                      | Specifies the global forward cache timeout in seconds. The default is 210 seconds.                                                                                                                |
| <b>Ipv6Shortcut</b>                                                              | Enables or disables SPBM IPv6 shortcut state. The default is disable.                                                                                                                             |
| <b>McastSpbPimGwControllerEnable</b>                                             | Enables or disables IS-IS PLSB Multicast SPB PIM Gateway controller. Disabled by default.                                                                                                         |
| <b>McastSpbPimGwGatewayEnable</b>                                                | Enables or disables IS-IS PLSB Multicast SPB PIM Gateway. Disabled by default.                                                                                                                    |
| <b>StpMultiHoming</b>                                                            | Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).                                                                                                            |
| <b>BVlanOrigin</b><br><b>Note:</b><br>Exception: not supported on XA1400 Series. | Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic. |

*View IP Multicast over Fabric Connect Routes*

Use this procedure to display the IP Multicast over Fabric Connect routes.

## Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **IpMcastRoutes** tab.

### IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vsnlsid</b>       | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.                                                                                                                                                                                                                                                                                                         |
| <b>Group</b>         | Specifies the group IP address for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                         |
| <b>Source</b>        | Specifies the IP address where the IP Multicast over Fabric Connect route originated.                                                                                                                                                                                                                                                                                                  |
| <b>NickName</b>      | Specifies the nick name used to filter criteria.                                                                                                                                                                                                                                                                                                                                       |
| <b>SourceBeb</b>     | Specifies the source BEB for the IP multicast route.                                                                                                                                                                                                                                                                                                                                   |
| <b>VlanID</b>        | Specifies the ID for the C-VLAN.                                                                                                                                                                                                                                                                                                                                                       |
| <b>VrfName</b>       | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Datalsid</b>      | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>Type</b>          | Specifies the type for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                     |
| <b>Bvlan</b>         | Specifies the B-VLAN for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                   |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route.<br>SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                              |

Configure IP Multicast config-lite for Fabric Connect

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

## Before You Begin

Create a VLAN. For more information see, [VLAN Configuration using EDM](#) on page 4145

## About This Task

You can now enable SPB Multicast on that VLAN without configuring an IP address.

### Note

If a VRF with the same I-SID already exists on the device, the VLAN is associated with the existing VRF when you enter **mvpn-isid** on the VLAN.

### Note

You cannot have an IP address and **mvpn-isid** configured on the same VLAN at the same time.

## Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the appropriate VLAN row, for **mvpnIsidStatus** select **Static**.
5. In the **mvpnIsidValue** column type the I-SID number.
6. (Optional) Enter the MAC offset value in the **mvpnIsidOffset** column.
7. Select **Apply**.
8. (Optional) Configure a routed SPB querier source IP address.
  - a. Select the **Configuration** tab.
  - b. Select the appropriate **IP**, and then select **IGMP**.
  - c. Select the **Interface** tab.
  - d. Enter the address in the **ExtnRoutedSpbQuerierAddr** field.
  - e. Select **Apply**.
9. Select the **Advanced** tab.
10. In the appropriate **VLAN** row, for **SpbMulticast**, select **Enable**.
11. Select **Apply**.

## Advanced Field Descriptions

Use the data in the following table to use the **Advanced** tab.

| Name                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Name</b>                                                                              | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>IfIndex</b>                                                                           | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Type</b>                                                                              | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                                                                    |
| <b>Isid</b>                                                                              | Specifies the Service Instance Identifier (I-SID) number assigned to a customer VLAN (C-VLAN). The default value is 0, which indicates that no I-SID is assigned.                                                                                                                                                                                                                                                          |
| <b>Isid Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Origin</b>                                                                            | Specifies the origin of the VLAN configuration, either manually configured through CLI or SNMP, or dynamically configured through RADIUS VSA or Zero Touch Fabric Configuration.                                                                                                                                                                                                                                           |
| <b>ProtocolId</b>                                                                        | Specifies the network protocol for protocol-based VLANs.<br>If the VLAN type is not protocol-based, a value of None displays in the <b>Basic</b> tab <b>ProtocolId</b> field.                                                                                                                                                                                                                                              |
| <b>AgingTime</b>                                                                         | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.                                                                                                                                                                    |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>MacAddress</b>             | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Vlan Operation Action</b>  | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.</li> <li>• flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.</li> <li>• flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.</li> <li>• flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports.</li> <li>• all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions.</li> </ul> <p>The default is none.</p> |
| <b>Result</b>                 | Specifies the result code after you perform an action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>NlbMode</b>                | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SpbMulticast</b>           | Enables or disables IP Multicast over Fabric Connect. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SpbPimGatewayMulticast</b> | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RmonEnable</b>             | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Ipv6FhsSnoopDhcpEnable</b> | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Name                                                                                                                          | Description                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6FhsNDInspectionEnable</b>                                                                                              | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.                                                                                                                                                                                           |
| <b>DvrEnable</b>                                                                                                              | Enables or disables Distributed Virtual Routing (DvR) on a VLAN that is configured on the DvR Controller. The default is disabled.<br><br><b>Note:</b><br>You must enable DvR on every VLAN that is configured on a DvR Controller.                                                  |
| <b>DvrGwIpv4Addr</b>                                                                                                          | Specifies the DvR gateway IPv4 address for a VLAN.<br><br><b>Important:</b><br>Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.                                                                                   |
| <b>DvrGwIpv4Onelp</b>                                                                                                         | Enables or disables the DvR One IP for a VLAN. The default is disabled (false).                                                                                                                                                                                                      |
| <b>DvrVrrpElection</b><br><br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Identifies the DvR VLAN, and associated I-SID, to become the primary Virtual Router Redundancy Protocol (VRRP) router through the election process. You can identify only one VLAN for election per DvR Controller. By default, no VLAN is configured as the DvR VRRP election VLAN. |
| <b>MvpnIsidValue</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                     | Configures the MVPN I-SID value for the VLAN.                                                                                                                                                                                                                                        |
| <b>MvpnIsidStatus</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                    | Identifies the MVPN I-SID status. CONFIG indicates that the VRF was created manually and DYNAMIC indicates that the VRF was created by configuring an MVPN I-SID on a VLAN.                                                                                                          |
| <b>MvpnIsidOffset</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                    | Allows you to add an offset parameter to the MVPN I-SID. This is an optional value and the range is 0-511.                                                                                                                                                                           |

**Interface Field Descriptions**

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                           |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                                  |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                            |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                  |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                                     |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                             |
| <b>QueryMaxResponseTime</b> | <p>Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)</p> <p><b>Important:</b><br/>You must configure this value lower than the QueryInterval.</p> |
| <b>WrongVersionQueries</b>  | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                             |
| <b>Joins</b>                | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                       |
| <b>Robustness</b>           | <p>Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.</p> <p>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.</p>           |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastMembQueryIntvl</b>          | <p>Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.</p> <p>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)</p> |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>FlushAction</b>                 | <p>Configures the flush action to one of the following:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RouterAlertEnable</b>           | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p><b>Important:</b><br/>To maximize network performance, configure this parameter according to the version of IGMP currently in use.</p> <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                             |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierAddr</b>            | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ExplicitHostTrackingEnable</b>  | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>McastMode</b>                 | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>• snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>• snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>• pim — Indicates PIM is enabled.</li> <li>• routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul> |
| <b>ExtnUpnpFilterEnable</b>      | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                                |
| <b>ExtnUpnpFilterAddress</b>     | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                           |
| <b>ExtnUpnpFilterAddressMask</b> | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SnoopOrigin</b>               | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                              |
| <b>ExtnRoutedSpbQuerierAddr</b>  | Specifies the IP address of the SPB querier.                                                                                                                                                                                                                                                                                                                                                                                                                        |

*Displaying the UNI ports for IP multicast routes*

Use this procedure to display UNI ports associated with particular IP multicast routes.

**Procedure**

1. In the navigation pane, expand **Configuration > Fabric > SPBM**.
2. Select the **IpMcastRoutes** tab.
3. Select the desired row and click the **UNI Ports** tab to display the UNI ports associated with a particular stream.

**IpMcastRoutes Uni Ports field descriptions**

Use the data in the following table to use the **IpMcastRoutes Uni Ports** tab.

| Name           | Description                                                                           |
|----------------|---------------------------------------------------------------------------------------|
| <b>Group</b>   | Specifies the group IP address for the IP Multicast over Fabric Connect route.        |
| <b>Source</b>  | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| <b>Vsnlsid</b> | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.        |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Datalsid</b>  | Specifies the data I-SID for the IP multicast route. After a BEB receives the IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>SourceBeb</b> | Specifies the source BEB for the IP multicast route.                                                                                                                                                                                                                                                                                                                         |
| <b>VlanId</b>    | Specifies the ID for the C-VLAN.                                                                                                                                                                                                                                                                                                                                             |
| <b>VrfName</b>   | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                      |
| <b>NniPorts</b>  | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports facing a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                          |
| <b>Type</b>      | Specifies the type for the IP multicast route.                                                                                                                                                                                                                                                                                                                               |
| <b>Bvlan</b>     | Specifies the B-VLANs for the IP multicast route.                                                                                                                                                                                                                                                                                                                            |

### *Displaying the multicast FIB*

Use the following procedure to display the multicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

### **Procedure**

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **Multicast FIB** tab.

**Multicast FIB field descriptions**

Use the data in the following table to use the **Multicast FIB** tab.

| Name                      | Description                                                                |
|---------------------------|----------------------------------------------------------------------------|
| <b>SysId</b>              | System ID of the node where the multicast FIB entry originated.            |
| <b>Vlan</b>               | VLAN of the multicast FIB entry.                                           |
| <b>McastDestMacAddr</b>   | Multicast destination MAC Address of the multicast FIB entry               |
| <b>Isid</b>               | I-SID of the multicast FIB entry.                                          |
| <b>Isid Name</b>          | Name assigned to the I-SID.                                                |
| <b>HostName</b>           | Host name of the node where the multicast FIB entry originated.            |
| <b>OutgoingInterfaces</b> | Specifies the switched UNI port outgoing interface of multicast FIB entry. |
| <b>IncomingInterface</b>  | Specifies the incoming interface (port or MLT) of the multicast FIB entry. |

**IP Multicast over Fabric Connect configuration examples**

This section provides configuration examples to configure IP Multicast over Fabric Connect.

*IP multicast over Fabric Connect global configuration*

The following sections show the steps required to configure IP multicast over Fabric Connect at a global level

**SwitchC**

```
enable
configure terminal
prompt SwitchC

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

**SwitchG**

```
enable
configure terminal
prompt SwitchG

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

### SwitchD

```
enable
configure terminal
prompt SwitchD

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

## IP Multicast over Fabric Connect Services Configuration

This section provides procedures to configure the following Fabric Connect Services using the command line interface (CLI):

- Layer 2 VSN
- IP Shortcuts
- Layer 3 VSN

### Layer 2 VSN Configuration Fundamentals

The topics in this section provide conceptual and procedural information about Layer 2 VSN.c

#### *Layer 2 VSN IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect supports Layer 2 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. An application for Layer 2 VSNs using IP Multicast over Fabric Connect is multicast traffic in data centers.

For more information on Layer 2 VSN configuration, see [Layer 2 VSN configuration](#) on page 1388.

After you configure **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN), that VLAN is automatically enabled for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

Multicast traffic remains in the same Layer 2 VSN across the SPBM cloud for Layer 2 VSN IP Multicast over Fabric Connect. IP Multicast over Fabric Connect constrains all multicast streams within the scope level in which they originate. If a sender transmits a multicast stream to a BEB on a Layer 2 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream.

#### **I-SIDs**

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 2 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 2 VSN associated with the local VLAN on which the IP multicast data was received.

### TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 2 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

### IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the request stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

### *Layer 2 VSN Configuration using the CLI*

This section provides procedures to configure Layer 2 VSN using the command line interface (CLI).

### **Configuring Layer 2 VSN IP Multicast over Fabric Connect**

Use this procedure to configure IP Multicast over Fabric Connect for Layer 2 VSN functionality. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

#### **Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must assign the same I-SID to the C-VLANs on all the BEBs where you configure the C-VLAN.
- You must enable IP Multicast over Fabric Connect globally.

#### **About This Task**

Traffic is only delivered to UNIs on the Layer 2 VSN where the switch receives IGMP joins and reports. Traffic does not cross the Layer 2 VSN boundary.

Configuring **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN) automatically enables that VLAN for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

SPBM supports enabling IGMP Snooping on a C-VLAN, but it does not support enabling Protocol Independent Multicast (PIM) on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

The switch only supports IPv4 multicast traffic.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable proxy snoop:

```
ip igmp proxy
```

3. Enable IGMP snooping:

```
ip igmp snooping
```

4. (Optional) If you want to configure an address for the IGMP queries, enter the following command:

```
ip igmp snoop-querier-addr <A.B.C.D>
```

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

5. (Optional) Enable IGMPv3 at a VLAN level by enabling SSM-snooping and IGMPv3:

```
ip igmp ssm-snoop

ip igmp version 3
```

You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

### Example

Enable IGMPv2 at a VLAN level:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config-if)#interface vlan 501
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
```

Enable IGMPv3 at a VLAN level:

```
Switch:>enable
Switch:#configure terminal
Switch:1(config)#interface vlan 2256
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1(config-if)#ip igmp version 3
Switch:1(config-if)#ip igmp ssm-snoop
```

### View Layer 2 VSN IP Multicast over Fabric Connect information

Use the following options to display Layer 2 VSN information to confirm proper configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:  

```
show isis spbm ip-multicast-route [all]
```
3. Display detailed IP Multicast over Fabric Connect route information:  

```
show isis spbm ip-multicast-route [detail]
```
4. Display IP multicast route information by VLAN:  

```
show isis spbm ip-multicast-route [vlan <1-4059>]
```
5. Display IP Multicast over Fabric Connect route information by VSN I-SID:  

```
show isis spbm ip-multicast-route [vsn-isid <1-16777215>]
```
6. Display IP Multicast over Fabric Connect route information by group address:  

```
show isis spbm ip-multicast-route [group {A.B.C.D}]
```
7. Display IP Multicast over Fabric Connect route information by source address:  

```
show isis spbm ip-multicast-route [source {A.B.C.D}]
```

#### Important

When you use the command `show isis spbm ip-multicast-route` without parameters or use the detail or group optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

8. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid
<xxxx.xxxx.xxxx.xx-xx>]
```

#### Example

```
Switch:1#show isis spbm ip-multicast-route all
```

```
=====
SPBM IP-MULTICAST ROUTE INFO ALL
```

```

## Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable                                          | Value                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                                        | Displays all IP Multicast over Fabric Connect route information.                                                                                              |
| <i>detail</i>                                     | Displays detailed IP Multicast over Fabric Connect route information.                                                                                         |
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i> | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. |
| <i>vlan &lt;0-4084&gt;</i>                        | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                          |
| <i>vrf WORD&lt;1-16&gt;</i>                       | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                           |
| <i>vsn-isis &lt;1-16777215&gt;</i>                | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                         |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                                  | Value                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------|
| <i>count</i>                              | Displays the total number of SPB multicast entries.                          |
| <i>host-name WORD&lt;0-255&gt;</i>        | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID.    |

### View IGMP Information for Layer 2 VSN Multicast

Use the following commands to display IGMP information.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-
512>]
```

Ensure that the output displays `snoop-spb` under MODE.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}]
[vrf WORD<1-16>][vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:  
 show ip igmp sender [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
6. Display information about IGMP snoop-trace information:  
 show ip igmp snoop-trace [group {A.B.C.D}][source {A.B.C.D}][vrf WORD<1-16>][vrfids WORD<0-512>]

**Example**

```
Switch:1#show ip igmp interface

## Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                  | Value                        |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF by name.   |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                      |
|----------------------------------|--------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.           |
| <i>group</i> {A.B.C.D}           | Specifies the group address.               |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |

| Variable                        | Value                                                                      |
|---------------------------------|----------------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp snoop-trace** command.

| Variable                        | Value                                                                      |
|---------------------------------|----------------------------------------------------------------------------|
| <i>group {A.B.C.D}</i>          | Specifies the group address.                                               |
| <i>source {A.B.C.D}</i>         | Specifies the source address.                                              |
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays the multicast route configuration for a particular VRF by VRF ID. |

### View TLV Information for Layer 2 VSN IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For Layer 2 VSN with IP multicast over Fabric Connect, TLV 185 on the BEB where the source is located, displays the multicast source and group addresses and has the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by Type-Length-Value (TLV):
 

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:
 

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```

**Example**

```

Switch:1# show isis lsdb tlv 185 detail

### Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                            | Value                                                                                                                                                                                       |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>                       | Displays detailed information about the IS-IS Link State database.                                                                                                                          |
| <i>home</i>                         | Displays the IS-IS LSDB information that the system configures in the home area.                                                                                                            |
| <i>level {11, 12, 112}</i>          | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 and combined Level 1 and 2 (112) function is disabled. |
| <i>local</i>                        | Displays information on the local LSDB.                                                                                                                                                     |
| <i>lspid</i> <xxxx.xxxx.xxxx.xx-xx> | Specifies information about the IS-IS Link State database by LSP ID.                                                                                                                        |
| <i>remote</i>                       | Displays the IS-IS LSDB information that the system configures in the remote area.                                                                                                          |
| <i>sub-tlv</i> <1-3>                | Specifies information about the IS-IS Link State database by sub-TLV.                                                                                                                       |
| <i>sysid</i> <xxxx.xxxx.xxxx>       | Specifies information about the IS-IS Link State database by System ID.                                                                                                                     |
| <i>tlv</i> <1-236>                  | Specifies information about the IS-IS Link State database by TLV.                                                                                                                           |

### Layer 2 VSN Configuration using EDM

This section provides procedures to configure Layer 2 VSN using Enterprise Device Manager (EDM).

### Viewing the IGMP interface table

Use the Interface tab to view the IGMP interface table. When an interface does not use an IP address, the system does not display it in the IGMP table.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Interface** tab.

### Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                           |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                                  |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                            |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                  |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                                     |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                             |
| <b>QueryMaxResponseTime</b> | <p>Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)</p> <p><b>Important:</b><br/>You must configure this value lower than the QueryInterval.</p> |
| <b>WrongVersionQueries</b>  | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                             |
| <b>Joins</b>                | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                       |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Robustness</b>                  | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.<br>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                                                                                                                                    |
| <b>LastMembQueryIntvl</b>          | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FlushAction</b>                 | Configures the flush action to one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>RouterAlertEnable</b>           | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                          |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SnoopQuerierAddr</b>            | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ExplicitHostTrackingEnable</b>  | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>McastMode</b>                 | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>pim — Indicates PIM is enabled.</li> <li>routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul> |
| <b>ExtnUpnpFilterEnable</b>      | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                        |
| <b>ExtnUpnpFilterAddress</b>     | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                   |
| <b>ExtnUpnpFilterAddressMask</b> | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopOrigin</b>               | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                          |
| <b>ExtnRoutedSpbQuerierAddr</b>  | Specifies the IP address of the SPB querier.                                                                                                                                                                                                                                                                                                                                                                                                                |

### Configure IP Multicast over Fabric Connect on a Layer 2 VSN

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 2 VSN. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

No explicit configuration exists for a Layer 2 VSN. After you configure IP IGMP snooping on a VLAN that has an I-SID configured, the device enables that VLAN for IP Multicast over Fabric Connect services.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

#### About This Task

SPBM supports enabling IGMP snooping on a C-VLAN, but it does not support enabling PIM on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

This switch only supports IPv4 multicast traffic.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.
6. Select the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. (Optional) Select the **SsmSnoopEnable** check box, if you use IGMP version 3.
9. (Optional) Select the **ProxySnoopEnable** check box.
10. (Optional) If you want to enable IGMP version 3, select version3 in the **Version** check box.

You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

11. If you want to enable IGMP version 2, select version2 in the **Version** check box.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

12. (Optional) If you want to enable snoop querier, select **SnoopQuerierEnable**.
13. (Optional) If you want to configure an address for IGMP queries, enter the IP address in **SnoopQuerierAddr**.

#### Note

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

14. Select **Apply**.

### Layer 2 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration steps to enable IP Multicast over Fabric Connect support on C-VLAN 1001 that is part of a Layer 2 VSN, including the querier address.

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION
```

```
interface vlan 9
ip igmp snooping
ip igmp snoop-querier-addr 192.0.2.201
exit
```

When using IGMPv3, the configuration is:

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 19
ip igmp snooping
ip igmp version 3
ip igmp ssm-snoop
ip igmp snoop-querier-addr 192.0.2.201
exit
```

#### Note

You must enable SSM snoop before you configure IGMP version to version 3, and you must enable both **ssm-snoop** and **snooping** for IGMPv3.

#### Note

You must configure basic SPBM and IS-IS infrastructure.

## IP Shortcuts Configuration

This section provides fundamentals concepts for IP Shortcuts configuration. For more information on IP Shortcuts basic configuration, see [IP Shortcuts Configuration](#) on page 1463.

### *IP Multicast over Fabric Connect within the GRT*

IP Multicast over Fabric Connect within the GRT enables you to exchange IP multicast traffic with all or a subset of VLANs that are in the Global Routing Table (GRT). This restriction is called the *scope level*, which IP Multicast over Fabric Connect uses to constrain the multicast streams within the level in which they originate. For example, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT with IP Multicast over Fabric Connect enabled, only receivers that are part of the same GRT can receive that stream.

Applications that can use IP Multicast over Fabric Connect within the GRT include: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.

Both **IP Shortcuts** and **IP Multicast over Fabric Connect within the GRT** use the GRT for the scope level to constrain multicast streams. However, they are separate features that work independently from each other.

### Important

You do not have to enable IP Shortcuts to support IP Multicast over Fabric Connect within the GRT.

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable **ip spb-multicast** on each of the VLANs within the GRT that need to support IP multicast traffic. Enable IP Multicast over Fabric Connect on all VLANs to which IP multicast senders and receivers attach. IP Multicast over Fabric Connect is typically configured only on BEBs.

### Note

If no IP interface exists on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

### I-SIDs

Unlike IP Shortcuts with unicast, a data I-SID (for mac-in-mac encapsulation of the multicast traffic) is required for IP Multicast over Fabric Connect within the GRT. When the multicast stream reaches the BEB, the BEB assigns a data I-SID to the stream. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

Unlike Layer 2 VSNs and Layer 3 VSNs, IP Multicast over Fabric Connect within the GRT does not have a scope I-SID to determine the scope of the multicast traffic. Instead the scope is the Global Routing Table.

### TLVs

The scope and data I-SID information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, and result in the multicast tree creation for that stream. For IP Multicast over Fabric Connect within the GRT, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 186.

### IGMP

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, the system displays an error message.

After you configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast

over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

### DvR

When you enable `ip spb-multicast` on the Controller nodes, the configuration is automatically pushed to all the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 738.

### *IP Shortcuts Configuration using the CLI*

This section provides procedures to configure IP Shortcuts using the command line interface (CLI).

### Configure IP Multicast over Fabric Connect within the GRT

Use this procedure to configure IP Multicast over Fabric Connect within the GRT. The default is disabled.

-  **Note**
  - You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
  - You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

### About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must configure `ip spb-multicast enable` on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled. After you enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric

Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an IP interface on the VLAN:

```
ip address <A.B.C.D/X>
```

3. Enable IP Multicast over Fabric Connect:

```
ip spb-multicast enable
```

#### Note

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, an error message displays.

#### Note

When you configure **ip spb-multicast enable** on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

4. (Optional) Disable IP Multicast over Fabric Connect:

```
no ip spb-multicast enable
```

```
default ip spb-multicast enable
```

5. Ensure IP Multicast over Fabric Connect within the GRT is configured properly:

```
show ip igmp interface
```

If `routed-spb` displays under mode, IP Multicast over Fabric Connect within the GRT is properly enabled on the VLAN.

## Example

Enable IP Multicast over Fabric Connect within the GRT:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 500
Switch:1(config-if)#ip address 192.0.2.1 255.255.255.0
Switch:1(config-if)#ip spb-multicast enable
Switch:1#show ip igmp interface
```

```

## Variable Definitions

The following table defines parameters for the **interface vlan** command.

| Variable | Value                  |
|----------|------------------------|
| <1-4059> | Specifies the VLAN ID. |

The following table defines parameters for the **interface GigabitEthernet** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip address** command.

| Variable    | Value                           |
|-------------|---------------------------------|
| <A.B.C.D/X> | Specifies the address and mask. |

## Configuring the VRF timeout value

Use this procedure to configure the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.

### Note

You can use this procedure for Layer 3 VSN with IP Multicast over Fabric Connect services and IP Multicast over Fabric Connect for IP Shortcuts.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Configure the timeout value on the VRF:

```
mvpn fwd-cache-timeout (seconds) <10-432000>
```

3. (Optional) Configure the timeout value to the default value of 210 seconds:

```
no mvpn fwd-cache-timeout

default mvpn fwd-cache-timeout (seconds)
```

## Example

Configure the timeout value on the VRF to 500 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#mvpn fwd-cache-timeout (seconds) 500
```

## Variable definitions

The following table defines parameters for the **router vrf** command.

| Variable   | Value                   |
|------------|-------------------------|
| WORD<1-16> | Specifies the VRF name. |

The following table defines parameters for the **mvpn fwd-cache-timeout(seconds)** command.

| Variable    | Value                                                    |
|-------------|----------------------------------------------------------|
| <10-432000> | Specifies the timeout value. The default is 210 seconds. |

### Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time in seconds. The default timeout value is 210 seconds.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the IP Multicast over Fabric Connect forward-cache timeout:
 

```
spbm <1-100> multicast fwd-cache-timeout(seconds) <10-432000>
```
3. (Optional) Configure the IP Multicast over Fabric Connect forward-cache timeout to the default value of 210 seconds:
 

```
default spbm <1-100> multicast fwd-cache-timeout(seconds)

no spbm <1-100> multicast fwd-cache-timeout(seconds)
```

#### Example

Configure the IP Multicast over Fabric Connect forward-cache timeout to 300:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast 1 fwd-cache-timeout 300
```

#### Variable definitions

The following table defines parameters for the **spbm** command.

| Variable    | Value                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------|
| <1-100>     | Specifies the SPBM instance. The switch only supports one instance.                                          |
| <10-432000> | Specifies the IP Multicast over Fabric Connect forward-cache timeout in seconds. The default is 210 seconds. |

### Viewing IP Multicast over Fabric Connect within the GRT information

Use the following options to display IP Multicast over Fabric Connect within the GRT information to confirm proper configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:  

```
show isis spbm ip-multicast-route [all]
```
3. Display detailed IP Multicast over Fabric Connect route information:  

```
show isis spbm ip-multicast-route [detail]
```
4. Display the IP Multicast over Fabric Connect multicast group and source address information:  

```
show isis spbm ip-multicast-route [group {A.B.C.D}] [source {A.B.C.D}] [source-beb WORD<0-255>]
```
5. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:  

```
show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]
```

#### Example

Display IP Multicast over Fabric Connect within the GRT information:

```
Switch:1#show isis spbm ip-multicast-route all

### Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable                                                                                     | Value                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                                                                                   | Displays all IP Multicast over Fabric Connect route information.                                                                                                                             |
| <i>detail</i>                                                                                | Displays detailed IP Multicast over Fabric Connect route information.                                                                                                                        |
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i><br>[ <i>source-beb WORD&lt;0-255&gt;</i> ] | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. Specifies the source BEB name. |
| <i>vlan</i>                                                                                  | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                                                         |

| Variable        | Value                                                                 |
|-----------------|-----------------------------------------------------------------------|
| <i>vrf</i>      | Displays IP Multicast over Fabric Connect route information by VRF.   |
| <i>vsn-isid</i> | Displays IP Multicast over Fabric Connect route information by I-SID. |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                               | Value                                                                        |
|----------------------------------------|------------------------------------------------------------------------------|
| <i>count</i>                           | Displays the total number of SPB multicast entries.                          |
| <i>host-name</i>                       | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid</i><br><xxxx.xxxx.xxxx.xx-xx> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID.    |

### View IGMP Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to display IGMP information.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

Ensure that the output displays `routed-spb` under `MODE`.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count] [group {A.B.C.D}] [member-subnet default|
{A.B.C.D/X}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:

```
show ip igmp sender [count] [group {A.B.C.D}] [member-subnet default|
{A.B.C.D/X}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

#### Example

Display IGMP information for IP multicast over Fabric Connect within the GRT:

```
Switch:1#show ip igmp interface
```

```
=====
=====
```

```
                Igmpp Interface - GlobalRouter
```

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                  | Value                        |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF by name.   |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group</i> {A.B.C.D}           | Specifies the group address.                                               |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask.                                 |
| <i>vrf</i> WORD<1-16>            | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids</i> WORD<0-512>        | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group</i> {A.B.C.D}           | Specifies the group address.                                               |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask.                                 |
| <i>vrf</i> WORD<1-16>            | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids</i> WORD<0-512>        | Displays the multicast route configuration for a particular VRF by VRF ID. |

#### View TLV Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to check TLV information.

For IP Multicast over Fabric Connect within the GRT, TLV 186 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set while on all BEB bridges, where a receiver exists, has the Rx bit set.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:
 

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:
 

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```

### Example

Display TLV information:

```
Switch:1# show isis lsdb tlv 186 detail

## Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                                  | Value                                                                                                                                                      |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>                             | Displays detailed information about the IS-IS Link State database.                                                                                         |
| <i>home</i>                               | Displays the IS-IS LSDB information that the system configures in the home area.                                                                           |
| <i>level {11, 12, 112}</i>                | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i>                              | Displays information on the local LSDB.                                                                                                                    |
| <i>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Specifies information about the IS-IS Link State database by LSP ID.                                                                                       |
| <i>remote</i>                             | Displays the IS-IS LSDB information that the system configures in the remote area.                                                                         |
| <i>sub-tlv &lt;1-3&gt;</i>                | Specifies information about the IS-IS Link State database by sub-TLV.                                                                                      |
| <i>sysid &lt;xxxx.xxxx.xxxx&gt;</i>       | Specifies information about the IS-IS Link State database by System ID.                                                                                    |
| <i>tlv &lt;1-236&gt;</i>                  | Specifies information about the IS-IS Link State database by TLV.                                                                                          |

## IP Shortcuts configuration using the EDM

This section provides procedures to configure IP Shortcuts using the EDM.

## Configuring IP Multicast over Fabric Connect on a VLAN within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled.

To configure a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3](#) on page 1909.

### Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

### About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing within the GRT does not depend on unicast routing. This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Choose a VLAN, and then click the **IP** button.

4. Click the **SPB Multicast** tab.

**Note**

After you enable IP Multicast over Fabric Connect, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where SPBM multicast is enabled, the system displays an error message.

**Note**

When you enable IP Multicast over Fabric Connect on a Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

5. Click **Enable**.
6. Click **Apply**.

### Configuring IP Multicast over Fabric Connect on a brouter port within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port IP interface. The default is enabled.

To configure a brouter port for a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN](#) on page 1910.

**Note**

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

### About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over

Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

### Procedure

1. Select an enabled port on the Physical Device View.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB Multicast** tab.
5. Click **Enable**.

#### Note

When you enable IP Multicast over Fabric Connect on a DvR Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

6. Click **Apply**.

### SPB Multicast field description

Use the data in the following table to use the SPB Multicast tab.

| Name          | Description                                                |
|---------------|------------------------------------------------------------|
| <b>Enable</b> | Enables or disables SPB Multicast. The default is disable. |

### Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time. The default timeout value is 210 seconds.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

### Procedure

1. In the navigation pane, expand **Configuration > Fabric > SPBM**.
2. Select the **SPBM** tab.

3. Modify the **McastFwdCacheTimeout** value.
4. Select **Apply**.

#### *IP multicast over SPBM within the GRT configuration example*

The following example shows the configuration steps to enable IP multicast over SPBM support on VLANs 10 and 11 that are part of the GRT:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION - PHASE I

interface vlan 500
ip address 192.0.2.1 255.255.255.0
ip spb-multicast enable
exit

interface vlan 501
ip address 192.0.2.2 255.255.255.0
ip spb-multicast enable
exit
```

## Layer 3 VSN Fundamentals

This section provides fundamentals concepts for Layer 3 VSN configuration. For more information on Layer 3 VSN basic configuration, see [Layer 3 VSN Configuration](#) on page 1537.

#### *Layer 3 VSN with IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect supports Layer 3 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. Layer 3 VSN using IP Multicast over Fabric Connect is helpful when you need complete security and total isolation of data. No one outside of the Layer 3 VSN can join or even see the Layer 3 VSN. Applications that can use Layer 3 VSN with IP Multicast over Fabric Connect include: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. This configuration automatically enables IGMP snooping and proxy on those VLANs. IGMPv2 at the VLAN level is the default setting, with no other configuration required. If you want to use IGMPv3, you must configure IGMPv3.

IP Multicast over Fabric Connect is only configured on BEBs.

#### Note

- You do not need to enable IP Shortcuts to support multicast routing in the Layer 3 VSN using SPBM. IPVPN creation and I-SID assignment for the IPVPN is required, but you do not need to enable IPVPN.
- If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing for Layer 3 VSNs using VRFs, which allows you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

With Layer 3 VSN with IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud. For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that has IP Multicast over Fabric Connect enabled. If a sender transmits a multicast stream to a BEB on a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 VSN can receive that stream.

#### I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 3 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 3 VSN associated with the local VLAN that the IP multicast data was received on.

#### TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 3 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

#### IGMP

After a BEB receives an IGMP join message from a receiver, the BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept,

but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

### DvR

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 738.

### Layer 3 VSN Configuration using the CLI

This section provides procedures to configure Layer 3 VSN using the command line interface (CLI).

#### Configure Layer 3 VSN with IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for a Layer 3 VSN.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. After you enable IP Multicast over Fabric Connect on VRF VLANs, snooping and proxy on those VLANs is enabled. IGMPv2 at the VLAN level is the default setting. No configuration is required.

#### Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- You must assign an I-SID for the IPVPN.

#### About This Task

With Layer 3 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud.

For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that have `ip spbm-multicast` enabled. The default is disabled.

All or a subset of VLANs within a Layer 3 VSN can exchange multicast traffic. The BEB only sends out traffic for a multicast stream on which IGMP joins and reports are received.

The switch only supports IPv4 multicast traffic.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.

**Procedure**

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
mvpn enable
```

The default is disabled.

3. Exit to Global Configuration mode:

```
exit
```

4. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} OR interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
ip spb-multicast enable
```

## 6. (Optional) Enable IGMP version 3:

```
ip igmp snooping

ip igmp ssm-snoop

ip igmp compatibility-mode

ip igmp version 3
```

**Note**

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to use these commands if you use IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

## 7. (Optional) Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```

**Note**

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

**Example**

Configure IP Multicast over Fabric Connect for a Layer 3 VSN:

```
Switch:>enable
Switch:#configure terminal
Switch:(config)# router vrf green
Switch:(config-vrf)#mvpn enable
Switch:(config)#exit
Switch:(config)#interface vlan 500
Switch:(config-if)#ip spb-multicast enable
```

**Variable Definitions**

The following table defines parameters for the **router vrf** command.

| Variable           | Value                          |
|--------------------|--------------------------------|
| <i>WORD</i> <1-16> | Specifies the name of the VRF. |

The following table defines parameters for the **interface vlan** command.

| Variable                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

The following table defines parameters for the **GigabitEthernet** command.

| Variable                                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>GigabitEthernet{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip igmp** command.

| Variable                                                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>access-list WORD&lt;1-64&gt; {A.B.C.D/X} &lt;eny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both&gt;</code> | Specifies the name of the access list from 1–64 characters.<br>Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.<br>Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic. |
| <code>compatibility-mode</code>                                                                                                    | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br>default ip igmp compatibility-mode<br>, or use the no option to disable compatibility mode:<br>no ip igmp compatibility-mode                                                                                                                                                                                            |

| Variable                                                                                                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dynamic-downgrade-version</i>                                                                                                                                                | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br>default ip igmp dynamic-downgrade-version<br>or use the no option to disable downgrade:<br>no ip igmp dynamic-downgrade-version |
| <i>igmpv3-explicit-host-tracking</i>                                                                                                                                            | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>immediate-leave</i>                                                                                                                                                          | Enables fast leave on a VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>immediate-leave-members</i><br>{slot/port[/sub-port] [-slot/port[/sub-port]]<br>[,...]}                                                                                      | Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <code>static-group {A.B.C.D} {A.B.C.D} [port] {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]} [static blocked]</code> | Configures IGMP static members to add members to a snoop group.<br><code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group.<br><code>[port] {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry.<br><code>[static blocked]</code> configures the route to static or blocked.                                                                                                                          |
| <code>stream-limit stream-limit-max-streams &lt;0-65535&gt;</code>                                                           | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |

| Variable                                                                                                                 | Value                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams &lt;0-65535&gt;</code> | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4.     |
| <code>version &lt;1-3&gt;</code>                                                                                         | Configures the version of IGMP that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2). |

### View Layer 3 VSN with IP Multicast over Fabric Connect Information

Use the following options to display Layer 3 VSN with IP Multicast over Fabric Connect information to confirm proper configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all the VRFs that have MVPN enabled and their corresponding forward cache timeout values:

```
show ip vrf mvpn
```

3. Display IP Multicast over Fabric Connect route information:

```
show isis spbm ip-multicast-route [all][detail]
```

4. Display IP Multicast over Fabric Connect by group and source address:

```
show isis spbm ip-multicast-route [group {A.B.C.D}][detail][source {A.B.C.D}]
```

5. Display IP Multicast over Fabric Connect route information by VRF:

```
show isis spbm ip-multicast-route [vrf WORD<1-16>] [group {A.B.C.D}]
```

6. Display IP Multicast over Fabric Connect route information by VLAN:

```
show isis spbm ip-multicast-route [vlan <1-4059>][detail][group {A.B.C.D}]
```

7. Display IP Multicast over Fabric Connect information by VSN I-SID:

```
show isis spbm ip-multicast-route [vsn-isid <1-16777215>][detail][group {A.B.C.D}]
```

8. Display summary information for each S, G, V tuple with the corresponding scope, Data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]
```

#### Example

Display Layer 3 VSN with IP Multicast over Fabric Connect information:

```
Switch:1>enable
Switch:1#show ip vrf mvpn

Vrf name : green
  mvpn : enable
  fwd-cache-timeout(seconds) : 210
```

```

Vrf name : 4
  mvpn : enable
  fwd-cache-timeout(seconds) : 210

```

```

Vrf name : blue
  mvpn : enable
  fwd-cache-timeout(seconds) : 210

```

```
Switch:1#show isis spbm ip-multicast-route all
```

```

### Variable Definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable      | Value                                                                 |
|---------------|-----------------------------------------------------------------------|
| <i>all</i>    | Displays all IP Multicast over Fabric Connect route information.      |
| <i>detail</i> | Displays detailed IP Multicast over Fabric Connect route information. |

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>group{A.B.C.D}</code>             | Displays information on the group IP address for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                                           |
| <code>vlan&lt;1-4059&gt;</code>         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrfWORD&lt;1-16&gt;</code>        | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>vsn-isid&lt;1-16777215&gt;</code> | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the `show isis spb-mcast-summary` command.

| Variable                                       | Value                                                                           |
|------------------------------------------------|---------------------------------------------------------------------------------|
| <code>count</code>                             | Displays the total number of SPB multicast entries.                             |
| <code>host-nameWORD&lt;0-255&gt;</code>        | Displays the IP Multicast over Fabric Connect summary information by host-name. |
| <code>lspid&lt;xxxx.xxxx.xxxx.xx-xx&gt;</code> | Displays the IP Multicast over Fabric Connect summary information by LSP ID.    |

### View IGMP Information for Layer 3 VSN Multicast

Use the following commands to check IGMP information.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>][vrf WORD<1-16>][vrfids WORD<0-512>]
```

Ensure that the output displays `routed-spb` under `MODE`.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:

```
show ip igmp sender [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
```

**Example**

Display IGMP information for Layer 3 VSN with IP multicast over Fabric Connect:

```
Switch:#enable
Switch:1#show ip igmp interface vrf green

## Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                                                                               |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                  | Value                        |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF by name.   |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group</i> {A.B.C.D}           | Specifies the group address.                                               |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask.                                 |
| <i>vrf</i> WORD<1-16>            | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids</i> WORD<0-512>        | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

### View TLV Information for a Layer 3 VSN with IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For a Layer 3 VSN multicast, TLV 185 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group should have its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display IS-IS Link State Database information by TLV:
 

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
- Display IS-IS Link State Database information by Link State Protocol ID:
 

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> [tlv <1-236>] [sub-tlv <1-3>] [detail] [home|remote]
```

#### Example

Display TLV information for a Layer 3 VSN with IP Multicast over Fabric Connect:

```
Switch:1# show isis lsdb tlv 185 detail
=====

## Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                   | Value                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>              | Displays detailed information about the IS-IS Link State database.                                                                                         |
| <i>home</i>                | Displays the IS-IS LSDB information that the system configures in the home area.                                                                           |
| <i>level {11, 12, 112}</i> | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i>               | Displays information on the local LSDB.                                                                                                                    |

| Variable                                       | Value                                                                              |
|------------------------------------------------|------------------------------------------------------------------------------------|
| <code>lspid&lt;xxxx.xxxx.xxxx.xx-xx&gt;</code> | Specifies information about the IS-IS Link State database by LSP ID.               |
| <code>remote</code>                            | Displays the IS-IS LSDB information that the system configures in the remote area. |
| <code>sub-tlv &lt;1-3&gt;</code>               | Specifies information about the IS-IS Link State database by sub-TLV.              |
| <code>sysid &lt;xxxx.xxxx.xxxx&gt;</code>      | Specifies information about the IS-IS Link State database by System ID.            |
| <code>tlv &lt;1-236&gt;</code>                 | Specifies information about the IS-IS Link State database by TLV.                  |

### Layer 3 VSN Configuration using EDM

This section provides procedures to configure Layer 3 VSN using Enterprise Device Manager (EDM).

#### Enable MVPN for a VRF

Use this procedure to enable MVPN for a particular VRF. IP Multicast over Fabric Connect, constrains multicast streams of senders to all receivers in the same Layer 3 VSN. MVPN functionality is disabled by default.

#### Note

VLAN level configuration is also required to turn on the service on each VLAN within the VRF on which this services is required. You can turn it on under the VLAN context or the brouter context.

#### Before You Begin

- You must enable IP Multicast over Fabric Connect globally.

#### Procedure

- In the navigation pane, expand **Configuration > IP**.
- Select **IP-MVPN**.
- Select the **MVPN** tab.
- Double-click in the **Enable** field in the table.
- Select **Enable** from the drop down menu.
- Double-click in the **FwdCacheTimeout** field in the table, and then type the VRF timeout value.
- Select **Apply**.

#### MVPN Field Descriptions

Use the data in the following table to use the **MVPN** tab.

| Name                   | Description                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vrfid</b>           | Specifies the VRF ID.                                                                                                                             |
| <b>Enable</b>          | Enables Layer 3 VSN IP Multicast over Fabric Connect services for a particular VRF. The default is disabled.                                      |
| <b>FwdCacheTimeout</b> | Specifies the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.. |

### Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 3 VSN. The default is disabled.

To configure a VLAN for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN within the GRT](#) on page 1889.

#### Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

### About This Task

You must configure VLANs to turn on the service on each VLAN with in the VRF on which the service is required. You can turn it on under the VLAN context or the brouter context.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing (for Layer 3 VSN). This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > VLAN**.
7. Click **VLANs**.
8. Choose a VLAN, and then click the **IP** from under the tab bar.
9. Click the **SPB Multicast** tab.
10. Check the **Enable** box.
11. Click **Apply**.

**Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN**

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port. The default is disabled.

To configure a brouter port for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port within the GRT](#) on page 1890.

**Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 2 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

**About This Task**

You must enable IP Multicast over Fabric Connect on each of the VLANs that need to support IP multicast traffic.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to

more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

### Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > Edit > Port**.
7. Click **IP**.
8. Click the **SPB Multicast** tab.
9. Click **Enable**.
10. Click **Apply**.

### Configuring IGMP on a VLAN interface for a Layer 3 VRF

Use this procedure to configure IGMP for each VLAN interface to enable the interface to perform multicast operations.

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to enable IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

#### Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance with an I-SID on the switch.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect for a Layer 3 VSN.

### About This Task

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

## Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. In the navigation pane, expand **Configuration > VLAN**.
6. Click **VLANs**.
7. Select the desired VLAN from the listing.
8. Click the **IP** button.
9. Click the **IGMP** tab.
10. (Optional) If you want to enable SsmSnoopEnable, select the **SsmSnoopEnable** box.
11. (Optional) If you want to enable Snoop, select the **SnoopEnable** box.
12. (Optional) In the **Version** box, select the correct IGMP version.

You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

13. (Optional) Select **SnoopQuerierEnable**, to enable Snoop Querier. Only select this option, if you want to configure an address for the IGMP queries.
14. (Optional) In the **SnoopQuerierAddr** box, type an IP address, if you want to configure a snoop querier address.

### Note

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPBM bridge sends IGMP queries with a source address of 0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

## IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1–65535 and the default is 125.                                                                                                                                                                                                                                                 |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval. |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Robustness</b>               | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                             |
| <b>LastMembQueryIntvl</b>       | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |
| <b>SnoopEnable</b>              | Enables or disables snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SsmSnoopEnable</b>           | Enables or disables support for SSM on the snoop interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ProxySnoopEnable</b>         | Enables or disables proxy snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Version</b>                  | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.                                                                                                                                                                                                 |
| <b>FastLeaveEnable</b>          | Enables or disables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Current Number Of Stream</b> | Displays the current number of streams. This value is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>FastLeavePortMembers</b>     | Selects the ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SnoopMRouterPorts</b>        | Selects the ports in this interface that provide connectivity to an IP multicast router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DynamicDowngradeEnable</b>     | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.                                                                             |
| <b>CompatibilityModeEnable</b>    | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.                                                                                                                                                                                                                                                                                                                                     |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                              |
| <b>SnoopQuerierEnable</b>         | Enables Snoop Querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.<br>Enable Layer 2 Querier on only one node in the VLAN. |
| <b>SnoopQuerierAddr</b>           | Specifies the pseudo IP address of the IGMP Snoop Querier. The default IP address is 0.0.0.0. If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPBM bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.                                                                                    |

### Layer 3 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration to enable IP Multicast over Fabric Connect support on VLANs 500 and 501 that are part of VRF Green:

```

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1

```

```
ip spb-multicast enable
exit

vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn
i-sid 100
mvpn enable
exit
```

When using IGMPv3, the configuration is:

```
ISIS SPBM CONFIGURATION

router isis
spb 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1
ip spb-multicast enable
ip igmp version 3
exit

vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
ip igmp version 3
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn
i-sid 100
mvpn enable
exit
```

## IP SPB Multicast Policy Configuration

---

You can configure IP SPB Multicast Policy to permit only multicast senders or multicast receivers or deny both for specific IP multicast group addresses.

### IP SPB Multicast Policy fundamentals

This section contains conceptual information about IP SPB Multicast Policy .

#### *IP SPB Multicast Policy*

The protocols that use IP multicast, for example, Universal Plug and Play (uPnP), cause performance issues in the network as they generate many changes in the Intermediate-System-to-Intermediate-System (IS-IS) Link State Database (LSDB). To address the network issues, the IP SPB Multicast Policy feature aggregates multiple multicast groups (senders or receivers) in a static data I-SID that you configure in GRT/VRF, by associating the IP SPB Multicast Policy with a route-map. You can also configure filtering on the multicast groups based on the traffic flow (senders only or receivers only) using the IP SPB Multicast Policy feature.

When IP SPB Multicast Policy matches the sender's multicast group IP address, the following list identifies potential IP multicast stream behavior:

- Dropped.
- Forwarded as one dynamic data I-SID per stream (pre-existing design).
- Forwarded as multiple IPMC streams mapped to the same static data-ISID.

#### **Restrictions**

The following list identifies restrictions of an IP SPB Multicast Policy :

- This feature is not supported on:
  - IGMP snooping
  - Distributed Virtual Routing (DVR) leaf
- Multi-area SPB boundary nodes with remote IS-IS enabled do not support IP SPB Multicast Policy .
- Multi-area SPB boundary nodes do not support static data I-SID configuration. However, it can redistribute the static data I-SID with MAC learning disabled.
- The system ignores the include and exclude lists for IGMPv3 membership reports and forwards all traffic that is received in the static data I-SID to the receiver.
- This feature is not compatible with multicast traffic processed on a PIM GW interface and will not influence its behavior.

#### *Static Data I-SID*

To reduce Link State Database (LSDB) changes and Intermediate-System-to-Intermediate-System (IS-IS) processing, the switch advertises or withdraws the static data I-SIDs from the Shortest Path Bridging (SPB) fabric when you issue the apply command for the routed multicast policy. As a result, the switch triggers most of the IS-IS computation for the I-SIDs by user configuration and not by volatile network changes or UNI IGMP messages.

For Multi-area SPB boundary nodes, the static data I-SID multicast redistribution policy takes precedence over the Layer 2 multicast redistribution.

You can configure the static I-SID redistribution in the Multi-area SPB for any direction (home-to-remote or remote-to-home).

Multi-area SPB boundary nodes do not support static data I-SID configuration.

For more information, see the following sections:

- [Configure Multi-area SPB IPv4 Static I-SID Routed Multicast Redistribution](#) on page 1341
- [Configure Multi-area SPB Layer 3 Static I-SID Routed Multicast Redistribution Policy in Home Area](#) on page 1355
- [Configure Multi-area SPB Layer 3 Static I-SID Routed Multicast Redistribution Policy in Remote Area](#) on page 1356
- [Multi-area SPB](#) on page 1306

## IP SPB Multicast Policy Configuration Using CLI

Perform the procedures in this section to configure the IP SPB Multicast Policy using the Command Line Interface (CLI).

### *Create an IP SPB Multicast Policy*

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

### Before You Begin

- Configure Multicast Label Switching Virtual Private Network (MVPN) on VRF.
- Enable IP Multicast over Fabric Connect globally.
- Configure IP prefix list in GRT/VRF.

### About This Task

Perform this procedure to create the IP SPB Multicast Policy globally.

#### Note

- You can also configure the IP SPB Multicast Policy on a VRF instance in the same way as you configure on the GlobalRouter, except that you must use the VRF Router Configuration mode and create the route-map in VRF Router Configuration mode. Not all parameters are configurable on non0 VRFs.
- This configuration does not apply to IGMP snooping and DvR Leaf.
- Multi-area SPB boundary nodes with remote IS-IS enabled do not support IP SPB Multicast Policy .

## Procedure

1. Enter Route-Map Configuration mode:  

```
enable
```

```
configure terminal
```

```
route-map WORD<1-64> <1-65535>
```
2. Enable the route policy:  

```
enable
```
3. Match the IP SPB Multicast Policy to the multicast group:  

```
match multicast-group WORD<0-259>
```
4. (Optional) Set the data flow for the IP SPB Multicast Policy :  

```
set {rx-only | tx-only}
```
5. Configure the data I-SID:  

```
set data-isid <1-15999999>
```
6. Permit the route:  

```
permit
```
7. Exit to Global Configuration mode:  

```
exit
```
8. Associate the IP SPB Multicast Policy with the route-map:  

```
ip spb-multicast-policy route-map WORD<0-64>
```
9. Enable the IP SPB Multicast Policy :  

```
ip spb-multicast-policy enable
```
10. Verify the configuration:  

```
show ip spb-multicast-policy
```
11. Apply the IP SPB Multicast Policy instance:  

```
ip spb-multicast-policy apply
```

## Example

Creating an IP SPB Multicast Policy globally.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#route-map rtest 210
Switch:1(route-map)#enable
Switch:1(route-map)#match multicast-group McastGroup
Switch:1(route-map)#set data-isid 210
Switch:1(route-map)#permit
Switch:1(route-map)#exit
Switch:1(config)#ip spb-multicast-policy route-map rtest
Switch:1(route-map)#ip spb-multicast-policy enable
Switch:1(config)#show ip spb-multicast-policy
=====
                SPB ROUTED IP MULTICAST POLICY - GlobalRouter
=====
ENABLE      RPOLICY
=====
TRUE        rtest
Switch:1(route-map)#ip spb-multicast-policy apply
```

### Creating an IP SPB Multicast Policy on VRF1.

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf VRF1
Switch:1(router-vrf)#route-map rtest 210
Switch:1(router-vrf-routemap)#enable
Switch:1(router-vrf-routemap)#match multicast-group McastGroup
Switch:1(router-vrf-routemap)#set data i-sid 5679
Switch:1(router-vrf-routemap)#permit
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#ip spb-multicast-policy route-map rtest
Switch:1(router-vrf)#ip spb-multicast-policy enable
Switch:1(router-vrf)#exit
Switch:1(config)#show ip spb-multicast-policy vrf VRF1
=====
                SPB ROUTED IP MULTICAST POLICY - VRF VRF1
=====
ENABLE      RPOLICY
-----
TRUE        rtest
Switch:1(config)#ip spb-multicast-policy apply vrf VRF1

```

### Variable Definitions

The following table defines parameters for the **ip spb-multicast-policy** command.

| Variable                          | Value                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------------|
| <i>apply</i>                      | Applies the IP SPB Multicast Policy on route-map.                                               |
| <i>enable</i>                     | Enables the IP SPB Multicast Policy on route-map.                                               |
| <i>route-map WORD&lt;0-64&gt;</i> | Specifies the route of the policy.<br><i>WORD&lt;0-64&gt;</i> specifies the name of the policy. |
| <i>vrf WORD&lt;1-16&gt;</i>       | Specifies the VRF name.                                                                         |

The following table defines parameters for the **match** command.

| Variable                                | Value                                                                                                                                                         |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>multicast-groupWORD&lt;0-259&gt;</i> | Specifies the multicast group for IP SPB Multicast Policy .<br><i>WORD&lt;0-259&gt;</i> specifies the name of one or more prefix lists, separated by a comma. |

The following table defines parameters for the **set** command.

| Variable                                  | Value                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>data-isid &lt;1-15999999&gt;</code> | Specifies the data services instance identifier (I-SID) for static I-SID routed multicast policy. |
| <code>rx-only</code>                      | Specifies the received traffic only, applicable to static I-SID routed multicast policy.          |
| <code>tx-only</code>                      | Specifies the transmitted traffic only, applicable to static I-SID routed multicast policy.       |

#### Display IS-IS SPBM Static I-SID IP Multicast Route Information

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

#### About This Task

Perform this procedure to display the Intermediate-System-to-Intermediate-System SPBM static I-SID IP multicast route information.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display the static I-SID IP multicast route information by group IP address:  

```
show isis spbm static-isid-ipmc-route group {A.B.C.D} [vrf WORD<1-16>]
```
- Display the local static I-SID IP multicast route information:  

```
show isis spbm static-isid-ipmc-route local [group {A.B.C.D} [vrf WORD<1-16>] | vrf WORD<1-16>]]
```
- Display the non-local static I-SID IP multicast route information:  

```
show isis spbm static-isid-ipmc-route non-local [group {A.B.C.D} [vrf WORD<1-16>] | vrf WORD<1-16>]]
```
- Display the static I-SID IP multicast route information on a VRF instance:  

```
show isis spbm static-isid-ipmc-route vrf WORD<1-16>
```

#### Example

Displaying the IS-IS SPBM static I-SID IP multicast route information on a VRF instance.

```
Switch:1>show isis spbm static-isid-ipmc-route vrf test
```

```

### Variable Definitions

The following table defines parameters for the **show isis spbm static-isis-ipmc-route** command.

| Variable                    | Value                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------|
| <i>group {A.B.C.D}</i>      | Displays the static I-SID IP multicast route information. <i>{A.B.C.D}</i> specifies the group IP address.       |
| <i>vrf WORD&lt;1-16&gt;</i> | Displays the static I-SID IP multicast route information. <i>WORD&lt;1-16&gt;</i> specifies the name of the VRF. |
| <i>local</i>                | Displays the local static I-SID IP multicast route information.                                                  |
| <i>non-local</i>            | Displays the non-local static I-SID IP multicast route information.                                              |

## IP SPB Multicast Policy Configuration using EDM

Perform the procedures in this section to configure the IP SPB Multicast Policy using the Enterprise Device Manager (EDM).

### Configure IP SPB Multicast Policy

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### About This Task

Perform this procedure to configure the IP SPB Multicast Policy on the switch.

#### Note

This functionality is not supported on IGMP snooping and DvR Leaf. Multi-area SPB boundary nodes with remote IS-IS enabled do not support IP SPB Multicast Policy.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP**.

3. Select the **Globals** tab.
4. Select **SpbMulticastPolicyEnable** to enable this functionality.
5. In the **SpbMulticastPolicyRmap** field, type the route-map.
6. In the **SpbMulticastPolicyApply** field, select **apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Forwarding</b>                     | Configures the system for forwarding (routing) or for dropping. The default value is forwarding.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DefaultTTL</b>                     | Configures the default time-to-live (TTL) value for a routed packet. TTL indicates the maximum number of seconds elapsed before a packet is discarded. Enter an integer from 1 to 255. The default value of 255 is used if a value is not supplied in the datagram header.                                                                                                                                                                                                                                                                |
| <b>ReasmTimeout</b>                   | Specifies the maximum number of seconds that received fragments are held while they wait for reassembly. The default value is 30 seconds.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ICMPUnreachableMsgEnable</b>       | <p>Enables the generation of Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this system. These messages help determine if the system is reachable over the network. The default is disabled.</p> <p><b>Important:</b><br/>As a best practice, enable icmp-unreach-msg only if it is absolutely required. If icmp-unreach-msg is enabled and a packet is received for which there is no route in the routing table, CPU utilization can dramatically increase.</p> |
| <b>ICMPRedirectMsgEnable</b>          | Enables or disables the system sending ICMP destination redirect messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>IcmpEchoBroadcastRequestEnable</b> | Enables or disables IP ICMP echo broadcast request feature. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Name                                                                                           | Description                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IcmpDropFragmentsEnable</b><br><b>Note:</b> Exception: Not supported on XA1400 Series.      | Enables or disables IPv4 Fragmented ICMP packet filtering globally. The default is disabled.                                                                                                                                                                                     |
| <b>AlternativeEnable</b>                                                                       | Globally enables or disables the Alternative Route feature.<br>If the alternative-route parameter is disabled, all existing alternative routes are removed. After the parameter is enabled, all alternative routes are re-added. The default is enabled.                         |
| <b>RouteDiscoveryEnable</b>                                                                    | Enables the ICMP Router Discovery feature. The default is disabled (not selected). Use ICMP Router Discovery to enable hosts attached to multicast or broadcast networks to discover the IP addresses of neighboring routers.                                                    |
| <b>AllowMoreSpecificNonLocalRouteEnable</b>                                                    | Enables or disables a more-specific nonlocal route. If enabled, the system can enter a more-specific nonlocal route into the routing table. The default is disabled.                                                                                                             |
| <b>SuperNetEnable</b>                                                                          | Enables or disables supernetting. If supernetting is globally enabled, the system can learn routes with a route mask less than 8 bits. Routes with a mask length less than 8 bits cannot have ECMP paths, even if you globally enable the ECMP feature. The default is disabled. |
| <b>UdpChecksumEnable</b>                                                                       | Enables or disables the UDP checksum calculation. The default is enable.                                                                                                                                                                                                         |
| <b>SourceRouteEnable</b>                                                                       | Enables or disables IP Source Routing globally. It is disabled by default.                                                                                                                                                                                                       |
| <b>SpbMulticastPolicyEnable</b><br><b>Note:</b><br>Exception: does not apply to XA1400 Series. | Enables the IP SPB Multicast Policy .                                                                                                                                                                                                                                            |
| <b>SpbMulticastPolicyRmap</b><br><b>Note:</b><br>Exception: does not apply to XA1400 Series.   | Configures the name of the route-map for IP SPB Multicast Policy .                                                                                                                                                                                                               |
| <b>SpbMulticastPolicyApply</b><br><b>Note:</b><br>Exception: does not apply to XA1400 Series.  | Applies the IP SPB Multicast Policy . The default value is noAction.                                                                                                                                                                                                             |

| Name                                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ARPLifeTime</b>                                                                                                                 | Specifies the lifetime of an ARP entry within the system, global to the switch. The default value is 360 minutes.                                                                                                                                                                                                                                                                                                                                              |
| <b>EcmpEnable</b>                                                                                                                  | Globally enables or disables the Equal Cost Multipath (ECMP) feature. The default is disabled. After ECMP is disabled, the EcmpMaxPath is reset to the default value of 1.                                                                                                                                                                                                                                                                                     |
| <b>EcmpMaxPath</b>                                                                                                                 | Globally configures the maximum number of ECMP paths. You cannot configure this feature unless ECMP is enabled globally. Different hardware platforms can support a different number of ECMP paths. For more information, see <a href="#">VOSS Release Notes</a> .                                                                                                                                                                                             |

The default varies depending on hardware platform: <ul style="list-style-type: none"> <li>• For XA1400 Series, the default value is auto-derived.</li> <li>• For VSP 4900 Series and VSP 7400 Series, the default value is 1300.</li> </ul> |

### Display Static Data I-SID IP Multicast Routes Information

#### Note

This procedure does not apply to XA1400 Series and VSP 8600 Series.

### About This Task

Perform this procedure to display the static data I-SID IP multicast routes information.

### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **StaticIsidIpMcastRoutes** tab.
4. Select the desired row and type the value of static data I-SID.

### StaticIsidIpMcastRoutes Field Descriptions

Use the data in the following table to use the **StaticIsidIpMcastRoutes** tab.

| Name            | Descriptions                                                                                       |
|-----------------|----------------------------------------------------------------------------------------------------|
| <b>IsidType</b> | Indicates the type of static data I-SID.                                                           |
| <b>Group</b>    | Indicates the group address of the IP multicast route that contains multicast routing information. |

| Name                 | Descriptions                                                                                                                                                                                                          |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Source</b>        | Indicates the IP address where the IP multicast route originated.                                                                                                                                                     |
| <b>Vsnlsid</b>       | Indicates the Virtual Routing Network (VSN) I-SID.                                                                                                                                                                    |
| <b>SourceBeb</b>     | Indicates the name of the source Backbone Edge Bridge for IP multicast route.                                                                                                                                         |
| <b>VrfName</b>       | Indicates the VRF name of the interface.                                                                                                                                                                              |
| <b>Datalsid</b>      | Indicates the static I-SID value for IP multicast route.                                                                                                                                                              |
| <b>Bvlan</b>         | Indicates the Backbone VLANs (B-VLANs) for the IP multicast route.                                                                                                                                                    |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route.SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports. |

**Table 135: Internet Protocol Flow Information eXport (IPFIX) product support (continued)**

| Feature                                                                     | Product         | Release introduced |
|-----------------------------------------------------------------------------|-----------------|--------------------|
| IPFIX — using Segmented Management Instance VLAN as source IP               | 5320 Series     | Fabric Engine 8.8  |
|                                                                             | 5420 Series     | Fabric Engine 8.8  |
|                                                                             | 5520 Series     | Fabric Engine 8.8  |
|                                                                             | 5720 Series     | Fabric Engine 8.8  |
|                                                                             | 7520 Series     | Fabric Engine 8.10 |
|                                                                             | 7720 Series     | Fabric Engine 8.10 |
|                                                                             | VSP 4450 Series | Not Supported      |
|                                                                             | VSP 4900 Series | Not Supported      |
|                                                                             | VSP 7200 Series | Not Supported      |
|                                                                             | VSP 7400 Series | VOSS 8.8           |
|                                                                             | VSP 8200 Series | Not Supported      |
|                                                                             | VSP 8400 Series | Not Supported      |
|                                                                             | VSP 8600 Series | Not Supported      |
|                                                                             | XA1400 Series   | Not Supported      |
| IPFIX — using Segmented Management Instance CLIP (GRT and VRF) as source IP | 5320 Series     | Fabric Engine 8.8  |
|                                                                             | 5420 Series     | Fabric Engine 8.8  |
|                                                                             | 5520 Series     | Fabric Engine 8.8  |
|                                                                             | 5720 Series     | Fabric Engine 8.8  |
|                                                                             | 7520 Series     | Fabric Engine 8.10 |
|                                                                             | 7720 Series     | Fabric Engine 8.10 |
|                                                                             | VSP 4450 Series | Not Supported      |
|                                                                             | VSP 4900 Series | Not Supported      |
|                                                                             | VSP 7200 Series | Not Supported      |
|                                                                             | VSP 7400 Series | VOSS 8.8           |
|                                                                             | VSP 8200 Series | Not Supported      |
|                                                                             | VSP 8400 Series | Not Supported      |
|                                                                             | VSP 8600 Series | Not Supported      |
|                                                                             | XA1400 Series   | Not Supported      |

## IPFIX Fundamentals

Internet Protocol Flow Information eXport (IPFIX) is an Internet Engineering Task Force (IETF) standard of export for Internet Protocol flow information.

IPFIX monitors flows that pass an observation point. The switch organizes flows into a flow group, which is contained in an observation domain.

An IPFIX flow is a set of packets that pass an observation point in the network during a certain time interval. Packets that belong to a particular flow have a common set of properties. The switch defines each property using values from the following:

- Source IP address
- Destination IP address
- IP protocol
- L4 source port
- L4 destination port

A packet belongs to a flow if it completely satisfies all defined properties of the flow.

The switch logically organizes flows into a flow group, which corresponds to a single observation point. A flow can belong to only 1 flow group. A flow group is a collection of packet flows that meet match criteria. Examples of flow groups are packets ingressing a specific physical port, or packets with a destination IP address belonging to a specific subnet.

A flow group is contained in an observation domain. The switch assigns the flow group to an observation domain. The observation domain has a unique observation domain ID that you can configure. You can configure only 1 observation domain.

The IPFIX solution consists of the following processes:

- Filtering Rules process: The Filtering Rules process gathers information about flows through different ports, or the observation point. Flow information includes the following:
  - The IPv4 source address.
  - The IPv4 destination address.
  - The L4 source port.
  - The L4 destination port.
  - The transport protocol.
  - The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The absolute timestamp of the first packet of this flow.
  - The absolute timestamp of the last packet of this flow.

The Filtering Rules process runs on the switch.

- Exporting process: The Filtering Rules process sends information to the Exporting process. The Exporting process uses the UDP transport protocol for network communication with the Collecting process.

The Exporting process runs on the switch.

- Collecting process: You can view flows and export flow information periodically to a collector. A collector can store a large number of flow records from several devices in the network. The IPFIX standard specifies the protocol for exporting the flows to a

collector, including the formatting of flow records and the underlying UDP transport protocol.

Use the collected information for network planning, troubleshooting a live network, and monitoring security threats.

The best practice is to use the ExtremeAnalytics™ solution as the collector. The ExtremeAnalytics™ solution provides an enhanced method of collecting IPFIX flow information.

The external collector for the IPFIX solution must support our IPFIX template, which contains the following element IDs defined by Internet Assigned Numbers Authority (IANA) IPFIX assignments.

**Table 136: IPFIX element IDs**

| Element ID | Name                      | Description                                                                                                                                                      |
|------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | unknown                   | Reserved                                                                                                                                                         |
| 4          | protocolIdentifier        | The value of the protocol number in the IP packet header.                                                                                                        |
| 7          | sourceTransportPort       | The source port identifier in the transport header.                                                                                                              |
| 8          | sourceIPv4Address         | The IPv4 source address in the IP packet header.                                                                                                                 |
| 11         | destinationTransport Port | The destination port identifier in the transport header.                                                                                                         |
| 12         | destinationIPv4Address    | The IPv4 destination address in the IP packet header.                                                                                                            |
| 85         | octetTotalCount           | The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point. |
| 86         | packetTotalCount          | The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.           |
| 152        | flowStartMilliseconds     | The absolute timestamp of the first packet of this flow.                                                                                                         |
| 153        | flowEndMilliseconds       | The absolute timestamp of the last packet of this flow.                                                                                                          |

IPFIX is a push protocol. The Filtering Rules and Exporting processes periodically send IPFIX messages to configured receivers without interaction from the Collecting process.

## Operational Considerations

IPFIX collects IPv4 flow information on the switch and conforms with the following:

- IPFIX supports only 1 collector.
- IPFIX learns only IPv4 flows.

- IPFIX sends and receives only TCP/UDP flows.
- IPFIX uses only UDP to export packets.
- You can configure only the template exporting timer.
- The Out-of-Band (OOB) port does not support IPFIX.
- IPFIX exports TCP/UDP IPv4 flows on IS-IS interfaces that are members of a VLAN. IPFIX does not capture Mac-In-Mac encapsulated flows on IS-IS interfaces.

IPFIX processes IPv4 UDP or TCP Mac-in-Mac packet flows that are terminated by the switch. IPFIX does not process Mac-in-Mac packet flows that are only traversing the switch (Layer 2 switching).

- Layer 3 Virtual Services Network (L3 VSN) flow packets on NNI ports are not learned by IPFIX.
- The switch supports only ingress sampling. The switch does not support egress sampling.
- IPFIX is supported on Segmented Management Instance interfaces VLAN and CLIP. Segmented Management Instance interface OOB is not supported.
- When you use Segmented Management Instance VLAN interface IP address as the source IP, IPFIX can function in Layer 2 only environments.
- You must use Segmented Management Instance CLIP to access VRFs and Layer 3 VSNs.
- IPFIX supports user created VRFs when you configure a Segmented Management Instance CLIP interface as the source IP.
- You can use the onboarding VLAN to manage the switch and enable IPFIX without any additional management or routing interface configuration.

## IPFIX Configuration Using CLI

---

This section provides procedures to configure IPFIX using Command Line Interface (CLI).

### Enabling IPFIX Globally

#### About This Task

Use the following procedure to enable IPFIX globally. IPFIX provides the ability to monitor IPv4 traffic flows.

The default global state is disabled.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable IPFIX:  
`ip ipfix enable`

*Examples***Enable IPFIX globally:**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix enable
```

**Disable IPFIX globally:**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no ip ipfix enable
```

By disabling IPFIX globally, all the processes and traffic sent to collector(s) will be stopped. Do you agree (y/n) ? y

## Displaying IPFIX Global Status

**About This Task**

Use the following procedure to display global status information for IPFIX.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display IPFIX global status:

```
show ip ipfix
```

**Example**

```
Switch:1#show ip ipfix
```

```
=====
                                IPFIX Global
=====
      Global-State : enable
      Observation-Domain ID : 1
      Flow Limit : 20000
      Flow Count : 0
      Aging Interval : 40
```

## Configure the IPFIX Aging Interval

**About This Task**

Use the following procedure to configure an aging interval for IPFIX. The aging interval determines how long a traffic flow that is no longer being received, is retained as a flow.

**Procedure**

Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix aging-interval 30
```

*Variable Definitions*

The following table defines parameters for the **ip ipfix aging-interval** command.

| Variable | Value                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-60>   | Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow.<br>The default is 40 seconds. |

**Configure the IPFIX Collector****About This Task**

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

You can configure IPFIX on Segmented Management Instance interfaces VLAN and CLIP. You can also use routing VLANs or loopback IPs as the exporter IP address. Configure the exporter IP address to match the Management Instance interface IP address.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

- Configure values for the collector ID, the IP address of the collector, and the IP address of the exporter. Optionally, you can configure values for the source port sending flow information and the destination port receiving flow information:

```
ip ipfix collector <1-1> {A.B.C.D} exporter-ip {A.B.C.D} [dest-port <1-65535>] [src-port <1-65535>]
```

### Note

You cannot configure collector or exporter IP addresses in the following formats:

- 255.255.255.255
- 127. x.x.x
- 0.x.x.x
- 224.0.0.0 to 239.255.255.255

If you configure a collector or exporter IP address in any of these formats, the following error message is displayed:

```
Error: Invalid IP address
```

- (Optional) Configure a value for the export interval:

```
ip ipfix collector 1 export-interval <1-120>
```

- (Optional) Configure a value for the initial burst of template packets:

```
ip ipfix collector 1 initial-burst <1-10>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix collector 1 192.0.2.15 exporter-ip 192.0.2.16
dest-port 2 src-port 4
Switch:1(config)#ip ipfix collector 1 export-interval 40
Switch:1(config)#ip ipfix collector 1 initial-burst 4
```

### Variable Definitions

Use the data in the following table to use the **ip ipfix collector** command.

| Variable              | Value                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-1>                 | Specifies the IPFIX collector ID.                                                                                                                                                                                                  |
| {A.B.C.D}             | Specifies the IP address of the collector.                                                                                                                                                                                         |
| exporter-ip {A.B.C.D} | Specifies the IP address of the exporter.<br><br><b>Note:</b><br>For Segmented Management Instance interfaces, the exporter-IP address is the IP address of the Segmented Management Instance interface on which datagrams egress. |
| dest-port <1-65535>   | Specifies the destination port receiving flow information.                                                                                                                                                                         |

| Variable           | Value                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| src-port <1-65535> | Specifies the source port sending flow information.                                                                |
| export-interval    | Specifies, in seconds, the frequency of template packet exports to the collector. The default value is 60 seconds. |
| initial-burst      | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.        |

## Displaying IPFIX Collector Information

### About This Task

Use the following procedure to display information about the IPFIX collector. The IPFIX collector can store flow information from multiple network devices.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the IPFIX collector:

```
show ip ipfix collector [<1-1>]
```

### Example

```

-----
                                IPFIX Collector-Info
-----
ID  Collector      Exporter      Source  Destination  Collector  Reachable  Exporting  Initial
   IP Address    IP Address    Port    Port          State     Via         Interval  Burst
-----
1   20.20.20.2     20.20.20.1   2055    2055         Enabled   -          60        5

```

### Variable Definitions

Use the data in the following table to use the **show ip ipfix collector** command.

| Variable | Value                             |
|----------|-----------------------------------|
| <1-1>    | Specifies the IPFIX collector ID. |

## Configuring an IPFIX Observation Domain

### About This Task

An observation domain consists of a collection of flow groups. Use this procedure to assign a unique ID to an observation domain. The default value is 0.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the observation domain ID:  

```
ip ipfix observation-domain <0-4294967295>
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix observation-domain 1
```

## Variable Definitions

Use the data in the following table to use the **ip ipfix observation-domain** command.

| Variable                             | Value                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| observation-domain<br><0-4294967295> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |

## Display IPFIX Flows

### About This Task

Use the following procedure to display information about IPFIX flows. You can display information for all IPFIX flows, or you can specify a single IPFIX flow and display additional information about that flow.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all IPFIX flows:  

```
show ip ipfix flows
```
3. Display information about an IPFIX flow learned on an ingress port:

#### Note

This step only applies to VSP 7400 Series.

```
show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-port <rx-nni
| {slot/port[/sub-port]}>
```

## Example

Display all IPFIX flows:

```
Switch:1>show ip ipfix flows
```

| IPFIX Flows |                |             |                  |          |         |
|-------------|----------------|-------------|------------------|----------|---------|
| Source IP   | Destination IP | Source Port | Destination Port | Protocol | In Port |
| 192.0.2.1   | 198.51.100.1   | 63          | 63               | UDP      | 1/17    |
| 203.0.113.2 | 203.0.113.1    | 63          | 63               | UDP      | RX-NNI  |

Display information about a specific IPFIX flow:

```
Switch:1>#show ip ipfix flows source-addr 203.0.113.2 dest-addr 203.0.113.1 s 63 d 63 p
udp in-port rx-nni
```

| IPFIX Flows                  |                        |                      |                                 |  |                             |
|------------------------------|------------------------|----------------------|---------------------------------|--|-----------------------------|
| Source IP/<br>Destination IP | Src Port/<br>Dest Port | Protocol/<br>In Port | Start Time/<br>Observation Time |  | Byte Count/<br>Packet Count |
| 203.0.113.2                  | 63                     | UDP                  | Tue Apr 09 06:48:57 2019 UTC    |  | 352376                      |
| 203.0.113.1                  | 63                     | RX-NNI               | Tue Apr 09 06:49:49 2019 UTC    |  | 5182                        |

### Variable Definitions

The following table defines parameters for the **show ip ipfix flows** command.

| Variable                                                              | Value                                             |
|-----------------------------------------------------------------------|---------------------------------------------------|
| <code>dest-addr {A.B.C.D}</code>                                      | Specifies an IP address for the flow destination. |
| <code>dest-port &lt;1-65535&gt;</code>                                | Specifies a value for the destination port.       |
| <code>in-port &lt;rx-nni<br/>  {slot/port[/sub-<br/>port]}&gt;</code> | Specifies the port that learns the flow.          |
| <code>protocol {udp tcp}</code>                                       | Specifies the transport protocol.                 |
| <code>source-addr {A.B.C.D}</code>                                    | Specifies an IP address for the flow source.      |
| <code>source-port &lt;1-65535&gt;</code>                              | Specifies a value for the source port.            |

## IPFIX Configuration Using EDM

This section provides procedures to configure IPFIX in Enterprise Device Manager (EDM).

### Enabling IPFIX Globally

#### About This Task

IPFIX allows you to monitor IPv4 traffic flows. Use the following procedure to enable IPFIX globally.

The default global state is disabled.

#### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **IPFIX**.

3. Click the **Globals** tab.
4. To enable IPFIX, click **enable** in the **ConfState** option box.
5. (Optional) To configure an observation domain ID, type a value in the **ObservationDomainID** field.
6. (Optional) To configure the aging interval, type a value in the **AgingInterval** field.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                       | Description                                                                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConfState</b>           | Specifies whether IPFIX is enabled or disabled. The default is disabled.                                                                                                                                |
| <b>ObservationDomainID</b> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |
| <b>AgingInterval</b>       | Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow.<br>The default is 40 seconds.      |

## Configure the IPFIX Collector

### About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

You can configure IPFIX on Segmented Management Instance interfaces VLAN and CLIP. You can also use routing VLANs or loopback IPs as the exporter IP address. Configure the exporter IP address to match the Management Instance interface IP address.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IPFIX**.
3. Select the **Collector** tab.
4. Click **Insert**.
5. In the **Num** field, specify a value for the collector ID number.
6. In the **AddressType** field, specify a value for the IP address type of the collector.
7. In the **Address** field, specify a value for the IP address of the collector.
8. (Optional) In the **SrcPort** field, specify a value for the source port sending flow information.

9. (Optional) In the **DestPort** field, specify a value for the destination port receiving flow information.
10. In the **ExporterIpType** field, specify a value for the IP address type of the exporter for the collector.
11. In the **ExporterIp** field, specify the IP address of the exporter for the collector.
12. (Optional) In the **ExportInterval** field, specify the frequency of template packets exports to the collector.
13. (Optional) In the **InitialBurst** field, specify the number of template packets to send when the collector becomes reachable.
14. Select **Insert**.

### Collector Field Descriptions

Use the data in the following table to use the **Collector** tab.

| Name                  | Description                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Num</b>            | Specifies the ID number of the collector                                                                                                                                                                                                             |
| <b>AddressType</b>    | Specifies the IP address type of the collector.                                                                                                                                                                                                      |
| <b>Address</b>        | Specifies the IP address of the collector.                                                                                                                                                                                                           |
| <b>Protocol</b>       | Specifies the protocol used to export data from the exporter to the collector.                                                                                                                                                                       |
| <b>SrcPort</b>        | Specifies the source port sending flow information. The default value is 2055.                                                                                                                                                                       |
| <b>DestPort</b>       | Specifies the destination port receiving flow information. The default value is 2055.                                                                                                                                                                |
| <b>ExporterIpType</b> | Specifies the IP address type of the exporter for the collector.                                                                                                                                                                                     |
| <b>ExporterIp</b>     | Specifies the IP address of the exporter for the collector.<br><br><b>Note:</b><br>For Segmented Management Instance interfaces, the exporter-IP address is the IP address of the Segmented Management Instance interface on which datagrams egress. |
| <b>State</b>          | Specifies the state of the collector. The default value is enabled.                                                                                                                                                                                  |
| <b>IsReachable</b>    | Specifies whether the collector is reachable. The default value is false (not reachable)                                                                                                                                                             |
| <b>ViaNextHopName</b> | Specifies the next-hop through which the collector is reachable.                                                                                                                                                                                     |

| Name                  | Description                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>ExportInterval</b> | Specifies, in seconds, the frequency of template packets exports to the collector. The default value is 60 seconds. |
| <b>InitialBurst</b>   | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.         |

## IPsec Fundamentals

Internet Protocol Security (IPsec) ensures the authenticity, integrity, and confidentiality of data at the network layer of the Open System Interconnection (OSI) stack.

The IPsec feature is a set of security protocols and cryptographic algorithms that protect communication in a network. Use IPsec in scenarios where you need to encrypt packets between two hosts, or two routers, or a router and a host.

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols.

IPsec adds support for OSPF virtual link for the security protection of the communication between the end points. You can also use IPsec with OSPFv3 on a

router port or VLAN interface, for example, if you want to encrypt OSPFv3 control traffic on a broadcast network. You can also use IPsec with ICMPv6.

#### Note

- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.
- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

#### Note

- When an OSPFv3 virtual link between two end points is secured using IPsec, the IPsec status on the IPv6 interfaces is automatically updated. This is applicable only on those interfaces that have no IPSEC policies manually configured on them

The following figure displays the movement of traffic using IPsec.

**Figure 159: Internet Protocol Security (IPsec)**

The IPsec feature uses security ciphers and encryption algorithms like AES, DES, and 3DES to ensure confidentiality of data, and keyed MAC for authenticity of data. The encryption algorithms require shared keys to secure the communication. The device only supports manual keying and configuration for IPsec. The IPsec feature supports IPv4 and IPv6 interfaces.

To configure IPsec, you create an IPsec policy, and then link the IPsec policy to an interface. You also link each IPsec policy to an IPsec security association. The IPsec

policies define the amount of security applied to specific traffic on a specific interface. The IPsec feature supports the following security protocols:

- Encapsulating security payload (ESP)
- Authentication header (AH)

The device restricts IPsec encryption to control traffic through the CPU. The IPsec feature processes either the ingress, the egress, or both the egress and ingress control packets to and from the CPU.

The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to the packet. The device consults the SPD for both ingress and egress traffic. For egress traffic, the device consults the SPD to determine if IPsec needs to apply security considerations. For ingress traffic, the device consults the SPD to determine whether the traffic received with IPsec encapsulation complies with the policies defined in the system.

For more information on IPsec, see [IPsec Support with OSPFv3](#) on page 2675, [View IPsec Statistics](#) on page 1972, and [Display IPsec Interface Statistics](#) on page 1986.

## Authentication header

The authentication header (AH) authenticates IP traffic and ensures you connect with who you want to connect. The authentication header can detect if data is altered in transit and protect against replay attacks. The authentication header does not encrypt traffic.

The authentication header provides a small header that precedes the payload with the use of the security parameters index (SPI) and sequence number. The authentication header provides:

- IP datagram sender authentication by HMAC or MAC
- IP datagram integrity assurance by HMAC or MAC
- Replay detection and protection by sequence number

The IPsec feature inserts the AH header after the IP header in transport mode. Transport mode with AH authenticates only the payload of the IP packet.

Tunnel mode authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

You can apply AH alone, or in combination with the Encapsulating Security Payload (ESP).

The following figures show an original IP packet and an IP packet with an AH header.

**Figure 160: Original IP packet**

**Figure 161: AH in transport mode**

## Encapsulating security payload

The encapsulating security payload (ESP) encrypts traffic with use of encryption algorithms, such as 3DES, AES-CBC, and AES-CTR. The security association specifies the algorithm and key used in ESP.

The encapsulating security payload can protect origin authenticity, integrity, and confidentiality of packets. ESP supports encryption-only and authentication-only configurations. The IPsec feature inserts the ESP header after the IP header and before the next layer protocol header in transport mode. Transport mode with ESP encrypts or authenticates only the payload of the IP packet.

Tunnel mode encrypts or authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

The following figures display the original IP packet and an IP packet with ESP.

**Figure 162: Original IP packet**

**Figure 163: ESP in transport mode**

## IPsec modes

The IPsec feature security protocols use two different modes to protect the entire IP payload or the upper layer protocols:

- Transport mode
- Tunnel mode

Transport mode IPsec protects the upper layer protocols. In transport mode, IPsec adds an IPsec header between the IP header and upper layer protocol header.

Tunnel mode IPsec protects the whole IP packet. In tunnel mode, IPsec inserts the IPsec header between another IP datagram IP header and inner IP header.

## Security association

A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet. IPsec identifies SAs by:

- Security Parameter Index (SPI)
- Protocol value (either AH or ESP)
- Destination address to which the SA applies

*Creation of a security association*

Typically SAs exist in pairs; one in each direction, either inbound or outbound.

You can create SAs manually or dynamically. After you create an SA manually, the SA has no defined lifetime and the SA exists until you manually delete the SA.

After the device creates the SA dynamically, the SA can have a lifetime value that IPsec peers negotiate through use of a key management protocol. If the device uses the key excessively unauthorized access can occur. You must define the IPsec lifetime and other configurable parameters manually.

Security associations reside in the Security Association Database (SADB), which maintains a list of active SAs. The IPsec feature uses outbound SAs to secure the outgoing traffic and inbound SAs to process the incoming traffic. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature restricts SAs to the source and destination address of the connected router.

## Security policy

Use IPsec to create IPsec security policies that define the levels of security for different types of traffic. You can use IPsec security policies to create rules to filter traffic with IPsec. IPsec policies determine what IP traffic to secure. An IPsec security policy typically consists of:

- An IP filter
- Security algorithms for authentication and key exchange
- An action

### *Creation of a security policy*

You can configure IPsec on IPv4/IPv6 interfaces. First, create and configure an IPsec policy, and then add and enable the policy on an interface.

After you enable IPsec, the device encrypts all control traffic on the interface based on the policy. You have to specify individual policies to target a particular interface address or multiple addresses. By default, this implementation does not work on a subnet.

The Security Policy Database (SPD) maintains the IPsec security policies. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature only adds policies if the source address in the policy specified matches an interface IP address.

The IPsec feature restricts the policy match source address to the interface address of the router and destination IPv6 address.

## IPsec NAT-T

IP security (IPsec) Network Address Translation Traversal (NAT-T) allows IPsec tunnel traffic through Network Address Translation (NAT) or Port Address Translation (PAT) points in the network. To enable IPsec NAT-T connectivity, you must deploy and configure an IPsec NAT-T supported IPsec logical interface on each side of the IPsec tunnel.

The following terms are specific to the IPsec NAT-T feature:

- **IPsec Initiator** - The initiator mode of an IPsec tunnel initiates IKE negotiation and rekeying. A supported IPsec logical interface configured as an IPsec Initiator initiates IKE message exchange and IPsec security association (SA) establishment, rekeys IKE, and initiates IPsec SAs. Configure the IPsec Initiator device on the branch side of the tunnel.

**Note**

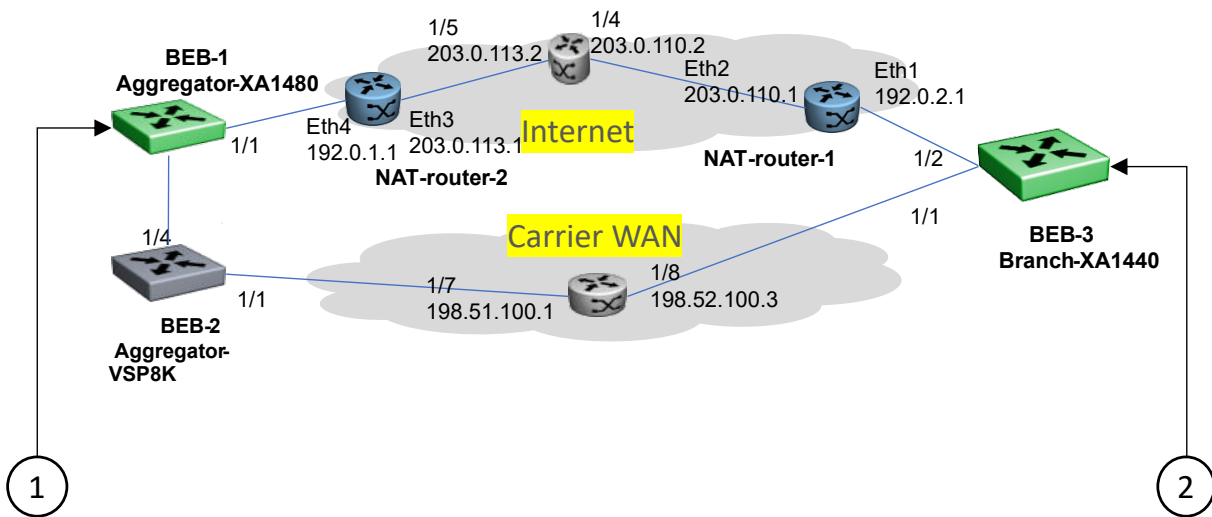

IPsec Initiator is the default mode of the logical interface IPsec tunnel.

- **IPsec Responder** - The responder-only mode of an IPsec tunnel responds to IKE negotiation and rekeying and only responds to IPsec negotiations from an IPsec Initiator. A VOSS device with a logical interface configured as an IPsec Responder does not initiate IKE message exchange and IPsec SA establishment, and does not rekey IKE and IPsec SAs. Configure the IPsec Responder device on the aggregator side of the tunnel.
- **IPsec Remote NAT IP** – The remote-nat-ip is the public IP address of the NAT router connected to the IPsec Responder device. Only configure an IPsec Initiator with the IPsec Remote NAT IP address when NAT routers are present on both sides of the IPsec tunnel. When you configure the IPsec remote NAT IP address, IKE protocol uses UDP port 4500.

**Note**

Only configure the logical interface of the IPsec Initiator device with the Remote NAT IP address of the responder.

The following diagram illustrates an example of an IPsec NAT-T configuration with both sides of the connection behind NAT:

**Figure 164: IPsec NAT-T with NAT router on both sides**

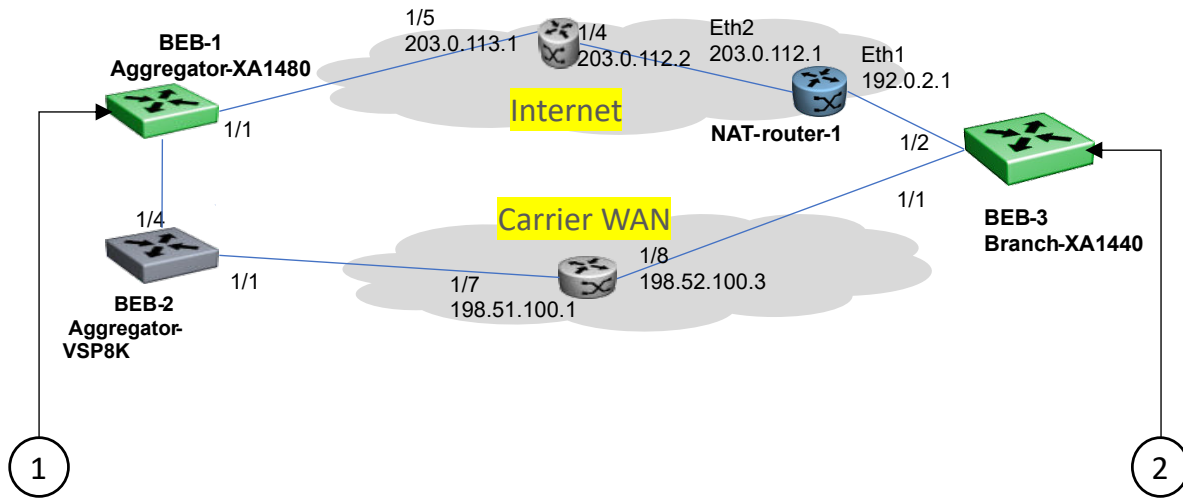

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.3
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec remote-nat-ip 203.0.113.1
ipsec
```

The following diagram illustrates an example of an IPsec NAT-T configuration with only 1 side of the connection behind NAT:

**Figure 165: IPsec NAT-T with NAT router on one side**

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.2
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec
```

#### *IPsec NAT-T Considerations*

The following considerations apply to IPsec NAT-T:

- You must configure one side of the IPsec NAT-T tunnel as an IPsec responder. If IPsec is configured on the IPsec Initiator device and subsequently configured on the IPsec Responder device, IPsec must be restarted on the Initiator device. If IPsec is not restarted, it can take approximately 3 minutes for the adjacency to open.
- You must configure the aggregator device as the IPsec Responder device, and configure the branch device as the IPsec Initiator device.
- Among all the IPsec responders, the system uses the lowest configured maximum transmission unit (MTU) value of any responder IPsec tunnel as the MTU value for all IPsec responder-only tunnels. The system uses the lowest configured IPsec tunnel MTU value regardless of manually configured MTU tunnel values, and higher MTU values might be visible in the IPsec information for the logical interface. For non-

responder IPsec tunnels or VXLAN tunnels, the configured and visible MTU value for the tunnel is used for fragmentation and reassembly.

- If both the IPsec Initiator device and the IPsec Responder device are behind NAT, you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.
- You must add route table entries on the IPsec Responder device with the public IP address and private IP address of the remote NAT for the IPsec Initiator device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.
- You must add a route table entry on the IPsec Initiator device with the public IPsec Remote NAT IP address for the IPsec Responder device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.

## Digital Certificates for IPsec Authentication

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. The default method for IPsec authentication is a pre-shared key, which is easy to configure, but does not scale well and is less secure than a certificate. You can use a digital certificate, instead of a pre-shared key, to authenticate IPsec for Fabric Extend.

Consider a hub and spoke topology with two branch locations. The network carries both private traffic and encrypted IPsec traffic. To use Public Key Infrastructure (PKI) with IPsec Fabric Extend technology, all devices must acquire the digital-signed certificates. The CA server can be accessed from the devices, a public network, or an internal network. Each device must configure a profile for the CA server. The switch uses Simple Certificate Enrollment Protocol (SCEP) to obtain the trusted, signed certificates.

### *XA1400 Series*

XA1400 Series supports digital certificate configuration through VOSS. VOSS supports both offline and online certificate management; they are mutually exclusive. Use offline certificate management if the switches cannot communicate with the certificate authority (CA).

Digital certificate support for IPsec authentication provides an alternate method to validate the CA certificate chain. You can configure the IPsec authentication type as RSA signature instead of pre-shared key.

VOSS supports only one CA server and one subject certificate.

To use IPsec with Digital Certificates for XA1400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1967.
- Configure certificate information in VOSS.

For information about certificate configuration, see [Security](#) on page 3267.

### *VSP 4900 Series and VSP 7400 Series*

VSP 4900 Series and VSP 7400 Series support digital certificate configuration through the Fabric IPsec Gateway virtual machine. Fabric IPsec Gateway supports both offline and online certificate management simultaneously. Use offline certificate management if the switches cannot communicate with the CA.

Fabric IPsec Gateway supports multiple CA trustpoints and multiple identity subject certificates. You can use different certificates for different IPsec tunnels. Fabric IPsec Gateway acts like a hub to isolate IPsec domains.

To use IPsec with Digital Certificates for VSP 4900 Series and VSP 7400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1967.
- Configure certificate information in Fabric IPsec Gateway.

For information about certificate configuration, see [Extreme Integrated Application Hosting](#) on page 926 for Fabric IPsec Gateway virtual machine configuration.

## IPsec Limitations

- The IPsec feature implementation is available only in software. Hardware implementation is not available. Only control packets to and from the CPU are subject to IPsec. IPsec implements IPsec policies in the software on the control path.
- The device does not support address ranges facility for an IPsec policy.
- No fast-path support exists for IPsec.

## IPsec configuration using CLI

---

The following section provides procedures to configure Internet Protocol Security (IPsec).

### Create an IPsec Policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

#### Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPsec policy:

```
ipsec policy WORD<1-32>
```

## Example

Create an IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy
```

### Variable Definitions

The following table defines parameters for the `ipsec policy` command.

| Variable                      | Value                            |
|-------------------------------|----------------------------------|
| <code>WORD&lt;1-32&gt;</code> | Specifies the IPsec policy name. |

## Enable an IPsec Policy

Use the following procedure to enable an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

### Before You Begin

- Create an IPsec policy.

### About This Task

The IPsec feature adds policies only if the admin status of the policy and the IPsec status on the interface are enabled.

If you disable the IPsec policy on an IPv4 or IPv6 interface, IPsec removes the policy-related information from the security policy database (SPD) and the security association database (SADB), but the information remains on the system. After you re-enable, the information reapplies on the interface.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable an IPsec policy:  

```
ipsec policy WORD<1-32> admin enable
```

### Example

Enable an IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy admin enable
```

### Variable Definitions

The following table defines parameters for the `ipsec policy` command.

| Variable                      | Value                            |
|-------------------------------|----------------------------------|
| <code>admin enable</code>     | Enables the policy.              |
| <code>WORD&lt;1-32&gt;</code> | Specifies the IPsec policy name. |

## Create an IPsec Security Association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create an IPsec security association:  

```
ipsec security-association WORD<1-32>
```

## Example

Create an IPsec security association named `newsa`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa
```

### Variable Definitions

The following table defines parameters for the **ipsec security-association** command.

| Variable                      | Value                                          |
|-------------------------------|------------------------------------------------|
| <code>WORD&lt;1-32&gt;</code> | Specifies the security association identifier. |

## Configure an IPsec Security Association

Use the following procedure to configure an IPsec security association (SA). An SA is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### Before You Begin

- Create an IPsec security association to configure.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from a policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the IPsec security association key-mode:
 

```
ipsec security-association WORD<1-32> key-mode <automatic|manual>
```

This device only supports manual mode.

3. Configure the IPsec security association mode:
 

```
ipsec security-association WORD<1-32> mode <transport|tunnel>
```

This device only supports transport mode.

4. Configure the IPsec security association encapsulation protocol:
 

```
ipsec security-association WORD<1-32> encap-proto <AH|ESP>
```

5. Configure the IPsec security association security parameters index:

```
ipsec security-association WORD<1-32> spi <1-4294967295>
```

For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.

6. Configure the IPsec security association encryption algorithm:

```
ipsec security-association WORD<1-32> Encrpt-algo <3DES|AES-CBC|AES-CTR|NULL> [EncrptKey WORD<1-256>] [KeyLength <1-256>]
```

The encryption algorithm parameters are only accessible if you configure the encapsulation protocol to ESP.

7. Configure the IPsec security association authentication algorithm:

```
ipsec security-association WORD<1-32> auth-algo <AES-XCBC-MAC|MD5|SHA1|SHA2> [auth-key WORD<1-256>] [KeyLength <1-256>]
```

8. Configure the IPsec security association lifetime value:

```
ipsec security-association WORD<1-32> lifetime <Bytes<1-4294967295>|seconds<1-4294967295>>
```

### Example

Configure an IPsec security association named `new_sa` to have a key-mode of `ASCII`, an SA mode of `transport`, and an encapsulation protocol of `ESP`. Configure the encryption algorithm to `3DES`, with an encryption key of `11111111111111111111111111111111`, and a keylength of `24`. Configure the authorization algorithm to `SHA1`, the authorization key to `11111111111111111111111111111111`, and key length to `20`. Configure the SPI to `1` and the lifetime in seconds to `1000`.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa mode transport
Switch:1(config)#ipsec security-association newsa encap-proto ESP
Switch:1(config)#ipsec security-association newsa Encrpt-algo 3DES Encrpt-key
11111111111111111111111111111111 KeyLength 48
Switch:1(config)#ipsec security-association newsa auth-algo SHA1 auth-key
11111111111111111111 KeyLength 20
Switch:1(config)#ipsec security-association newsa key-mode manual
Switch:1(config)#ipsec security-association newsa spi 1
Switch:1(config)#ipsec security-association newsa lifetime seconds 1000
```

### Variable Definitions

The following table defines parameters for the `ipsec security-association` command.

| Variable                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-32&gt;</code>                                                                                         | Specifies the security association.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>auth-algo &lt;AES-XCBC-MAC  MD5  SHA1  SHA2&gt; [auth-key WORD&lt;1-256&gt;] [KeyLength &lt;1-256&gt;]</code>   | <p>Specifies the authorization algorithm, which includes one of the following values:</p> <ul style="list-style-type: none"> <li>• AES-XCBC-MAC</li> <li>• MD5</li> <li>• SHA1</li> <li>• SHA2</li> </ul> <p>The default authentication algorithm name is MD5. The parameter <code>auth-key</code> specifies the authentication key. The <code>KeyLength</code> parameter specifies a string value of 1 to 256 characters in length. The default <code>KeyLength</code> is 128. The <code>KeyLength</code> values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.</p>                                                                                                                                                                     |
| <code>encap-proto &lt;AH  ESP&gt;</code>                                                                              | <p>Specifies the encapsulation protocol:</p> <ul style="list-style-type: none"> <li>• AH—Specifies authentication header.</li> <li>• ESP—Specifies encapsulation security payload.</li> </ul> <p>If you configure the encapsulation protocol as AH, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. The default value is ESP.</p>                                                                                                                                                                                                                                                                          |
| <code>Encrpt-algo &lt;3DES  AES-CBC  AES-CTR  NULL&gt; [EncrptKey WORD&lt;1-256&gt;] [KeyLength &lt;1-256&gt;]</code> | <p>Specifies the encryption algorithm value as one of the following:</p> <ul style="list-style-type: none"> <li>• 3DES-CBC</li> <li>• AES-CBC</li> <li>• AES-CTR</li> <li>• NULL—Only use the NULL parameter to debug. Do not use this parameter in other circumstances.</li> </ul> <p>The default encryption algorithm is AES-CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. The <code>EncrptKey</code> specifies the encryption key. The <code>KeyLength</code> specifies the key length value in a string from 1 to 256 characters. The default <code>KeyLength</code> is 128. The <code>KeyLength</code> values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.</p> |
| <code>key-mode &lt;automatic   manual&gt;</code>                                                                      | <p>Specifies the key-mode as one of the following:</p> <ul style="list-style-type: none"> <li>• automatic</li> <li>• manual</li> </ul> <p>The default is manual.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>lifetime &lt;Bytes&lt;1-4294967295&gt;   seconds&lt;1-4294967295&gt;</code>                                     | <p>Specifies the lifetime value in seconds or bytes. The default lifetime value in seconds is 28800. The default lifetime value in bytes is 4294966272.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Variable                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode &lt;transport   tunnel&gt;</code> | <p>Specifies the mode value as one of the following:</p> <ul style="list-style-type: none"> <li>• <code>transport</code>—Transport mode encapsulates the IP payload and provides a secure connection between two end points.</li> <li>• <code>tunnel</code>—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel.</li> </ul> <p>The default is transport mode.</p>                    |
| <code>spi&lt;1-4294967295&gt;</code>         | <p>Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet. For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy. The default value is 0.</p> |

## Configure an IPsec Policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

### Before You Begin

- Create an IPsec policy.

### About This Task

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the remote address:
 

```
ipsec policy WORD<1-32> raddr WORD<1-32>
```

## 3. (Optional) Configure the local address:

```
ipsec policy WORD<1-32> laddr WORD<1-32>
```

The `laddr` parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.

## 4. Configure the protocol:

```
ipsec policy WORD<1-32>[protocol <icmp|icmpv6|ospfv3|tcp|udp>] [sport <1-65535|any>] [dport <1-65535|any>]
```

## 5. Configure the policy action:

```
ipsec policy WORD<1-32> [action <drop|permit>]
```

**Example**

Configure the remote address to `2001:db8:0:0:0:0:0:1` and local address to `2001:db8:0:0:0:0:0:15`. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to permit.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv6policy raddr 2001:db8:0:0:0:0:0:1
Switch:1(config)#ipsec policy Ipv6policy laddr 2001:db8:0:0:0:0:0:15
Switch:1(config)#ipsec policy Ipv6policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv6policy action permit
```

Configure the remote address to `192.0.1.1` and local address to `192.0.1.2`. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to drop.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv4policy raddr 192.0.1.1
Switch:1(config)#ipsec policy Ipv4policy laddr 192.0.1.2
Switch:1(config)#ipsec policy Ipv4policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv4policy action drop
```

*Variable Definitions*

The following table defines parameters for the `ipsec policy` command.

| Variable                                | Value                                                                                                                                                                                        |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>action &lt;drop permit&gt;</code> | Specifies the action the policy takes. The default is permit.                                                                                                                                |
| <code>laddr WORD&lt;1-32&gt;</code>     | Specifies the local address. The <code>laddr</code> parameter is an optional parameter that you can configure to have multiple local addresses for each remote address. The default is 0::0. |

| Variable                                                                                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>protocol &lt;icmp <br/>icmpv6 ospfv3 tcp <br/>udp&gt;]</code><br><code>[sport&lt;1-65535&gt; <br/>any&gt;] [dport&lt;1-<br/>65535&gt; any&gt;]</code> | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> <li>• ICMP</li> <li>• ICMPv6</li> <li>• OSPFv3</li> <li>• TCP</li> <li>• UDP</li> </ul> <p>sport — Specifies the source port for TCP and UDP. You can specify any to configure any port as the source port.</p> <p>dport — Specifies the destination port for TCP and UDP. You can specify any to configure any port as the destination port. The default protocol is TCP any. IPv4 only supports ICMP, UDP, and TCP.</p> |
| <code>raddr WORD&lt;1-32&gt;</code>                                                                                                                         | Specifies the remote address. The default is 0::0.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>WORD&lt;1-32&gt;</code>                                                                                                                               | Specifies the policy name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Link the IPsec Security Association to an IPsec Policy

Use the following procedure to link the security association to an IPsec policy.

### Before You Begin

- The IPsec security association and IPsec policy must exist.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Link the IPsec security association to the IPsec policy:

```
ipsec policy WORD<1-32> security-association WORD<1-32>
```

### Example

Link the IPsec security association named `new_sa` to the IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy security-association newsa
```

### Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable                                | Value                                  |
|-----------------------------------------|----------------------------------------|
| <i>WORD</i> <1-32>                      | Specifies the policy ID.               |
| <i>security-association WORD</i> <1-32> | Specifies the security association ID. |

## Enable IPsec on an Interface

Use the following procedure to enable IPsec on an interface. You can configure IPsec on a port, VLAN, or loopback interface.

### Note

Management interface does not support IPsec configuration.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}`
- `interface loopback <1-256>`
- `interface vlan <1-4059>`

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPsec on an IPv6 interface:

```
ipv6 ipsec enable
```

3. Enable IPsec on an IPv4 interface:

```
ip ipsec enable
```

### Example

Enable IPsec for IPv6 on VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec enable
```

### Variable Definition

The following table defines parameters for the **ip ipsec** and **ipv6 ipsec** commands.

| Variable      | Value                           |
|---------------|---------------------------------|
| <i>enable</i> | Enables IPsec on the interface. |

## Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

### Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

### About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

### Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][, ...]}`
- `interface loopback <1-256>`
- `interface vlan <1-4059>`

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Link the IPsec policy to an IPv4 interface:

```
ip ipsec policy WORD<1-32> dir <both|in|out>
```

- Link the IPsec policy to an IPv6 interface:

```
ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

### Example

Link the IPsec policy newpolicy to the IPv6 interface VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec policy newpolicy dir both
```

*Variable Definitions*

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

| Variable                             | Value                                                                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-32&gt;</code>        | Specifies the policy ID.                                                                                                                                                                                                                                           |
| <code>dir &lt;both in out&gt;</code> | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>• both—Specifies both ingress and egress traffic.</li> <li>• in—Specifies ingress traffic.</li> <li>• out—Specifies egress traffic.</li> </ul> The default is both. |

## Configure the IPsec Initiator with the IPsec Responder Remote NAT IP Address

### About This Task

If both the Responder device and the Initiator device are behind Network Address Translation (NAT), you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.

#### Note

Only perform this procedure on the IPsec Initiator device.

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:
 

```
enable
configure terminal
logical-intf isis <1-255>
```
2. Configure the public IP address of the NAT router connected to the IPsec Responder device:
 

```
ipsec remote-nat-ip {A.B.C.D}
```

*Variable Definitions*

The following table defines parameters for the **logical-intf isis** command.

| Variable                        | Value                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------|
| <code>isis &lt;1-255&gt;</code> | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID. |
| <code>dest-ip {A.B.C.D}</code>  | Specifies the destination IP address for the logical interface.                        |

| Variable                                                                       | Value                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name WORD<1-64>                                                                | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.                                                                                                                |
| mtu <mtu_value><br><b>Note:</b><br>Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch.<br>The default value is 1950. |

The following table defines parameters for the `ipsec remote-nat-ip` command.

| Variable  | Value                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies the public IP address of the NAT router connected to the Responder device in an IPsec Network Address Translation Traversal (NAT-T) connection.<br><br><b>Note:</b><br>When you configure the IPsec remote NAT IP address, IKE protocol uses UDP port 4500. |

## Configure an IPsec NAT-T Responder

### About This Task

One side of an IPsec Network Address Translation Traversal (NAT-T) connection must be a responder device and the other side must be the Initiator device. By default, both sides of an IPsec NAT-T connection are Initiators. Use the following procedure to configure one side of an IPsec NAT-T connection as a Responder device.

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:
 

```
enable
configure terminal
logical-intf isis <1-255>
```
2. Configure an IPsec Responder:
 

```
ipsec responder-only
```

### Variable Definitions

The following table defines parameters for the **logical-intf isis** command.

| Variable                                                                       | Value                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| isis <1-255>                                                                   | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID.                                                                                                                                |
| dest-ip {A.B.C.D}                                                              | Specifies the destination IP address for the logical interface.                                                                                                                                                       |
| name WORD<1-64>                                                                | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.                                                                                                             |
| mtu <mtu_value><br><b>Note:</b><br>Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch. The default value is 1950. |

## Configure Public Key Infrastructure for IPsec Tunnels

### Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

### Before You Begin

- Configure the Fabric Extend tunnels between the branch and hub switches.
- Configure digital certificates on the switch using either VOSS or the Fabric IPsec Gateway virtual machine, as appropriate.

### About This Task

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. You can use a digital certificate to authenticate IPsec for Fabric Extend.

The default IPsec authentication method for Fabric Extend tunnels is a pre-shared key. If you configure the authentication method to RSA signature, the tunnels use the installed digital certificate.

### Procedure

1. On XA1400 Series, configure IPsec authentication in the VOSS CLI:
  - a. Enter Layer 3 Logical IS-IS Interface Configuration mode:
 

```
enable

configure terminal

logical-intf isis <1-255>
```

- b. Configure the authentication type as RSA signature:
 

```
ipsec auth-method rsa-sig [cert-subject-name WORD<1-45>]
```
2. On VSP 4900 Series and VSP 7400 Series, configure IPsec authentication in the Fabric IPsec Gateway virtual machine:
  - a. Enter Fabric IPsec Gateway Configuration mode:
 

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type CTRL+Y to exit the console.
  - b. Configure the authentication type as RSA signature:
 

```
set ipsec <1-255> auth-method rsasig
```

### Variable Definitions

The following table defines parameters for the **set ipsec** command.

| Variable                    | Value                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-255>                     | Specifies the tunnel ID.                                                                                                                                                   |
| <subject-label>             | Specifies the subject identity.                                                                                                                                            |
| cert-subject-nameWORD<1-45> | Specifies the digital certificate subject name to be used as the identity certificate. If a subject name is not specified, the default certificate subject name is Global. |

## Display IPsec Information on an Interface

Use the following procedure to display IPsec information on an interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IPsec status on an Ethernet interface:
 

```
show ipsec interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
3. Display the IPsec status on a VLAN interface:
 

```
show ipsec interface vlan <1-4059>
```
4. Display the IPsec status on a loopback interface:
 

```
show ipsec interface loopback <1-256>
```

### Example

Display the IPsec status on a VLAN interface:

```
Switch:1>show ipsec interface vlan 22
=====
VLAN Interface Policy Table
```

| Vlan | Interface | Policy Name | IPsec State | Direction |
|------|-----------|-------------|-------------|-----------|
| 22   |           | AAA         | Enable      | both      |
| 22   |           | tcp         | Enable      | both      |
| 22   |           | icmp        | Enable      | both      |

### Variable Definitions

The following table defines parameters for the **show ipsec interface** command.

| Variable                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i><br>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>loopback</i> <1-256>                                                         | Specifies the loopback interface.                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>vlan</i> <1-4059>                                                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Displaying configured IPsec policies

Use the following procedure to display IPsec policies.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all of the IPsec policies on the switch:  
`show ipsec policy all`
3. Display a specific IPsec policy based on the policy name on the interface:  
`show ipsec policy interface WORD<1-32>`
4. Display the IPsec policy based on the policy name:  
`show ipsec policy name WORD<1-32>`

### Example

Display IPsec policy information:

```
Switch:1>show ipsec policy all
=====
IPSEC Policy Table
=====
PolicyName      : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
```

```

src-port: 0
dest-port: 0
Action: Permit
Admin: Enable

Switch:1>show ipsec policy interface ospf1

=====
                        IPsec Policy Interface Table
=====
POLICY NAME      InterfaceIndex      Policy State      Direction
-----
ospf1            2/3                 Enable            both

Switch:1>show ipsec policy name ospf1

=====
                        IPSEC Policy Table
=====
PolicyName      : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable
    
```

*Variable Definitions*

The following table defines parameters for the **show ipsec policy** command.

| Variable                          | Value                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------|
| <i>all</i>                        | Displays all of the IPsec policies on the switch.                           |
| <i>interface WORD&lt;1-32&gt;</i> | Displays a specific IPsec policy based on the policy name on the interface. |
| <i>name WORD&lt;1-32&gt;</i>      | Displays the IPsec policy based on the name of the policy.                  |

Displaying IPsec security association information

Use the following procedure to display IPsec security association information.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Display all IPsec security associations:  
`show ipsec sa all`
3. Display a specific IPsec security association:  
`show ipsec sa name WORD<1-32>`
4. Display all security associations linked to a specific policy:  
`show ipsec sa-policy`

## Example

Display information on IPsec security association policies:

```
Switch:1>enable
Switch:1#show ipsec sa all
=====
                        IPSEC Security Association Table
=====
sa-name: ospf1
key-Mode: manual
Encap protocol: ESP
SPI Value: 9
Encrypt Algorithm: 3dec-cbc
Encrypt-key: 52fb29f723b0800870dc83e3
Encrypt-key-Len: 24
Auth Algorithm: hmac-md5
Auth-key: 123456789abcdef0
Auth-key-Len: 16
Mode: transport
Lifetime-Sec: 1000
Lifetime-Byte: 20000

Switch:1#show ipsec sa name ospf1
=====
                        IPSEC Security Association Table
=====
sa-name: ospf1
key-Mode: manual
Encap protocol: ESP

-----
```

### Variable Definitions

The following table defines parameters for the **show ipsec sa** command.

| Variable                     | Value                                                   |
|------------------------------|---------------------------------------------------------|
| <i>all</i>                   | Displays all security associations.                     |
| <i>name WORD&lt;1-32&gt;</i> | Displays a specific security association based on name. |

Use the data in the following table to use the **show ipsec** command.

| Variable         | Value                                                           |
|------------------|-----------------------------------------------------------------|
| <i>sa-policy</i> | Displays all security associations linked to a specific policy. |

## Display Logical Interface IPsec and Authentication Key

Displays the IS-IS logical interface IPsec ID and authentication keys.

### About This Task

Use the following procedure to display the IS-IS logical interface IPsec ID and authentication keys.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interface ID and related IPsec authentication key:

```
show isis logical-interface ipsec
```

### Example

```
Switch:1>show isis logical-interface ipsec
=====
                ISIS Logical Interface IPsec
=====
ID   Status   Auth-Method   Auth-Key   ESP           Responder-Only   Remote NAT IP   Auth-Key-Len   Compression   Frag-before-encrypt
-----
1   Enable   RSA-SIG      *****   aes128gcm16-sha256   False           -               128            False         True
-----
1 out of 1 Total Num of Logical ISIS interfaces
-----

                IPsec Tunnel General Info
=====
IPsec tunnel global source-ip-address : 203.0.113.1
=====

                ISIS IPsec Tunnels
=====

-----
```

## View IPsec Statistics

Use the following procedure to clear Internet Protocol Security (IPsec) system statistics counters and view IPsec statistics on an interface. The device only clears system statistics counters on system reboot.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPsec statistics for the system:

```
show ipsec statistics system
```

## 3. View IPsec statistics for an Ethernet interface:

```
show ipsec statistics gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## 4. View IPsec statistics for a VLAN interface:

```
show ipsec statistics vlan <1-4059>
```

## 5. View statistics for IPsec on the loopback interface:

```
show ipsec statistics loopback <1-256>
```

## 6. Clear IPsec system statistics counters:

```
clear ipsec stats all
```

**Example**

View IPsec statistics. Output is partial due to length.

```
Switch:1>show ipsec statistics system

=====
IPSEC Global Statistics

### Variable Definitions

Use the data in the following table to use the **show ipsec statistics** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>loopback &lt;1-256&gt;</i>                                | Identifies the loopback interface.                                                                                                                                                                                                                                                                                                                            |
| <i>system</i>                                                | Shows statistics for the entire system.                                                                                                                                                                                                                                                                                                                       |
| <i>vlan &lt;1-4059&gt;</i>                                   | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |

## IPsec configuration using EDM

The following section provides procedures to configure Internet Protocol security (IPsec).

## Create an IPsec Policy

Use the following procedure to configure an IPsec policy for an IPv4 or an IPv6 interface. An IPsec policy defines the level of security for different types of traffic.

### Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

### About This Task

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IPSec**.
3. Select the **Policy** tab.
4. Select **Insert**.
5. In the **Name** field, type a policy name.
6. Complete the remaining optional configuration to customize the policy.
7. Select **Insert**.

### Policy field descriptions

Use the data in the following table to use the **Policy** tab.

| Name              | Description                                                                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>       | Specifies the IPsec policy name.                                                                                                                                                                                                                   |
| <b>DstAddress</b> | Specifies the remote address. This field accepts IPv4 and IPv6 address, depending on the selected source address type.                                                                                                                             |
| <b>SrcAddress</b> | Specifies the local address. The local address is optional that you can configure to have multiple local addresses for each remote (destination) address. This field accepts IPv4 and IPv6 address, depending on the selected source address type. |
| <b>SrcPort</b>    | Specifies the source port for TCP and UDP. Leave this field empty to configure any port as the source port. The default is value is 1.                                                                                                             |

| Name              | Description                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstPort</b>    | Specifies the destination port for TCP and UDP. Leave this field empty to configure any port as the destination port. The default value is 1.                                                                                                    |
| <b>AdminFlag</b>  | Enables or disables the policy. The default is disabled.                                                                                                                                                                                         |
| <b>L4Protocol</b> | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> <li>• tcp</li> <li>• udp</li> <li>• icmp</li> <li>• icmpv6</li> <li>• ospfv3</li> </ul> IPv4 interfaces only support TCP, UDP, and ICMP. The default is TCP. |
| <b>Action</b>     | Specifies the action the policy takes. The default is to permit the packet.                                                                                                                                                                      |

## Create an IPsec Security Association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IPSec**.
3. Select the **Security Association** tab.
4. Select **Insert**.
5. In **Name**, type a name to identify the SA.

6. In **SPI**, type the security parameters index.

**Note**

For IPsec to function, each peer must have the same SPI value configured for a particular policy.

7. Complete the remaining optional configuration.

8. Select **Insert**.

*Security Association field descriptions*

Use the data in the following table to use the **Security Association** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>             | Specifies the name of the security association.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Spi</b>              | Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet. For IPsec to function, each peer must have the same SPI value configured for a particular policy. The default value is 0.                                                     |
| <b>HashAlgorithm</b>    | Specifies the authorization algorithm, which includes one of the following values: <ul style="list-style-type: none"> <li>• AESXCBC</li> <li>• MD5</li> <li>• SHA1</li> <li>• SHA2</li> </ul> The default authentication algorithm name is MD5.                                                                                                                                                                                            |
| <b>EncryptAlgorithm</b> | Specifies the encryption algorithm value as one of the following: <ul style="list-style-type: none"> <li>• DES3CBC</li> <li>• AES128CBC</li> <li>• AESCTR</li> <li>• NULL—Only use the NULL parameter to debug. Do not use this parameter in any other circumstance.</li> </ul> The default encryption algorithm is AES128CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthMethod</b>       | <p>Specifies the encapsulation protocol:</p> <ul style="list-style-type: none"> <li>• ah—Specifies authentication header.</li> <li>• es—Specifies encapsulation security payload.</li> </ul> <p>If you configure the encapsulation protocol as ah, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to es. The default value is es.</p> |
| <b>Mode</b>             | <p>Specifies the mode value as one of the following:</p> <ul style="list-style-type: none"> <li>• transport—Transport mode encapsulates the IP payload and provides a secure connection between two end points. This device only supports transport mode.</li> <li>• tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. This device does not support tunnel mode.</li> </ul> <p>The default is transport mode.</p>                                 |
| <b>KeyMode</b>          | <p>Specifies the key-mode as one of the following:</p> <ul style="list-style-type: none"> <li>• manual</li> <li>• auto</li> </ul> <p>The default is manual.</p>                                                                                                                                                                                                                                                                                                                    |
| <b>EncryptKeyName</b>   | Specifies the encryption key.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EncryptKeyLength</b> | <p>Specifies the numbers of bits used in the encryption key. The key length values are as follows:</p> <ul style="list-style-type: none"> <li>• DES3CBC is 48</li> <li>• AES128CBC is 32, 48, 64</li> <li>• AESCTR is 32</li> </ul>                                                                                                                                                                                                                                                |
| <b>HashKeyName</b>      | Specifies the authentication key.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>HashKeyLength</b>    | <p>Specifies the numbers of bits used in the hash key. The key length values are as follows:</p> <ul style="list-style-type: none"> <li>• AESXCBC is 32</li> <li>• MD5 is 32</li> <li>• SHA1 is 40</li> </ul>                                                                                                                                                                                                                                                                      |

| Name                   | Description                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LifetimeSeconds</b> | Specifies the lifetime value in seconds. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in seconds is 28800.      |
| <b>LifetimeKbytes</b>  | Specifies the lifetime value in kilobytes. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in bytes is 4294967295. |

## Link the IPsec Security Association to an IPsec Policy

Use the following procedure to link the security association to an IPsec policy.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Before You Begin

- The IPsec security association and IPsec policy must exist.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Policy SA Link** tab.
4. Click **Insert**.
5. In the **PolicyName** field, type the IPsec policy name.
6. In the **SAName** field, type the security association name.
7. Click **Insert**.

### *Policy SA Link field descriptions*

Use the data in the following table to use the **Policy SA Link** tab.

| Name              | Description                                     |
|-------------------|-------------------------------------------------|
| <b>PolicyName</b> | Specifies the name of the IPsec policy.         |
| <b>SAName</b>     | Specifies the name of the security association. |

## Enable IPsec on an IPv6 Interface

Use the following procedure to enable IPsec on an IPv6 interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IPSec**.
3. Select the **IPv6 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Select **Apply**.

## Enable IPsec on an IPv4 Interface

Use the following procedure to enable IPsec on an IPv4 interface.

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **IPv4 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Click **Apply**.

### *IPv4 Interfaces tab field descriptions*

Use the data in the following table to use the **IPv4 Interfaces** tab.

| Name               | Description                                                 |
|--------------------|-------------------------------------------------------------|
| <b>Interface</b>   | Specifies the interface.                                    |
| <b>IpsecEnable</b> | Specifies if IPsec is enabled on that particular interface. |

## Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

### Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

### About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Select **IPSec**.
- Select the **Interface Policy** tab.
- Select **Insert**.
- In the **Name** field, type the name of the IPsec policy.
- In the **IfIndex** field, select either **Port** or **Vlan**, and then select an interface.
- Select **Okay**.
- Complete the remaining optional configuration.
- Select **Insert**.

### Interface Policy Field Descriptions

Use the data in the following table to use the **Interface Policy** tab.

| Name               | Description                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>        | Specifies the IPsec policy name.                                                                                                                                                                                                                                                           |
| <b>IfIndex</b>     | Links a policy to an interface.                                                                                                                                                                                                                                                            |
| <b>IfEnabled</b>   | Shows if the IPsec is enabled on the interface and if the administrative state of the policy is enabled.                                                                                                                                                                                   |
| <b>IfDirection</b> | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>inbound—Specifies ingress traffic.</li> <li>outbound—Specifies egress traffic.</li> <li>bothDirections—Specifies both ingress and egress traffic.</li> </ul> The default is bothDirections. |

## Configure IPsec NAT-T

### About This Task

By default, both sides of an IPsec connection are Initiator devices. IPsec Network Address Translation Traversal (NAT-T) connections require that one side of the connection is a Responder device and the other side of the connection is an Initiator device.

If the Responder device and the Initiator device are both behind NAT, the IPsec NAT-T Initiator device requires the public IP address of the Responder device.

### Procedure

Perform the following steps to configure one side of an IPsec NAT-T connection as a Responder device:

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **IS-IS**.
3. Select **Logical Interfaces**.
4. Select **Insert**.
5. Select **IpssecNatConfigResponderOnly**.

If required, perform the following steps on the IPsec NAT-T Initiator device to configure the public IP address of the Responder device:

6. In the navigation pane, expand **Configuration > Fabric**.
7. Select **IS-IS**.
8. Select **Logical Interfaces**.
9. Select **Insert**.
10. For **IpssecNatConfigRemoteNatIPAddr**, enter the public IP address of the Responder device.

### **Logical Interfaces** Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

| Name           | Description                                                                                                                                                            |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>      | Specifies the index number that uniquely identifies this logical interface.<br>This field displays on the <b>Insert Logical Interfaces</b> dialog only.                |
| <b>IfIndex</b> | Specifies the index number that uniquely identifies this logical interface. This field is read-only.<br>This field displays on the <b>Logical Interfaces</b> tab only. |
| <b>Name</b>    | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.                                                              |

| Name                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Type</b></p> <p><b>Note:</b><br/>Exception: Type Layer 2 is not supported on XA1400 Series.</p> | <p>Specifies the type of logical interface to create:</p> <ul style="list-style-type: none"> <li>Specify <b>layer 2</b> for a Layer 2 core network that the tunnel will traverse.</li> <li>Specify <b>ip</b> for a Layer 3 core network that the tunnel will traverse.</li> </ul>                                                                                                                                  |
| <p><b>DestIPAddr</b></p>                                                                              | <p>Specifies the destination IP address for the IP-type logical interface.</p>                                                                                                                                                                                                                                                                                                                                     |
| <p><b>DestIfIndex</b></p> <p><b>Note:</b><br/>Exception: Not supported on XA1400 Series.</p>          | <p>Specifies the physical port or MultiLink Trunking (MLT) that the Layer 2 logical interface is connected to.</p>                                                                                                                                                                                                                                                                                                 |
| <p><b>Vids</b></p> <p><b>Note:</b><br/>Exception: Not supported on XA1400 Series.</p>                 | <p>Specifies the list of VLANs that are associated with this logical interface.</p>                                                                                                                                                                                                                                                                                                                                |

## Display IPsec Interface Statistics

Use this procedure to view IPsec statistics and counter values for each IPsec-enabled interface.

### About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.

### Interface Stats Field Descriptions

Use the data in the following table to use the **Interface Stats** tab.

| Name               | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| <b>IfIndex</b>     | Shows the interface index for which the statistic is captured.      |
| <b>InSuccesses</b> | Specifies the number of ingress packets IPsec successfully carries. |

| Name                        | Description                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>InSPViolations</b>       | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation.                |
| <b>InNotEnoughMemories</b>  | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available.                |
| <b>InAHESPReplays</b>       | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.                     |
| <b>InESPReplays</b>         | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.                    |
| <b>InAHFailures</b>         | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.             |
| <b>InESPFailures</b>        | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails.            |
| <b>OutSuccesses</b>         | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutSPViolations</b>      | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.             |
| <b>OutNotEnoughMemories</b> | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| <b>generalError</b>         | Specifies a general error.                                                                                                    |
| <b>InAhSuccesses</b>        | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.                                 |
| <b>OutAHSuccesses</b>       | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>InESPSuccesses</b>       | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.                |
| <b>OutESPSuccesses</b>      | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutKBytes</b>            | Specifies the total number of kilobytes on egress.                                                                            |
| <b>OutBytes</b>             | Specifies the total number of bytes on egress.                                                                                |
| <b>InKBytes</b>             | Specifies the total number of bytes on ingress.                                                                               |
| <b>InBytes</b>              | Specifies the total number of bytes on ingress.                                                                               |

| Name                         | Description                                                                                                       |
|------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>TotalPacketsProcessed</b> | Specifies the total number of packets processed.                                                                  |
| <b>TotalPacketsByPassed</b>  | Specifies the total number of packets bypassed.                                                                   |
| <b>OutAHFailures</b>         | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.  |
| <b>OutESPFailures</b>        | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails. |
| <b>InMD5Hmacs</b>            | Specifies the number of inbound HMAC MD5 occurrences since boot time.                                             |
| <b>InSHA1Hmacs</b>           | Specifies the number of inbound HMAC SHA1 occurrences since boot time.                                            |
| <b>InAESXCBCs</b>            | Specifies the number of inbound AES XCBC MAC occurrences since boot time.                                         |
| <b>InAnyNullAuth</b>         | Specifies the number of inbound null authentication occurrences since boot time.                                  |
| <b>In3DESCBCs</b>            | Specifies the number of inbound 3DES CBC occurrences since boot time.                                             |
| <b>InAESCBCs</b>             | Specifies the number of inbound AES CBC occurrences since boot time.                                              |
| <b>InAESCTRs</b>             | Specifies the number of inbound AES CTR occurrences since boot time.                                              |
| <b>InAnyNulEncrypt</b>       | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.                    |
| <b>OutMD5Hmacs</b>           | Specifies the number of outbound HMAC MD5 occurrences since boot time.                                            |
| <b>OutSHA1Hmacs</b>          | Specifies the number of outbound HMAC SHA1 occurrences since boot time.                                           |
| <b>OutAESXCBCs</b>           | Specifies the number of outbound AES XCBC MAC occurrences since boot time.                                        |
| <b>OutInAnyNullAuth</b>      | Specifies the number of outbound null authentication occurrences since boot time.                                 |
| <b>Out3DESCBCs</b>           | Specifies the number of outbound 3DES CBC occurrences since boot time.                                            |
| <b>OutAESCBCs</b>            | Specifies the number of outbound AES CBC occurrences since boot time.                                             |

| Name                       | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <b>OutAESCTRs</b>          | Specifies the number of outbound AES CTR occurrences since boot time.                           |
| <b>OutInAnyNullEncrypt</b> | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

## Graphing IPsec Interface Statistics

Use this procedure to graphically view IPsec statistics and counter values for each IPsec-enabled interface.

### About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

### Procedure

1. In the navigation pane, expand the **Security > Control Path** folders.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.
4. Select a row, and click **Graph**.
5. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart, or a pie chart.
6. To clear existing counters, and fix a reference point in time to restart the counters, click **Clear Contents**.
7. To export the statistical data to a file, click **Export**.
8. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

## Display Switch Level Statistics for IPsec-Enabled Interfaces

Use this procedure to view IPsec statistics and counter values at the switch level for all IPsec-enabled interfaces.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Global Stats** tab.

### *Global Stats Field Descriptions*

Use the data in the following table to use the **Global Stats** tab.

| Name                        | Description                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>InSuccesses</b>          | Specifies the number of ingress packets IPsec successfully carries.                                                           |
| <b>InSPViolations</b>       | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation.                |
| <b>InNotEnoughMemories</b>  | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available.                |
| <b>InAHESPReplays</b>       | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.                     |
| <b>InESPReplays</b>         | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.                    |
| <b>InAHFailures</b>         | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.             |
| <b>InESPFailures</b>        | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails.            |
| <b>OutSuccesses</b>         | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutSPViolations</b>      | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.             |
| <b>OutNotEnoughMemories</b> | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| <b>generalError</b>         | Specifies a general error.                                                                                                    |
| <b>InAHSuccesses</b>        | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.                                 |
| <b>OutAHSuccesses</b>       | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>InESPSuccesses</b>       | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.                |
| <b>OutESPSuccesses</b>      | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutKBytes</b>            | Specifies the total number of kilobytes on egress.                                                                            |
| <b>OutBytes</b>             | Specifies the total number of bytes on egress.                                                                                |
| <b>InKBytes</b>             | Specifies the total number of bytes on ingress.                                                                               |

| Name                         | Description                                                                                                       |
|------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>InBytes</b>               | Specifies the total number of bytes on ingress.                                                                   |
| <b>TotalPacketsProcessed</b> | Specifies the total number of packets processed.                                                                  |
| <b>TotalPacketsByPassed</b>  | Specifies the total number of packets bypassed.                                                                   |
| <b>OutAHFailures</b>         | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.  |
| <b>OutESPFailures</b>        | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails. |
| <b>InMD5Hmac</b>             | Specifies the number of inbound HMAC MD5 occurrences since boot time.                                             |
| <b>InSHA1Hmac</b>            | Specifies the number of inbound HMAC SHA1 occurrences since boot time.                                            |
| <b>InAESXCBCs</b>            | Specifies the number of inbound AES XCBC MAC occurrences since boot time.                                         |
| <b>InAnyNullAuth</b>         | Specifies the number of inbound null authentication occurrences since boot time.                                  |
| <b>In3DESCBCs</b>            | Specifies the number of inbound 3DES CBC occurrences since boot time.                                             |
| <b>InAESCBCs</b>             | Specifies the number of inbound AES CBC occurrences since boot time.                                              |
| <b>InAESCTRs</b>             | Specifies the number of inbound AES CTR occurrences since boot time.                                              |
| <b>InAnyNullEncrypt</b>      | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.                    |
| <b>OutMD5Hmac</b>            | Specifies the number of outbound HMAC MD5 occurrences since boot time.                                            |
| <b>OutSHA1Hmac</b>           | Specifies the number of outbound HMAC SHA1 occurrences since boot time.                                           |
| <b>OutAESXCBCs</b>           | Specifies the number of outbound AES XCBC MAC occurrences since boot time.                                        |
| <b>OutInAnyNullAuth</b>      | Specifies the number of outbound null authentication occurrences since boot time.                                 |
| <b>Out3DESCBCs</b>           | Specifies the number of outbound 3DES CBC occurrences since boot time.                                            |
| <b>OutAESCBCs</b>            | Specifies the number of outbound AES CBC occurrences since boot time.                                             |

| Name                       | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <b>OutAESCTR</b>           | Specifies the number of outbound AES CTR occurrences since boot time.                           |
| <b>OutInAnyNullEncrypt</b> | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

## Configure IPsec for the OSPF Virtual Link

Use the following procedure to configure and enable IPsec for the OSPF virtual link.

IPsec is disabled by default.

### About This Task

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You must disable IPsec before you can perform virtual link policy configuration changes.

### Before You Begin

- Configure the OSPF virtual link.
- Create the IPsec security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Panel**.
2. Click **IPSec**.
3. Click the **OSPF Virtual Link** tab.
4. Click **Insert**.
5. Specify the area ID.
6. Specify the neighbor address.
7. Complete the remaining optional configuration.
8. Click **Insert**.

### *OSPF Virtual Link field descriptions*

Use the data in the following table to use the **OSPF Virtual Link** tab.

| Name               | Description                                              |
|--------------------|----------------------------------------------------------|
| <b>Areaid</b>      | Identifies the OSPF virtual link area.                   |
| <b>Neighbor</b>    | Identifies the OSPF virtual link neighbor.               |
| <b>SAName</b>      | Links the security association to the OSPF virtual link. |
| <b>AdminStatus</b> | Enables the policy. The default is disabled.             |

| Name              | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b>     | Configures the action of the IPsec policy under the OSPF virtual tunnel to one of the following: <ul style="list-style-type: none"> <li>· permit—Permits the IP packets.</li> <li>· drop—Drops the IP packets.</li> </ul> The default is permit.                                                 |
| <b>Direction</b>  | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>· inBound—Specifies ingress traffic.</li> <li>· outBound—Specifies egress traffic.</li> <li>· bothDirections—Specifies both ingress and egress traffic.</li> </ul> The default is bothDirections. |
| <b>SrcAddress</b> | Shows the address of the source interface to which the policy applies.                                                                                                                                                                                                                           |
| <b>DstAddress</b> | Shows the address of the destination interface to which the policy applies.                                                                                                                                                                                                                      |
| <b>LinkID</b>     | Shows a unique ID for the OSPF virtual link. The default is 0.                                                                                                                                                                                                                                   |
| <b>IfIndex</b>    | Shows the interface index to which OSPF virtual link the policy applies.                                                                                                                                                                                                                         |
| <b>OperStatus</b> | Shows the operational status of the link, either up or down. The default is down.                                                                                                                                                                                                                |

## IPsec configuration examples

The following section provides examples to configure Internet Protocol Security (IPsec).

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

## IPsec configuration example

Review the following information to understand IPsec configuration.

Use the following steps to configure IPsec.

1. Create and configure an IPsec policy.
2. Enable the policy.
3. Create an IPsec security association to correspond with the IPsec policy.
4. Configure the key mode format.
5. Configure the security association.
6. Link the IPsec security association to the IPsec policy.

7. Enable the IPsec policy on the interface.
8. Link the IPsec policy with the interface.
9. Enable the IPsec on the interface that links to the IPsec policy.

For an example configuration and for more information on IPsec OSPFv3 and OSPFv3 virtual link, see [OSPF](#) on page 2651.

Create a policy named `newpolicy` with a security association named `new_sa` on VLAN 100.

The following displays the IPsec policy configuration:

```
ipsec policy newpolicy raddr 2001:db8:0:0:0:0:0:1
ipsec policy newpolicy laddr 2001:db8:0:0:0:0:0:15
ipsec policy newpolicy protocol tcp sport 4 dport 5
ipsec policy newpolicy action permit
```

The following example displays the IPsec security association:

```
ipsec security-association new_sa
ipsec security-association new_sa key-mode manual
ipsec security-association new_sa mode transport
ipsec security-association new_sa encap-proto ESP
ipsec security-association new_sa Encrpt-algo 3DES-CBC encrypt-key
11111111111111111111111111111111 KeyLength 24
ipsec security-association new_sa auth-algo SHA1 auth-key 11111111111111111111111111111111 KeyLength
20
ipsec security-association new_sa spi 1
ipsec security-association new_sa lifetime seconds 1000
```

## IPsec with ICMPv6 configuration example

The following displays configuration of IPsec with ICMPv6.

**Figure 166: IPsec configuration with ICMPv6**

*Switch 10 security association configuration*

The following example displays the configuration of the security association on Switch 10.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
```

```

ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
1234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1

```

### Switch 10 policy configuration

The following example displays the configuration of the security policy on Switch 10.

```

ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::2
ipsec policy ICMP_Policy laddr 2001::1
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy security-association icmp

```

### Switch 10 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```

interface gigabitEthernet 1/10
no shut
interface vlan 3
interface address 2000::1
interface enable
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable

```

### Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3 with IPsec.

```

interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
interface enable
interface address 2000::1
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable

```

### Switch 30 security association configuration

The following example displays the configuration of the security association on Switch 30.

```

ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
1234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual

```

```
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1
```

### Switch 30 policy configuration

The following example displays the configuration of the security policy on Switch 30.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::1
ipsec policy ICMP_Policy laddr 2001::2
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy security-association icmp
```

### Switch 30 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface enable
ipv6 interface vlan 3
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

### Switch 30 VLAN configuration

The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/20
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

## OSPFv3 IPsec configuration example

The following example displays a network using IPsec used with OSPFv3.

The following example displays the configuration of IPsec with OSPFv3. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2651.

#### *Switch 10 security associations*

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1

ipsec security-association ospf2
ipsec security-association ospf2 encap-proto ESP
ipsec security-association ospf2 mode transport
ipsec security-association ospf2 spi 2
ipsec security-association ospf2 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf2 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf2 key-mode manual
ipsec security-association ospf2 lifetime seconds 1
ipsec security-association ospf2 lifetime bytes 1

ipsec security-association ospf3
ipsec security-association ospf3 encap-proto ESP
ipsec security-association ospf3 mode transport
ipsec security-association ospf3 spi 3
ipsec security-association ospf3 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf3 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf3 key-mode manual
ipsec security-association ospf3 lifetime seconds 1
ipsec security-association ospf3 lifetime bytes 1

ipsec security-association ospf4
ipsec security-association ospf4 encap-proto ESP
ipsec security-association ospf4 mode transport
ipsec security-association ospf4 spi 4
ipsec security-association ospf4 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf4 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf4 key-mode manual
ipsec security-association ospf4 lifetime seconds 1
ipsec security-association ospf4 lifetime bytes 1

ipsec security-association ospf5
ipsec security-association ospf5 encap-proto ESP
ipsec security-association ospf5 mode transport
ipsec security-association ospf5 spi 5
ipsec security-association ospf5 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf5 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
```

```

ipsec security-association ospf5 key-mode manual
ipsec security-association ospf5 lifetime seconds 1
ipsec security-association ospf5 lifetime bytes 1

ipsec security-association ospf6
ipsec security-association ospf6 encap-proto ESP
ipsec security-association ospf6 mode transport
ipsec security-association ospf6 spi 6
ipsec security-association ospf6 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf6 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf6 key-mode manual
ipsec security-association ospf6 lifetime seconds 1
ipsec security-association ospf6 lifetime bytes 1

```

### Switch 10 policy configuration

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as outbound.

```

ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 protocol ospfv3
ipsec policy ospf1 action permit

```

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as inbound.

For a policy direction of inbound, laddr and raddr are reversed before storing to the stack. Because of this, even though the policy requires you to configure the laddr as the remote link local address, you need to configure laddr as the link local address in the configuration.

```

ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit

```

Laddr is configured to the link local and raddr is configured to ff02::05 with the direction configured as outbound.

```

ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit

```

Laddr is configured to the remote link local and raddr is configured to ff02::05 with the direction configured as inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local and raddr is configured to ff02::06 with the direction as outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::06 with the direction configured as inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

#### *Switch 10 link table configuration*

The following example displays the linking of the policy with the security association on Switch 10.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf3
ipsec policy ospf4 security-association ospf4
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

#### *Switch 10 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
```

#### *Switch 10 interface configuration*

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
```

```

ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable

```

### Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```

interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable

```

### Switch 30 security associations

The following example displays the configuration of security associations for OSPFv3 for Switch 30.

```

ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 2
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
ipsec security-association ospf2
ipsec security-association ospf2 encap-proto ESP
ipsec security-association ospf2 mode transport
ipsec security-association ospf2 spi 1

ipsec security-association ospf6 lifetime bytes 1

```

### Switch 30 policy configuration

In the example, the local address is fe80:0:0:0:b2ad:aaff:fe43:4d00, and the remote address is fe80:0:0:0:b2ad:aaff:fe43:100. The policy has the laddr configured to the link local address and the raddr is configured to the remote link local address with the direction configured to outbound.

```

ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 protocol ospv3
ipsec policy ospf1 action permit

```

Laddr is configured to the remote link local address and raddr is configured to the local link local address with the direction configured to inbound.

```

ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit

```

Laddr is configured to the link local address and raddr is configured to ff02::05 with the direction configured to outbound.

```
ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit
```

Laddr is configured to the remote link local address and the raddr is configured to ff02::05 with the direction configured to inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::06 with the direction configured to outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local address and raddr is configured to ff02::06 with the direction configured to inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

### *Switch 30 link table configuration*

The following example displays the linking of the policy with the security association on Switch 30.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf4
ipsec policy ospf4 security-association ospf3
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

### *Switch 30 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 30.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

### Switch 30 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

### Switch 30 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
minvlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

## OSPFv3 virtual link IPsec configuration example

The following example displays a network using IPsec with OSPFv3 virtual link.

**Figure 167: OSPFv3 virtual link with IPsec configuration**

The following example displays the configuration of IPsec with OSPFv3 virtual link. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2651.

#### *Switch 10 security association configuration*

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

#### *Switch 10 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
ipv6 as-boundary-router
ipv6 area 0.0.0.0
```

#### *Switch 10 virtual link and policy configuration*

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 3.3.3.3
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec action permit
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec direction both
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec enable
```

### Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

### Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 port-member
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

### Switch 20 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 20.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

### Switch 20 interface configuration

The following example displays the interface configuration on slot/port 1/10 and 1/20.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

*Switch 20 VLAN configuration*

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3 and VLAN 4.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20 portmember
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

*Switch 40 security association configuration*

The following example displays the configuration of security associations for OSPFv3 for Switch 40.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Enchrpt-algo AES-CTR EnchrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

*Switch 40 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 40.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 3.3.3.3
ipv6 area 0.0.0.1
ipv6 area 0.0.0.2
ipv6 as-boundary-router
```

*Switch 40 OSPFv3 virtual link and policy configuration*

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 1.1.1.1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec action permit
```

```
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec direction both
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec enable
```

#### Switch 40 interface configuration

The following example displays the interface configuration on slot/port 1/20.

```
interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

#### Switch 40 VLAN interface configuration

The following example displays the creation of VLAN 4 and the configuration of IPsec on VLAN 4.

```
interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

## IPsec configuration of TCP

The following example displays the configuration of IPsec for TCP.

#### Switch 10 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
```

```
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

### Switch 10 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::2
ipsec policy tcp1 raddr 2000::2 laddr 2000::1
ipsec policy tcp1 raddr 2000::2 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::2 action permit
```

### Switch 10 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

### Switch 10 interface configuration

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

### Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

### Switch 30 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
```

```
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

### *Switch 30 IPsec policy configuration*

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::1
ipsec policy tcp1 raddr 2000::1 laddr 2000::2
ipsec policy tcp1 raddr 2000::1 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::1 action permit
```

### *Switch 30 linking the IPsec policy with the IPsec security association*

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

### *Switch 30 interface configuration*

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

### *Switch 30 VLAN configuration*

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

# IPv4 Routing Basics

---

[IP routing operations fundamentals](#) on page 2010

[IP routing configuration using the CLI](#) on page 2026

[IP routing configuration using Enterprise Device Manager](#) on page 2055

This section provides conceptual information and procedures to configure IP Routing using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

## IP routing operations fundamentals

---

Use the information in this section to understand IP routing.

For more information about Border Gateway Protocol (BGP), see [BGP](#) on page 430.

For more information about Open Shortest Path First (OSPF), see [OSPF](#) on page 2651.

For more information about Routing Information Protocol (RIP), see [RIP](#) on page 3057.

## IP addressing

An IP version 4 address consists of 32 bits expressed in dotted-decimal format (x.x.x.x). The IP version 4 address space is divided into classes, with classes A, B, and C reserved for unicast addresses and accounting for 87.5 percent of the 32-bit IP address space. Class D is reserved for multicast addressing. The following table lists the breakdown of IP address space by address range and mask.

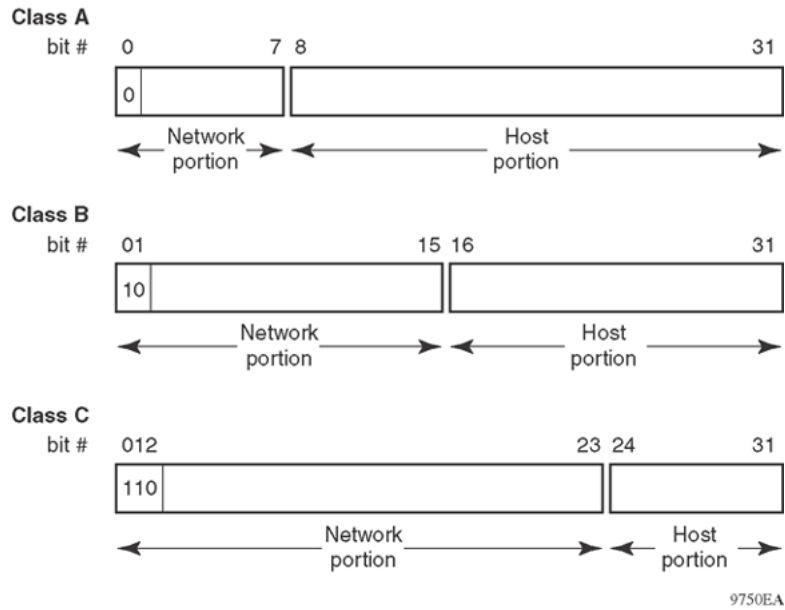

| Class | Address range          | Mask          | Number of addresses |
|-------|------------------------|---------------|---------------------|
| A     | 1.0.0.0 to 126.0.0.0   | 255.0.0.0     | 126                 |
| B     | 128.0.0.0 to 191.0.0.0 | 255.255.0.0   | 127 * 255           |
| C     | 192.0.0.0 to 223.0.0.0 | 255.255.255.0 | 31 * 255 * 255      |
| D     | 224.0.0.0 to 239.0.0.0 |               |                     |

To express an IP address in dotted-decimal notation, you convert each octet of the IP address to a decimal number and separate the numbers by decimal points. For example, you specify the 32-bit IP address 10000000 00100000 00001010 10100111 in dotted-decimal notation as 128.32.10.167.

Each IP address class, when expressed in binary, has a different boundary point between the network and host portions of the address as illustrated in the following

figure. The network portion is a network number field from 8 through 24 bits. The remaining 8 through 24 bits identify a specific host on the network.

**Figure 168: Network and host boundaries in IP address classes**

*Subnet Addressing*

Subnetworks (or subnets) extend the IP addressing scheme an organization uses to one with an IP address range for multiple networks. Subnets are two or more physical networks that share a common network-identification field (the network portion of the 32-bit IP address).

You create a subnet address by increasing the network portion to include a subnet address, thus decreasing the host portion of the IP address. For example, in the address 128.32.10.0, the network portion is 128.32, while the subnet is found in the first octet of the host portion (10). A subnet mask is applied to the IP address and identifies the network and host portions of the address.

The following table illustrates how subnet masks used with class B and class C addresses can create differing numbers of subnets and hosts. This example includes the zero subnet, which is permitted on the switch.

**Table 138: Subnet masks for class B and class C IP addresses**

| Number of bits | Subnet mask   | Number of subnets | Number of hosts for each subnet |
|----------------|---------------|-------------------|---------------------------------|
| Class B        |               |                   |                                 |
| 2              | 255.255.192.0 | 2                 | 16 382                          |
| 3              | 255.255.224.0 | 6                 | 8 190                           |
| 4              | 255.255.240.0 | 14                | 4 094                           |
| 5              | 255.255.248.0 | 30                | 2 046                           |

**Table 138: Subnet masks for class B and class C IP addresses (continued)**

| Number of bits | Subnet mask     | Number of subnets | Number of hosts for each subnet |
|----------------|-----------------|-------------------|---------------------------------|
| 6              | 255.255.252.0   | 62                | 1 022                           |
| 7              | 255.255.254.0   | 126               | 510                             |
| 8              | 255.255.255.0   | 254               | 254                             |
| 9              | 255.255.255.128 | 510               | 126                             |
| 10             | 255.255.255.192 | 1 022             | 62                              |
| 11             | 255.255.255.224 | 2 046             | 30                              |
| 12             | 255.255.255.240 | 4 094             | 14                              |
| 13             | 255.255.255.248 | 8 190             | 6                               |
| 14             | 255.255.255.252 | 16 382            | 2                               |
| Class C        |                 |                   |                                 |
| 1              | 255.255.255.128 | 0                 | 126                             |
| 2              | 255.255.255.192 | 2                 | 62                              |
| 3              | 255.255.255.224 | 6                 | 30                              |
| 4              | 255.255.255.240 | 14                | 14                              |
| 5              | 255.255.255.248 | 30                | 6                               |
| 6              | 255.255.255.252 | 62                | 2                               |

You use variable-length subnet masking (VLSM) to divide your intranet into pieces that match your requirements. Routing is based on the longest subnet mask or network that matches. Routing Information Protocol version 2 and Open Shortest Path First are routing protocols that support VLSM.

### *Supernet Addressing and CIDR*

A supernet, or classless interdomain routing (CIDR) address, is a group of networks identified by contiguous network addresses. IP service providers can assign customers blocks of contiguous addresses to define supernets as needed. You can use supernetting to address an entire block of class C addresses and avoid using large routing tables to track the addresses.

Each supernet has a unique supernet address that consists of the upper bits shared by all of the addresses in the contiguous block. For example, consider the class C addresses shown in the following figure. By adding the mask 255.255.128.0 to IP address 192.32.128.0, you aggregate the addresses 192.32.128.0 through 192.32.255.255 and 128 class C addresses use a single routing advertisement. In the bottom half of the following figure, you use 192.32.0.0/17 to aggregate the 128 addresses (192.32.0.0/24 to 192.32.127.0/24).

9577EA

### Figure 169: Class C address supernet

Another example is the block of addresses 192.32.0.0 to 192.32.7.0. The supernet address for this block is 11000000 00100000 00000, with the 21 upper bits shared by the 32-bit addresses.

A complete supernet address consists of an address and mask pair:

- The address is the first 32-bit IP address in the contiguous block. In this example, the address is 11000000 00100000 00000000 00000000 (192.32.0.0 in dotted-decimal notation).
- The mask is a 32-bit string containing a set bit for each bit position in the supernet part of the address. The mask for the supernet address in this example is 11111111 11111111 11111000 00000000 (255.255.248.0 in dotted-decimal notation).

The complete supernet address in this example is 192.32.0.0/21.

Although classes prohibit using an address mask with the IP address, you can use CIDR to create networks of various sizes using the address mask. With CIDR, the routers outside the network use the addresses.

**NEW!** IPv4 Interface State**Table 139: IPv4 Interface state product support**

| Feature                                      | Product         | Release introduced |
|----------------------------------------------|-----------------|--------------------|
| Ability to Enable or Disable an IP Interface | 5320 Series     | Fabric Engine 8.10 |
|                                              | 5420 Series     | Fabric Engine 8.10 |
|                                              | 5520 Series     | Fabric Engine 8.10 |
|                                              | 5720 Series     | Fabric Engine 8.10 |
|                                              | 7520 Series     | Fabric Engine 8.10 |
|                                              | 7720 Series     | Fabric Engine 8.10 |
|                                              | VSP 4450 Series | VOSS 8.10          |
|                                              | VSP 4900 Series | VOSS 8.10          |
|                                              | VSP 7200 Series | VOSS 8.10          |
|                                              | VSP 7400 Series | VOSS 8.10          |
|                                              | VSP 8200 Series | VOSS 8.10          |
|                                              | VSP 8400 Series | VOSS 8.10          |
|                                              | XA1400 Series   | VOSS 8.10          |

To create an IP interface (to enable IP-Layer functionality), you must assign a primary IP address to the VLAN or brouter port. By default, the switch enables the IP interface after you configure the primary IP address.

You can administratively enable or disable an IPv4 interface after you create it or you can instruct the switch to create the IP interface in a disabled state when you configure the primary IP address. The following examples provide different use cases to change the administrative state of an IP interface.

To change the feature configuration on an existing IP interface, you must perform the following actions:

1. Disable the IP interface.
2. Make the configuration change.
3. Reenable the IP interface.

To preconfigure a new interface, including routing protocols on the interface, and enable it later during a maintenance window, you can configure the primary IP address for the interface and configure the disabled state simultaneously.

For more information, see the following CLI tasks:

- [Assign an IP address to a Port](#) on page 2031
- [Modify an Existing IP Interface](#) on page 2033
- [Assign an IP Address to a VLAN](#) on page 4115

### *Operational Notes*

The following list identifies feature restrictions:

- You can change the IP interface administrative state of IPv4 interfaces only.
- You can change the IP interface (IP-layer) administrative state only for VLAN and router ports.
- In the case of coexistence for both a NOS routing VLAN and VLAN Management Instance, the IP interface state change only affects the local VLAN.
- Layer 3 information passes to DvR leaf nodes only if you enable the IP interface on the DvR controller.
- You cannot change the administrative state of a VLAN that does not support an IP address configuration, for example, a VLAN used for IP Multicast config-lite for Fabric Connect.
- You cannot change the administrative state of an IP interface on a Shortest Path Bridging MAC (SPBM) VLAN.
- To change the administrative state of a VLAN used with virtual interswitch trunk (vIST), you must first disable vIST.
- The ability to create a new IP interface in a disabled state in one step is available only using CLI and not EDM.

## Loopback

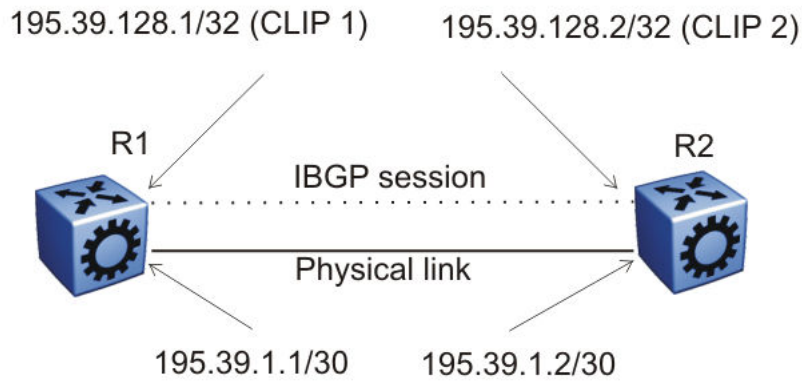

Circuitless IP (CLIP) is a virtual (or loopback) interface that is not associated with a physical port. You can use the CLIP interface to provide uninterrupted connectivity to your device as long as a path exists to reach the device.

For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Use an interior Border Gateway Protocol (iBGP) session between two additional addresses, 195.39.128.1/30 (CLIP 1) and 195.39.281.2/30 (CLIP 2).

CLIP 1 and CLIP 2 represent the virtual CLIP addresses that you configure between R1 and R2. These virtual interfaces are not associated with the physical link or hardware interface, which permits the BGP session to continue as long as a path exists between R1 and R2. An IGP (such as OSPF) routes addresses that correspond to the CLIP addresses. After the routers learn all the CLIP addresses in the AS, the system establishes iBGP and exchanges routes.

The system advertises loopback routes to other routers in the domain either as external routes using the route-redistribution process, or after you enable OSPF in passive mode to advertise an OSPF internal route.

You can also use CLIP for PIM-SM, typically, as a Rendezvous Point (RP), or as a source IP address for sending SNMP traps and Syslog messages.

**Figure 170: Routers with iBGP connections**

The system treats the CLIP interface as an IP interface. The network associated with the CLIP is treated as a local network attached to the device. This route always exists and the circuit is always up because there is no physical attachment.

Static routes

**Table 140: Static routing product support**

| Feature        | Product         | Release introduced                                                                                       |
|----------------|-----------------|----------------------------------------------------------------------------------------------------------|
| Static routing | 5320 Series     | Fabric Engine 8.6<br>Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration. |
|                | 5420 Series     | VOSS 8.4                                                                                                 |
|                | 5520 Series     | VOSS 8.2.5                                                                                               |
|                | 5720 Series     | Fabric Engine 8.7                                                                                        |
|                | 7520 Series     | Fabric Engine 8.10                                                                                       |
|                | 7720 Series     | Fabric Engine 8.10                                                                                       |
|                | VSP 4450 Series | VSP 4000 4.0                                                                                             |
|                | VSP 4900 Series | VOSS 8.1                                                                                                 |
|                | VSP 7200 Series | VOSS 4.2.1                                                                                               |
|                | VSP 7400 Series | VOSS 8.0                                                                                                 |
|                | VSP 8200 Series | VSP 8200 4.0                                                                                             |
|                | VSP 8400 Series | VOSS 4.2                                                                                                 |
|                | VSP 8600 Series | VSP 8600 4.5                                                                                             |
|                | XA1400 Series   | VOSS 8.0.50                                                                                              |

**Note**

Static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management](#) on page 86. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

A static route is a route to a destination IP address that you manually create.

Create static routes to enhance network stability. Use the local next hop option to configure a static route with or without local next hop.

You can configure static routes with a next hop that is not directly connected, but that hop must be reachable. Otherwise, the static route is not enabled.

Layer 3 redundancy supports only address resolution protocol (ARP) and static route. Static ARP must configure the nonlocal next-hop of static routes. No other dynamic routing protocols provide nonlocal next-hop.

**Note**

Static ARP entries are not supported for NLB Unicast or NLB Multicast operations.

You can use a default static route to specify a route to all networks for which no explicit routes exist in the forwarding information base or the routing table. This route has a prefix length of zero (RFC1812). You can configure the switch with a route through the IP static routing table.

To create a default static route, you must configure the destination address and subnet mask to 0.0.0.0.

**Note**

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

### *Static Route Tables*

A router uses the system routing table to make forwarding decisions. In the static route table, you can change static routes directly. Although the two tables are separate, the static route table manager entries are automatically reflected in the system routing table if the next-hop address in the static route is reachable, and if the static route is enabled.

The system routing table displays only active static routes with a best preference. A static route is active only if the route is enabled and the next-hop address is reachable (for example, if a valid ARP entry exists for the next hop).

You can enter multiple routes (for example, multiple default routes) that have different costs, and the routing table uses the lowest cost route that is available. However, if you enter multiple next hops for the same route with the same cost, the software does not replace the existing route. If you enter the same route with the same cost and a different next-hop, the first route is used. If the first route becomes unreachable, the second route (with a different next-hop) is activated with no connectivity loss.

## Routing Protocols

Routers and routing switches use routing protocols to exchange reachability information. Routers use a routing protocol to advertise available paths on which the router can forward data. The routers use the protocol to determine the most efficient path to use. Routers use dynamic routing protocols to avoid sending data to inoperable links, and to send data to links that generally result in the fastest transmission times.

The switch routes frames using one of the following dynamic unicast IP routing protocols for path selection:

- Routing Information Protocol version 1 (RIPv1) (RFC 1058)
- RIPv2 (RFC 2453)
- Open Shortest Path First version 2 (OSPFv2) (RFC 2328)
- OSPFv3 (RFC 2740)
- Border Gateway Protocol version 4 (BGPv4) (RFC 1771)

Unlike static IP routing, where you must create a manual entry in the routing table to specify a routing path, dynamic IP routing uses a learning approach to determine the paths and routes to other routers. Dynamic routing uses two basic types of routing: distance vector and link-state. Routing Information Protocol (RIP) is a distance vector protocol and Open Shortest Path First (OSPF) is a link-state protocol.

The switch uses routing protocols like OSPF and RIP to populate routing tables. Routers use a routing protocol to exchange network topology information. A router uses the IP address of an incoming data packet to send the packet according to the routing tables.

The most commonly used unicast routing protocols include OSPF, RIP, and BGP. For more information about BGP, see [BGP](#) on page 430. For information about multicast routing protocols, see [IP Multicast](#) on page 1586. For information about OSPFv3 routing protocols, see [OSPF](#) on page 2651.

## Black Hole Static Routes

A black hole static route is a route with an invalid next hop, and the device drops data packets destined for this network.

While the router aggregates or injects routes to other routers, the router does not have a path to the aggregated destination. In such cases, the result is a black hole and a routing loop. To avoid routing loops, configure a black hole static route to the destination the router is advertising.

You can configure a preference value for a black hole route. However, you must configure that preference value appropriately so that when you want to use the black hole route, it is elected as the best route.

Before you add a black hole static route, perform a check to ensure that no other static route to that identical destination is enabled. If such a route exists, you cannot add the black hole route and the system displays an error message.

If you enable a black hole route, you cannot add another static route to that destination. You must first delete or disable the black hole route before you add a regular static route to that destination.

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

## VLANs and routing

When traffic is routed on a virtual local area network (VLAN), an IP address is assigned to the VLAN and is not associated with a particular physical port. Router ports are VLANs that route IP packets and bridge nonroutable traffic in a single-port VLAN.

### *Virtual Routing Between VLANs*

The switch supports wire-speed IP routing between VLANs. As shown in the following figure, VLAN 1 and VLAN 2 are on the same device, yet for traffic to flow from VLAN 1 to VLAN 2, the traffic must be routed.

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN (a virtual router interface is not associated with a particular port). You can reach the VLAN IP address through the VLAN ports, and frames are routed from the VLAN through the gateway IP address. Routed traffic is forwarded to another VLAN within the device.

**Figure 171: IP routing between VLANs**

When Spanning Tree Protocol is enabled in a VLAN, the spanning tree convergence must be stable before the routing protocol begins. This requirement can lead to an additional delay in the IP traffic forwarding.

Because a port can belong to multiple VLANs (some of which are configured for routing on the device and some of which are not), a one-to-one correspondence no longer exists between the physical port and the router interface.

As with an IP address, virtual router interface addresses using Virtual Router Redundancy Protocol (VRRP) are also used for device management. For Simple

Network Management Protocol (SNMP) or Telnet management, you can use virtual router interface address to access the device as long as routing is enabled on the VLAN.

### Router Ports

The switch also supports router ports. A router port is a single-port VLAN that routes IP packets and bridges all nonroutable traffic. The difference between a router port and a standard IP protocol-based VLAN configured to route traffic is that the routing interface of the router port is not subject to the spanning tree state of the port. A router port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

Because a router port is a single-port VLAN, each router port decreases the number of available VLANs by one and uses one VLAN ID.

The switch allows IP routing to be enabled on VLANs and router ports. For the maximum number of interfaces, see the Software scaling capabilities section of the [VOSS Release Notes](#).

## Equal Cost Multipath

**Table 141: Equal Cost Multiple Path for IPv4 product support**

| Feature                                  | Product         | Release introduced                                                                                       |
|------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------|
| Equal Cost Multiple Path (ECMP) for IPv4 | 5320 Series     | Fabric Engine 8.6<br>Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration. |
|                                          | 5420 Series     | VOSS 8.4                                                                                                 |
|                                          | 5520 Series     | VOSS 8.2.5                                                                                               |
|                                          | 5720 Series     | Fabric Engine 8.7                                                                                        |
|                                          | 7520 Series     | Fabric Engine 8.10                                                                                       |
|                                          | 7720 Series     | Fabric Engine 8.10                                                                                       |
|                                          | VSP 4450 Series | VSP 4000 4.0                                                                                             |
|                                          | VSP 4900 Series | VOSS 8.1                                                                                                 |
|                                          | VSP 7200 Series | VOSS 4.2.1                                                                                               |
|                                          | VSP 7400 Series | VOSS 8.0                                                                                                 |
|                                          | VSP 8200 Series | VSP 8200 4.0                                                                                             |
|                                          | VSP 8400 Series | VOSS 4.2                                                                                                 |
|                                          | VSP 8600 Series | VSP 8600 4.5                                                                                             |
| XA1400 Series                            | VOSS 8.0.50     |                                                                                                          |

With Equal Cost Multipath (ECMP), the switch can determine up to eight equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of

traffic. These multiple paths provide faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use links between routers more efficiently when sending IP traffic. Equal Cost Multipath is formed using routes from the same source or protocol.

All IP ECMP routes that share the same combination of ECMP next hops consume the same ECMP group resource. The following list illustrates how shared next hops affect resource consumption:

- Prefix 3.1.1.0/16 is learned as an ECMP route with next hops A and B, and consumes one entry in the ECMP GROUP table.
- Prefix 4.1.1.0/16 is learned as an ECMP route with the same next hops, A and B. No additional resource is taken in the ECMP GROUP table.
- Prefix 5.1.1.0/16 is learned as an ECMP route with next hops B and C, and consumes one additional entry in the ECMP GROUP table.

ECMP is supported on both the Global Routing Table (GRT) and Virtual Routing and Forwarding (VRF).

The ECMP feature supports and complements the following protocols and route types:

- Border Gateway Protocol (BGP)
- Default route
- Intermediate System-to-Intermediate System (IS-IS)
- Open Shortest Path First (OSPF)
- Routing Information Protocol (RIP)
- Static route
- VRF

#### *ECMP Pathlist*

Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

#### **Note**

Product Notice: Not all products support Equal Cost Multipath Pathlist with Fabric Connect. For more information, see [Fabric Engine and VOSS Feature Support Matrix](#).

## IP Source Routing

**Table 142: IP Source Routing product support**

| Feature                             | Product         | Release introduced                                                                                       |
|-------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------|
| IP Source Routing enable or disable | 5320 Series     | Fabric Engine 8.6<br>Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration. |

| XA1400 Series                       | Not Supported   |                                                                                                          |

IP Source Routing allows the sender of a packet to specify the route that the packet must travel through the network. When the Source Route option is not enabled, the router chooses the primary routing path to send the packets. If IP Source Routing flag is on, the source host dictates the datapath for the packet to reach the destination using the information contained in the IP header.

The routing behavior in VSP 8600 Series is controlled by the datapath specified, and not by status of the IP Source Route. VSP 8600 Series inspects the packets only if the router itself is specified in the Source Routing. Otherwise, the switch forwards the packets to another router in the network using IP Routing, whether or not IP Source Route is enabled. You can use an ACL filter to block the datapath from forwarding any IP Source Routing packets.

IP Source Routing is considered a security risk because it allows the users to specify their own path through the network outside of the primary forwarding path. This can cause packets to bypass the security devices. Therefore, IP Source Routing is disabled by default.

## Multihoming

The switch uses the multihoming feature to support clients or servers that have multiple IP addresses associated with a single MAC address. Multihomed hosts can be connected to port-based and policy-based VLANs.

The IP addresses associated with a single MAC address on a host must be in the same IP subnet.

## IPv4 ICMP Broadcast

**Table 143: Internet Control Message Protocol product support**

| Feature                                  | Product         | Release introduced                                                                                       |

| XA1400 Series                                  | VOSS 8.5        |                                                                                                          |

**Table 143: Internet Control Message Protocol product support (continued)**

| Feature                                   | Product         | Release introduced                                                                                       |
|-------------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------|
| Fragmented ICMP Packet Filtering for IPv6 | 5320 Series     | Fabric Engine 8.6<br>Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration. |
|                                           | 5420 Series     | VOSS 8.5                                                                                                 |
|                                           | 5520 Series     | VOSS 8.5                                                                                                 |
|                                           | 5720 Series     | Fabric Engine 8.7                                                                                        |
|                                           | 7520 Series     | Fabric Engine 8.10                                                                                       |
|                                           | 7720 Series     | Fabric Engine 8.10                                                                                       |
|                                           | VSP 4450 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 4900 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 7200 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 7400 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 8200 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 8400 Series | VOSS 8.5                                                                                                 |
|                                           | VSP 8600 Series | Not supported                                                                                            |
|                                           | XA1400 Series   | Not supported                                                                                            |

On IPv4 networks, a packet can be directed to an individual machine or broadcast to an entire network. When a packet is sent to an IP broadcast address from a machine on the local network, that packet is delivered to all machines on that network.

If a packet that is broadcast is an ICMP echo request packet, the machines on the network receive this ICMP echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMP echo request, the result can be severe network congestion or outages.

The switch always responds to IPv4 ICMP packets sent to a broadcast address. You can disable the processing of these IPv4 ICMP packets sent to the broadcast address. On disabling the ICMP broadcast processing, all the packets containing ICMP sent to the broadcast addresses will be dropped when the packets reach the control plane.

You can disable or enable the IPv4 ICMP broadcast processing at the VRF level.

#### *Fragmented ICMP Packet Filtering*

ICMP fragmentation distributed denial-of-service (DDoS) attacks flood the destination resources with fragmented packets and overwhelm the network because of massive volumes of traffic. With Fragmented ICMP packet filtering, the system inspects each incoming IPv4 ICMP packet to determine if it should drop the packet or forward it.

You can configure ICMP drop packet filtering globally, on a specific VRF, and on the following management interfaces:

- Out-of-Band (OOB) management
- Circuitless IP (CLIP) management
- VLAN management

## IP routing configuration using the CLI

Configure the IP router interface so that you can configure and use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

### Enabling routing globally or on a VRF instance

Use IP forwarding (routing) on a global level so that the device supports routing. You can use the IP address of an interface for IP-based network management.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Activate IP forwarding:

```
ip routing
```

3. View the forwarding configuration:

```
show ip routing [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

#### Example

Activate IP forwarding and view the forwarding configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#ip routing
Switch:1(router-vrf)#show ip routing
```

```
=====
IP - GlobalRouter
=====
```

```
IP Forwarding is enabled
IP ECMP feature is disabled
Maximum ECMP paths number is 1
ECMP 1 pathlist :
ECMP 2 pathlist :
ECMP 3 pathlist :
ECMP 4 pathlist :
ECMP 5 pathlist :
ECMP 6 pathlist :
```

```

ECMP 7 pathlist :
ECMP 8 pathlist :
Gratuitous-Arp : enable
IP Alternative Route feature is enabled
IP More Specific Non Local Route feature is disabled
IP ICMP Unreachable Message is disabled
IP Supernetting is disabled
IP Icmp-echo-broadcast-request is enabled

IP Default TTL is 255 seconds
IP ARP life time is 360 minutes
IP Source Route Option is disabled

```

### Variable Definitions

Use the data in the following table to use the **show ip routing** command.

| Variable                              | Value                                   |
|---------------------------------------|-----------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by VRF name.   |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a VRF instance by VRF number. |

## Enabling routing on an IP interface

### About This Task

You can enable or disable routing capabilities on a VLAN or brouter port.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable routing:

```
routing enable
```

### Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#routing enable

```

## Deleting a dynamically learned route

### About This Task

Delete a dynamically learned route from the routing table if you do not want the switch to use the route. Exercise caution when you delete entries from the routing table.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. View IP route information:
 

```
show ip route [<A.B.C.D>] [-s default|-s <A.B.C.D/X>] [alternative]
[count-summary] [spbm-nh-as-mac][preference] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [static]
```
3. Delete the dynamically learned route:
 

```
no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> dynamic
```

### Example

Delete a dynamically learned route:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip route 192.0.2.32 255.255.255.0 198.51.100.31 dynamic
```

### Variable Definitions

Use the data in the following table to use the **show ip route** commands.

| Variable                        | Value                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------|
| <A.B.C.D>                       | Specifies the IP address of the route to the network.                                       |
| <i>alternative</i>              | Displays the alternative routes.                                                            |
| <i>count-summary</i>            | Displays a summary of the number of routes learned from each routing protocol for each VRF. |
| <i>preference</i>               | Displays the route preference.                                                              |
| <i>-s &lt;A.B.C.D/X&gt;</i>     | Indicates the IP address and subnet mask for which to display routes.                       |
| <i>-s default</i>               | Indicates the default subnet.                                                               |
| <i>static</i>                   | Displays the static route information.                                                      |
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays the route for a particular VRF.                                                    |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays the route for a particular VRF number.                                             |
| <i>spbm-nh-as-mac</i>           | Displays the spbm route next hop as mac.                                                    |

Use the data in the following table to use the **no ip route** command.

| Variable                                                         | Value                                                                                 |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D&gt; &lt;A.B.C.D&gt;<br/>&lt;A.B.C.D&gt;</code> | Specifies the IP address, the subnet mask, and the next-hop IP address, respectively. |
| <code>dynamic</code>                                             | Specifies that a dynamic route is to be deleted.                                      |
| <code>enable</code>                                              | Disables the route.                                                                   |
| <code>local-next-hop enable</code>                               | Disables the local-next-hop option.                                                   |
| <code>preference</code>                                          | Deletes the value of the route preference.                                            |
| <code>next-hop-vrf WORD&lt;1-16&gt;</code>                       | Specifies the name of the next-hop VRF router.                                        |

## Configuring IP route preferences

### Before You Begin

- Disable ECMP before you configure route preferences

### Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. You must therefore change a prefix list or a routing protocol before you activate the protocols.

### About This Task

Configure IP route preferences to give preference to routes learned for a specific protocol. You must disable ECMP before you configure route preferences.

To configure route preferences for a VRF, access VRF Router Configuration mode, rather than Global Configuration mode.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Configure the route preference:

```
ip route preference protocol <static|ospf-intra|ospf-inter|ebgp|ibgp|rip|ospf-extern1|ospf-extern2|spbm-level1> <0-255>
```

3. Confirm that the configuration is correct:

```
show ip route preference [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Configure the route preference to SPBM Level 1 and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route preference protocol spbm-level1 7
Switch:1(config)#show ip route preference
=====
IP Route Preference - GlobalRouter
=====
PROTOCOL      DEFAULT    CONFIG
-----
LOCAL         0          0
STATIC        5          5
SPBM_L1       7          7
OSPF_INTRA    20         20
OSPF_INTER    25         25
EBGP          45         45
RIP           100        100
OSPF_E1       120        120
OSPF_E2       125        125
IBGP          175        175
```

View the route preference configuration for a specific VRF, for example 444.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf test
Switch:1(router-vrf)#show ip route preference vrf 444
=====

```

#### Variable definitions

Use the data in the following table to use the **ip route preference protocol** command.

| Variable            | Value                      |
|---------------------|----------------------------|
| <i>ebgp</i>         | Protocol type eBGP         |
| <i>ibgp</i>         | Protocol type iBGP         |
| <i>ospf-extern1</i> | Protocol type ospf-extern1 |

| Variable            | Value                      |
|---------------------|----------------------------|
| <i>ospf-extern2</i> | Protocol type ospf-extern2 |
| <i>ospf-intra</i>   | Protocol type ospf-intra   |
| <i>ospf-inter</i>   | Protocol type ospf-inter   |
| <i>rip</i>          | Protocol type rip          |
| <i>spbm-level1</i>  | Protocol type spbm-level1  |

## Flushing routing tables by VLAN or port

### About This Task

For administrative and troubleshooting purposes, flush the routing tables.

To flush tables on a VRF instance for a port or VLAN, ensure that the VRF is associated with the port or VLAN.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush the routing tables:

```
action flushIp
```

### Example

Flush the routing tables:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#action flushIp
```

## Assign an IP address to a Port

Assign an IP address to a port so that it supports routing operations.

### Before You Begin

- Ensure routing (forwarding) is globally enabled.

- Ensure the VLAN is configured.
- If required, ensure the VRF instance exists.

### About This Task

Use a brouter port to route IP packets and to bridge all nonroutable traffic. The routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

If you configure an IP interface without specifying the VRF instance, it maps to VRF 0 by default.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IP address to the port:

```
brouter port {slot/port[/sub-port]} vlan <2-4059> subnet <A.B.C.D/X>  
[mac-offset <MAC-offset> | name WORD <0-64> | state-disabled]
```

3. (Optional) If required, associate the port with a VRF:

```
vrf WORD<1-16>
```

4. Confirm that the configuration is correct:

```
show brouter [<1-4059>]
```

### Example

Assign an IP address to a port:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitethernet 1/11  
Switch:1(config-if)#brouter port 1/11 vlan 2202 subnet 47.17.10.31/255.255.255.0
```

### Variable Definitions

Use the data in the following table to use the **brouter port** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mac-offset</i> <MAC-offset>  | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help. |
| <i>name</i> WORD <0-64>         | Specifies the IP address name in the range of 0 to 64 characters.                                                                                                                                                                                                                                                                                                        |
| { <i>slot/port</i> [/sub-port]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                             |
| <i>state-disabled</i>           | Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, including the routing protocol configuration for that interface, and enable it later during a maintenance window. By default, the switch enables an IP interface after you configure the primary IP address.                       |
| <i>subnet</i> <A.B.C.D/X>       | Specifies the IP address and subnet mask (0-32).                                                                                                                                                                                                                                                                                                                         |
| <2-4059>                        | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged.                                                                                                                                                                                                            |

Use the data in the following table to use the **show brouter** command.

| Variable | Value                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged. |

## **NEW!** Modify an Existing IP Interface

By default, the switch enables an IP interface (a VLAN or brouter port) after you configure the primary IP address. You can administratively disable, and then reenable, an IPv4 interface after you create it. For example, if you want to change the routing protocol configuration on the interface.

### About This Task

You can also instruct the switch to create the IP interface in a disabled state when you initially configure the primary IP address. For more information, see [Assign an IP address to a Port](#) on page 2031 or [Configure a Primary IP Address for a VLAN](#) on page 4155.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable the IP interface:

```
no ip interface enable
```

3. Make feature configuration changes for the IP interface.

4. Reenable the IP interface:

```
ip interface enable
```

## View Primary IP Addresses for all Router Interfaces

Perform the following procedure to display information about all primary IP interfaces configured on the device.

**About This Task**

This command displays only primary IP interfaces. To view Secondary IP Interfaces, see [Display All Configured IP Addresses](#) on page 4117.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. Show the IP interfaces and addresses on the device:

```
show ip interface
```

**Example**

Show the primary IP interfaces and addresses on the device:

```
Switch:1>show ip interface
=====
                        IP Interface - GlobalRouter
=====
INTERFACE  IP          NET          ADMIN    OPER    VLAN  BROUTER  IPSEC  IP
           ADDRESS  MASK         STATUS   STATE   ID    PORT    STATE  NAME
-----
Port1/2    192.0.2.1   255.255.255.0  enable   up      20    true     disable
Vlan10     198.51.100.0 255.255.255.0  disable  down    10    false    disable

All 2 out of 2 Total Num of IP interfaces displayed
```

Variable Definitions

Use the data in the following table to **show ip interface** command.

| Variable               | Value                                                         |
|------------------------|---------------------------------------------------------------|
| <i>gigabitethernet</i> | Displays IP interface information for Gigabit Ethernet ports. |
| <i>vrf</i>             | Displays interface information for a particular VRF.          |
| <i>vrfids</i>          | Displays interface information for particular VRF IDs.        |

View the IPv4 and IPv6 Interface Configuration on a Port

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify the interface configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

Example

Verify the IPv4 configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet

=====
                        Brouter Port Ip
=====
PORT VRF   IP_ADDRESS   NET_MASK   ADMIN OPER   ADVERTISE DIRECT  RPC   RPCMODE
NUM  NAME
-----
1/1  Glob~ 192.0.2.3   255.255.255.0 enable up    disable  disable disable exist-only
1/10 spbo~ 198.51.100.4 255.255.255.0 enable up    disable  disable disable exist-only

PORT VRF           BROADCAST REASM
NUM  NAME           MAXSIZE
-----
1/1  GlobalRouter   ones     1500
1/10 spboip       ones     1500
```

Verify the IPv6 configuration on the port:

```
Switch:1(config-if)#show ipv6 interface gigabitethernet

=====
                        Port IPv6 Interface
=====
IFINDX BRROUTER PHYSICAL      ADMIN OPER  TYPE MTU  HOP REACHABLE  RETRANSMIT MCAST  IPSEC  RPC  RPCMODE

## Configure IP Routing Globally or for a VRF

Configure the IP routing protocol stack to specify which routing features the device can use. You can configure global parameters before or after you configure the routing protocols.

### About This Task

To configure IP routing globally for a VRF instance, use VRF Router Configuration mode rather than Global Configuration mode.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the default TTL for all routing protocols to use:

```
ip ttl <1-255>
```

This value is placed into routed packets that have no TTL specified.

3. Activate the alternative route feature globally:

```
ip alternative-route
```

4. Configure the remaining global parameters as required.

## Variable Definitions

The following table defines parameters for the **ip** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>alternative-route</i>             | Enables or disables the alternative route feature. The default value is enabled.<br>If the alternative-route parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readded.<br>The default form of this command is <code>default ip alternative-route</code> . The no form of this command is <code>no ip alternative-route</code> .                         |
| <i>max-routes-trap enable</i>        | Enables the device to send a trap after the maximum number of routes is exceeded.<br>The no form of this command is <code>no max-routes-trap enable</code> . The default form of this command is <code>default max-routes-trap enable</code> .                                                                                                                                                                                        |
| <i>more-specific-non-local-route</i> | Enables the more-specific-non-local-route feature. If enabled, the device can enter a more-specific nonlocal route into the routing table. The default is disabled.<br>The default form of this command is <code>default ip more-specific-non-local-route</code> . The no form of this command is <code>no ip more-specific-non-local-route</code> .                                                                                  |
| <i>routing</i>                       | Enables routing.<br>The no form of this command is <code>no ip routing</code> .                                                                                                                                                                                                                                                                                                                                                       |
| <i>supernet</i>                      | Enables or disables supernetting.<br>If you globally enable supernetting, the device can learn routes with a route mask of less then eight bits. Routes with a mask length less than eight bits cannot have ECMP paths, even if the ECMP feature is globally enabled. The default is disabled.<br>The default form of this command is <code>default ip supernet</code> . The no form of this command is <code>no ip supernet</code> . |
| <i>ttl &lt;1-255&gt;</i>             | Configures the default time-to-live (TTL) value for a routed packet. The TTL is the maximum number of seconds before a packet is discarded. The default value of 255 is used whenever a time is not supplied in the datagram header.<br>The default form of this command is <code>default ip ttl</code> .                                                                                                                             |

The following table defines parameters for the `ip icmp` commands.

| Variable                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>unreachable</code> | Enables the device to send ICMP unreachable messages. When enabled, this variable generates Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this router. These messages help determine if the device is reachable over the network. The default is disabled.<br>The default form of this command is <code>default ip icmp unreachable</code> . |

## Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which provides fast convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

### About This Task

To configure ECMP for a VRF instance, after you enable ECMP globally, use VRF Router Configuration mode rather than Global Configuration mode.

Different hardware platforms can support a different number of ECMP paths. For more information, see [VOSS Release Notes](#).

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable ECMP globally:
 

```
ip ecmp
```
3. (Optional) Configure the maximum number of ECMP paths:
 

```
ip ecmp max-path <ECMP-Paths>
```
4. (Optional) Configure a prefix-list for the target destination:
 

```
ip prefix-list WORD<1-64> <A.B.C.D/X> [ge <0-32>] [le <0-32>]
```
5. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths:
 

```
ip ecmp pathlist-<1-8> WORD<1-64>
```
6. (Optional) Return to Privileged EXEC mode:
 

```
end
```
7. (Optional) Apply changes to all ECMP pathlist configurations:
 

```
ip ecmp pathlist-apply [vrf WORD<1-16>]
```

## Example

Define which IP prefixes use ECMP and which do not.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ecmp
Switch:1(config)#ip prefix-list ecmpAllowed 192.0.2.0/24 ge 24 le 24
Switch:1(config)#ip prefix-list ecmpDenied 0.0.0.0/0 ge 0 le 32
Switch:1(config)#ip ecmp pathlist-2 ecmpAllowed
Switch:1(config)#ip ecmp pathlist-1 ecmpDenied
Switch:1(config)#end
Switch:1#ip ecmp pathlist-apply
```

## Variable Definitions

The following table defines parameters for the **ip ecmp** command.

| Variable                                           | Value                                                                                                                                                                                                                                                                        |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max-path &lt;ECMP-Paths&gt;</code>           | Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in <a href="#">VOSS Release Notes</a> . |
| <code>pathlist-1 WORD&lt;0-64&gt;</code>           | Specifies one equal-cost path to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                                    |
| <code>pathlist-2 WORD&lt;0-64&gt;</code>           | Specifies up to two equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                             |
| <code>pathlist-3 WORD&lt;0-64&gt;</code>           | Specifies up to three equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-4 WORD&lt;0-64&gt;</code>           | Specifies up to four equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                            |
| <code>pathlist-5 WORD&lt;0-64&gt;</code>           | Specifies up to five equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                            |
| <code>pathlist-6 WORD&lt;0-64&gt;</code>           | Specifies up to six equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                             |
| <code>pathlist-7 WORD&lt;0-64&gt;</code>           | Specifies up to seven equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-8 WORD&lt;0-64&gt;</code>           | Specifies up to eight equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-apply [vrf WORD&lt;1-16&gt;]</code> | Applies the pathlist configuration changes. You can optionally specify a VRF name.                                                                                                                                                                                           |

The following table defines parameters for the `ip prefix-list` command.

| Variable                       | Value                                                                                                                                                                                  |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;0-64&gt;</code>  | Specifies the prefix list name.                                                                                                                                                        |
| <code>&lt;A.B.C.D/X&gt;</code> | Specifies the IP address and network mask in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d/x</li> <li>• a.b.c.d/x.x.x.x</li> <li>• default</li> </ul> |
| <code>ge &lt;0-32&gt;</code>   | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                              |
| <code>le &lt;0-32&gt;</code>   | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                              |

## Configure Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface. Specify the name of the VRF context in [Step 1](#).

Static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 107. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

### Before You Begin

- Ensure no black hole static route exists. If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

#### Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.
