**Table 109: 802.1x session termination mapping (continued)**

| IEEE 802.1Xdot1xAuthSessionTerminateCause Value | RADIUSAcct-Terminate-Cause Value    |
|-------------------------------------------------|-------------------------------------|
| portAdminDisabled(7)                            | Port Administratively Disabled (22) |
| notTerminatedYet(999)                           | —                                   |

## RADIUS Attributes

The section provides a list of RADIUS attributes for EAP.

### Vendor Specific Attributes

#### RADIUS Vendor Specific Frame Format

The following figure shows the frame format for RADIUS vendor specific attributes (VSA).

**Figure 47: RADIUS vendor-specific frame format**

#### FA-VLAN-ISID

On EAP-enabled Flex-UNI ports, the context for the authenticating MAC is the association using the FA-VLAN-ISID attribute. This attribute provides one VLAN:I-SID binding.

- defined under vendor IDs 562 and 1584 and uses the value 171
- I-SID values are 0-15999999
- VLAN values are 0 - 4096 to create untagged S-UNIs in MHSA mode and MAC-BasedS-UNIs in MHMV mode
- RADIUS server provides up to 94 bindings
- for MHMV with multiple bindings, only the last binding is created

#### FA-Client-Type

This attribute is used in packets transmitted to the RADIUS server to inform that the current authenticated MAC is associated to a FA Client of type x. This attribute is defined under Nortel vendor id (562) and uses the value 182.

Only one FA Client per port is supported.

The following values are defined for FA Client type:

- 0: FA Element Not Found
- 1: FA Element Type Other
- 2: FA Server
- 3: FA Proxy
- 4: FA Server No Authentication
- 5: FA Proxy No Authentication

- 6: FA Client Wireless AP Type 1 [clients direct network attachment]
- 7: FA Client Wireless AP Type 2 [clients tunneled to controller]
- 8: FA Client Switch
- 9: FA Client Router
- 10: FA Client IP Phone
- 11: FA Client Camera
- 12: FA Client IP Video
- 13: FA Client Security Device
- 14: FA Client Virtual Switch
- 15: FA Client Server Endpoint
- 16: FA Client ONA SDN mode
- 17: FA Client ONA SPBOIP mode
- 63: FA Client Unknown

Any integer value provided by the FA is sent to the RADIUS server without any check from the EAP application.

### Extreme-Dynamic-MHSA

On EAP-enabled Flex UNI ports, this attribute changes the current interface EAPoL operating mode from MHMV to MHSA.

- defined under Extreme Networks vendor ID 1916 and uses the value 250
- parsed only on ports with Flex-UNI enabled
- value contained in this attribute must be 1

### Extreme-Dynamic-ACL

On EAP-enabled ports, this attribute assigns a dynamic ACL for an EAP-enabled port. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA).

- defined under Extreme Networks vendor ID 1916 and uses the value 251

For more information, see [RADIUS Dynamic User-Based Policies](#) on page 755.

Examples

The following examples provide the RADIUS configuration for the corresponding CLI filter configuration. This example is for MAC 0a:0a:0a:0a:0a:0a on port 1/1 and EAP is in MHMV mode.

```
filter acl 1 type inPort
filter acl port 1 1/1

filter acl ace 1 1 name RadiusGuest-Rule01
filter acl ace ethernet 1 1 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 1 ether-type eq 0x800
filter acl ace ip 1 1 ip-protocol-type eq 17
filter acl ace protocol 1 1 dst-port eq 53
filter acl ace 1 1 action permit
filter acl ace 1 1 enable

filter acl ace 1 2 name RadiusGuest-Rule02
filter acl ace ethernet 1 2 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 2 ether-type eq 0x800
```

```

filter acl ace ip 1 2 dst-ip mask 192.0.2.1 24
filter acl ace 1 2 action permit
filter acl ace 1 2 enable

filter acl ace 1 3 name RadiusGuest-Rule03
filter acl ace ethernet 1 3 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace 1 3 action deny
filter acl ace 1 3 enable

```

The RADIUS VSA does not specify the MAC or the port number because they are already known at the EAP level.

```

Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec ethernet ether-type eq 0x800 & ip ip-protocol-type eq
17 & protocol dst-port eq 53 action permit",
Extreme-Dynamic-ACL += "ace 2 sec ethernet ether-type eq 0x800 & ip dst-ip mask 192.0.2.1
24 action permit",
Extreme-Dynamic-ACL += "ace 3 sec action deny"

```

## EAP-Port-Priority

### Important

Configure these attributes only if you require dynamic port priority.

Port priority (vendor-specific) attributes:

- Vendor ID: value 562 (Nortel)

### Note

Vendor ID 1916 (Extreme) does not support port priority.

- Attribute Number: value 1, Port Priority
- Attribute Value: value 0 (zero) to 6 (this value indicates the port priority value assigned to the specified user)

The following list provides the switch Port Priority frame format:

- vendor specific type = 26
- length = 12
- vendor-id = 562
- string = vendor type = 1 + vendor length = 6 + attribute specific = priority

The following figure shows an example of the port priority frame format.

|    |    |     |    |    |        |
|----|----|-----|----|----|--------|
| 26 | 12 | 562 | 01 | 06 | (0..6) |
|----|----|-----|----|----|--------|

**Figure 48: Port priority frame format**

*IETF Attributes***VLAN RADIUS Attributes**

To control the tagging for traffic egressing a port, configure the preferred tagging option and one of the following attributes on the RADIUS server:

- EGRESS-VLAN-ID
- EGRESS-VLAN-NAME

VLAN attributes are defined by RFC 4675.

**EGRESS-VLAN-ID**

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- untagged EGRESS-VLAN-ID + VLAN-ISID -> VLAN from S-UNI becomes untagged
- untagged EGRESS-VLAN-ID + vid[NEW\_RADIUS\_VID] + autolsidOffset -> create S-UNI for I-SID (VLAN+autolsidOffset)

**Examples**

From the RADIUS attributes, for untagged VLAN 15. The VLAN from S-UNI becomes untagged:

```
Egress-VLANID = "838860815" (untagged vlan 15)
Fabric-Attach-ISID += "15:23513"
```

The following example results in the value 0:1015 for creating an untagged S-UNI.

From the RADIUS attributes, for untagged VLAN 15 and RADIUS-assigned VLAN. Creates S-UNI for I-SID (VLAN+autolsidOffset):

```
Egress-VLANID = "838860815"
Tunnel-Private-Group-Id = "15"
```

From the EAP configuration:

```
eapol auto-isid-offset 1000
eapol auto-isid-offset enable
```

**Considerations**

Consider the following when using this attribute:

- Any combinations with EGRESS-VLAN-ID for a tagged VLAN are ignored.
- When EGRESS-VLAN-ID and VLAN:ISID binding attributes are used, the VLAN must have the same value.
- The RADIUS server can provide more than one VLAN:ISID binding but one must match the VLAN used in EGRESS-VLAN-ID to create an untagged S-UNI.
- Only one EGRESS-VLAN-ID attribute is used. If more than one is found in the packet, only the first one is used.
- If the untagged S-UNI is derived from EGRESS-VLAN-ID + VLAN-ID + VLAN attribute + auto-isid-offset, the packet must not contain any S-UNI bindings.

## EGRESS-VLAN-NAME

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- EGRESS-VLAN-ID + VLAN:I-SID
- EGRESS-VLAN-ID + VLAN + autolsidOffset

This attribute includes the following information:

- Egress-VLAN-Name = "1VLAN\_NAME" for tagged VLAN
- Egress-VLAN-Name = "2VLAN\_NAME" for untagged VLAN
- VLAN\_NAME is the name of the VLAN on the switch

## Example

The following example creates an untagged Switched UNI with I-SID 1000. VLAN 10 is named "Dummy\_VLAN".

```
b0adaa41b830 Cleartext-Password :="b0adaa41b830"
 Service-Type = Framed-User,
 Framed-Protocol = PPP,
 Auth-Type := Accept,
 Fabric-Attach-ISID = "10:1000",
 Egress-VLAN-name = "2Dummy_VLAN"
```

**RADIUS Tunnel Attributes**

The switch uses the RADIUS tunnel attributes to place a port into a particular VLAN to support dynamic VLAN switching based on authentication. The server must send these attributes together in the same RADIUS packet. If one attribute is missing, the switch ignores the others.

The RADIUS server indicates the desired VLAN by including the tunnel attribute within the Access-Accept message. RADIUS uses the following tunnel attributes for VLAN membership:

- RAD\_ATTR\_TUNNEL\_TYPE(64)
  - Tunnel-Type: value 13, Tunnel-Type-VLAN
- RAD\_ATTR\_TUNNEL\_MEDIUM\_TYPE(65)
  - Tunnel-Medium-Type: value 6, Tunnel-Medium-Type-802
- RAD\_ATTR\_TUNNEL\_PRI\_GROUP\_ID
  - Tunnel-Private-Group-ID: ASCII value 1-4094 (this value identifies the specified VLAN)

Tunnel attributes are defined by RFC 2868.

**Important**

Configure these attributes only if you require Dynamic VLAN membership.

The VLAN ID is 12 bits, uses a value from <1-4094>, and is encoded as a string.

In addition, you can configure the RADIUS server to send a vendor-specific attribute (VSA) to configure port priority. You can assign the switch Supplicant port a QoS value from 0 to 6.

For more information, see [EAP-Port-Priority](#) on page 752.

## RADIUS Dynamic User-Based Policies

RADIUS Dynamic User-Based Policies is a security feature to control access services on user devices that connect to the network. Before enabling any services on the user device, the RADIUS server authenticates each device that connects to the switch port and assigns that port to a VLAN or a VLAN to I-SID binding. RADIUS Dynamic User-Based Policies implement a dynamic method to apply filter Access Control List (ACL) rules to Extensible Authentication Protocol (EAP) and Non-EAP (NEAP) authenticated user traffic. The RADIUS server authenticates the user device for switch access and sends rules for that user device to the switch.

The system clears the rules when the following events occur:

- You disable EAPoL globally on the switch.
- EAP and NEAP sessions are cleared.
- You shutdown the port.

### Note

- You must enable RADIUS and EAP over LAN (EAPoL) on the switch. For more information, see [Enabling RADIUS authentication](#) on page 2606 and [Globally enabling EAP on the device](#) on page 767.
- You must configure an EAP-enabled RADIUS server. For more information, see [Configure an EAP-enabled RADIUS Server](#) on page 770.

RADIUS Dynamic User-Based Policies support one time configuration of policy attributes on the RADIUS server and dynamically creates the policies on multiple switches within the network. This process of automatically creating policies enhances the speed of network access for authenticated users and also facilitates faster network synchronization in the event of network-wide policy changes.

Extreme Vendor ID 1916 supports the following RADIUS Vendor Specific Attribute (VSA) for RADIUS Dynamic User-Based Policies:

- Extreme-Dynamic-ACL (ID 251)

For more information, see [RADIUS Attributes](#) on page 750.

The RADIUS server contains the RADIUS VSAs in a configuration file for each EAP or NEAP client that the switch authenticates. Following is an example of a RADIUS VSA configured on the RADIUS server:

```
00000000000a Cleartext-Password :="00000000000a"
Service-Type = Framed-User,
Framed-Protocol = PPP,
Auth-Type := Accept,
Fabric-Attach-ISID = 10:100,
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec name ACE-A1 ethernet ether-type eq 0x800 & action deny count & ip ip-
protocol-type eq 17 & protocol dst-port eq 4000",
```

```
Extreme-Dynamic-ACL += "ace 2 sec name ACE-A2 ethernet ether-type eq ip & ip dst-ip eq 10.10.10.1 &
action deny",
Extreme-Dynamic-ACL += "acl set default-action deny",
```

When the switch receives a new VSA with ACL and Access Control Entries (ACE) rules from the RADIUS server, the switch dynamically creates the ACL infrastructure based on the following:

- Dynamic ACLs - the switch allocates one dynamic ACL for each EAP enabled port. You cannot manually configure the dynamic ACL. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA). RADIUS Dynamic User-Based Policies support the inPort and outPort ACL types. You can display the filter ACL configuration on the switch using the **show filter acl** command, to identify the source of ACL configuration (static or dynamic).
- Dynamic ACEs - after the switch configures an ACL as dynamic, the system automatically considers the ACEs in that ACL as dynamic. You cannot manually configure the ACEs in a dynamic ACL. When the switch receives an ACE rule from the RADIUS server, the system allocates an ACE ID to it. Each ACE rule carries a relative order that helps the switch to set priority for the ACE rules that the switch receives. For handling of Radius ACL rules, the switch parses the rules first. Based on the actions, the system classifies the rules as security ACEs or QoS ACEs. If the switch is unable to recognize the qualifiers or actions in a rule, then the switch ignores that rule.
- Multiple Host Multiple VLAN (MHMV) operating mode - the system authenticates each MAC that the switch receives on the EAP-enabled port and assigns the MAC to a specific VLAN or VLAN to I-SID binding. The system uses the VLAN to I-SID binding when Flex UNI is enabled on a port. The system processes the ACE rules that the switch receives from the RADIUS server on a per MAC basis, the system translates the default-action into an ACE rule with actions, deny or permit. When the switch processes the RADIUS VSAs, the system adds the MAC as a qualifier for each ACE rule.
- Multiple Host Single Authentication (MHSA) operating mode - the system processes the ACE rules that it receives from the RADIUS server on a per port basis.

## NEAP host

The following section provides information about NEAP hosts on EAP-enabled ports and RADIUS authentication.

### *NEAP Hosts on EAP Enabled Ports*

For an EAP-enabled port configured for NEAP host support, devices with MAC addresses getting authenticated are allowed access to the port.

The switch allows the following types of NEAP users:

- NEAP hosts whose MAC addresses are authenticated by RADIUS.

Support for NEAP hosts on EAP-enabled ports is primarily intended to accommodate printers and other passive devices sharing a hub with EAP clients.

Support for NEAP hosts on EAP-enabled ports includes the following features:

- Authenticated NEAP clients are hosts that satisfy one of the following criteria:
  - Host MAC address is authenticated by RADIUS.
- NEAP hosts are allowed even if no authenticated EAP hosts exist on the port.

- When a new host is seen on the port, NEAP authentication is performed as follows:
  - The switch generates a <username, password> pair, which it forwards to the network RADIUS server for authentication.

### NEAP MAC RADIUS Authentication

For RADIUS authentication of a NEAP host MAC address, the switch generates a <username, password> pair as follows:

- The username is the NEAP MAC address in string format.
- The password is a string that combines the switch IP address, MAC address, port number and user-configurable key string. If padding option is enabled, the system will specify a dot(.) for every missing parameter. IP address is represented by three decimal characters per octet.

#### Important

Follow these Global Configuration examples to select a password format that combines one or more of these three elements:

- Padding enabled , password = 010010011253..05. (when the switch IP address and port are used).
- Padding enabled, password = 010010011253... (when only the switch IP address is used).
- No padding (default option). Password = 000011220001 (when only the user's MAC address is used).

The following example illustrates the <username, password> pair format with no padding enabled and using the IP address, MAC address, and key-string as the password.

```
switch IP address = 192.0.2.5
non-EAP host MAC address = 00 C0 C1 C2 C3 C4
port = 25
Key-String = abcdef
```

- username = 00C0C1C2C3C4
- password = 010010011253.00C0C1C2C3C4.25.abcdef

Use the command **show eapol system** to verify the formatting.

```
Switch:1(config)#show eapol system
```

```
=====
 Eapol System
=====
 eap : enabled
 Eapol Version : 3
 non-eap-pwd-fmt : mac-addr
 non-eap-pwd-fmt key : *****
 non-eap-pwd-fmt padding : disabled
 auto-isid-offset status : disabled
 auto-isid-offset value : 15980000
```

## NEAP client

The following section provides information for NEAP client.

### NEAP Client Re-Authentication

The NEAP client re-authentication feature supports the re-authentication of NEAP clients at defined intervals.

When you enable NEAP client re-authentication, an authenticated NEAP client is only removed from the authenticated client list if you remove the client account from the RADIUS server, or if you clear the NEAP authenticated client from the switch.

If an authenticated NEAP client does not generate traffic on the network, the system removes the MAC address for that client from the MAC address table when MAC ages out. Although the client MAC address does not appear in the MAC Address table, the client can appear as an authenticated client.

If you enable NEAP client re-authentication and the RADIUS server that the switch connects to becomes unavailable, the system clears all authenticated NEAP and removes those clients from the switch NEAP client list.

You cannot authenticate one NEAP client on more than one switch port simultaneously. If you connect NEAP clients to a switch port through a hub, those clients are authenticated on that switch port. If you disconnect a NEAP client from the hub and connect it directly to another switch port, the client is authenticated on the new port and its authentication is removed from the port to which the hub is connected.

### MAC Move for Authenticated Non-EAP Clients

When you move a Non-EAP client that is authenticated on a specific port, to another port on which EAPoL or Non-EAP is enabled, MAC move of the client to the new port does not automatically happen. This is as designed.

As a workaround, do one of the following:

- Clear the non-EAP session on the port that the client is first authenticated on, before you move the client to another port.
- Create a VLAN on the switch with the same VLAN ID as that dynamically assigned by the RADIUS server during client authentication. Use the command **vlan create <2-4059> type port-mstprstp <0-63>**. Ensure that the new port is a member of this VLAN.

### NEAP MAC Learning and Authentication

The system learns the MACs based on the I-SID to MAC binding. When a packet ingresses on a port, which is associated with Switched UNI (S-UNI) I-SID, the system performs MAC look up based on the I-SID. The RADIUS server provides the VLAN:ISID assignment.

#### Important

If the default untagged S-UNI is used, you must have a platform VLAN associated with it. This is required to properly transmit traffic and to generate MAC learning events for traffic sent to MAC-based S-UNIs.

When an untagged S-UNI is present on the port, the untagged MAC is initially learned on that S-UNI. When an untagged S-UNI does not exist on the port, the untagged MAC is learned on a special (internal) VLAN. The RADIUS server provides the VLAN:ISID assignment.

MAC learning for tagged traffic occurs only if there is a tagged S-UNI with the corresponding C-VID on that port. The RADIUS server reconfirms the S-UNI that performed MAC learning.

## EAP and NEAP Limitations

The EAP and NEAP MAC clients on port limits the maximum number of all EAP and NEAP clients per port. EAP and NEAP MAC clients on port enhancements independently limits the EAP and NEAP clients per port.

The following enhancements are added:

- EAP-MAC-MAX : Limits the total number of EAP clients
- NON-EAP-MAC-MAX: Limits the total number of NEAP clients

### Note

Do not connect more than 100 EAP and 100 NEAP devices on the switch.

### *EAP and NEAP mac-max Settings*

The total number of EAP clients can be set between 0 and 32, while the total number of NEAP clients can be set between 0 and 8192.

### Note

EAP-MAC-MAX is overwritten by MAC-MAX. Even if EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

### Note

NON-EAP-MAC-MAX is overwritten by MAC-MAX. Even if NON-EAP-MAC-MAX is set to a higher limit, then MAC-MAX must not exceed and you must not authenticate more than MAC-MAX clients.

## Example Scenarios

1. Scenario 1:
  - EAP-MAC-MAX 32
  - NON-EAP-MAC-MAX 32
  - MAC-MAX 10

In this scenario, there are ten EAP and NEAP authenticated clients, in the order of authentication.

2. Scenario 2:
  - EAP-MAC-MAX 1
  - NON-EAP-MAC-MAX 1
  - MAC-MAX 1

In this scenario, only one EAP or one NEAP client is authenticated, in the order of authentication.

3. Scenario 3:
  - EAP-MAC-MAX 5
  - NON-EAP-MAC-MAX 10
  - MAC-MAX 32

In this scenario, up to five EAP clients and ten NEAP clients are allowed.

4. Scenario 4:

- EAP-MAC-MAX 5
- NON-EAP-MAC-MAX 8
- MAC-MAX 7

In this scenario, up to five EAP clients and seven NEAP clients are allowed. The total number of EAP or NEAP clients is limited to seven.

## Multiple Host Single Authentication

Multiple Host Single Authentication (MHSA) allows MACs to access the network without EAP and NEAP authentication. Unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on a port. The VLAN to which the devices are allowed is the client authenticated VLAN. Unless Guest VLAN is configured, there is no authenticated client on the port, and no MAC is allowed to access the network.

MHSA is primarily intended to accommodate printers and other passive devices sharing a hub with EAP and NEAP clients.

MHSA support is on a port-by-port basis for EAP enabled ports.

MHSA supports the following functionality:

- The port remains unauthorized when no authenticated hosts exist on the port. Before the first successful authentication occurs, both EAP and NEAP clients are allowed to negotiate access on that port but only one host is allowed to perform authentication.
- In MHSA mode, QoS level is configured when processing the Port-Priority attribute, because there can only be one authenticated client. The devices behind the authenticated client use the port priority established by the main client.
- In MHSA mode, the Guest VLAN applies only when no authenticated client is present on the port.
- After the first EAP or NEAP client successfully authenticates on a port, other clients cannot negotiate authentication on that port.
- After the first successful authentication, MACs that are already learned on that port is flushed.
- NEAP clients are not removed at age event in MHSA mode.
- There is no limit to the number of MACs that are allowed after first successful authentication.

### *EAP and NEAP MAC Clients on a Port with MHSA*

EAP and NEAP client counters, such as MAC-MAX, EAP-MAC-MAX, and NON-EAP-MAC-MAX do not apply when the port operates in MHSA mode. In MHSA mode, there can be only one authenticated client (EAP or NEAP). Subsequent MACs seen on the port are allowed automatically without authentication.

## Guest VLAN

Guest VLAN support provides limited network access until the client is authenticated. Guest VLAN is configured irrespective of the number of authenticated clients present on the port. Guest VLAN is

available for each port. Only port based VLANs are used as Guest VLANs. When the Guest VLAN is active, port is added to the VLAN ID, and port default VLAN ID changes to Guest VLAN ID.

#### Guest VLAN on a MHMV Port Usage Scenario

The following example illustrates the configuration of Guest VLAN support with an EAP MHMV port:

- Clients connect to a switch port through a hub.
- The initial VLANs are the VLANs on which the ports resides after a switch reboot.
- EAP is enabled.
- The port is a member of initial VLANs. The clients cannot access the VLANs since the VLANs are not authenticated. The port default VLAN ID corresponds to one of the initial VLAN IDs.
- Guest VLAN support is not activated.

The following figure represents the functionality when clients are not authenticated.

#### Note

The clients cannot access the network as they are not authenticated and Guest VLAN is not configured.

- Guest VLAN support is activated.
- The MHMV port is in the initial VLAN stage but gets added to the Guest VLAN ID. The default VLAN ID is updated to correspond to the Guest VLAN ID.

- All Clients behind the port can access the Guest VLAN.

The following figure represents the functionality when Guest VLAN is activated.

#### Note

All clients have Guest VLAN access.

- A client behind the MHSV port gets authenticated. For this usage scenario let us consider PC1 as the authenticated client.
- The port default VLAN ID is equal to the Guest VLAN ID and remains unchanged.
- The port is copied into the RADIUS assigned VLAN (if any).
- The untagged traffic that originates from PC1 (identified by MAC address) can access only the RADIUS assigned VLAN or the initial port default VLAN ID, if the RADIUS VLAN attribute is missing.
- The remaining clients that send untagged traffic are unauthenticated devices. The unauthenticated devices can access only the Guest VLAN because the port VLAN ID is equal to the Guest VLAN ID.
- The initial VLANs are accessed by the following devices:
  - Authenticated devices that are missing RADIUS VLAN attributes.
  - Authenticated devices that send corresponding tagged packets.
- When another client gets authenticated, the authenticated client undergoes the same process as PC1.

The following figure represents the functionality when a client gets authenticated:

#### Note

PC1 is authenticated with RADIUS VLAN 1. The remain clients have guest VLAN access.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN. If other clients are authenticated on that RADIUS VLAN, then the VLAN MAC rule is deleted.
- If RADIUS VLAN attribute is not used when the client is authenticated, then only the VLAN MAC rule is deleted.

#### *Guest VLAN on a MHSV Port Usage Scenario*

The following is a usage example when Guest VLAN is configured with an EAP MHSV port:

- There are no authenticated EAP or NEAP clients on a port.
- The port is removed from the initial VLANs and moved to Guest VLAN ID.
- The default port VLAN ID changes to Guest VLAN ID.
- All MACs seen on the port have Guest VLAN access.
- Port is removed from the Guest VLAN ID.
- If no RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is restored to default settings.

- If the RADIUS assigned VLAN is present, then the VLAN membership and the default port VLAN ID is changed according to its value.
- Guest VLAN loses its purpose because all MACs are allowed automatically without authentication

In MHSa mode, the Guest VLAN applies only when no authenticated client is present on the port.

## Guest I-SID

Guest I-SID support provides limited network access until the client is authenticated. The switches uses the Guest I-SID to forward traffic until the client authenticates and receives other VLAN:I-SID bindings from the RADIUS server.

Guest I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Guest I-SID. After you configure the Guest I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Guest I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

In MHSa mode, only one untagged S-UNI can exist on a port at one time. Consider the following:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID replaces it.
- If the RADIUS server provides an untagged S-UNI after the client is authenticated, it replaces the untagged S-UNI, which was created based on the Guest I-SID.
- If the Guest I-SID is removed, the previous manually configured untagged S-UNI is automatically restored.
- If the RADIUS-assigned untagged S-UNI is no longer present, EAP recreates the untagged S-UNI created base on the Guest I-SID.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNI on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Guest I-SID, replaces it.
- If the Fail-Open I-SID and the Guest I-SID are both configured, the Guest I-SID is applied, as long as a RADIUS server is reachable.
- If the RADIUS server becomes unreachable, the untagged S-UNI based on the Fail-Open I-SID is removed and the untagged S-UNI is created based on the Guest I-SID.

## EAP and NEAP separation

EAP and NEAP separation provide the ability to have only NEAP clients allowed on one port. This is done by allowing `eap-mac-max` to be set to 0. This enhancement gives you the ability to disable EAP clients authentication without disabling NEAP clients. There are no additional configuration commands. For more information, see [Configuring maximum EAP clients](#) on page 782 and [Configuring maximum NEAP clients](#) on page 783.

## EAP and NEAP VLAN names

VLAN names configures VLAN membership of EAP and NEAP clients. You do not have to configure this feature as this mode is always enabled by default.

## Fail Open VLAN

Fail Open VLAN provides network connectivity when the switch cannot connect to a RADIUS server. If the switch cannot connect to the primary and secondary RADIUS servers, then after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable. Fail Open VLAN provides the below functionality:

- When the EAP RADIUS servers are not reachable, Fail Open VLAN provides restricted access to devices, which is separate from the Guest VLAN.
- The EAP and NEAP clients are not affected when the RADIUS servers are not reachable.

Fail Open VLAN is a per-port option. Enable Fail Open VLAN by setting a valid Fail Open VLAN ID. Configure the selected VLAN ID on the switch. Only port based VLANs must be used as Fail Open VLANs.

When you configure Fail Open VLAN on a port and the RADIUS servers are not reachable, then the Fail Open VLAN provides the following functionality:

- The port is removed from Guest VLAN if configured, but all other VLAN membership is kept and in addition the port is added to the Fail Open VLAN.
- Default VLAN ID is changed to Fail Open VLAN ID.
- Traffic from the authenticated EAP and NEAP clients are forwarded as before.
- If re-authentication is enabled in Fail Open VLAN mode, then EAP and NEAP clients stop performing re-authentication.
- All new MACs seen on the port are considered as potential EAP and NEAP clients and is granted Fail Open VLAN access.

When at least one RADIUS server recovers, all EAP enabled ports are removed from the Fail Open VLAN. All unauthenticated MACs are flushed in order to give the MACs an opportunity to authenticate.

### *Fail Open VLAN with Guest VLAN scenarios*

When an EAP port is configured with both Fail Open VLAN and Guest VLAN, consider the following scenarios:

1. EAP port operating in MHMV mode:
  - If the EAP RADIUS servers are reachable, then all the authenticated clients have Guest VLAN ID access.
  - If the EAP RADIUS servers are not reachable, then Guest VLAN must be removed from the port completely. Fail Open VLAN is the new default VLAN. All unauthenticated MACs have Fail Open VLAN access.
2. EAP port operating in MHSA mode:
  - Fail Open VLAN has no impact on the Guest VLAN functionality in MHSA mode.

## Fail Open I-SID

Fail Open I-SID provides network connectivity with restricted access to devices when the switch cannot connect to a RADIUS server. If the switch cannot connect to the primary and secondary RADIUS servers after a specified number of attempts to restore connectivity, the switch declares the RADIUS servers unreachable.

### Note

EAP and NEAP clients are not affected when the RADIUS servers are unreachable.

Fail Open I-SID is a per-port option. You must configure an I-SID either as a C-VLAN or as an ELAN with an associated platform VLAN before you can configure it as the Fail-Open I-SID. After you configure the Fail Open I-SID and you enable EAP, an untagged S-UNI is created based on the supplied I-SID. When you change the Fail Open I-SID while EAP is enabled, the untagged S-UNI is replaced on the port.

### Note

Fail-Open I-SID is not supported in MHSA mode.

In MHMV mode, the untagged S-UNIs provided by the RADIUS server are treated as MAC-based untagged S-UNIs, which are different from the untagged S-UNIs on the port. Consider the following factors:

- If there is a manually configured untagged S-UNI on the port, the untagged S-UNI, which uses the Fail Open I-SID, replaces it.
- Caution is advised when both Fail-Open I-SID and Guest I-SID are configured. In this scenario, if a RADIUS server becomes reachable, the untagged S-UNI created based on the Fail-Open I-SID is removed and another untagged S-UNI based on the Guest I-SID is created.

## EAP Auto-ISID-Offset

EAP auto-isid-offset functionality is used for MACs that do not receive an I-SID attribute from the RADIUS server. The configured I-SID offset value is used to calculate an I-SID value for a Switched UNI (S-UNI) when the switch receives only the VLAN attribute from the RADIUS server (not the FA VLAN:ISID binding). In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

## Wake On LAN

Wake On LAN (WoL) networking standard enables remotely powering-up a shutdown computer from a sleeping state. In this process, the computer is shutdown with power reserved for the network card. A packet known as Magic Packet is broadcast on the local LAN or subnet. The network card on, receiving the Magic Packet, verifies the information. If the information is valid, the network card powers-up the shutdown computer.

The WoL Magic Packet is a broadcast frame sent over a variety of connectionless protocols, such as UDP. The most commonly used connectionless protocol is UDP. The Magic Packet contains data that is a defined constant represented in hexadecimal as FF:FF:FF:FF:FF:FF, followed by 16 repetitions of the target computer MAC address and possibly by a four or six byte password.

If you implement enhanced network security using 802.1X, the transmission of Magic Packets to sleeping or unauthorized network devices is blocked. You can use an interface specific 802.1X feature known as traffic-control to address this requirement of supporting both WoL and 802.1X Authentication simultaneously. The default mode is *in-out*. This mode blocks both ingress and egress unauthenticated traffic on an 802.1X port. Configuring the traffic control mode to *in* enables the transmission of Magic Packets to sleeping or unauthenticated devices. This mode allows any network control traffic, such as a WoL Magic Packet, to be sent to a workstation irrespective of the authentication or sleep status.

**Important**

If a PC client is assigned to a VLAN based on a previous RADIUS Assigned VLAN, when the client goes into sleep or hibernation mode it reverts to either the default port-based VLAN or Guest VLAN configured for that port. Therefore, the WoL Magic Packet must be sent to the default VLAN or Guest VLAN.

## EAPoL configuration using CLI

---

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.

You cannot configure EAP on ports that are currently configured for:

- Shared segments
- MultiLink Trunking (MLT)

Change the status of each port that you want to be controlled to auto. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is authorized.

You can connect only a single client on each port configured for EAP. If you attempt to add additional clients on the EAP authorized port, then the system denies access to the new client and displays a warning message.

### Globally enabling EAP on the device

Enable EAP globally on the switch before you enable it on a port or interface.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Globally configure EAP:  
`eapol enable`

## Example

Enable EAP globally:

```
Switch:1> enable
Switch:1#config t
Switch:1(config)#eapol enable
```

## Configuring EAP on an interface

Configure EAP on an interface.

### Before You Begin

- EAP must be globally enabled.

### About This Task

When you configure a port with the EAP status of auto (Authorization depends on result of EAP authentication), only one supplicant is allowed on this port. Multiple EAP supplicants are not allowed on the same physical switch port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable EAP on an interface:

```
eapol status {authorized|auto}
```

3. Disable EAP on on interface:

```
no eapol status
```

### Example

Enable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# eapol status auto
```

Disable EAP on an interface:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)# no eapol status
```

### Variable Definitions

The following table defines parameters for the **eapol status** command.

| Variable          | Value                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authorized</i> | Specifies that the port is always authorized. The default value is authorized.                                                            |
| <i>auto</i>       | Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized. |

## Configuring EAP on a port

Configure EAP on a specific port when you do not want to apply EAP to all of the switch ports.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} max-
request <1-10>
```

3. Configure the time interval between authentication failure and the start of a new authentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
quiet-interval <1-65535>
```

4. Enable reauthentication:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication enable
```

5. Configure the time interval between successive authentications:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication-period <1-65535>
```

#### Note

The EAP re-authentication period value is between 1-65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1-2147483647. Trying to configure above 65535 results in an error.

6. Configure the EAP authentication status:

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
status {authorized|auto}
```

### Example

Configure the maximum EAP requests sent to the supplicant before timing out the session:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#eapol max-request 10
Switch:1(config-if)#eapol port 1/2 quiet-interval 500
```

### Variable Definitions

The following table defines parameters for the **eapol port** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Specifies the port or list of ports used by EAP. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>max-request &lt;1-10&gt;</i>                              | Specifies the maximum EAP requests sent to the supplicant before timing out the session. The default is 2.                                                                                                                                                                                                                                                                                                     |
| <i>quiet-interval &lt;1-65535&gt;</i>                        | Specifies the time interval in seconds between the authentication failure and start of a new authentication. The default is 60.                                                                                                                                                                                                                                                                                |
| <i>re-authentication enable</i>                              | Enables reauthentication of an existing supplicant at a specified time interval.                                                                                                                                                                                                                                                                                                                               |
| <i>re-authentication-period &lt;1-65535&gt;</i>              | Specifies the time interval in seconds between successive reauthentications. The default is 3600 (1 hour).<br><br><b>Note:</b><br>The EAP re-authentication period value is between 1–65535. Early releases support up to 2147483647. To maintain backward compatibility the CLI value is between 1–2147483647. Trying to configure above 65535 results in an error.                                           |
| <i>status {authorized auto}</i>                              | Specifies the desired EAP authentication status for this port.                                                                                                                                                                                                                                                                                                                                                 |

## Configure an EAP-enabled RADIUS Server

The switch uses RADIUS servers for authentication and accounting services. Use the no form to delete a RADIUS server.

### Before You Begin

- You must enable EAP globally.

## About This Task

The RADIUS server uses the secret key to validate users.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add an EAP-enabled RADIUS server:

```
radius server host WORD <0-46> used-by eapol acct-enable
```

```
radius server host WORD <0-46> used-by eapol acct-port <1-65536>
```

```
radius server host WORD <0-46> used-by eapol enable
```

```
radius server host WORD <0-46> used-by eapol key WORD<0-20>
```

```
radius server host WORD <0-46> used-by eapol port <1-65536>
```

```
radius server host WORD <0-46> used-by eapol priority <1-10>
```

```
radius server host WORD <0-46> used-by eapol retry <0-6>
```

```
radius server host WORD <0-46> used-by eapol secure-enable
```

```
radius server host WORD <0-46> used-by eapol secure-log-level
```

```
radius server host WORD <0-46> used-by eapol secure-mode
```

```
radius server host WORD <0-46> used-by eapol secure-profile
```

```
radius server host WORD <0-46> used-by eapol source-ip WORD <0-46>
```

```
radius server host WORD <0-46> used-by eapol timeout <1-180>
```

By default, the switch uses RADIUS UDP port 1812 for authentication, and port 1813 for accounting.

You can change the port numbers or other RADIUS server options.

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Add an EAP RADIUS server:

```
Switch:1(config)# radius server host fe80:0:0:0:21b:4fff:fe5e:73fd key
radiustest used-by eapol
```

### Variable Definitions

The following table defines parameters to configure an EAP-enabled RADIUS server with the **radius server host** command.

| Variable               | Value                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host</i> WORD<0-46> | Specifies the IP address of the selected server. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration. |
| <i>WORD</i> <0-20>     | Specifies the secret key, which is a string of up to 20 characters.                                                                             |

The following table defines parameters to use optional arguments of the **radius server host** command.

| Variable                                                                                     | Value                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port</i> <1-65535>                                                                        | Specifies the port ID number.                                                                                                                                                                       |
| <i>priority</i> <1-10>                                                                       | Specifies the priority number. The lowest number is the highest priority.                                                                                                                           |
| <i>retry</i> <0-6>                                                                           | Specifies the retry count of the account.                                                                                                                                                           |
| <i>timeout</i> <1-180>                                                                       | Specifies the timeout of the server. The default is 30.                                                                                                                                             |
| <i>enable</i>                                                                                | Enables the functions used by the RADIUS server host.                                                                                                                                               |
| <i>acct-port</i> <1-65536>                                                                   | Specifies the port account.                                                                                                                                                                         |
| <i>acct-enable</i>                                                                           | Enables the account.                                                                                                                                                                                |
| <i>secure-enable</i>                                                                         | Enable secure mode on the server.                                                                                                                                                                   |
| <i>secure-log-level</i>                                                                      | Specifies the RADIUS secure server log severity level. Possible values are: <ul style="list-style-type: none"> <li>critical</li> <li>debug</li> <li>error</li> <li>info</li> <li>warning</li> </ul> |
| <i>secure-mode</i>                                                                           | Specifies the protocol for establishing the secure connection with the server.                                                                                                                      |
| <i>secure-profile</i>                                                                        | Specifies the secure profile name.                                                                                                                                                                  |
| <i>source-ip</i> WORD<0-46><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Specifies the IP source. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                             |

## Configuring the switch for EAP and RADIUS

Perform the following procedure to configure the switch for EAP and RADIUS.

## About This Task

You must configure the switch, through which user-based-policy (UBP) users connect to communicate with the RADIUS server to exchange EAP authentication information, as well as user role information. You must specify the IP address of the RADIUS server, as well as the shared secret (a password that authenticates the device with the RADIUS server as an EAP access point). You must enable EAP globally on each device, and you must configure EAP authentication on each device port, through which EAP/UBP users connect.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

For more information about EPM and UBP, see the user documentation for your Enterprise Policy Manager (EPM) application.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create a RADIUS server that is used by EAP:  

```
radius server host WORD <0-46> key WORD<0-20> used-by eapol
```
3. Log on to the Interface Configuration mode:  

```
interface vlan <1-4059>
```
4. Enable the device to communicate through EAP:  

```
eapol enable
```
5. Exit from VLAN interface mode:  

```
exit
```
6. Enter Interface Configuration mode:  

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```
7. Enable device ports for EAP authentication:  

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} status
auto
```
8. Enable periodic supplicant re-authenticating:  

```
eapol port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} re-
authentication enable
```
9. Save your changes:  

```
save config
```

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Create a RADIUS server that is used by EAP:

```
Switch:1(config)# radius server host fe90:0:0:0:21b:4eee:fe5e:75fd key
radiustest used-by eapol

Switch:1(config)# interface vlan 2

Enable the device to communicate through EAP:

Switch:1(config-if)# eapol enable

Save your changes:

Switch:1(config-if)# save config
```

### Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host WORD&lt;0-46&gt;</i> | Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                                    |
| <i>key WORD&lt;0-20&gt;</i>  | Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here. |

## Change the Authentication Status of a Port

The switch authorizes ports by default, which means that the ports are always authorized and are not authenticated by the RADIUS server.

You can also make the ports controlled so that they are dependent on being authorized by the Radius Server when you globally enable EAP (auto).

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the authorization status of a port:

```
eapol status {authorized|auto}
```

### Example

Configure the authorization status of a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 3/1
Switch:1(config-if)#eapol status auto
```

### Variable Definitions

The following table defines parameters for the **eapol status** command.

| Variable          | Value                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authorized</i> | Specifies that the port is always authorized. The default value is authorized.                                                            |
| <i>auto</i>       | Specifies that port authorization depends on the results of the EAP authentication by the RADIUS server. The default value is authorized. |

## Deleting an EAP-enabled RADIUS server

Delete an EAP-enabled RADIUS server if you want to remove the server.

### About This Task

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Delete an EAP-enabled RADIUS server:
 

```
no radius server host WORD<0-46> used-by eapol
```

### Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# no radius server host fe79:0:0:0:21d:4fdf:fe5e:73fd
used-by eapol
```

### Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> usedby eapol** command.

| Variable                     | Value                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>host WORD&lt;0-46&gt;</i> | Specifies the IP address of the selected server. This address tells the device where to find the RADIUS server, from which it obtains EAP authentication and user role information. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration.                                                                                    |
| <i>key WORD&lt;0-20&gt;</i>  | Specifies the shared secret key that you use for RADIUS authentication. The shared secret is held in common by the RADIUS server and all EAP-enabled devices in your network. It authenticates each device with the RADIUS server as an EAP access point. When you configure your RADIUS server, you must configure the same shared secret value as you specify here. |

## Configuring Fail Open VLAN

### About This Task

Use this procedure to configure Fail Open VLAN.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open VLAN:

```
eapol fail-open-vlan <1-4059>
```

### Example

Configure the Fail Open VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol fail-open-vlan 10
```

### Variable Definitions

The following table defines parameters for the **eapol fail-open-vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Display the Current EAP-Based Security Status

Use the following procedure to display the status of the EAP-based security.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the current EAP-based security status:  

```
show eapol auth-stats interface [gigabitEthernet {slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]

show eapol multihost non-eap-mac status [vlan <1-4059>] [{slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]]

show eapol port {interface [gigabitEthernet {slot/port[/sub-port]} [-
slot/port[/sub-port]] [,...]] | {slot/port[/sub-port]} [-slot/port[/
sub-port]] [,...]]

show eapol session-stats interface [gigabitEthernet {slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]]

show eapol status interface [vlan <1-4059>] [gigabitEthernet {slot/
port[/sub-port]} [-slot/port[/sub-port]] [,...]]

show eapol summary port [{slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]]

show eapol system
```

### Examples

#### Note

Product Notice: auto-isid-offset functionality is not available on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

```
Switch:#enable
Switch:1#show eapol system
=====
```

```

 Eapol System
=====
 eap : disabled
 Eapol Version : 3
 non-eap-pwd-fmt : mac-addr
 non-eap-pwd-fmt key : *****
 non-eap-pwd-fmt padding : disabled
 auto-isid-offset status : disabled
 auto-isid-offset value : 1000

```

Variable Definitions

The following table defines parameters for the **show eapol** command.

| Variable                                                                                                                                               | Value                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>auth-stats</i><br><i>[gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i>                                                     | Displays the authentication statistics interface.<br><br><b>Note:</b><br><i>auth-stats [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i> is useful only for EAP supplicants. The command output changes only when the EAP supplicant tries to access the network. |
| <i>multihost non-eap-mac status [vlan &lt;1-4059&gt;]</i><br><i>[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i>                             | Displays EAP multihost configuration.                                                                                                                                                                                                                                                      |
| <i>port {interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]   {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]}</i> | Specifies the ports to display. If no port is entered, all ports are displayed.                                                                                                                                                                                                            |
| <i>session-stats interface [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i>                                                  | Displays the authentication session statistics interface.                                                                                                                                                                                                                                  |
| <i>status interface [vlan &lt;1-4059&gt;] [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i>                                   | Displays the port EAP operation statistics.                                                                                                                                                                                                                                                |
| <i>summary port[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]</i>                                                                              | Displays EAP and NEAP clients.                                                                                                                                                                                                                                                             |
| <i>system</i>                                                                                                                                          | Displays EAP settings.                                                                                                                                                                                                                                                                     |

## Displaying the port VLAN information

Use the following procedure to display the port VLAN information.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the port VLAN information:

```
show interfaces [gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] [vlan <1-4059>]
```

### Example

```
Switch:#enable
Switch:1#show interfaces gigabitEthernet vlan
=====
Port Vlans
=====
PORT DISCARD DISCARD DEFAULT VLAN PORT UNTAG DYNAMIC UNTAG
NUM TAGGING TAGFRAM UNTAGFRAM VLANID IDS TYPE DEFVLAN VLANS VLANS

1/1 disable false false 1 1 normal disable P 1
1/2 enable false false 1 1,3,10 normal disable P 1,10
1/3 enable false false 1 1,10,20 normal disable P
```

### Variable Definitions

The following table defines parameters for the **show interfaces** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Configuring the format of the RADIUS password attribute when authenticating NEAP MAC addresses using RADIUS

Use the following procedure to configure the format of the RADIUS password when authenticating NEAP MAC addresses using RADIUS.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the RADIUS password format:
 

```
eapol multihost non-eap-pwd-fmt {[ip-addr] [key WORD<1-32>] [mac-addr]
[padding] [port-number]}
```

### Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-pwd-fmt** command.

| Variable                    | Value                                                              |
|-----------------------------|--------------------------------------------------------------------|
| <i>ip-addr</i>              | Management ip-address of the switch.                               |
| <i>key WORD&lt;1-32&gt;</i> | Key value used for non-eap password format.                        |
| <i>mac-addr</i>             | Mac-Address of the client.                                         |
| <i>padding</i>              | Includes a dot in the RADIUS password for every missing parameter. |
| <i>port-number</i>          | Index of the port on which MAC is received.                        |

#### Note

To derive the port number for an interface, use the command **show interfaces gigabit** **[{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]]** .

If you configure interface 1/6 on the product, to derive the port-number for this interface, use the command **show interfaces gigabitEthernet 1/6**. From this command, you can ascertain that port number used in the NEAP password is 197.

```
Switch:1(config)# show interfaces gigabitEthernet 1/6

=====
 Port Interface
=====
PORT INDEX DESCRIPTION LINK PORT PHYSICAL STATUS
NUM INDEX DESCRIPTION TRAP LOCK ADDRESS ADMIN OPERATE

1/6 197 1000BaseTX true false f8:15:47:e1:dd:05 up up
```

## Enabling RADIUS authentication of NEAP hosts on EAP enabled ports

For RADIUS authentication of NEAP hosts on EAP-enabled ports, you must enable EAP globally on the switch and then enable NEAP hosts on the local interface.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS authentication of NEAP hosts on the local interface:

```
eapol multihost radius-non-eap-enable
```

## Configuring the maximum MAC clients

Use this procedure to configure the maximum EAP and NEAP MAC clients supported on a port.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the maximum limit of allowed EAP and NEAP MAC clients supported on the port:

```
eapol multihost mac-max <1-8192>
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/16
Switch:1(config-if)# eapol multihost mac-max <1-8192>
```

### Variable Definitions

The following table defines parameters for the **eapol multihost mac-max** command.

| Variable                | Value                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>mac-max</i> <1-8192> | Specifies the maximum number of EAP and NEAP MAC addresses allowed on the port. The maximum limit is 8192 MAC addresses. |

## Configuring maximum EAP clients

### About This Task

Use this procedure to configure the maximum EAP clients allowed on the port at one time.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum EAP clients:

```
eapol multihost eap-mac-max <0-32>
```

#### Note

*eap-mac-max* is also used to provide EAP and NEAP separation functionality. By default the EAP clients are enabled per port and *eap-mac-max* limit is 2. If *eap-mac-max* is set to 0 then EAP client authentication is disabled.

### Example

Configure the maximum EAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost eap-mac-max 10
```

### Variable Definitions

The following table defines parameters for the `eapol multihost eap-mac-max` command.

| Variable | Value                                                                                |
|----------|--------------------------------------------------------------------------------------|
| <0-32>   | Specifies the maximum EAP clients allowed on the port at one time. The default is 2. |

## Configuring maximum NEAP clients

### About This Task

Use this procedure to configure the maximum NEAP clients allowed on the port at one time.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum NEAP clients:

```
eapol multihost non-eap-mac-max <0-8192>
```

#### Note

`non-eap-mac-max` is also used to provide EAP and NEAP separation functionality. By default the NEAP clients are enabled per port and `non-eap-mac-max` limit is 2. If `non-eap-mac-max` is set to 0 then NEAP client authentication is disabled.

### Example

Configure the maximum NEAP clients allowed on the port at one time.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol multihost non-eap-mac-max 10
```

### Variable Definitions

The following table defines parameters for the **eapol multihost non-eap-mac-max** command.

| Variable | Value                                                                                 |
|----------|---------------------------------------------------------------------------------------|
| <0-8192> | Specifies the maximum NEAP clients allowed on the port at one time. The default is 2. |

## Configuring the Guest VLAN ID

### About This Task

Use this procedure to configure the Guest VLAN ID.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest VLAN ID:

```
eapol guest-vlan <1-4059>
```

### Example

Configure the Guest VLAN ID.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol guest-vlan 10
```

### Variable Definitions

The following table defines parameters for the **eapol guest-vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Clearing NEAP session

Use this procedure to clear the NEAP session that is learnt on the switch.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the NEAP session:

```
clear eapol non-eap [<0x00:0x00:0x00:0x00:0x00:0x00>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
<0x00:0x00:0x00:0x00:0x00:0x00>]
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# clear 1/16 00:1b:63:84:45:e6
```

### Variable Definitions

The following table defines parameters for the **clear eapol non-eap** command.

| Variable                                               | Value                                                    |
|--------------------------------------------------------|----------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | Specifies the port list on which the NEAP MAC is learnt. |
| 0x00:0x00:0x00:0x00:0x00:0x00                          | Specifies the MAC-Address on the NEAP session.           |

## Configuring EAP operational mode

### About This Task

Use this procedure to configure the EAP operational mode.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. configure the EAP operational mode:

```
eapol multihost eap-oper-mode {mhmV | mhSa}
```

**Note**

The default EAP operational mode is MHMV.

**Example**

Configure the EAP operational mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config)#eapol eap-oper-mode mhSa
```

*Variable Definitions*

The following table defines parameters for the **eapol multihost eap-oper-mode** command.

| Variable    | Value                                                                     |
|-------------|---------------------------------------------------------------------------|
| <i>mhmV</i> | Specifies the EAP operational mode as Mutiple Host Multiple VLAN.         |
| <i>mhSa</i> | Specifies the EAP operational mode as Mutiple Host Single Authentication. |

**Enabling dynamic changes to EAP sessions on a port****About This Task**

Configure a port to allow dynamic changes to EAP sessions. The default is enable.

**Before You Begin**

You must enable EAP globally and at the port level.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RADIUS dynamic authorization server processing requests.

```
eapol radius-dynamic-server enable
```

**Example**

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/4
Switch:1(config-if)#eapol radius-dynamic-server enable
```

**Configure EAP auto-isid-offset****Note**

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

**Before You Begin**

- Enable EAP globally or on the port.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an I-SID offset value:

```
eapol auto-isid-offset <0-15995903>
```

3. Enable EAP globally:

```
eapol enable
```

4. Confirm that your configuration is correct:

```
show eapol system
```

*Examples*

Configure an I-SID offset value and enable I-SID offset globally on the switch:

```
Switch:1> enable
Switch:1#config terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#eapol auto-isid-offset 1000
Switch:1(config)#eapol enable
```

View the current device configuration:

#### Note

Not all fields are supported on all hardware platforms.

```
Switch:#enable
Switch:1#show eapol system
=====
 Eapol System
=====
 eap : disabled
 Eapol Version : 3
 non-eap-pwd-fmt : mac-addr
 non-eap-pwd-fmt key : *****
 non-eap-pwd-fmt padding : disabled
 auto-isid-offset status : disabled
 auto-isid-offset value : 1000
=====
```

### Variable Definitions

The following table defines parameters for the **eapol auto-isid-offset** command.

| Variable                                                                                                                          | Value                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <p>&lt;0-15995903&gt;</p> <p><b>Note:</b><br/>Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p> | <p>Specifies the auto isid offset value.<br/>The default is 15995903.</p> |
| <p><i>enable</i></p> <p><b>Note:</b><br/>Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.</p>      | <p>Enables auto isid offset.<br/>The default is disabled.</p>             |

## Configure the Guest I-SID

#### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

Configure a platform VLAN and associate the Guest I-SID. 0 indicates that Guest I-SID is not enabled for this port.

## About This Task

Use this procedure to configure the Guest I-SID.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the Guest I-SID:

```
eapol guest-isid <1-16000000>
```

## Example

Configure the Guest I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol guest-isid 1000
```

### Variable Definitions

The following table defines parameters for the **eapol guest-isid** command.

| Variable     | Value                                                                                          |
|--------------|------------------------------------------------------------------------------------------------|
| <0-16000000> | Specifies the Guest I-SID value.<br>0 indicates that Guest I-SID is not enabled for this port. |

## Configure Fail Open I-SID

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

## Before You Begin

Configure a platform VLAN and associate the Fail Open I-SID.

## About This Task

Use this procedure to configure Fail Open I-SID. If the switch declares the RADIUS servers unreachable, then all new devices gain access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Fail Open I-SID:

```
eapol fail-open-isid <0-16000000>
```

## Example

Configure the Fail Open I-SID.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#interface gigabitEthernet 1/10
Switch:1(config-if)#eapol fail-open-isid 1000
```

### Variable Definitions

The following table defines parameters for the **eapol fail-open-isid** command.

| Variable     | Value                                                                                                  |
|--------------|--------------------------------------------------------------------------------------------------------|
| <0-16000000> | Specifies the Fail Open I-SID value.<br>0 indicates that Fail Open I-SID is not enabled for this port. |

## Configure Wake-On-LAN

Use the following procedure to configure Wake-On-LAN functionality.

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Wake-On-LAN:

```
eapol traffic-control <in | in-out>
```

### Variable Definitions

The following table defines parameters for the **eapol traffic-control** command.

| Variable      | Value                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>in</i>     | Specifies incoming traffic is blocked when there is no authenticated device.                                              |
| <i>in-out</i> | Specifies incoming and outgoing traffic is blocked when there is no authenticated device.<br>The default value is in-out. |

## EAP configuration using Enterprise Device Manager

EAPoL (EAP) uses RADIUS protocol for EAP-authorized logons. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

### Before You Begin

- Before configuring your device, you must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for:
  - Shared segments
  - MultiLink Trunking (MLT)
- Change the status of each port that you want to be controlled to auto. For more information on changing the status, see [Configure EAP on a Port](#) on page 793. The auto setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is force-authorized.
- You can connect only a single client on each port configured for EAP. If you attempt to add additional clients on the EAP authorized port, the client traffic will be blocked from the switch till mac-ageing occurs for that client.

## Globally Configure EAP on the Server

### About This Task

Globally enable or disable EAP on the switch. By default, EAP is disabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **Global** tab.
4. From the AccessControl options, select **enable**.
5. (Optional) Select the appropriate **NonEapRadiusPwdAttrFmt** check boxes to configure the format of the RADIUS password when authenticating non-EAP MAC addresses using RADIUS.
6. (Optional) Enter the key string in the **NonNonEapRadiusPwdAttrkeystring** field.
7. (Optional) Check the **ClearNonEap** check box to clear the NEAP session that is learned on the switch.
8. (Optional) Type an I-SID offset number in the **AutolsidOffset** field.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
9. (Optional) Select the **AutolsidOffsetEnable** check box to enable Auto I-SID offset on the switch.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
10. Select **Apply**.

### *Global* field descriptions

Use the data in the following table to use the **Global** tab.

| Name                                | Description                                                                                                                                                                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EapOlVersion</b>                 | Displays the EAP version on the switch.                                                                                                                                                                                                                                                    |
| <b>AccessControl</b>                | Enables system authentication control. EAP is disabled by default.                                                                                                                                                                                                                         |
| <b>NonEapRadiusPwdAttrFmt</b>       | Specifies the password attribute format for non EAP RADIUS authentication. <ul style="list-style-type: none"> <li>• ipAdd: Specifies IP address.</li> <li>• macAddr: Specifies MAC address.</li> <li>• portNumber: Specifies port number</li> <li>• padding: Specifies padding.</li> </ul> |
| <b>NonEapRadiusPwdAttrKeyString</b> | Specifies the attribute key string for non EAP RADIUS password. The range is 0– 32 characters.                                                                                                                                                                                             |
| <b>ClearNonEap</b>                  | Clears the NEAP session that is learned on the switch.                                                                                                                                                                                                                                     |

| Name                                                                                                                        | Description                                                     |
|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>AutolsidOffset</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.       | Specifies the Auto I-SID Offset value. The range is 0-15995903. |
| <b>AutolsidOffsetEnable</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Enables or disables the Auto I-SID Offset feature.              |

## Configure EAP on a Port

### About This Task

Configure EAP or change the authentication status on one or more ports.

Ports are force-authorized by default. Force-authorized ports are always authorized and are not authenticated by the RADIUS server. You can change this setting so that the ports are always unauthorized.

### Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **EAPOL** tab.
5. (Optional) Select the **AllowNonEapHost** check box to enable hosts that do not participate in 802.1X authentication to get network access.
6. Select the **Status** option as **auto** or **forceAuthorized**.
7. In the **MultiHostMaxClients** field, type the maximum limit of allowed EAP and NEAP clients supported on this port.
8. In the **GuestVlanId** field, type the VLAN ID to be used as a Guest VLAN ID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
9. In the **FailOpenVlanId** field, type the Fail Open VLAN ID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
10. In the **NonEapMaxClients** field, type the maximum number NEAP authentication MAC addresses allowed on this port.
11. In the **EapMaxClients** field, type the maximum number of EAP authentication MAC addresses allowed on this port.
12. Select the **MultiHostSingleAuthEnabled** check box to automatically authenticate NEAP MAC addresses on this port.
13. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
14. In the **FailOpenIsid** field, type the Fail Open I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.

15. Select the **AdminTrafficControl** option as **inOut** or **in**.
16. (Optional) Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.  
This step does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.
17. Select the **ReAuthEnabled** field.
18. In the **QuietPeriod** field, type the time interval.
19. In the **ReauthPeriod** field, type the time between reauthentication.
20. In the **RetryMax** field, type the number of times.
21. Select **Apply**.

### **EAPoL** Field Descriptions

Use the data in the following table to use the **EAPoL** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortCapabilities</b>        | Displays the capabilities of the Port Access Entity (PAE) associated with the port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the port. The following capabilities are supported by the PAE of the port: <ul style="list-style-type: none"> <li>• <b>authImplemented</b>: A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented.</li> <li>• <b>virtualPortsImplemented</b>: Virtual Port functions are implemented.</li> </ul> |
| <b>PortVirtualPortsEnable</b>  | Displays the status of the Virtual Ports function for the real port as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>PortCurrentVirtualPorts</b> | Displays the current number of virtual ports running in the port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PortAuthenticatorEnable</b> | Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PortSupplicantEnable</b>    | Displays the Supplicant function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AllowNonEapHost</b>         | Enables network access to hosts that do not participate in 802.1X authentication. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Status</b>                  | Configures the authentication status for this port. The default is <b>forceAuthorized</b> . <ul style="list-style-type: none"> <li>• <b>auto</b>: enables the EAP authentication process by sending the EAP request messages to the RADIUS server.</li> <li>• <b>forceAuthorized</b>: disables the EAP authentication and puts the port into force-full authorized mode.</li> </ul>                                                                                                                                                                                                           |
| <b>MultiHostMaxClients</b>     | Specifies the value representing the maximum number of supplicants allowed to get authenticated on the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>GuestVlanId</b>             | Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.                                                                                                                                                                                                                                                                                                                                                                                                |

| Name                                                                                                                   | Description                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FailOpenVlanId</b>                                                                                                  | Specifies the Fail Open VLAN ID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.                          |
| <b>NonEapMaxClients</b>                                                                                                | Specifies the maximum number of NEAP authentication MAC addresses allowed on this port. Zero indicates that NEAP authentication is disabled for this port.                                                                                                               |
| <b>EAPMaxClients</b>                                                                                                   | Specifies the maximum number of EAP authentication MAC addresses allowed on this port. Zero indicates that EAP authentication is disabled for this port.                                                                                                                 |
| <b>MultiHostSingleAuthEnabled</b>                                                                                      | Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false.                 |
| <b>PortGuestIside</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                    | Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.                                                                       |
| <b>FailOpenIside</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                     | Specifies the Fail Open I-SID for this port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.                          |
| <b>FlexUniStatus</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.   | Displays the current Flex-UNI status for this port.                                                                                                                                                                                                                      |
| <b>AdminTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.               | Configures the Administrative Traffic Control. The default is inOut. <ul style="list-style-type: none"> <li>• inOut: enables the Admin Traffic Control for input and output traffic.</li> <li>• in: enables the Admin Traffic Control for input traffic only.</li> </ul> |
| <b>OperTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                | Displays the current Operational Traffic Control status.                                                                                                                                                                                                                 |
| <b>LldpAuthEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Enables LLDP authentication for this port. The default is disabled.                                                                                                                                                                                                      |

| Name                                                                                                                          | Description                                                                                                                                                                                             |

The default is disabled.                                                                                         |
| <b>QuietPeriod</b>                                                                                                            | Configures the time interval (in seconds) between authentication failure and the start of a new authentication.                                                                                         |
| <b>ReAuthPeriod</b>                                                                                                           | Reauthenticates an existing supplicant at the time interval specified in ReAuthPeriod.<br>Configures the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour). |
| <b>RetryMax</b>                                                                                                               | Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2.                                                         |
| <b>RetryCount</b>                                                                                                             | Specifies the maximum number of retries attempted.                                                                                                                                                      |

## Configure EAP on an Extreme Integrated Application Hosting Port

### About This Task

Perform this procedure to configure EAP or change the authentication status on Extreme Integrated Application Hosting (IAH) ports. IAH ports are force-authorized by default and are not authenticated by the RADIUS server. You can change this setting so that the IAH ports stay unauthorized.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **EAPOL** tab.
4. (Optional) Select **AllowNonEapHost**.
5. In the **Status** field, select the required option.
6. In the **MultiHostMaxClients** field, enter a value.

7. In the **GuestVlanId** field, enter a VLAN ID.
8. In the **FailOpenVlanId** field, enter a VLAN ID.
9. In the **NonEapMaxClients** field, enter a value.
10. In the **EapMaxClients** field, enter a value.
11. Select **MultiHostSingleAuthEnabled**.
12. In the **PortGuestIsid** field, type the I-SID to be used as a Guest I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
13. In the **FailOpensid** field, type the Fail Open I-SID.  
This step does not apply to VSP 8600 Series or XA1400 Series.
14. Select the **AdminTrafficControl** option as **inOut** or **in**.  
This step does not apply to VSP 8600 Series or XA1400 Series.
15. Select the **LldpAuthEnabled** check box to enable LLDP authentication for network access.  
This step does not apply to VSP 8600 Series or XA1400 Series.
16. Select **ReAuthEnabled**.
17. In the **QuietPeriod** field, enter a time interval.
18. In the **ReAuthPeriod** field, enter a time interval.
19. In the **RetryMax** field, type a value.
20. Select **Apply**.

### **EAPOL** Field Descriptions

Use data in the following table to use the **EAPOL** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortCapabilities</b>        | Shows the capabilities of the Port Access Entity (PAE) associated with the Extreme Integrated Application Hosting (IAH) port. This parameter indicates whether Authenticator functionality, supplicant functionality, both, or neither, is supported by the PAE of the IAH port.<br>The following capabilities are supported by the PAE of the IAH port: <ul style="list-style-type: none"> <li>• <b>authImplemented:</b> A Port Access Controller Protocol (PACP) Extensible Authentication Protocol (EAP) authenticator functions are implemented.</li> <li>• <b>virtualPortsImplemented:</b> Virtual Port functions are implemented.</li> </ul> |
| <b>PortVirtualPortsEnable</b>  | Shows the status of the Virtual Ports function for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>PortCurrentVirtualPorts</b> | Shows the current number of virtual ports running on the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>PortAuthenticatorEnable</b> | Shows the status of the Authenticator function in the PAE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>PortSupplicantEnable</b>    | Shows the Supplicant function in the PAE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Name                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Authenticated</b>                                                                                                          | Shows the current Authenticator Port Access Entity (PAE) authenticated status.                                                                                                                                                                                           |
| <b>Failed</b>                                                                                                                 | Shows the current Authenticator Port Access Entity (PAE) failure status.                                                                                                                                                                                                 |
| <b>ReAuthEnabled</b>                                                                                                          | Enables reauthentication of an existing supplicant based on the specified reauthentication time interval. The default is disabled.                                                                                                                                       |
| <b>QuietPeriod</b>                                                                                                            | Specifies the time interval (in seconds) between authentication failure and start of authentication.                                                                                                                                                                     |
| <b>ReauthPeriod</b>                                                                                                           | Specifies the time interval (in seconds) between successive reauthentications. The default is 3600 (1 hour).                                                                                                                                                             |

| Name              | Description                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RetryMax</b>   | Specifies the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2. |
| <b>RetryCount</b> | Specifies the maximum number of retries attempted.                                                                                              |

## Show the Port Access Entity Port Table

### About This Task

Use the Port Access Entity (PAE) Port Table to display system-level information for each port the PAE supports. An entry display in this table for each port of this system.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **EAP Security** tab.

### *EAP Security* Field Descriptions

Use the data in the following table to use the **EAP Security** tab.

| Name                           | Description                                                                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortNumber</b>              | Indicates the port number associated with this port.                                                                                                                                                                                                                                |
| <b>PortCapabilities</b>        | Indicates the capabilities of this PAE port. <ul style="list-style-type: none"> <li>• <b>authImplemented</b>—PACP EAP authenticator functions are implemented in this PAE.</li> <li>• <b>virtualPortsImplemented</b>—Virtual Port functions are implemented in this PAE.</li> </ul> |
| <b>PortVirtualPortsEnable</b>  | Displays the status of the Virtual Ports function for the real port as True or False.                                                                                                                                                                                               |
| <b>PortCurrentVirtualPorts</b> | Displays the current number of virtual ports running in the port                                                                                                                                                                                                                    |
| <b>PortAuthenticatorEnable</b> | Displays the status of the Authenticator function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                 |
| <b>PortSupplicantEnable</b>    | Displays the Supplicant function in the Port Access Entity (PAE) as True or False.                                                                                                                                                                                                  |
| <b>AllowNonEapHost</b>         | Displays the status if the system is enabled to allow hosts that do not participate in 802.1X authentication to get network access.                                                                                                                                                 |
| <b>Status</b>                  | Displays the authentication status for this port. The default is <b>forceAuthorized</b> .                                                                                                                                                                                           |
| <b>MultiHostMaxClients</b>     | Indicates the value representing the maximum number of supplicants allowed to get authenticated on the port.                                                                                                                                                                        |

| Name                                                                                                                 | Description                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GuestVlanId</b>                                                                                                   | Specifies the VLAN to be used as a Guest VLAN. Access to unauthenticated hosts connected to this port is provided through this VLAN. 0 indicates that Guest VLAN is not enabled for this port.                                                           |
| <b>FailOpenVlanId</b>                                                                                                | Specifies the Fail Open VLAN ID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open VLAN. 0 indicates that Fail Open VLAN is not enabled for this port.           |
| <b>NonEapMaxClients</b>                                                                                              | Indicates the maximum number of non-EAPoL authentication MAC addresses allowed on this port. Zero indicates that non-EAPoL authentication is disabled for this port.                                                                                     |
| <b>EapMaxClients</b>                                                                                                 | Indicates the maximum number of EAPoL authentication MAC addresses allowed on this port. Zero indicates that EAPoL authentication is disabled for this port.                                                                                             |
| <b>MultiHostSingleAuthEnabled</b>                                                                                    | Indicates that the unauthenticated devices can access the network only after an EAP or NEAP client is successfully authenticated on the port. The VLAN to which the devices are allowed access is the authenticated client's VLAN. The default is false. |
| <b>ProcessRadiusCOAPackets</b>                                                                                       | Specifies whether to process any RADIUS requests-server packets that are received on this port.                                                                                                                                                          |
| <b>PortGuestIsid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                   | Specifies the I-SID to be used as a Guest I-SID. Access to unauthenticated hosts connected to this port is provided through this I-SID. 0 indicates that Guest I-SID is not enabled for this port.                                                       |
| <b>FailOpenIsid</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                    | Specifies the Fail Open I-SID for the port. If the switch declares the RADIUS servers unreachable, then all new devices are allowed access into the configured Fail Open I-SID. 0 indicates that Fail Open I-SID is not enabled for this port.           |
| <b>FlexUniStatus</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Displays the Flex-UNI status for the port.                                                                                                                                                                                                               |
| <b>AdminTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.             | Specifies the Administrative Traffic Control for the port. The default is inOut.                                                                                                                                                                         |
| <b>OperTrafficControl</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.              | Displays the Operating Traffic Control for the port.                                                                                                                                                                                                     |

| Name                                                                                                                      | Description                                                               |
|---------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>LldpAuthEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                      | Specifies if LLDP Authentication is enabled. The default is 0 (disabled). |
| <b>PortOrigin</b><br><b>Note:</b> Exception: Not supported on VSP 8600 Series or XA1400 Series.                           | Displays the Port Origin configuration status for the port.               |
| <b>DynamicMHSAEnabled</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Displays the Dynamic MHSA status for the port.                            |

## Show EAP Authentication

### About This Task

Use the Authenticator Configuration table to display configuration objects for the Authenticator PAE associated with each port.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **Authentication** tab.

### **Authentication** field descriptions

Use the data in the following table to use the **Authentication** tab.

| Name                 | Description                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortNumber</b>    | Indicates the number associated with this port.                                                                                        |
| <b>Authenticate</b>  | Indicates the status of the Port Access Entity (PAE) authenticator requesting authentication.                                          |
| <b>Authenticated</b> | Indicates the current authentication status of the Port Access Entity (PAE) authenticator.                                             |
| <b>Failed</b>        | Indicates the authentication status for failed or terminated state .                                                                   |
| <b>ReAuthEnabled</b> | Indicates the re-authentication status of an existing supplicant at the time interval specified in ReAuthPeriod. The default is false. |
| <b>QuietPeriod</b>   | Indicates the time interval (in seconds) between authentication failure and the start of a new authentication.                         |

| Name                | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | The default is 60.                                                                                                                              |
| <b>ReAuthPeriod</b> | Indicates the time interval in seconds between successive re-authentications. The default is 3600 (1 hour ).                                    |
| <b>RetryMax</b>     | Indicates the maximum Extensible Authentication Protocol (EAP) requests sent to the supplicant before timing out the session. The default is 2. |
| <b>RetryCount</b>   | Indicates the count of the number of authentication attempts.                                                                                   |

## View Multihost Status Information

Use the following procedure to display multiple host status for a port.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **802.1X - EAPOL**.
3. Select the **MultiHost Status** tab.

### **MultiHost Status** Field Descriptions

The following table describes values on the **MultiHost Status** tab.

| Name                                                                                         | Description                                                                                                                        |
|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>PortNumber</b>                                                                            | Indicates the port number associated with this port.                                                                               |
| <b>ClientMACAddr</b>                                                                         | Indicates the MAC address of the client.                                                                                           |
| <b>PaeState</b>                                                                              | Indicates the current state of the authenticator PAE state machine.                                                                |
| <b>VlanId</b>                                                                                | Indicates the VLAN assigned to the client.                                                                                         |
| <b>Priority</b>                                                                              | Specifies the priority associated with this client MAC. This priority could be the Radius assigned priority or the port QOS level. |
| <b>SwUniBindings</b>                                                                         | Indicates the Extensible Authentication Protocol (EAP) VLAN:I-SID bindings that the switch represents as an hexadecimal value.     |
| <b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. |                                                                                                                                    |

| Name                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IsidSource</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Indicates the origin of I-SID value: <ul style="list-style-type: none"> <li>radius - received from the RADIUS server.</li> <li>autoconfig - calculated using the <b>auto-isid-offset</b> command, that the user configures on the switch.</li> <li>config - configured statically.</li> <li>notAvaliable - does not use EAP with FlexUNI, hence there is no I-SID to use.</li> </ul> |
| <b>AcId</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.       | Indicates the dynamic Access Control List (ACL) on the specific port.                                                                                                                                                                                                                                                                                                                |
| <b>AceldList</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.  | Indicates the list of dynamic Access Control Entries (ACE) on the specific port.                                                                                                                                                                                                                                                                                                     |

## View EAP Session Statistics

Use the following procedure to display multiple host session information for a port.

### Procedure

1. In the navigation pane, expand **Configuration --> Security --> Data Path**.
2. Click **802.1X - EAPOL**.
3. Click the **MultiHost Session** tab.

### MultiHost Session Field Descriptions

The following table describes values on the **MultiHost Session** tab.

| Name                      | Description                                                                 |
|---------------------------|-----------------------------------------------------------------------------|
| <b>StatsPortNumber</b>    | Indicates the port number associated with this port.                        |
| <b>StatsClientMACAddr</b> | Indicates the MAC address of the client.                                    |
| <b>Id</b>                 | Indicates the unique identifier for the session.                            |
| <b>AuthenticMethod</b>    | Indicates the authentication method used to establish the session.          |
| <b>Time</b>               | Indicates the elapsed time of the session.                                  |
| <b>TerminateCause</b>     | Indicates the cause of the session termination.                             |
| <b>UserName</b>           | Indicates the user name that represents the identity of the supplicant PAE. |

## View NEAP MAC Information

Use this procedure to view NEAP client MAC information on a port.

### Procedure

1. In the navigation pane, expand **Configuration** --> **Security** --> **Data Path**.
2. Select **802.1X - EAPOL**.
3. Select **NEAP Radius** tab.

### NEAP Radius Field Descriptions

The following table describes values on the **NEAP Radius** tab.

| Name                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacPort</b>                                                                                                        | Indicates the port number associated with this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>MacAddr</b>                                                                                                        | Indicates the MAC address of the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MacStatus</b>                                                                                                      | Indicates the authentication status of the NEAP host that is authenticated using the RADIUS server.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>VlanId</b>                                                                                                         | Indicates the VLAN assigned to the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MacClear</b>                                                                                                       | Clears the non EAP MAC entry associated with a specific index.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>MacPriority</b>                                                                                                    | Indicates the priority associated with this Non-EAP client MAC. This priority could be the Radius assigned priority or the port QOS level.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SwUniBindings</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.  | Indicates the VLAN and I-SID bindings. VLAN is represented with 2 bytes and I-SID is represented with 4 bytes. The output is a continuous hexadecimal representation of the VLAN that is followed by the corresponding I-SID.                                                                                                                                                                                                                                                                                                          |
| <b>IsidSource</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.     | Indicates the source of the I-SID value. An I-SID value is generated in one of the following ways: <ul style="list-style-type: none"> <li>• radius—Indicates that that I-SID value is learned from the RADIUS server.</li> <li>• autoconfig—Indicates that I-SID value is calculated by using the auto-isid-offset that you configured.</li> <li>• config—Indicates that the I-SID value is statically configured.</li> <li>• notAvailable—Indicates that no I-SID value is available because EAP with FlexUNI is not used.</li> </ul> |
| <b>NonEapAuthType</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Indicates the authentication type of the Non-EAP client: <ul style="list-style-type: none"> <li>• radius - received from RADIUS server.</li> <li>• lldp - received from Link Layer Discovery Protocol (LLDP).</li> </ul>                                                                                                                                                                                                                                                                                                               |

| Name                                                                                                            | Description                                                                      |
|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>AcId</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.     | Indicates the dynamic Access Control List (ACL) on the specific port.            |
| <b>AcIdList</b><br><b>Note:</b> Exception: Not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Indicates the list of dynamic Access Control Entries (ACE) on the specific port. |

|                                                                  | VSP 7400 Series | VOSS 8.2                                                                               |
|                                                                  | VSP 8200 Series | Not supported                                                                          |
|                                                                  | VSP 8400 Series | Not supported                                                                          |
|                                                                  | VSP 8600 Series | Not supported                                                                          |
|                                                                  | XA1400 Series   | VOSS 8.2                                                                               |

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

ExtremeCloud IQ provides cloud-managed networking, and delivers unified, full-stack management of wireless access points, switches, and routers. It enables onboarding, configuration, monitoring, troubleshooting, reporting, and more. Using innovative machine learning and artificial intelligence technologies, ExtremeCloud IQ analyzes and interprets millions of network and user data points, from the network edge to the data center, to power actionable business and IT insights, and to deliver new levels of network automation and intelligence.

VOSS supports a zero touch connection to ExtremeCloud IQ. Zero touch deployment is used to deploy and configure a switch using ExtremeCloud IQ.

VOSS integrates with ExtremeCloud IQ using ExtremeCloud IQ Agent. When you enable IQAgent, you can configure and monitor VOSS devices using ExtremeCloud IQ.

ExtremeCloud IQ supports the following features for VOSS:

- Firmware upgrade
- IQAgent upgrade
- Supplemental CLI

You can configure the following features using the ExtremeCloud IQ interface:

- Hostname configuration
- SNMP location
- Device-level MTU
- Flow control
- Port state, usage type, and settings
- VLAN configuration
- DNS, NTP, SNMP, and Syslog servers

For more information about ExtremeCloud IQ, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## ExtremeCloud IQ Agent Configuration Considerations

---

The following configuration considerations apply to ExtremeCloud IQ Agent:

- SSH and SSH password authentication is required.

**boot config flag ssh** is enabled when ExtremeCloud IQ Agent is enabled. **boot config flag ssh** cannot be disabled while ExtremeCloud IQ Agent is enabled.

- SNMP is required.

**boot config flag block-snmp** is disabled when ExtremeCloud IQ Agent is enabled. **boot config flag block-snmp** cannot be enabled while ExtremeCloud IQ Agent is enabled.

- High Secure mode disables ExtremeCloud IQ Agent automatically. ExtremeCloud IQ Agent must be enabled manually when this mode is enabled.
- ExtremeCloud IQ Agent is not supported in Enhanced Secure mode.
- An IP address that corresponds to the ExtremeCloud IQ pool can appear in the NTP list. The IP does not try to synchronize if NTP is globally disabled on the switch. If NTP is enabled, you can see synchronization failure messages if the IP for the pool is blocked or is unreachable. As a best practice, if you have issues connecting to the cloud, check the clock on the switch and if it is incorrect, resolve this by either configuring an NTP server or manually configuring the correct time.

### Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management](#) on page 49.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## Zero Touch Deployment

---

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still must onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or to ExtremeCloud IQ cloud management applications.

With Zero Touch Deployment, ExtremeCloud IQ Agent is enabled by default.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

For more information about preparing your switch for Zero Touch Deployment, see [Zero Touch Deployment](#) on page 40.

## DHCP Option 43 Support

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (nac.extremecloudiq.com) is not desired.

To use this functionality, DHCP Client must be enabled. For information about DHCP Client for a Segmented Management Instance, see [DHCP Client](#) on page 57.

## Considerations

The following considerations apply with DHCP option 43:

- A dynamic IP address overwrites the default value (nac.extremecloudiq.com) or 0.0.0.0.
- A static server IP address overwrites a dynamic server IP address.
- A dynamic server IP address does not overwrite an existing static server IP address.

If a static server IP address is already configured and a new value is received from the DHCP server, the following warning displays on the console: *WARNING Dynamic Cloud IQ Server Address x.x.x.x provided by DHCP option 43 could not be set. Static configured server address y.y.y.y cannot be overwritten by a dynamic address.*

- The default value (nac.extremecloudiq.com) replaces the dynamic server IP address if the DHCP Client is disabled on the switch.
- The dynamic server IP address is not saved in the running-config.

## ExtremeCloud IQ Agent Configuration using CLI

---

After your VOSS device is onboarded (that is, the serial number for the device is associated with your ExtremeCloud IQ account), you are only required to enable ExtremeCloud IQ Agent. Other feature

configuration, such as configuring proxy parameters and configuring access to ExtremeCloud IQ is optional.

#### Note

You must configure a Segmented Management Instance to use ExtremeCloud IQ Agent. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 64.

For information about onboarding switches, see <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## Configure ExtremeCloud IQ Agent

You must first onboard the VOSS device. When zero touch connection establishes, IQ Agent is enabled, by default. Before IQ Agent is operational, you must first disable IQ Agent, configure the ExtremeCloud IQ IPv4 address or DNS name, and then reenable IQ Agent.

### Before You Begin

You must first onboard the VOSS device.

### Procedure

1. Enter Application Configuration mode:
 

```
enable

configure terminal

application
```
2. Disable IQ Agent:
 

```
no iqagent enable
```
3. Configure the ExtremeCloud IQ IPv4 address or DNS name:
 

```
iqagent server address WORD<1-255>
```
4. Enable IQ Agent:
 

```
iqagent enable
```

### Example

Configure IQ Agent:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#no iqagent enable
Switch:1(config-app)#iqagent server address hac.extremecloudiq.com
Switch:1(config-app)#iqagent enable
```

Display default IQ Agent configuration:

```
Switch:1>show application iqagent
```

```
=====
IQAgent Info
=====
```

```
Agent Admin State : true
Agent Version : 0.2.7
Agent Oper State : disconnected
Server Address : hac.extremecloudiq.com
Server Address Origin : None
Proxy Address : 0.0.0.0
Proxy TCP Port : 0
Proxy Username :
```

## Configure Access to ExtremeCloud IQ

Use this task to configure IQ Agent parameters to access ExtremeCloud IQ.

### Before You Begin

You must onboard the VOSS device and configure any optional IQ Agent parameters on the supported VOSS device before you enable IQ Agent.

You can configure the IQ Agent parameters on the supported VOSS devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

### Procedure

1. Enter Application Configuration mode:  
`enable`  
`configure terminal`  
`application`
2. Configure the ExtremeCloud IQ IPv4 address or DNS name:  
`iqagent server address WORD<1-255>`

### Example

Configure access to ExtremeCloud IQ using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address 192.0.2.1
```

Configure access to ExtremeCloud IQ using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent server address extremecloudiq.com
```

## Variable Definitions

The following table defines parameters for the **iqagent server** command.

| Variable                                | Value                                                   |
|-----------------------------------------|---------------------------------------------------------|
| <code>address &lt;WORD 1-255&gt;</code> | Specifies the ExtremeCloud IQ IPv4 address or DNS name. |

## Configure Proxy Parameters

If you use a proxy https server in your network, you must configure proxy parameters so that the IQ Agent on the device can communicate with ExtremeCloud IQ through the proxy.

Use this task to configure the proxy parameters for ExtremeCloud IQ on the IQ Agent.

### Note

You must onboard the VOSS device and configure any optional IQ Agent parameters on the supported VOSS device before you enable IQAgent.

You can configure the IQ Agent parameters on the supported VOSS devices first, and then onboard the devices (that is, add the serial numbers for the devices in the ExtremeCloud IQ GUI) or vice versa.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

## Procedure

1. Enter Application Configuration mode:
 

```
enable

configure terminal

application
```
2. Configure the proxy IPv4 address or DNS name:
 

```
iqagent proxy address <WORD 1-255> tcp-port <1-49151>
```
3. Configure the proxy username and password for the ExtremeCloud IQ account:
 

```
iqagent proxy username <WORD 1-64> password <WORD 1-128>
```

## Example

Configure proxy parameters using an IPv4 address:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address 192.0.2.254 tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

Configure proxy parameters using a DNS name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#application
Switch:1(config-app)#iqagent proxy address hac.extremecouldiq.com tcp-port 21
Switch:1(config-app)#iqagent proxy username admin password ****
```

## Variable Definitions

The following table defines parameters for the **iqagent proxy** command.

| Variable                     | Value                                         |
|------------------------------|-----------------------------------------------|
| <i>address</i> <WORD 1-255>  | Specifies the proxy IPv4 address or DNS name. |
| <i>tcp-port</i> <1-49151>    | Specifies the TCP port.                       |
| <i>username</i> <WORD 1-64>  | Specifies the proxy server username.          |
| <i>password</i> <WORD 1-128> | Specifies the proxy server password.          |

## Display ExtremeCloud IQ Agent Information

### About This Task

Use this task to display ExtremeCloud IQ Agent configuration information and status.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent configuration information and status:

```
show application iqagent
```

### Example

Display IQ Agent configuration information and status when IQ Agent is enabled using the default ExtremeCloud IQ server:

```
Switch:1>show application iqagent

=====
 IQAgent Info
=====
Agent Admin State : true
Agent Version : 0.2.7
Agent Oper State : connected
Server Address : hac.extremecloudiq.com
Server Address Origin : None
Proxy Address : extremeiq.com
Proxy TCP Port : 21
Proxy Username : admin
```

Display IQ Agent disabled state:

```
Switch:1>show application iqagent

=====
 IQAgent Info
=====
Agent Admin State : false
Agent Version : 0.2.7
Agent Oper State : disconnected
Server Address : 0.0.0.0
Server Address Origin : None
Proxy Address : 0.0.0.0
Proxy TCP Port : 0
Proxy Username :
```

Display IQ Agent configuration information and status when DHCP provides a dynamic server IP address:

```
Switch:1>show application iqagent

=====
 IQAgent Info
=====
Agent Admin State : true
Agent Version : 0.2.7
Agent Oper State : disconnected
Server Address : 192.0.2.1
Server Address Origin : DHCP
Proxy Address : 0.0.0.0
Proxy TCP Port : 0
Proxy Username :
```

Display IQ Agent configuration information and status when DHCP Client is disabled on the switch:

```
Switch:1>show application iqagent

=====
 IQAgent Info
=====
Agent Admin State : false
Agent Version : 0.2.7
Agent Oper State : disconnected
Server Address : hac.extremecloudiq.com
Server Address Origin : None
Proxy Address : 0.0.0.0
Proxy TCP Port : 0
Proxy Username :
```

*Job Aid*

The following sections describe the fields in the output for the **show application iqagent** command.

**Table 111:**

| Output                | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Agent Admin State     | Specifies the administrative state of the IQ Agent.                                                                                                                                                                                                                                                                                                   |
| Agent Version         | Specifies the IQ Agent version that runs on the device.                                                                                                                                                                                                                                                                                               |
| Agent Oper State      | Specifies the operational status of the IQ Agent, whether IQ Agent is connected to ExtremeCloud IQ.                                                                                                                                                                                                                                                   |
| Server Address        | Specifies the default ExtremeCloud IQ server.                                                                                                                                                                                                                                                                                                         |
| Server Address Origin | Specifies the origin of the server IP address. <ul style="list-style-type: none"> <li>None - displays the default value (hac.extremecloudiq.com) or 0.0.0.0</li> <li>Configured - displays the static server IP address configured using CLI or EDM.</li> <li>DHCP - displays the dynamic server IP address configured by the DHCP server.</li> </ul> |
| Proxy Address         | Specifies the proxy address.                                                                                                                                                                                                                                                                                                                          |

**Table 111: (continued)**

| Output         | Description                          |
|----------------|--------------------------------------|
| Proxy TCP Port | Specifies the proxy TCP port.        |
| Proxy Username | Specifies the proxy server username. |
| Proxy Password | Specifies the proxy server password. |

## Display ExtremeCloud IQ Agent Status

### About This Task

Use this task to display IQ Agent status information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IQ Agent status information:

```
show application iqagent status
```

### Example

```
Switch:1>show application iqagent status

## ExtremeCloud IQ Agent Configuration using EDM

Perform the procedures in this section to configure ExtremeCloud IQ Agent on the switch using the Enterprise Device Manager (EDM).

## Configure ExtremeCloud IQ Agent

### Before You Begin

You must first onboard the VOSS device and configure any optional IQ Agent parameters before you enable IQ Agent.

### About This Task

## Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **IQAgent**.
3. Select the **Globals** tab.
4. Select the **GlobalEnable** check box to enable the server.
5. Configure optional parameters as required.
6. Select **Apply**.

### **CloudIQ** Field Descriptions

Use the data in the following table to use the **CloudIQ** tab and to configure the ExtremeCloud IQ Agent.

| Name                  | Description                                                                   |
|-----------------------|-------------------------------------------------------------------------------|
| <b>Address</b>        | Specifies the proxy IPv4 address or DNS name.                                 |
| <b>Enable</b>         | Specifies whether IQ Agent is enabled. The default is enabled.                |
| <b>Server/Address</b> | Specifies the ExtremeCloud IQ DNS name. The default is hac.extremcloudiq.com. |
| <b>Password</b>       | Specifies the proxy server username.                                          |
| <b>TcpPort</b>        | Specifies the TCP port.                                                       |
| <b>UserName</b>       | Specifies the proxy server password.                                          |

| Fabric IPsec Gateway virtual machine                             | 5520 Series     | Not supported                                             |
|                                                                  | VSP 4450 Series | Not Supported                                             |
|                                                                  | VSP 4900 Series | VOSS 8.3                                                  |
|                                                                  | VSP 7200 Series | Not Supported                                             |
|                                                                  | VSP 7400 Series | VOSS 8.2                                                  |
|                                                                  | VSP 8200 Series | Not Supported                                             |
|                                                                  | VSP 8400 Series | Not Supported                                             |
|                                                                  | VSP 8600 Series | Not Supported                                             |
|                                                                  | XA1400 Series   | Not Supported                                             |

## Extreme Integrated Application Hosting

---

Extreme Integrated Application Hosting (IAH) architecture provides a flexible and open solution that enables organizations to deploy high-performance and flexible visibility applications pervasively throughout their network for improved monitoring and troubleshooting. Enabled by VOSS, this preconfigured Quick Emulator (QEMU) Kernel-based Virtual Machine (KVM) environment leverages high performance x86 CPUs to host these applications, extending visibility customized to the business and operational needs of the organization across the entire network.

The QEMU KVM environment supports several pretested and well-known packet capture applications in a Linux virtual machine, including Wireshark and tcpdump. There are a wide variety of additional applications, tools, and utilities that organizations are able to run in this environment, such as data analytics applications, packet generators, monitoring tools, troubleshooting utilities, and many others. While the QEMU KVM environment is open and can host any application, it is designed and ideally suited for networking applications, tools, and utilities.

IAH architecture supports the creation and use of virtualization domains, such as virtual machines, and Docker containers. This design creates a common-use host, which coordinates and automates multiple guest-networking functions into chains. The hardware boots into the virtual Linux OS, providing the ability to run additional applications or services within a specific virtual machine or a Docker container, and simultaneously supporting the regular functionality of the switch.

Yet Another Next Generation (YANG) model is used to manage configuration and retrieve operational data. You access the YANG model through Representational State Transfer Configuration Protocol (RESTCONF) using a northbound interface, namely Extreme Management Center, that provides an additional way to configure and monitor the switch. For more information on RESTCONF, see [Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals](#) on page 2645.

### Virtual Services Resources

The virtual services resources are isolated from each other, as well as from the Network Operating System (NOS) running the switch.

The resources available for all virtual services on VSP 7400 Series switches are as follows:

- ◦ Six Central Processing Unit (CPU) cores
- 12 GB Random Access Memory (RAM)
- 100 GB Solid State Drive (SSD) flash memory

The resources available for all virtual services on VSP 4900 Series switches are as follows:

#### Note

You must install a modular SSD unit to use virtual services on VSP 4900 Series switches.

- ◦ Two CPU cores
- 4 GB RAM
- 120 GB SSD flash memory (separately available modular SSD unit), with 104 GB dedicated for IAH storage.

The switch OS uses the following resources on VSP 7400 Series and VSP 4900 Series:

- Two CPU cores
- 4 GB RAM
- 8 GB internal flash memory storage

## Extreme Integrated Application Hosting Ports

Extreme Integrated Application Hosting (IAH) ports are labeled as Insight ports, which are internal ports used to support Ethernet connectivity by the virtual services configured on the switch. IAH ports operate at 10 Gigabits per second (Gbps). The following features support IAH ports on the switch:

- VLANs
- Filters
- Port Statistics
- Basic Interface Configuration
- Mirroring
- Switched UNI
- Transparent Port UNI

### Note

Network-to-network (NNI) interface support is not available for IAH ports. IS-IS adjacencies cannot be established on IAH ports.

For information about how to configure IAH ports, see the following tasks:

- [Configure a Virtual Service](#) on page 827
- [Configure Virtual Ports](#) on page 839

### Connection Types

The VM and Docker virtual ports map to a physical Extreme Integrated Application Hosting port using the following connection types:

- Open vSwitch (OVS)
- Single Root I/O Virtualization (SR-IOV).

- Virtualization Technology for Directed I/O (VT-d)

#### Note

You must enable trunking on the Extreme Integrated Application Hosting port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2254.

You can configure Extreme Integrated Application Hosting ports 1/s1 and 1/s2 to accommodate different connect types. Extreme Integrated Application Hosting ports 1/s1 and 1/s2 can accommodate virtual ports of SR-IOV, OVS, or VT-d connect types. Two VT-d connection types are supported on either 1/s1 or 1/s2 Extreme Integrated Application Hosting ports. Using the **virtual-service** command, you can specify which Extreme Integrated Application Hosting port is associated with the configured connect type. You can also configure the Network Interface Card (NIC) type of the virtual port using the **virtual-service** command.

The following table lists the compatible Extreme Integrated Application Hosting port connect type configurations.

#### Note

You cannot configure two virtual services with conflicting connect types or two virtual services with VT-d connect type on the same Extreme Integrated Application Hosting port.

| Extreme Integrated Application Hosting port 1/s1 | Extreme Integrated Application Hosting port 1/s2 |
|--------------------------------------------------|--------------------------------------------------|
| SR-IOV                                           | OVS                                              |
| SR-IOV                                           | SR-IOV                                           |
| OVS                                              | SR-IOV                                           |
| OVS                                              | OVS                                              |
| VT-d                                             | VT-d                                             |

### Link Flapping

When the switch initializes, the Extreme Integrated Application Hosting ports connect to the underlying Linux hypervisor. When a virtual port of connection type OVS or SR-IOV is configured on the switch, the Linux hypervisor saves this connection, and the link state of the Extreme Integrated Application Hosting port does not change. However, when a virtual port of connection type VT-d is configured on the switch, control of the Extreme Integrated Application Hosting port is passed from the Linux hypervisor to the configured Virtual Machine (VM). The Extreme Integrated Application Hosting port flaps due to this transition, and the switch reports it in the system log. The Extreme Integrated Application Hosting port flaps twice during the transition:

1. when the Extreme Integrated Application Hosting port is removed from the Linux hypervisor.
2. when the Extreme Integrated Application Hosting port is added to the VM.

A similar link flap sequence takes place on the Extreme Integrated Application Hosting port when the associated VM is disabled on the switch, and the control of the Extreme Integrated Application Hosting port is passed from the VM back to the Linux hypervisor.

### Configuration Requirements

- To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.
- To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.
- To enable Flex UNI on an Extreme Integrated Application Hosting port with a connect type of VT-d, enable dot1q encapsulation on the VM interfaces. Flex UNI enables tagging on these ports by default; you must tag the VM ports with the VLANs that these ports use.

## Third Party Virtual Machine

The Extreme Integrated Application Hosting (IAH) feature supports the pre-installed Third Party Virtual Machine (TPVM). For switches that use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the modular SSD. For switches that do not use a modular Solid State Drive (SSD) for IAH, the virtual machine is pre-installed on the switch.

You can use the **show virtual-service config** command to view the information about the pre-installed virtual machine on the switch. For more information, see [Display Virtual Service Configuration](#) on page 832.

#### Important

You must upgrade virtual services independently of a VOSS upgrade; separate images for virtual services are available. For more information, see [Upgrade a Virtual Service](#) on page 835.

For more information about how to configure virtual services, see [Virtual Services Configuration using CLI](#) on page 825 and [Virtual Services Configuration using EDM](#) on page 836.

Third Party Virtual Machine (TPVM) provides a set of troubleshooting tools on the switch. The following installed packages are available on TPVM:

- build-essential
- checkinstall
- iperf
- mtools
- netperf
- qemu-guest-agent
- tshark
- valgrind
- vim-gnome

- wireshark
- xterm

### Important

TPVM includes an administrator account with a default username and password. To ensure security, you must change the default password when you access TPVM for the first time, before enabling the IAH ports using the **no shutdown** command. The software automatically prompts you to change this password at first boot; no action can be taken with the VM until you change the password.

The following user applications are available on TPVM:

- Dynamic Host Configuration Protocol (DHCP) server
- Domain Name Server (DNS)
- Authentication, authorization, and accounting (AAA) server for Remote Access Dial-In User Service (RADIUS) and Terminal Access Controller Access Control Service Plus (TACACS+).
- Syslog server
- Simple Network Management Protocol (SNMP) trap receiver
- Suricata - a free and open-source robust network threat detection engine that provides real time intrusion detection (IDS), inline intrusion prevention (IPS), network security monitoring (NSM), and offline packet capture (pcap) processing.
- Wireshark - a protocol analyzer that provides packet capturing and analysis.
- Ostinato - provides packet crafting, network traffic generation, and analysis with a user-friendly Graphical User Interface (GUI).

### Note

If you start the console for TPVM without network connectivity to a DHCP server, the VM remains in a retry loop for approximately 5 minutes while it tries to obtain a DHCP address. The system displays the following message: `[FAILED] Failed to start Raise network interfaces`, and then the VM continues to boot. The VM does start but with the virtual port, eth0, in the administratively down state.

The following are the virtual services resources for TPVM:

- Two CPU cores
- 4 GB RAM

- One virtual port of VT-d connection type
- 1.8 GB up to 32 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

**Important**

To enable SR-IOV and VT-d, the guest OS must have Ethernet drivers (ixgbe) that support these Intel technologies. These drivers are not available by default in many OS distribution versions. The TPVM version based on Ubuntu 16.04 is enhanced to include updated driver versions to support SR-IOV and VT-d. If you upgrade the TPVM guest OS kernel, you override these drivers and the VM does not support SR-IOV or VT-d vport connection types.

Do not perform a kernel upgrade from within the TPVM. If necessary, you can upgrade individual packages. You can upgrade to Ubuntu 18.04, which includes support for these new driver versions by default.

## Fabric IPsec Gateway Fundamentals

---

The Fabric IPsec Gateway feature introduces a Virtual Machine (VM) that supports aggregation of Fabric Extend Tunnels with fragmentation, reassembly, and Internet Protocol Security (IPsec) encryption functions.

The minimum configuration requirements for the Fabric IPsec Gateway VM are as follows:

- Two Central Processing Unit (CPU) cores
- 4 GB Random Access Memory (RAM)
- One Virtualization Technology for Directed I/O (VT-d) vport (eth0)
- Minimum 10 GB SSD

**Note**

To use this feature on the applicable models of VSP 4900 Series, you must install an SSD module in the switch.

To configure IPsec on a switch through the Fabric IPsec Gateway VM, see [Fabric IPsec Gateway Configuration using CLI](#) on page 841.

Fabric IPsec Gateway supports the following services through the VM:

- IPsec with fragmentation and reassembly - for the VXLAN traffic that needs IPsec, the network routes the packets through the Fabric IPsec Gateway VM that provides IPsec encryption and decryption for VXLAN packets. The system also supports fragmentation and reassembly for IPsec tunnels that you configure on the VM, and a minimum of 1300 bytes of Maximum Transmission Unit (MTU) value.
- Fragmentation and reassembly - the Fabric IPsec Gateway VM performs fragmentation and reassembly for VXLAN and IPsec tunnels, for which the network routes the packets through the VM. The system supports a minimum of 750 bytes of Maximum Transmission Unit (MTU) value.

## IPsec Coupled and Decoupled Mode

A device is in IPsec decoupled mode when IPsec and Fabric Extend (FE) termination takes place on two different IP addresses. It is in IPsec coupled mode when IPsec and Fabric Extend (FE) termination takes place on the same IP address.

The XA1400 Series devices support both IPsec decoupled and coupled modes. The VSP 4900 Series and VSP 7400 Series devices support IPsec in decoupled mode only. You must configure the IPsec tunnel in decoupled mode to enable IPsec termination in the Fabric IPsec Gateway VM. For more information about how to configure IPsec tunnels on the VM, see [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 847.

## Digital Certificates for Fabric IPsec Gateway

Fabric IPsec Gateway supports digital certificates for IPsec authentication of Fabric Extend tunnels. To support different certificates for different IPsec tunnels, you can configure multiple certificate authority (CA) trustpoints and identity subject certificates.

If you are not familiar with digital certificates, see [Digital Certificate/PKI](#) on page 2875 for additional background information like digital certificate terminology.

### *Online Certificate Provisioning*

The switch uses IPsec Simple Certificate Enrollment Protocol (SCEP) to obtain the CA certificate, and then validates the CA certificate against the certificate chain.

#### **Note**

Extreme validated the Fabric IPsec Gateway SCEP implementation with EJBCA CA Server only. Fabric IPsec Gateway SCEP cannot currently use Win CA like digital certificate support in VOSS.

Use trustpoints to manage and track CAs and certificates. The switch can enroll with a trustpoint to obtain an identity certificate. You must configure the CA URL, the CA common name, and select the HTTP request type to configure the CA server trustpoint.

Configure the certificate subject parameters to provide the device distinguished name (DN) and key name for the generated key pair (the private key). If you do not configure a private key, the switch generates one. The switch validates the returned certificate against the trustpoint's CA certificate.

You can remove subject certificates from the CA trustpoint or clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

### *Offline Certificate Provisioning*

Offline certificate management supports switches that cannot communicate with the CA to obtain the identity certificate online by certificate enrollment operation.

The switch generates the certificate signing request (CSR) using the subject DN and the private key that you configure in the CLI. If you do not configure a private key, the switch generates one.

Transfer the CSR to the offline CA to be signed. Retrieve the signed certificate to validate against the original CSR. You must manually transfer all certificates in the certificate chain to the switch. The signed certificate must include the subject-label to map it to a locally-generated CSR for validation.

You must manually download Certificate Revocation List (CRL) files. You can remove offline subject certificates only if the subject-label is not configured on an IPsec tunnel.

## Operational Considerations and Restrictions

Consider the following when deploying Extreme Integrated Application Hosting (IAH) on various switches:

**Table 113: Operational Considerations**

|                                | VSP 7400 Series                                     | VSP 4900 Series                                     |
|--------------------------------|-----------------------------------------------------|-----------------------------------------------------|
| Number of IAH ports            | VSP 7432CQ: 2<br>VSP 7400-48Y: 1                    | VSP4900-12MXU-12XE: 2<br>VSP4900-24XE: 2            |
| Multiple simultaneous VMs      | Supported                                           | Not supported                                       |
| Pre-installed VM               | Third Party Virtual Machine<br>Fabric IPsec Gateway | Third Party Virtual Machine<br>Fabric IPsec Gateway |
| Additional components required | None                                                | Modular Solid State Drive (SSD)                     |

## Virtual Services Configuration using CLI

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the command line interface (CLI).

### Access a Virtual Service Console

The virtual services running on a Virtual Machine (VM) require a console for configuration and monitoring purposes.

#### About This Task

Perform this procedure to access the virtual service console port for the specific VM.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Enter the following command to access the virtual service console:  
`virtual-service WORD<1-80> console`

#### Note

Type CTRL+Y to exit the console.

#### Example

```
Switch:1>enable
Switch:1#virtual-service tpvm console
```

*Variable Definitions*

Use data in the following table to use the **virtual-service** command.

| Variable                | Value                                                  |
|-------------------------|--------------------------------------------------------|
| <i>WORD&lt;1-80&gt;</i> | Specifies the virtual service name.                    |
| <i>console</i>          | Accesses the console for the specific virtual service. |

**Install a Virtual Service**

A virtual service provides the ability to support additional applications or services and simultaneously support the regular switching functionality. Each virtual service provides an Open Virtual Appliance (OVA) image, which is installed on Extreme Integrated Application Hosting (IAH) through Extreme Management Center.

**Before You Begin**

- Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

**About This Task**

Perform this procedure to install a package file to a specific location indicated by a virtual service name. This procedure also verifies if the package is in OVA format, and if a certificate is provided in the package.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Install the virtual service package:  
`virtual-service WORD<1-80> install package WORD<1-512>`

*Variable Definitions*

The following table defines parameters for the **virtual-service** command.

| Variable                         | Value                                 |
|----------------------------------|---------------------------------------|
| <i>WORD&lt;1-80&gt;</i>          | Specifies the virtual service name.   |
| <i>install</i>                   | Installs the virtual service package. |
| <i>package WORD&lt;1-512&gt;</i> | Specifies the package name and path.  |

## Configure a Virtual Service

### About This Task

Perform this procedure to configure a virtual service on the switch.

#### Note

- Following procedure lists the general sequence to configure a virtual service.
- The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.
- By default, all virtual ports of OVS connection type appear first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

### Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types. For more information about enabling trunking, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2254.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a VLAN:

#### Note

Virtual service configuration supports port-based VLANs only.

```
vlan create <2-4059> name WORD<0-64> type {port-mstprstp <0-63>}
[color <0-32>]
```

3. Add the IAH and faceplate port to the VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable the IAH and faceplate ports:

```
no shutdown
```

6. Exit to Global Configuration mode:  

```
exit
```
7. (Optional) Create a virtual service:  

```
virtual-service WORD<1-80>
```
8. (Optional) Configure the number of CPU cores to be assigned to the virtual service created:  

```
virtual-service WORD<1-80> num-cores <1-6>
```
9. (Optional) Configure the memory size to be assigned to the virtual service created:  

```
virtual-service WORD<1-80> mem-size <1-50000>
```
10. (Optional) Configure the disk to be assigned to the virtual service created:  

```
virtual-service WORD<1-80> disk WORD<1-32> size <1-30>
```
11. Configure the virtual port connection type:

**Note**

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

```
virtual-service WORD<1-80> vport WORD<1-32> connect-type {ovs | sriov
| vtd}
```

12. Configure the IAH port to associate with the connection type:

```
virtual-service WORD<1-80> vport WORD<1-32> port WORD<1-32>
```

**Important**

You cannot configure two virtual services with conflicting connect types on the same IAH port. You cannot configure two virtual services with VT-d connect type on the same IAH port.

13. Configure the NIC type of the IAH port:

```
virtual-service WORD<1-80> vport WORD<1-32> port WORD<1-32> nic-type
{virtio | e1000}
```

14. Add the virtual port to the VLAN created:

```
virtual-service WORD<1-80> vport WORD<1-32> vlan <1-4096>
```

15. Enable the virtual service:

```
virtual-service WORD<1-80> enable
```

**Example**

Configuring the TPVM virtual service using IAH port 1/s1 with an SR-IOV connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/s1
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#exit
Switch:1(config)#vlan create 10 name tpvm-lan-vlan type port-mstprstp 0
Switch:1(config)#vlan members add 10 1/s1,1/6/2
Switch:1(config)#interface GigabitEthernet 1/s1,1/6/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
```

```
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
```

Configuring the TPVM virtual service on IAH port 1/s2 with a VT-d connection type:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 10 type port-mstprstp 0
Switch:1(config)#vlan member add 10 1/1,1/s2
Switch:1(config)#interface GigabitEthernet 1/s2,1/1
Switch:1(config-if)#no shutdown
Switch:1(config-if)#exit
Switch:1(config-if)virtual-service tpvm vport eth0 port 1/s2
Switch:1(config)#virtual-service tpvm enable
```

### Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable                   | Value                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                   | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| color<0-32>                | Specifies the color of the VLAN.                                                                                                                                                                                                                                                                                                                                                   |
| nameWORD<0-64>             | Specifies a name for the VLAN to be created.                                                                                                                                                                                                                                                                                                                                       |
| type {port-mstprstp<0-63>} | Creates a VLAN by port, with the STP instance ID ranging from 0 to 63.<br><br><b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                                                                                                                                                              |

The following table defines parameters for the **vlan members** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>                                       | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>add</code>                                                  | Adds ports to a specified VLAN ID.                                                                                                                                                                                                                                                                                                                                                                                         |

The following table defines parameters for the **virtual-service** command.

| Variable                                      | Value                                                                                                                                                                                                                                                             |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-80&gt;</code>                 | Specifies a name for virtual service.                                                                                                                                                                                                                             |
| <code>connect-type {ovs   sriov   vtd}</code> | Specifies the connection type for the virtual port created. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> <li>• OVS - 16</li> <li>• SR-IOV - 16</li> <li>• VT-d - 2</li> </ul>            |
| <code>disk WORD&lt;1-32&gt;</code>            | Specifies the disk assigned to the virtual service.                                                                                                                                                                                                               |
| <code>mem-size &lt;1-50000&gt;</code>         | Specifies the memory size in Megabytes assigned to the virtual service. The default value is 1024 Megabytes.                                                                                                                                                      |
| <code>nic-type [virtio   e1000]</code>        | Specifies the Virtual Port NIC type. The default is e1000.<br><br><b>Note:</b><br>Configure this value only when the <b>connect-type</b> parameter is <i>ovs</i> .                                                                                                |
| <code>num-cores &lt;1-6&gt;</code>            | Specifies the number of cores assigned to the virtual service. The default value is 1.                                                                                                                                                                            |
| <code>port WORD&lt;1-32&gt;</code>            | Specifies the name of the Extreme Integrated Application Hosting (IAH) port associated with the virtual port. Depending on the hardware, the switch can support the following IAH ports: <ul style="list-style-type: none"> <li>• 1/s1</li> <li>• 1/s2</li> </ul> |
| <code>size &lt;1-30&gt;</code>                | Specifies the size of the disk in Gigabytes.                                                                                                                                                                                                                      |

| Variable                            | Value                                           |
|-------------------------------------|-------------------------------------------------|
| <code>vlan &lt;1-4096&gt;</code>    | Specifies the VLAN ID used by the virtual port. |
| <code>vport WORD&lt;1-32&gt;</code> | Specifies the name of the virtual port.         |

## Shut Down a Virtual Service

### About This Task

Perform this procedure to disable the virtual service.

### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Disable the virtual service:  

```
no virtual-service WORD<1-80> enable
```

### Example

Disable the virtual service.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
```

## Delete Virtual Service Resources

### About This Task

Perform this procedure to delete the virtual service resource allocation.

#### Note

If a corresponding virtual machine is running, it is stopped, and then the virtual service configuration is deleted.

### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Delete the virtual service resource allocation:  

```
no virtual-service WORD<1-80> [disk WORD<1-32>] [vport WORD<1-32>]
```

**Example**

Delete all virtual service resource allocation.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm
```

## Uninstall a Virtual Service

**About This Task**

Perform this procedure to uninstall a configured virtual service.

**Note**

If a virtual machine is running, it is stopped, and then the service directory is uninstalled.

**Before You Begin**

You must disable the virtual service before you uninstall it.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Uninstall a specific virtual service:  
virtual-service WORD<1-80> uninstall

**Example**

```
Switch:1>enable
Switch:1#virtual-service tpvm uninstall
```

*Variable Definitions*

Use data in the following table to use the **virtual-service** command.

| Variable                | Value                                          |
|-------------------------|------------------------------------------------|
| <i>WORD&lt;1-80&gt;</i> | Specifies the virtual service name.            |
| <i>uninstall</i>        | Uninstalls the specified virtual service name. |

## Display Virtual Service Configuration

**About This Task**

Perform this procedure to display the virtual service configuration on the switch.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the virtual-service configuration:  
show virtual-service config [WORD<1-80>]

## Example

Display the configuration of a specific virtual service:

### Note

Name displayed in the following show output is the Virtual Machine (VM) image name and not the version of the application within the VM. You can see the version of the application by logging in to the console. For more information, see [Access a Virtual Service Console](#) on page 825.

```
Switch:1>show virtual-service config tpvm
=====
 Virtual Services Config
=====

Virtual Service :tpvm
Additional Disk Assigned:
 Name Size (GB)
 vdb 2

VPort Information:
 Name Vlan Connect Type Insight Port NIC Type
 InsightPort
 eth0 ovs 1/s1 VIRTIO

Management Status : Enabled

```

## Display Virtual Service Installation Status

### About This Task

Perform this procedure to display the installation status for the specific virtual service. This procedure indicates if the installation finished successfully or failed to complete.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display installation status for a specific virtual service:

```
show virtual-service install WORD<1-80>
```

### Example

Display installation status for a specific virtual service:

```
Switch:1>show virtual-service install tpvm
Stage: Convert
Status: In Progress
```

## Display Virtual Services Resources

### About This Task

Perform the following procedure to display the number of remaining virtual services resources on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display statistics for all virtual services configured on the switch or a specific virtual service:

```
show virtual-service statistics [WORD<1-80>]
```

### Example

```
Switch:1>show virtual-service statistics
=====
 Virtual Services
=====

Virtual Service : tpvm

Memory Utilization (Mega Bytes)
 Allocated Used Available
 0 0 0

Number of Cores Remaining: 6
Total Memory Remaining(M): 12435
Total Disk Remaining(GB): 85
```

## Upgrade a Virtual Service

If Extreme Networks makes a new version of the virtual service available, uninstall the original virtual service and install the newer virtual service.

### Important

You can perform an upgrade of Linux inside the virtual service by standard Linux upgrade procedures. For example, TPVM is Ubuntu based, so you can use **sudo apt-get update** and **sudo apt-get upgrade**. If you complete such an upgrade, Extreme Networks is not responsible for the behavior of the VM; it has not been tested with that version on the OS.

### Before You Begin

- If you installed applications in the Third Party Virtual Machine (TPVM), you must migrate important data for those applications before you perform this procedure.
- If you created new users in the TPVM, follow standard Linux procedures to back up user names and passwords.
- For Fabric IPsec Gateway, back up the configuration files (\*.cfg) and the `shadow.txt` file, which is an encrypted file that contains the authentication keys for the IPsec tunnels. You can use the **ls** command within the VM to see the file list. Use FTP within the VM to transfer the files for backup.
- Use FTP or SFTP to transfer the new OVA image to the `/var/lib/insight/packages/` directory on the switch.

### About This Task

When you uninstall the original virtual service, the system removes the complete virtual service configuration from the configuration file.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Disable the virtual service:  
`no virtual-service WORD<1-80> enable`
3. Return to Privileged EXEC mode:  
`end`
4. Uninstall the virtual service:  
`virtual-service WORD<1-80> uninstall`
5. Install the virtual service package using the new OVA image:  
`virtual-service WORD<1-80> install package WORD<1-512>`
6. Reconfigure the virtual service; for more information, see [Configure a Virtual Service](#) on page 827.
7. Remove the original OVA image from the `/var/lib/insight/packages/` directory on the switch.  
`remove WORD<1-255>`

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

```

Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no virtual-service tpvm enable
Switch:1(config)#end
Switch:1#virtual-service tpvm uninstall
Switch:1#virtual service tpvm install package var/lib/insight/packages/
TPVM_4900_8.2.0.0.img
Switch:1#configure terminal
Switch:1(config)#virtual-service tpvm vport eth0 connect-type sriov
Switch:1(config)#virtual-service tpvm vport eth0 vlan 10
Switch:1(config)#virtual-service tpvm enable
Switch:1(config)#remove /intflash/var/lib/insight/packages/TPVM_4900_8.1.5.0.img

```

## Virtual Services Configuration using EDM

Perform the procedures in this section to configure Extreme Integrated Application Hosting (IAH) virtual services on the switch using the Enterprise Device Manager (EDM).

### Viewing Virtual Services Resources

#### About This Task

Perform the following procedure to view the number of remaining virtual services resources on the switch.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Globals** tab.

#### *Globals* Field Descriptions

Use data in the following table to use the **Globals** tab.

| Name                  | Description                                                             |
|-----------------------|-------------------------------------------------------------------------|
| <b>DiskRemain</b>     | Shows the remaining disk space available, in Gigabytes (GB).            |
| <b>NumCoresRemain</b> | Shows the remaining number of CPU cores available.                      |
| <b>MemSizeRemain</b>  | Shows the remaining amount of memory size available, in Megabytes (MB). |

### Configure a Virtual Service

#### About This Task

Perform this procedure to configure a virtual service on the switch.

#### Before You Begin

You must configure at least one virtual port to enable the virtual service. For more information, see [Configure Virtual Ports](#) on page 839.

## Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **Virtual Service**.
3. Select the **Virtual Service** tab.
4. Select **Insert**.
5. In the **Name** field, enter a unique name.
6. (Optional) In the **NumCores** field, enter a value.
7. (Optional) In the **MemSize** field, enter a value.
8. Select **Insert**.
9. In the **Enable** field for the newly inserted row, change the value to true.
10. Select **Apply**.

### **Virtual Service** Field Descriptions

Use data in the following table to use the **Virtual Service** tab.

| Name                    | Description                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>             | Specifies the name of the virtual service. Every virtual service must have a unique name.                                       |
| <b>NumCores</b>         | Specifies the number of CPU cores assigned to the virtual service. The default is 1.                                            |
| <b>MemSize</b>          | Specifies the memory size (in Megabytes) assigned to the virtual service. The default value is 1024 Megabytes.                  |
| <b>Enable</b>           | Enables the virtual service.<br><br><b>Note:</b><br>You must configure at least one virtual port to enable the virtual service. |
| <b>UtilCpuAllot</b>     | Specifies the number of CPUs allocated to the virtual service.                                                                  |
| <b>UtilCpuUtil</b>      | Specifies the average percentage of CPU utilization over the past 30 seconds.                                                   |
| <b>UtilMemAllot</b>     | Specifies the memory (in Megabytes) allocated to the virtual service.                                                           |
| <b>UtilMemUsed</b>      | Specifies the memory used (in Megabytes) by the virtual service.                                                                |
| <b>UtilMemAvailable</b> | Specifies the memory available (in Megabytes) for the virtual service.                                                          |
| <b>State</b>            | Specifies the operational state of the virtual service.                                                                         |
| <b>UpTime</b>           | Specifies the operational time of the virtual service.                                                                          |

## Configuring Disks to be used by the Virtual Service

### About This Task

Perform the following procedure to configure the number of disks to be used by the virtual service configured on the switch.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **Disks** tab.
4. Click **Insert**.
5. In the **ServName** field, enter the virtual service name.
6. In the **Name** field, enter the disk name.
7. (Optional) In the **Size** field, enter a value.
8. Click **Insert**.

### *Disks* Field Descriptions

Use data in the following table to use the **Disks** tab.

| Name                 | Description                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServName</b>      | Specifies the virtual service name.<br><br><b>Note:</b><br>The specified name must match the virtual service name configured on the switch. |
| <b>Name</b>          | Specifies the name of the disk used by the virtual service.                                                                                 |
| <b>Size</b>          | Specifies the disk size (in Gigabytes). The default is 10 Gigabytes.                                                                        |
| <b>SizeAllot</b>     | Shows the disk size (in Megabytes) allocated to the virtual service.                                                                        |
| <b>SizeAvailable</b> | Shows the available disk storage space (in Megabytes).                                                                                      |
| <b>SizeUsed</b>      | Shows the amount of disk storage space (in Megabytes) used by the virtual service.                                                          |

## Configure Virtual Ports

### About This Task

Perform the following procedure to configure virtual ports to be used by the virtual service configured on the switch.

#### Note

The names of Ethernet ports appearing in a specific Virtual Machine (VM) are not correlated to the configured virtual port names. Each VM renames the Ethernet ports as per its requirements, after they are discovered during the VM initialization.

By default, all virtual ports of OVS connection type appear first in the alphabetical order of their configured names, followed by the virtual ports of SR-IOV and VT-d connection types.

### Before You Begin

- You must enable trunking on the Extreme Integrated Application Hosting (IAH) port when you use SR-IOV and OVS connection types.
- Ensure the switch has the Ethernet drivers installed as per the SR-IOV standard, to support the VT-d and the SR-IOV connection type for the configured virtual ports.

### Procedure

- In the navigation pane, expand the **Configuration > Serviceability** folders.
- Select **Virtual Service**.
- Select the **VPorts** tab.
- Select **Insert**.
- In the **Virtual Service Name** field, enter the virtual service name.
- In the **Interface Name** field, enter a name for the virtual port.
- (Optional) In the **VlanIdList** field, enter a VLAN ID.
- (Optional) In the **ConnectType** field, select a connection type.

#### Note

Ensure the connection type you configure for the virtual port matches the connection type supported by the IAH port.

- Select **Insert**.

### **VPorts** Field Descriptions

Use data in the following table to use the **VPorts** tab.

| Name                        | Description                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Virtual Service Name</b> | Specifies the virtual service name.<br><br><b>Note:</b><br>The specified name must match the virtual service name configured on the switch. |
| <b>Interface Name</b>       | Specifies the virtual port.                                                                                                                 |

| Name               | Description                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanIdList</b>  | Specifies the VLAN ID to which the virtual port is assigned.                                                                                                                                                                                                                               |
| <b>ConnectType</b> | Specifies the virtual port connect type. The default is VT-d. The switch supports the following maximums for virtual ports: <ul style="list-style-type: none"> <li>• OVS - 16</li> <li>• SR-IOV - 16</li> <li>• VT-d - 2</li> </ul>                                                        |
| <b>Port</b>        | Specifies the name of the Extreme Integrated Application Hosting port associated with the virtual port. Depending on hardware, the switch can support the following Extreme Integrated Application Hosting ports: <ul style="list-style-type: none"> <li>• 1/s1</li> <li>• 1/s2</li> </ul> |
| <b>NicType</b>     | Specifies the Virtual Port NIC type. The default is e1000. <ul style="list-style-type: none"> <li>• virtio</li> <li>• e1000</li> </ul> <p><b>Note:</b><br/>Configure this value only when the <b>ConnectType</b> field is ovs.</p>                                                         |

## Install a Virtual Service

### Before You Begin

- Use FTP or SFTP to transfer the OVA image to the `/var/lib/insight/packages/` directory on the switch.

### About This Task

Perform the following procedure to configure the package information to be used by the virtual service.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Select **Virtual Service**.
3. Select the **Application** tab.
4. Select **Insert**.
5. In the **Name** field, enter the virtual service name.
6. Next to the **PackageName** field, select the ellipsis, select the package to install, and then select Ok.
7. Select **Insert**.

**Application** Field Descriptions

Use data in the following table to use the **Application** tab.

| Name                 | Description                                           |
|----------------------|-------------------------------------------------------|
| <b>Name</b>          | Specifies the name of the virtual service.            |
| <b>PackageName</b>   | Specifies the name and location of the package.       |
| <b>InstallResult</b> | Shows the status of the virtual service installation. |
| <b>InstallStage</b>  | Shows the stages of a package installation.           |

## Viewing Virtual Services Package File Information

**About This Task**

Perform the following procedure to view information about the package files available in the `/var/lib/insight/packages` directory, which you can use to install a new virtual service.

**Procedure**

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Virtual Service**.
3. Click the **PackageFile** tab.

**PackageFile** Field Descriptions

Use data in the following table to use the **PackageFile** tab.

| Name        | Description                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b> | Shows the name and absolute path information for package files available in the <code>/var/lib/insight/packages</code> directory. |
| <b>Date</b> | Shows the date and time when the package file was added to the directory.                                                         |
| <b>Size</b> | Shows the size (in bytes) of the package file.                                                                                    |

## Fabric IPsec Gateway Configuration using CLI

Perform the procedures in this section to configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway Virtual Machine using the command line interface (CLI).

## Configure FTP Connection to an IP Address

Fabric IPsec Gateway Virtual Machine (VM) provides a File Transfer Protocol (FTP) CLI to copy the configuration files to the VM.

**About This Task**

Perform this procedure to configure an FTP connection to a specific IP Address.

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type CTRL+Y to exit the console.

2. Configure FTP connection:  

```
ftp {A.B.C.D}
```

**Example**

Configuring FTP connection to 192.0.2.50:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ftp 192.0.2.50
```

*Variable Definitions*

The following table defines the variable for **ftp** command.

Variable	Value
{A.B.C.D}	Specifies the IP Address to establish the FTP connection with.

**Display the Default Directory on Fabric IPsec Gateway VM**

**About This Task**

Perform this procedure to display content in the default directory on the Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type CTRL+Y to exit the console.

2. Display the configured directory:  

```
ls
```

**Example**

Displaying the configured directory on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ls
coupled.cfg
```

## Load Configuration File to Fabric IPsec Gateway VM

**About This Task**

Perform this procedure to load a configuration file to the Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type CTRL+Y to exit the console.

2. Load a specific configuration file to the VM :

```
load WORD <1-255>
```

**Example**

Loading a configuration file to the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> load coupled.cfg
```

*Variable Definitions*

The following table defines the variable for **load** command.

Variable	Value
<i>WORD</i> <1-255>	Specifies the configuration file name.

## Ping an IP Address on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to ping an IP Address on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Ping an IP Address:

```
ping {A.B.C.D}
```

### Example

Pinging an IP Address on the VM.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> ping 192.0.2.35
```

### Variable Definitions

The following table defines parameters for the **ping** command.

Variable	Value
{A.B.C.D}	Specifies the IP address.

## Configure Global Parameters on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure IPsec source IP address, Local Area Network (LAN ) interface IP and gateway IP address, maximum transmission unit (MTU) value, and so on globally, on the Fabric IPsec Gateway Virtual Machine (VM).

#### Note

You must perform this procedure only after the VM boots up.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type CTRL+Y to exit the console.

2. Configure IPsec source IP address for a Fabric Extend (FE) tunnel for IPsec in decoupled mode:

```
set global ipsec-tunnel-src-ip {A.B.C.D/X}
```

3. Assign VLAN ID to the configured IPsec source IP address:

```
set global ipsec-tunnel-src-vlan <2-4059>
```

4. Configure the LAN interface IP address on the first Ethernet interface (eth0) of Fabric IPsec Gateway VM:

```
set global lan-intf-ip {A.B.C.D/X}
```

5. Assign VLAN ID to the configured LAN interface IP address:

```
set global lan-intf-vlan <2-4059>
```

6. Configure the LAN interface gateway IP address on the VOSS switch:

```
set global lan-intf-gw-ip {A.B.C.D}
```

7. Configure the logical interface gateway IP address, to add routes for FE tunnels that need Fragmentation:

```
set global fe-tunnel-gw-ip {A.B.C.D}
```

8. Configure the logical interface source IP address for the FE tunnel:

```
set global fe-tunnel-src-ip {A.B.C.D}
```

### Note

The logical interface source IP address must be same as the source IP address configured on the VOSS switch.

9. Configure the global MTU value:

```
set global mtu <mtu-value>
```

### Note

- The switch applies the global MTU value, if you do not configure MTU during the IPsec tunnel configuration.
- If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.

10. Configure the Wide Area Network (WAN) interface gateway IP address, which is the next hop for IPsec tunnels.

```
set global wan-intf-gw-ip {A.B.C.D}
```

11. Configure the virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-ip {A.B.C.D/X}
```

**Note**

You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.

12. Assign VLAN ID to the configured virtual reassembly interface IP address:

```
set global virtual-reassembly-intf-vlan <2-4059>
```

13. Disable IPsec on all configured tunnels:

```
set global ipsec-disable
```

14. Set IPsec log level:

```
set global ipsec-log-level <-1-5>
```

**Example**

Configuring global parameters on Fabric IPsec Gateway VM to configure an IPsec tunnel between two switches:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set global ipsec-tunnel-src-ip 192.0.2.10/24
FIGW> set global ipsec-tunnel-src-vlan 101
FIGW> set global lan-intf-ip 192.0.2.20/24
FIGW> set global lan-intf-vlan 30
FIGW> set global lan-intf-gw-ip 192.0.2.30
FIGW> set global fe-tunnel-src-ip 192.0.2.40
FIGW> set global wan-intf-gw-ip 192.0.2.50
FIGW> set global mtu 1950
```

*Variable Definitions*

The following table defines parameters for the **set global** command.

Variable	Value
<i>ipsec-tunnel-src-ip</i> {A.B.C.D/X}	Specifies the source IP address and subnet mask for IPsec tunnel.
<i>ipsec-tunnel-src-vlan</i> <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>lan-intf-ip</i> {A.B.C.D/X}	Specifies the IP address and subnet mask for Local Area Network (LAN) interface.

Variable	Value
<i>lan-intf-vlan</i> <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>lan-intf-gw-ip</i> {A.B.C.D}	Specifies the gateway IP address for LAN interface.
<i>fe-tunnel-gw-ip</i> {A.B.C.D}	Specifies the gateway IP address for Fabric Extend (FE) tunnel.
<i>fe-tunnel-src-ip</i> {A.B.C.D}	Specifies the source IP address for FE tunnel.
<i>mtu</i> <750-9000>	Specifies the Maximum Transmission Unit (MTU) value.  <b>Note:</b> If an IPsec tunnel is not using the fragmentation and reassembly capabilities, the default MTU value is 1950.
<i>wan-intf-gw-ip</i> {A.B.C.D}	Specifies the Wide Area Network (WAN) interface gateway IP address.
<i>virtual-reassembly-intf-ip</i> {A.B.C.D/X}	Specifies the virtual-reassembly interface IP address and subnet mask on the Fabric IPsec Gateway (VM).  <b>Note:</b> You must configure the virtual reassembly interface IP address to use the fragmentation and reassembly service.
<i>virtual-reassembly-intf-vlan</i> <2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<i>ipsec-disable</i>	Disables IPsec operationally on all tunnels in the Fabric IPsec Gateway VM.
<i>ipsec-log-level</i> <-1-5>	Specifies the IPsec log levels on Fabric IPsec Gateway VM. Following are the three levels: <ul style="list-style-type: none"> <li>• -1: Absolutely Silent</li> <li>• 0-4: Log levels</li> <li>• 5: Clear Logs</li> </ul>

## Configure IPsec Tunnels on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure IPsec tunnels on Fabric IPsec Gateway Virtual Machine (VM).

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type CTRL+Y to exit the console.

2. Configure the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel:

```
set ipsec <1-255> mtu <1300 - 9000>
```

### Note

The MTU range <1300-9000> is applicable for FE tunnels with IPsec and fragmentation and reassembly capabilities.

3. Configure the encryption key length for IPsec Tunnel:

```
set ipsec <1-255> encryption-key-length <128 | 256>
```

### Note

By default, the encryption key length is 128 bytes.

4. Configure the authentication key for specific IPsec tunnel:

```
set ipsec <1-255> auth-key WORD <1-32>
```

### Note

You must not use special characters ?, \, &, <, >, #.

5. Configure VXLAN destination IP address for IPsec tunnel:

```
set ipsec <1-255> fe-tunnel-dest-ip {A.B.C.D}
```

### Note

The VXLAN destination IP address for IPsec tunnel must be the same as the VXLAN destination IP address for FE tunnel.

6. Configure the IPsec destination IP address for the specific tunnel deployed in decoupled mode:

```
set ipsec <1-255> ipsec-dest-ip {A.B.C.D}
```

7. Configure a name for the IPsec tunnel:

```
set ipsec <1-255> tunnel-name WORD <1-64>
```

8. Identify if the specific tunnel is a responder or initiator in Network Address Translation (NAT) cases:

```
set ipsec <1-255> responder-only <true | false>
```

9. Enable or disable IPsec on a specific tunnel:

```
set ipsec <1-255> <enable | disable>
```

## Example

Configuring parameters for IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
```

```
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set ipsec 1 ipsec-dest-ip 192.0.2.5
FIGW> set ipsec 1 mtu 1950
FIGW> set ipsec 1 auth-key abcd
FIGW> set ipsec 1 tunnel-name Tunnel-to-BEB2
FIGW> set ipsec 1 fe-tunnel-dest-ip 192.0.2.15
FIGW> set ipsec 1 encryption-key-length 128
FIGW> set ipsec 1 admin-state enable
```

Variable Definitions

The following table defines parameters for the **set ipsec** command.

Variable	Value
<1-255>	Specifies the unique ID for the IPsec tunnel.
<i>admin-state</i> <enable   disable>	Enables or disables IPsec on the specific IPsec tunnel.
<i>auth-key</i> WORD <1-32>	Specifies the pre-shared authentication key.  <b>Note:</b> You must not use special characters ?, \, &, <, >, #.
<i>encryption-key-length</i> <128   256>	Specifies the encryption key length for the IPsec tunnel. The default encryption key length is 128.
<i>fe-tunnel-dest-ip</i> {A.B.C.D}	Specifies the destination IP address for Fabric Extend (FE) tunnel.
<i>ipsec-dest-ip</i> {A.B.C.D}	Specifies the destination IP address for IPsec tunnel.
<i>mtu</i> <1300-9000	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with both IPsec and fragmentation and assembly capabilities.
<i>responder-only</i> <true   false>	Specifies if the IPsec session in the FE tunnel will be in responder only mode or initiator mode. When in responder mode the FE tunnel will only respond to the incoming request and not initiate the IPsec connection. By default both sides of IPsec connection will be initiators in the FE tunnel. Configure the IPsec tunnel to be in responder only mode when there is Network Address Translation (NAT) between the IPsec connection. For more information about NAT, see <a href="#">IPsec NAT-T</a> on page 1683.
<i>tunnel-name</i> WORD <1-64>	Specifies a name for the IPsec tunnel.

Configure the Subject Identity on Fabric IPsec Gateway VM

About This Task

Use this procedure to configure the subject parameters to identify the device.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type CTRL+Y to exit the console.

2. Configure the distinguished name of the device:  

```
set certificate subject <subject-label> DN <name>
```
3. (Optional) Configure the name of the generated key-pair:  

```
set certificate subject <subject-label> key-label <key-label>
```

## Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate subject ExtremeLab DN "CN=subca5, OU=Test, O=Extreme, L=Town,
ST=State, E=email@extremenetworks.com"
FIGW>set certificate subject ExtremeLab key-label key1
```

## Variable Definitions

The following table defines parameters for the **set certificate subject** command.

Variable	Value
<i>DN &lt;name&gt;</i>	Specifies the distinguished name. You can create a comma-separated list.
<i>key-label &lt;key-label&gt;</i>	Specifies the key name of the generated key pair. This parameter is optional. If you do not configure one, the switch generates one the same as the subject-label.
<i>&lt;subject-label&gt;</i>	Specifies the subject identity. You cannot use the following special characters: <ul style="list-style-type: none"> <li>• question mark (?)</li> <li>• backslash (\)</li> <li>• ampersand (&amp;)</li> <li>• less than (&lt;)</li> <li>• greater than (&gt;)</li> <li>• pound (#)</li> </ul>

## Generate the Key Pair on Fabric IPsec Gateway VM

### About This Task

Use the following procedure to generate the private and public key pair. By default, VOSS generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new key.

### Before You Begin

- Configure an EJBCA CA server.

- Configure a route from Fabric IPsec Gateway to the EJBCA CA server.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Generate the key:

```
certificate generate key <type> <size> <key-label>
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>certificate generate key rsa 2048 key_rsa
fingerprint: 09ac0c64b9bf3ad04dc67f20942c674e
```

### Variable Definitions

The following table defines parameters for the **certificate generate key** command.

Variable	Value
<i>key-label</i>	Specifies the key name of the generated key pair.
<i>size</i>	Specifies the size of key-pair to be generated. The switch supports 2048.
<i>type</i>	Specifies the type of cryptography algorithm used to generate the key-pair. The switch uses only rsa as the cryptography algorithm type.

## Configure a Trustpoint CA on Fabric IPsec Gateway VM

### About This Task

Use this procedure to configure the certificate authority (CA) to use Simple Certificate Enrollment Protocol (SCEP) with a CA server for online certificate provisioning.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Configure the trusted CA URL:

```
set certificate ca-trustpoint <ca-label> ca-url <ca-url>
```

3. Configure the common name of the CA:

```
set certificate ca-trustpoint <ca-label> caname <caname>
```

4. Configure the HTTP request type to support the type of CA:

```
set certificate ca-trustpoint <ca-label> get-method <post | get>
```

5. Configure the appropriate action:

- Configure the trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca <ca-trustpoint> caAuth
```

- Generate the certificate enrollment request, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca <ca-trustpoint> enroll <subject-label>
```

- Get the Certificate Revocation List (CRL) from the CDP and store into a file:

```
certificate get crl-from <A.B.C.D> <user> <file-path> <cacert-
filename>
```

- Get the CA certificate obtained from the trustpoint CA:

```
certificate get cacert-from <A.B.C.D> <user> <file-path>
```

- Get the subject certificate obtained from the trustpoint CA:

```
certificate get signedcert-from <A.B.C.D> <user> <file-path>
<subject-label>
```

- Release the locally stored certificate associated with the trustpoint CA after revocation:

```
certificate ca <ca-trustpoint> remove <subject-label>
```

- Remove all certificates from the CA trustpoint:

#### Note

You can clean the CA trustpoint only if the subject-label is not configured on an IPsec tunnel.

```
certificate ca <ca-trustpoint> clean
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>set certificate ca-trustpoint caExtremeEJBCA ca-url http://192.0.2.9:8080/ejbca/
publicweb/apply/scep/test/pkiclient.exe
FIGW>set certificate ca-trustpoint caExtremeEJBCA caname subca5
FIGW>set certificate ca-trustpoint caExtremeEJBCA get-method post
```

### Variable Definitions

The following table defines parameters for the **set certificate ca-trustpoint** command.

Variable	Value
<code>&lt;ca-label&gt;</code>	Specifies the name of the certificate authority (CA). The name can use alphanumeric characters and is case-sensitive. The maximum length is 45 characters.
<code>ca-url &lt;ca-url&gt;</code>	Specifies the trusted CA URL.
<code>caname &lt;caname&gt;</code>	Specifies the name of the owner of the device or user.
<code>get-method &lt;post   get&gt;</code>	Specifies the HTTP request style. You can use post for EJBCA or get for Win2012 CA. The default value is post.

The following table defines parameters for the **certificate ca** command.

Variable	Value
<code>&lt;ca-trustpoint&gt;</code>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<code>&lt;subject-label&gt;</code>	Specifies the subject identity.

The following table defines parameters for the **certificate get** command.

Variable	Value
<code>cacert-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt;</code>	Specifies where to obtain the CA certificate. Specify the IP address, username, and remote file path.
<code>crl-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt; &lt;cacert-filename&gt;</code>	Specifies where to obtain the Certificate Revocation List. Specify the IP address, username, remote file path, and the CA certificate file to verify the CRL.
<code>signedcert-from &lt;A.B.C.D&gt; &lt;user&gt; &lt;file-path&gt; &lt;subject-label&gt;</code>	Specifies where to obtain the subject certificate. Specify the IP address, username, remote file path, and subject label.

## Generate the Certificate Signing Request on Fabric IPsec Gateway VM

### About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate.

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type CTRL+Y to exit the console.

2. Generate the CSR:  

```
certificate generate csr <subject-label>
```
3. Configure where to send the CSR for signing:  

```
certificate send-csr-to <A.B.C.D> <user> <remote-path> <subject-label>
```

*Variable Definitions*

The following table defines parameters for the **certificate generate csr** command.

Variable	Value
<subject-label>	Specifies the subject identity.

The following table defines parameters for the **certificate send-csr-to** command.

Variable	Value
<A.B.C.D>	Specifies the IP address for the certificate authority.
<remote-path>	Specifies the file path on the certificate authority.
<subject-label>	Specifies the subject identity.
<user>	Specifies the username for the certificate authority.

**Remove Keys and Certificates on Fabric IPsec Gateway VM**

**Before You Begin**

You can remove subject certificates from the certificate authority (CA) trustpoint only if the subject-label is not configured on an IPsec tunnel.

**About This Task**

Use this procedure to remove keys or certificates from the certificate store.

## Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

### Note

Type CTRL+Y to exit the console.

2. Remove a key:  

```
certificate remove key <key-label>
```
3. Remove a specific certificate from the store:  

```
certificate remove offline-cacert <filename>
```
4. Remove a Certificate Revocation List (CRL) certificate from the store:  

```
certificate remove offline-crl <filename>
```
5. Remove signed certificates for a specific subject label:  

```
certificate remove offline-subject-certs <subject-label>
```
6. Remove a specific identity certificate from the CA trustpoint:  

```
certificate ca <ca-trustpoint> remove <subject-label>
```
7. Remove all certificates from the CA trustPoint:  

```
certificate ca <ca-trustpoint> clean
```

## Variable Definitions

The following table defines parameters for the **certificate remove** command.

Variable	Value
<i>key</i> <key-label>	Specifies the key name to remove.
<i>offline-cacert</i> <filename>	Specifies the certificate filename to remove.
<i>offline-crl</i> <filename>	Specifies the Certificate Revocation List (CRL) certificate filename to remove.
<i>offline-subject-certs</i> <subject-label>	Specifies the subject label for which to remove signed certificates.

The following table defines parameters for the **certificate ca** command.

Variable	Value
<ca-trustpoint>	Specifies the name of the certificate authority. The name can be alphanumeric and is case-sensitive. The maximum length is 45 characters.
<subject-label>	Specifies the subject identity.

## View the Certificate Details on Fabric IPsec Gateway VM

### About This Task

Use this procedure for the following tasks:

- Display the digital certificate for a certificate type or list all the certificate details from the local store.
- Display the certificate authority (CA) details for a trustpoint CA name or list all the CA details from the local store if the CA name is not specified.
- Display the configured key details for a key name.
- Display the configured subject details.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display all digital certificates:

```
show certificates all
```

3. Display the CA details:

```
show certificates cacert [<ca-label>]
```

4. Display Certificate Revocation List (CRL) certificate details:

```
show certificates crl [<ca-label>]
```

5. Display the certificate signing request (CSR) details:

```
show certificates csr [<ca-label>]
```

6. Display the name and public key of all the key-pairs:

```
show certificate keys
```

7. Display the details of signed certificates:

```
show certificate signed [<ca-label>]
```

### Example

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificates keys key_rsa
Key Label: key_rsa
private key with:
pubkey: RSA 2048 bits
keyid: ef:4c:1d:a7:cc:84:6f:87:da:e4:de:99:07:3d:96:fc:9a:d1:c9:f4
subjkey: cb:d1:67:a0:da:9c:05:ce:c0:0d:a3:5c:1b:ba:ce:3f:ff:af:8f:77
```

### Variable Definitions

The following table defines parameters for the **show certificates** command.

Variable	Value
ca <ca-label>	Specifies the name of the certificate authority (CA). If you do not specify the name, the command displays the details of all configured CAs.

## View the Certificate Configuration on Fabric IPsec Gateway VM

### About This Task

Use this procedure to view the certificate configuration for the VM.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display all configured entries:

```
show running-config
```

3. Display the CA trustpoint configuration:

```
show certificate-config ca-trustpoint [<ca-label>]
```

4. Display the subject-related configuration:

```
show certificate-config subject [<subject-label>]
```

### Examples

```
Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config ca-trustpoint
certificate {
 ca-trustpoint {
 ca-label a;
 caname subCaVpn;
 ca-url http://10.2.38.35:8080/ejbca/publicweb/apply/scep/test/pkiclient.exe;
 get-method post;
 }
}

Switch:1>enable
Switch:1#virtual-service FIGW console
FIGW>show certificate-config subject
certificate {
 subject {
 subject-label fig;
 DN CN=FIGW;
 key-label gigi;
 }
 subject {
 subject-label figv;
 DN CN=figvpn;
 }
}
```

## Configure Logical Interface Tunnel on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to configure a Fabric Extend (FE) tunnel with only fragmentation and reassembly capabilities, on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Configure the logical interface destination IP address for the specific tunnel:

```
set logical-intf-tunnel <1-255> fe-tunnel-dest-ip {A.B.C.D}
```

3. Configure the Maximum Transmission Unit (MTU) value for the specific tunnel:

```
set logical-intf-tunnel <1-255> mtu <750-9000>
```

#### Note

The MTU range <750-9000> is applicable for FE tunnels with only fragmentation and reassembly capabilities.

4. Configure tunnel name:

```
set logical-intf-tunnel <1-255> tunnel-name WORD <1-64>
```

### Example

Configuring logical interface tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> set logical-intf-tunnel 2 fe-tunnel-dest-ip 192.0.2.50
FIGW> set logical-intf-tunnel 2 mtu 1300
FIGW> set logical-intf-tunnel 2 tunnel-name Tunnel-to-BEB2
```

### Variable Definitions

The following table defines parameters for the **set logical-intf-tunnel** command.

Variable	Value
<1-255>	Specifies the unique ID for the logical interface tunnel.
<i>fe-tunnel-dest-ip</i> {A.B.C.D}	Specifies the FE tunnel destination IP address for the logical interface.

Variable	Value
<code>mtu &lt;750-9000&gt;</code>	Specifies the Maximum Transmission Unit (MTU) value for the FE tunnel with only fragmentation and assembly capabilities.
<code>tunnel-name WORD &lt;1-64&gt;</code>	Specifies a name for the the logical interface tunnel.

## Save Running Configuration to a File

### About This Task

Perform this procedure to save the current configuration on Fabric IPsec Gateway Virtual Machine (VM) to a specific file.

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Save configuration to the default configuration file:  

```
save config
```
3. Save configuration to a specific file in the Fabric IPsec Gateway VM.  

```
save config file WORD <1-255>
```

### Example

Saving configuration of Fabric IPsec Gateway VM to file "test":

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> save config file test
```

### Variable Definitions

The following table defines parameters for the **save config** command.

Variable	Value
<code>file WORD &lt;1-255&gt;</code>	Specifies the name of file to save the configuration of the Fabric IPsec Gateway VM.

## Remove Configuration File from Fabric IPsec Gateway VM

### About This Task

Perform this procedure to remove a specific configuration file from Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Remove the configuration file:

```
remove WORD <1-255>
```

### Example

Remove configuration file "test" from Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> remove test
```

### Variable Definitions

The following table defines parameters for the **remove** command.

Variable	Value
<i>WORD</i> <1-255>	Specifies the configuration file name that the system removes from Fabric IPsec Gateway VM.

## Delete Global Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to delete the global parameters that you configure on Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:  

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**  
Type CTRL+Y to exit the console.

2. Delete configuration of specific global parameters:  

```
delete global <fe-tunnel-gw-ip | fe-tunnel-src-ip | ipsec-disable | ipsec-tunnel-src-ip | ipsec-tunnel-src-vlan | lan-intf-gw-ip | lan-intf-ip | lan-intf-vlan | mtu | virtual-reassembly-intf-ip | virtual-reassembly-intf-vlan | wan-intf-gw-ip>
```

**Example**

Deleting the global Maximum Transmission Unit (MTU) configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete global mtu
```

*Variable Definitions*

The following table defines parameters for the **delete global** command.

Variable	Value
<i>fe-tunnel-gw-ip</i>	Deletes the global gateway IP address for Fabric Extend (FE) tunnel.
<i>fe-tunnel-src-ip</i>	Deletes the global source IP address for FE tunnel.
<i>ipsec-disable</i>	Deletes the global IPsec configuration.
<i>ipsec-tunnel-src-ip</i>	Deletes the global source IP address and subnet mask for IPsec tunnel.
<i>ipsec-tunnel-src-vlan</i>	Deletes the global source VLAN configuration for IPsec tunnel.
<i>lan-intf-gw-ip</i>	Deletes the global gateway IP address on the Local Area Network (LAN) interface.
<i>lan-intf-ip</i>	Deletes the global IP address and subnet mask on LAN interface.
<i>lan-intf-vlan</i>	Deletes the global VLAN configuration on LAN interface.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value to its default, that is 1950 bytes.
<i>virtual-reassembly-intf-ip</i>	Deletes the global virtual-reassembly interface IP address and subnet mask.

Variable	Value
<i>virtual-reassembly-intf-vlan</i>	Deletes the global virtual-reassembly interface VLAN configuration.
<i>wan-intf-gw-ip</i>	Deletes the global gateway IP address on the Wide Area Network (WAN) interface.

## Delete IPsec Tunnel Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to delete the configuration of specific IPsec tunnel on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Delete the configuration of specific IPsec tunnel:

```
delete ipsec <1-255> <admin-state enable | auth-key | encryption-key-length | fe-tunnel-dest-ip | ipsec-dest-ip | mtu | responder-only | tunnel-name>
```

### Example

Deleting the authentication key and tunnel name configured on IPsec tunnel with ID 2:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete ipsec 2 auth-key
FIGW> delete ipsec 2 tunnel-name
```

### Variable Definitions

The following table defines parameters for the **delete ipsec** command.

Variable	Value
<1-255>	Specifies the unique ID of the configured IPsec tunnel.
<i>admin-state enable</i>	Disables the IPsec status on the specific IPsec tunnel.
<i>auth-key</i>	Deletes the authentication key that you configure on the specific IPsec tunnel.

Variable	Value
<i>encryption-key-length</i>	Resets the encryption key length for the specific IPsec tunnel to its default value, that is 128 bit.
<i>fe-tunnel-dest-ip</i>	Deletes the destination IP address that you configure on the Fabric Extend (FE) tunnel.
<i>ipsec-dest-ip</i>	Deletes the destination IP address that you configure on the IPsec tunnel.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value for the specific IPsec tunnel to the MTU value configured globally.
<i>responder-only</i>	Deletes the mode that you configure for the IPsec session in FE tunnel.
<i>tunnel-name</i>	Deletes the name that you configure for the IPsec tunnel.

## Delete Logical Interface Tunnel Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to delete configuration of a specific logical interface tunnel on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Delete configuration of specific logical interface tunnel:

```
delete logical-intf-tunnel <1-255> < fe-tunnel-dest-ip | mtu>
```

### Example

Deleting the destination IP address for Fabric Extend (FE) tunnel configured on the logical interface tunnel with ID 3.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> delete logical-intf-tunnel 3 fe-tunnel-dest-ip
```

## Variable Definitions

The following table defines parameters for the **delete logical-intf-tunnel** command.

Variable	Value
<1-255>	Specifies the unique ID of the logical interface tunnel.
<i>fe-tunnel-dest-ip</i>	Deletes the destination IP address that you configure on the logical interface tunnel.
<i>mtu</i>	Resets the Maximum Transmission Unit (MTU) value for the specific logical interface tunnel to the MTU value configured globally.

## Display Data in a File on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the data in a specific file on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display data in a file:

```
more WORD <1-255>
```

### Example

Display the data from coupled.cfg file:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> more coupled.cfg
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.10/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.20/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.45
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.50
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable
```

## Reboot Fabric IPsec Gateway VM

### About This Task

Perform this procedure to reboot the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Reboot the VM:

```
reboot
```

### Example

Rebooting Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reboot
```

## Reset Current Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to reset the current configuration on Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Reset current configuration:

```
reset-config
```

#### Note

Reboot the Fabric IPsec Gateway VM after you reset the configuration.

**Example**

Resetting current configuration on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> reset-config
```

**Traceroute to an IP address on Fabric IPsec Gateway VM****About This Task**

Perform this procedure to traceroute to an IP address on Fabric IPsec Gateway Virtual Machine (VM).

**Procedure**

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

**Note**

Type CTRL+Y to exit the console.

2. Traceroute to an IP address:

```
traceroute {A.B.C.D}
```

**Example**

Traceroute to IP address.

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> traceroute 192.0.2.100
```

*Variable Definitions*

The following table defines parameters for the **traceroute** command.

Variable	Value
{A.B.C.D}	Specifies the IP address to initiate traceroute to.

## Display the Default Configuration File on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the default configuration file on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display default configuration file:  
show default-config-file

### Example

Displaying default configuration file on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show default-config-file
coupled.cfg
```

## Display IPsec Logs on Fabric IPsec Gateway

### About This Task

Perform this procedure to display IPsec session logs on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display IPsec session logs:  
show ipsec-logs

### Example

Displaying IPsec session logs on Fabric IPsec Gateway VM:

```
Switch:1> enable
```

```

Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-logs
<<Month dd>> <<hh:mm:ss>> 15[IKE] <ipsec0-192.0.2.10|29> sending DPD request

```

## Display IPsec Routes on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the IPsec routes configured on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type CTRL+Y to exit the console.

2. Display IPsec routes installed:  
show ipsec-routes

### Example

Displaying the IPsec routes configured on Fabric IPsec Gateway VM:

```

Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>

```

```
FIGW> show ipsec-routes
192.0.2.30 via 192.0.2.20 dev eth0.125 mtu lock 1950
192.0.2.1/24 dev eth0.30 proto kernel scope link src 192.0.2.2
192.0.2.10 via 192.0.2.45 dev eth0.30
192.0.2.100/24 dev eth0.125 proto kernel scope link src 192.0.2.60
192.0.2.11/16 dev docker0 proto kernel scope link src 192.0.2.12 linkdown
```

## Display IPsec Encryption Statistics on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the IPsec encryption statistics on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type CTRL+Y to exit the console.

2. Display IPsec encryption statistics:  
show ipsec-stats

### Example

Displaying IPsec encryption statistics on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-stats

## Display the Status of IPsec Tunnels on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the status of configured IPsec tunnel on the Fabric IPsec Gateway Virtual Machine (VM):

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display the status of IPsec tunnels configured on the VM:  
show ipsec-status

### Example

Displaying the status of configured IPsec tunnel on Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show ipsec-status
Status of IKE charon daemon (strongSwan 5.3.5, Linux 4.4.0-128-generic, x86_64):
 uptime: 13 days, since <<month, day hh:mm:ss year>>
 malloc: sbrk 2433024, mmap 0, used 369408, free 2063616
 worker threads: 11 of 16 idle, 5/0/0/0 working, job queue: 0/0/0/0, scheduled: 3
 loaded plugins: charon test-vectors aes rc2 sha1 sha2 md4 md5 random nonce x509
 revocation constraints
 pubkey pkcs1 pkcs7 pkcs8 pkcs12 pgp dnskey sshkey pem openssl fips-prf gmp agent xcbc

ipsec0-192.0.2.5(377): 192.0.2.60/32 === 192.0.2.5/32

```

## Display Current Configuration on Fabric IPsec Gateway VM

### About This Task

Perform this procedure to display the parameters configured currently on the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:

```
enable
```

```
virtual-service WORD<1-128> console
```

#### Note

Type CTRL+Y to exit the console.

2. Display the parameters currently configured on the VM:

```
show running-config
```

### Example

Displaying the parameters configured on Fabric IPsec Gateway VM:

```

Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show running-config
set global ipsec-tunnel-src-vlan 125
set global ipsec-tunnel-src-ip 192.0.2.1/24
set global lan-intf-vlan 30
set global lan-intf-ip 192.0.2.10/24
set global lan-intf-gw-ip 192.0.2.25
set global fe-tunnel-src-ip 192.0.2.55
set global wan-intf-gw-ip 192.0.2.11
set global mtu 1950
set ipsec 1 auth-key *****
set ipsec 1 fe-tunnel-dest-ip 192.0.2.70
set ipsec 1 encryption-key-length 128
set ipsec 1 admin-state enable

```

## Display Current Version of Fabric IPsec Gateway VM

### About This Task

Display current version of the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type CTRL+Y to exit the console.

2. Display current version of the VM:  
show version

### Example

Displaying current version of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y

<cr>
FIGW> show version
FabricIPSecGW_VM_1.0
```

## Log Out of Fabric IPsec Gateway VM

### About This Task

Perform this procedure to log out of the Fabric IPsec Gateway Virtual Machine (VM).

### Procedure

1. Enter Fabric IPsec Gateway Configuration mode:  
enable  
  
virtual-service WORD<1-128> console

#### Note

Type CTRL+Y to exit the console.

2. Log out of VM:  
exit

### Example

Logging out of the Fabric IPsec Gateway VM:

```
Switch:1> enable
Switch:1# virtual-service figw console
Connected to domain figw
Escape character is ^Y
```

```
<cr>
FIGW> exit
```

# Fabric Configuration Work Flow

---

The following section describes the generic work flow to configure SPBM and IS-IS infrastructure and services on your network.

## Note

This section is an overview. For further details on the SPBM and IS-IS infrastructure and configuration, see the sections described in the Documentation Sources section that follows.

### 1. Infrastructure configuration

As a first step, you must configure your basic infrastructure for Shortest Path Bridging MAC (SPBM).

### 2. Services configuration

After you complete the infrastructure configuration, you configure the appropriate services for your network to run on top of your base architecture. This includes:

- Layer 2 and Layer 3 VSNs
- IP Shortcuts
- Inter-VSN routing

### 3. Fabric interoperations

You can also configure Fabric gateway functionality like SPB-PIM Gateway and VXLAN Gateway.

### 4. Operations and Management

To debug connectivity issues and isolate network faults in the SPBM network, you can use Connectivity Fault Management (CFM).

## Documentation Sources

---

See the following documentation sources:

- For information on basic SPBM infrastructure and IS-IS configuration and Layer 2 services, see [Fabric Basics and Layer 2 Services](#) on page 876.

This section also contains information on configuring Fabric Extend, which enables your enterprise to extend Fabric Connect technology over Layer 2 or Layer 3 core networks.

- For information on Fabric Layer 3 services configuration, see [Fabric Layer 3 Services](#) on page 1226.
- For information on IP Multicast over Fabric Connect configuration and services, see [IP Multicast over Fabric Connect](#) on page 1579. [SPB-PIM Gateway configuration](#) on page 3045 also contains information about configuring the SPB-PIM Gateway (SPB-PIM GW), which provides multicast inter-domain communication between an SPB network and a PIM network. The SPB-PIM GW can also connect two independent SPB domains.

- For information on CFM, see [Connectivity Fault Management](#) on page 3553.
- For information on VXLAN Gateway configuration, see [VXLAN Gateway](#) on page 3963.

## SPBM and IS-IS infrastructure configuration

---

This chapter provides concepts and procedures to configure the basic infrastructure for Shortest Path Bridging MAC (SPBM).

### SPBM and IS-IS Infrastructure Fundamentals

Shortest Path Bridging MAC (SPBM) is a next generation virtualization technology that revolutionizes the design, deployment, and operations of carriers and service providers, along with enterprise campus core networks and the enterprise data center. SPBM provides massive scalability while at the same time reducing the complexity of the network.

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet based link-state protocol that provides all virtualization services in an integrated model. In addition, by relying on endpoint service provisioning only, the idea of building your network once and not touching it again becomes a true reality. This technology provides all the features and benefits required by carrier-grade, enterprise and service provider deployments without the complexity of alternative technologies, for example, Multiprotocol Label Switching (MPLS).

SPBM simplifies deployments by eliminating the need to configure multiple points throughout the network. When you add new connectivity services to an SPBM network you do not need intrusive core provisioning. The simple endpoint provisioning is done where the application meets the network, with all points in between automatically provisioned through the robust link-state protocol, Intermediate-System-to-Intermediate-System (IS-IS).

Most Ethernet based networks use 802.1Q tagged interfaces between the routing switches. SPBM uses two Backbone VLANs (BVLANS) that are used as the transport instance. A B-VLAN is not a traditional VLAN in the sense that it does not flood unknown, broadcast or multicast traffic, but only forwards based on IS-IS provisioned backbone MAC (B-MAC) tables. After you configure the B-VLANs and the IS-IS protocol is operational, you can map the services to service instances.

SPBM uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network. SPBM uses IS-IS shortest path trees to populate forwarding tables for the individual B-MAC addresses of each participating node.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops have no effect on the backbone infrastructure.)

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- **Unicast**

- For a Layer 2 VSN, the device associates the I-SID with a customer VLAN, which the device then virtualizes across the backbone. Layer 2 VSNs associate one VLAN per I-SID.
- With Layer 3 VSN, the device associates the I-SID with a customer VRF, which the device virtualizes across the backbone. Layer 3 VSNs associate one VRF per I-SID.
- With Inter-VSN routing, Layer 3 devices, routers, or hosts connect to the SPBM cloud using the SPBM Layer 2 VSN service. The Backbone Core Bridge can transmit traffic between different VLANs with different I-SIDs.
- With IP shortcuts, no I-SID is required, forwarding for the Global Routing Table (GRT) is done using IS-IS based shortest path BMAC reachability.

For more information on Fabric Layer 3 services, see [Fabric Layer 3 Services](#) on page 1226.

- **Multicast**

- With Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 2 VSN I-SID.
- With Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and the scope I-SID is based on the Layer 3 VSN I-SID.
- With IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream, but there is no I-SID for the scope, which is the Global Routing Table (GRT).

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1579.

**Note**

Inter-VSN routing for IP multicast over Fabric Connect is not supported.

The switch supports the IEEE 802.1aq standard of SPBM, which allows for larger Layer 2 topologies and permits faster convergence.

### *Multiple tenants using different SPBM services*

The following figure shows multiple tenants using different services within an SPBM metro network. In this network, you can use some or all of the SPBM implementation options to meet the needs of the community while maintaining the security of information within VLAN members.

**Figure 49: Multi-tenant SPBM metro network**

To illustrate the versatility and robustness of SPBM even further, the following figure shows a logical view of multiple tenants in a ring topology. In this architecture, each tenant has its own domain where some users have VLAN requirements and are using Layer 2 VSNs and others have VRF requirements and are using Layer 3 VSNs. In all three domains, they can share data center resources across the SPBM network.

**Figure 50: SPBM ring topology with shared data centers**

### *spbm-config-mode boot flag*

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. The boot flag called **spbm-config-mode** ensures that SPB and PIM stay mutually exclusive.

- The **spbm-config-mode** boot flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you enable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

#### Important

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you disable the boot flag, save the configuration and reboot with the saved configuration. After you disable the flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

For more information, see [IP Multicast](#) on page 1319.

### *vxlan-gw-full-interworking-mode Boot Configuration Flag*

The VXLAN Gateway implementation is available in the following modes:

- **Base Interworking Mode** – This is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
- **Full Interworking Mode** – This mode supports the Base mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. To enter this mode, you must enable the **vxlan-gw-full-interworking-mode** boot configuration flag.

#### Note

Changing the mode requires a reboot for the change to take effect.

### *MAC-in-MAC encapsulation*

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC source address (BMAC-SA) and a B-MAC destination address (BMAC-DA) to identify the backbone source and destination addresses.

The originating node creates a MAC header that is used for delivery from end to end. As the MAC header stays the same across the network, there is no need to swap a label or do a route lookup at each node, allowing the frame to follow the most efficient forwarding path end to end.

Encapsulating customer MAC addresses in B-MAC addresses improves network scalability (no end-user C-MAC learning is required in the core) and also significantly improves network robustness (loops in access networks do not impact forwarding results in the backbone infrastructure.)

## I-SID

SPBM introduces a service instance identifier called I-SID. SPBM uses I-SIDs to separate services from the infrastructure. After you create an SPBM infrastructure, you can add additional services (such as VLAN extensions or VRF extensions) by provisioning the endpoints only. The SPBM endpoints are Backbone Edge Bridges (BEBs), which mark the boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain. I-SIDs are provisioned on the BEBs to be associated with a particular service instance. In the SPBM core, the bridges are Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the B-MAC-DA.

The SPBM B-MAC header includes a Service Instance Identifier (I-SID) with a length of 32 bits with a 24-bit ID. I-SIDs identify a service instance for virtualized traffic in an encapsulated SPBM frame. You can use I-SIDs in a Virtual Services Network (VSN) for VLANs or VRFs across the MAC-in-MAC backbone:

- For a Layer 2 VSN, the I-SID is associated with a customer VLAN, which is then virtualized across the backbone. Layer 2 VSNs offer an any-any LAN service type. Layer 2 VSNs associate one VLAN per I-SID.
- For a Layer 2 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 2 VSN. A multicast stream with a scope of Layer 2 VSN can only transmit a multicast stream for the same Layer 2 VSN.
- For a *Transparent Port UNI*, the I-SID is associated with a port or MLT, which is then virtualized across the backbone. *Transparent Port UNI* associates multiple ports or MLT to an I-SID.
- For a Layer 3 VSN, the I-SID is associated with a customer VRF, which is also virtualized across the backbone. Layer 3 VSNs are always full-mesh topologies. Layer 3 VSNs associate one VRF per I-SID.
- For a Layer 3 VSN with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and a scope I-SID that defines the scope as Layer 3 VSN. A multicast stream with a scope of Layer 3 VSN can only transmit a multicast stream for the same Layer 3 VSN.
- For IP Shortcuts with IP multicast over Fabric Connect, the BEB associates a data I-SID with the multicast stream and defines the scope as Layer 3 GRT. A multicast stream with a scope of Layer 3 GRT can only transmit a multicast stream for a Layer 3 GRT.

### Note

I-SID configuration is required only for virtual services such as Layer 2 VSN and Layer 3 VSN. With IP Shortcuts with unicast, no I-SID is required, forwarding for the Global Routing table is done using IS-IS based shortest path B-MAC reachability.

### Note

I-SID to VLAN binding is used to automatically determine the path between client and server in order to attach network devices to FA Zero touch services.

## BCBs and BEBs

**Table 114: Fabric Mode product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .

	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 6.1
	XA1400 Series	VOSS 8.0.50

The boundary between the core MAC-in-MAC SPBM domain and the edge customer 802.1Q domain is handled by Backbone Edge Bridges (BEBs). I-SIDs are provisioned on the BEBs to be associated with a particular service instance.

In the SPBM core, the bridges are referred to as Backbone Core Bridges (BCBs). BCBs forward encapsulated traffic based on the BMAC-DA.

**Important**

SPBM separates the payload from the transport over the SPBM infrastructure. Configure all virtualization services on the BEBs at the edge of the network. There is no provisioning required on the core SPBM switches. This provides a robust carrier grade architecture where configuration on the core switches never needs to be touched when adding new services.

A BEB performs the same functionality as a BCB, but it also terminates one or more Virtual Service Networks (VSN). A BCB does not terminate any VSNs and is unaware of the VSN traffic it transports. A BCB simply knows how to reach any other BEB in the SPBM backbone.

### *VLANs without member ports*

If a VLAN is attached to an I-SID there must be another instance of that same I-SID in the SPBM network.

- If another instance of that I-SID exists, the device designates that VLAN as operationally up regardless of whether it has a member port or not.

When the VLAN is operationally up, the IP address of the VLAN will be in the routing table.

- If no matching instance of the I-SID exists in the SPBM network, then that VLAN has no reachable members and does not act as an NNI interface.

The VLAN does not act as a UNI interface because it does not have a member port.

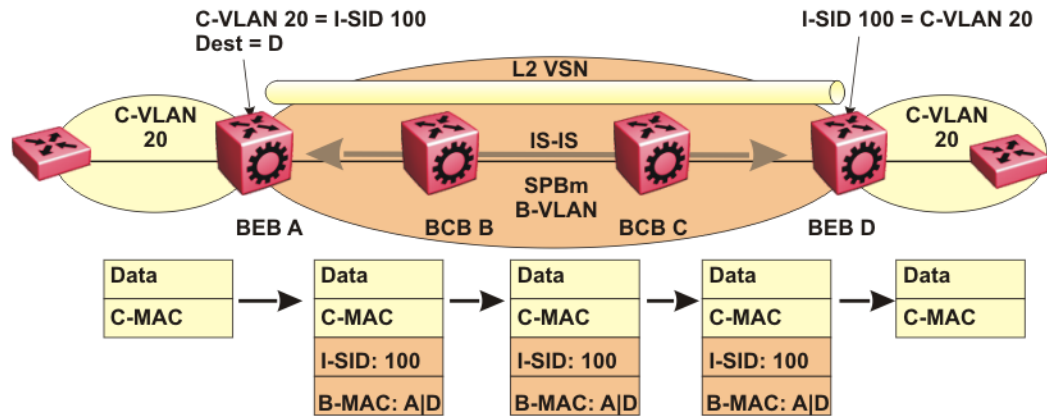

Therefore, the device does not designate the VLAN as operationally up because the VLAN does not act as a UNI or an NNI interface.

If the device acts as a BCB with two VLANs configured and two I-SIDs, there must be a UNI side with the corresponding I-SID existing in the network.

If the device acts as both BEB and BCB, then there must be a member port in that VLAN to push out the UNI traffic.

### *Basic SPBM network topology*

The following figure shows a basic SPBM network topology, specifically a Layer 2 VSN. Switches A and D are the Backbone Edge Bridges (BEB) that provide the boundary between the customer VLANs (C-VLAN) and the Backbone. Switches B and C are the Backbone Core Bridges (BCB) that form the core of the SPBM network.

**Figure 51: SPBM L2 VSN**

SPBM uses IS-IS in the core so that all BEBs and BCBs learn the IS-IS System-ID (B-MAC) of every other switch in the network. For example, BEB-A uses IS-IS to build an SPBM unicast forwarding table containing the B-MAC of switches BCB-B, BCB-C, and BEB-D.

The BEBs provide the boundary between the SPBM domain and the virtualized services domain. For a Layer 2 VSN service, the BEBs map a C-VLAN to an I-SID based on local service provisioning. Any BEB in the network that has the same I-SID configured can participate in the same Layer 2 VSN.

In this example, BEB A and BEB D are provisioned to associate C-VLAN 20 with I-SID 100. When BEB A receives traffic from C-VLAN 20 that must be forwarded to the far-end location, it performs a lookup and determines that C-VLAN 20 is associated with I-SID 100 and that BEB D is the destination for I-SID 100. BEB A then encapsulates the data and C-MAC header into a new B-MAC header, using its own nodal B-MAC: A as the source address and B-MAC: D as the destination address. BEB A then forwards the encapsulated traffic to BCB B.

To forward traffic in the core toward the destination node D, BCB B and BCB C perform Ethernet switching using the B-MAC information only.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 100. BEB D identifies the destination on the C-VLAN header as C-VLAN 20 and forwards the packet to the appropriate destination VLAN and port.

E-Tree and Private VLAN topology

**Table 115: E-Tree and Private VLANs product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
E-Tree and Private VLANs	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Ethernet Private Tree (E-Tree) extends Shortest Path Bridging MAC (SPBM) to Private VLANs (PVLAN).

Transport within the SPBM network is achieved by associating the private VLAN with an I-SID. Flooded traffic from both promiscuous and isolated devices is transported over the same I-SID multicast tree and suppression for spoke-to-spoke traffic is done on the egress SPB Backbone Edge Bridge (BEB). This means the Private VLAN IDs are globally significant and must be the same on all BEBs

The following list provides details for E-Tree and Private VLAN topology:

- E-Tree associates a Private VLAN with an I-SID.

**Note**

The same I-SID could be attached to a regular VLAN. In that case, all ports on the regular VLAN behave like Promiscuous ports on the PVLAN.

- Other SPB BEBs can associate a regular CVLAN to the same I-SID that E-Tree uses.

**Note**

The CVLAN ID must match the primary PVLAN ID.

- CVLAN devices assigned to the same I-SID that E-Tree uses have Promiscuous connectivity within the segment.

The following figure shows a basic E-Tree network topology consisting of groups of private VLANs connected by the SPBM core network.

**Figure 52: Sample E-Tree configuration**

### Private VLAN port types

The private VLAN port type is isolated, promiscuous, or trunk. If the port is a member of an MLT, then the port inherits the private VLAN type of the MLT.

In terms of network topology, the isolated port is considered a spoke. The isolated port, or spoke, does not communicate with any other isolated port in the network. The isolated port only communicates with the promiscuous ports, or hubs.

### E-Tree and Private VLAN limitations

The following limitations apply to E-Tree and Private VLAN topology:

- A port that is of Private VLAN type trunk must be tagged. Isolated and Promiscuous Private VLAN ports can be either tagged or untagged.
- When a port or MLT that has a Private VLAN type set to Isolated or Promiscuous is added to a private VLAN, if that port is used by other non private VLANs, then those non private VLANs are removed.
- A port which is Private VLAN type Isolated and is tagged can belong to only one Private VLAN.

IS-IS

	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

SPBM eliminates the need for multiple overlay protocols in the core of the network by reducing the core to a single Ethernet-based, link-state protocol (IS-IS). IS-IS provides virtualization services using a pure Ethernet technology base. SPBM also uses IS-IS to discover and advertise the network topology, which enables it to compute the shortest path to all nodes in the SPBM network.

IS-IS is a link-state, interior gateway protocol that was developed for the International Organization for Standardization (ISO). ISO terminology refers to routers as Intermediate Systems (IS), hence the name Intermediate System-to-Intermediate System (IS-IS).

To provide a loop-free network and to learn and distribute network information, SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol. IS-IS is designed to find the shortest path from any one destination to any other in a dynamic fashion. IS-IS creates any-to-any connectivity in a network in an optimized, loop-free manner, without the long convergence delay experienced with the Spanning Tree Protocol. IS-IS does not block ports from use, but rather employs a specific path. As such, all links are available for use.

IS-IS dynamically learns the topology of a network and constructs unicast and multicast mesh connectivity. IS-IS parallel adjacency support allows you to configure multiple IS-IS links between the two nodes. Each node in the network calculates a shortest-path tree to every other network node based on System-IDs (B-MAC addresses). Only one adjacency with the shortest path is selected as an active adjacency.

**Note**

Only an active interface with an active adjacency is added into local SPF calculations. This mechanism ensures the local node selects the shortest path and has the same view as the rest of the SPBM network.

In the SPBM environment for Layer 2 VSNs, IS-IS carries only pure Layer 2 information with no requirement for an underlying IP control plane or forwarding path. IS-IS runs directly over Layer 2.

**Note**

SPBM carries Layer 3 information for Layer 3 VSNs.

In SPBM networks, IS-IS performs the following functions:

- Discovers the network topology
- Builds shortest path trees between the network nodes:
  - Forwards unicast traffic
  - Determines the forwarding table for multicast traffic
- Communicates network information in the control plane:
  - Service Instance Identifier (I-SID) information

SPBM can distribute I-SID service information to all SPBM nodes, as the I-SIDs are created. SPBM includes I-SID information in the IS-IS Link State protocol data units (PDUs). When a new service instance is provisioned on a node, its membership is flooded throughout the topology using an IS-IS advertisement.

### *Standard TLVs*

IS-IS uses Type-Length-Value (TLV) encoding. SPBM employs IS-IS as the interior gateway protocol and implements additional TLVs to support additional functionality. The switch also supports Sub-TLVs. TLVs exist inside IS-IS packets and Sub-TLVs exist as additional information in TLVs.

The switch supports and is in full compliance with standard 802.1aq TLVs. The IEEE ratified the 802.1aq standard that defines SPBM and the Type-Length-Value (TLV) encoding that IS-IS uses to support SPBM services. The following table lists all the TLVs that the switch supports.

**Table 117: Standard TLVs**

TLV	Description	Usage
1	Area addresses — The Area Addresses TLV contains the area addresses to which the IS-IS is connected.	IS-IS area
22	Extended IS reachability — The Extended IS Reachability TLV contains information about adjacent neighbors.	IS-IS adjacencies Sub-TLV 29: SPBM link metric is carried within this TLV.
129	Protocols supported — The Protocol supported TLV carries the Network Layer Protocol Identifiers (NLPID) for the Network Layer protocols where the IS-IS can be used.	SPBM in addition to existing NLPID (IPV4 0xCC, IPV6 0x*E.), IEEE 802.1aq defined SPBM NLPID as 0xC1.
135	Extended IP reachability — The Extended IP Reachability TLV 135 is used to distribution IP reachability between IS-IS peers.	SPBM uses this existing IS-IS TLV to carry IP Shortcut routes in the Global Routing Table (GRT).

**Table 117: Standard TLVs (continued)**

TLV	Description	Usage
143	<p>Multi-topology port aware capability (MT-Port-Capability) TLV</p> <p>This TLV carries the SPB instance ID in a multiple SPB instances environment. This TLV is carried within IS-IS Hello Packets (IIH), only when parallel links exist.</p>	<p>This TLV carries the following SPBM Sub TLV:</p> <ul style="list-style-type: none"> <li>Sub-TLV 6: SPB B-VID Sub TLV indicates the mapping between a VLAN and its equal cost tree (ECT) algorithm. To form an adjacency, both nodes must have a matching primary (BVLAN, ECT) pair, and secondary (BVLAN, ECT) pair, the number of B-VLANs must be equal, B-VLAN values must match, ECT values for the B-VLANs must match. Used in IS-IS Hellos only.</li> <li>MCID Sub TLV: The MCID is a digest of the VLANs and MSTI. Neighboring SPBM nodes must agree on the MCID to form an adjacency. The MCID is set to all zeros (0).</li> </ul> <p>After the switch receives a non-zero MCID Sub TLV, it reflects content back to the neighbor.</p> <ul style="list-style-type: none"> <li>Link L1 Metric Sub-TLV 7: Contains L1 metric of the link</li> </ul>
144	<p>Multi-topology Capability (MT-Capability) TLV.</p> <p>This TLV carries the SPB instance ID in a multiple SPB instance environment. This TLV is carried within LSPs.</p> <p>In multicast over Fabric Connect, TLV 144 on the BEB bridge, where the sender is located, has the transmit (Tx) bit set. On the BEB bridge, where the receiver is located the receive (Rx) bit is set.</p>	<p>TLV 144 is the service identifier TLV. TLV 144 advertizes B-MAC and I-SID information.</p> <p>This TLV carries the following Sub TLVs:</p> <p>Sub-TLV 1: SPB instance Sub TLV contains a unique SPSourceID (nickname) to identify the SPBM node within this SPB topology.</p> <p>Sub-TLV 3: SPB Service ID (I-SID) is stored in TLV 144 sub-TLV 3. Sub-TLV 3 carries service group membership (I-SIDs) for a particular SPBM B-VLAN.</p>
184	<p>SPBM IP VPN reachability – IS-IS TLV 184 is used to advertise SPBM L3 VSN route information across the SPBM cloud.</p>	<p>IP reachability for Layer 3 VSNs</p>

**Table 117: Standard TLVs (continued)**

TLV	Description	Usage
185	IPVPN multicast TLV with IPMC sub TLV — The IPVPN multicast TLV contains information about the scope I-SID.	TLV 185 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses. As part of the IPVPN TLV, sub-TLVs define IPv4 unicast, IPv6 unicast and IPv4 multicast information. Layer 2 VSN IP multicast over Fabric Connect and Layer 3 VSN IP multicast over Fabric Connect (using VRF) use TLV 185.
186	IP multicast TLV (GRT) — TLV 186 on the BEB bridge, where the source is located, displays the multicast source and group addresses and has the transmit (Tx) bit set. Each multicast group has its own data I-SID that maps to the source and group addresses.	IP Shortcuts with IP multicast over Fabric Connect use TLV 186. All multicast streams are constrained within the level in which they originate, which is called the scope level.
236	IPv6 Reachability — The IPv6 reachability TLV 236 is used to distribute IPv6 network reachability between IS-IS peers.	SPBM uses the existing IS-IS TLV to carry IPv6 shortcut routes through the SPBM core.

For more information on IP multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1579.

### *IS-IS hierarchies*

IS-IS is a dynamic routing protocol that operates within an autonomous system (or domain). IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. When used separately from SPBM, IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. When used separately from SPBM, the Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas. SPBM currently uses only Level 1 areas.

#### **Important**

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

### *IS-IS PDUs*

Intermediate System to Intermediate System Hello (IIH) packets discover IS-IS neighbors and establish and maintain IS-IS adjacencies. An IIH is sent in every Hello-interval to maintain the established

adjacency. If a node has not heard IIHs from its neighbor for (hello-interval x hello-multiple) seconds, the node tears down the adjacency. IIH carries TLV 143 and SPB-B-VLAN Sub-TLV (among other sub-TLVs). For two nodes to form an adjacency the B-VLAN pairs for primary B-VLAN and secondary B-VLAN must match.

Link State Packets (LSP) advertise link state information. The system uses the link state information to compute the shortest path. LSP also advertises MT-capability TLV 144 and SPB instance Sub-TLV, and SPB I-SIDs Sub-TLV.

Complete Sequence Number Packets (CSNP) contain the most recent sequence numbers of all LSPs in the database. CSNP notifies neighbors about the local LSDB. After a neighbor receives a CSNP, it compares the LSPs in the CSNP with the LSP in the local LSDB. If the neighbor is missing LSPs, it sends a Partial Sequence Number Packets (PSNP) to request the missing LSPs. This process synchronizes the LSDBs among neighbors. A synchronized LSDB among all nodes in the network is crucial to producing a loop-free shortest path.

### *IS-IS configuration parameters*

#### **IS-IS system identifiers**

The IS-IS system identifiers consist of three parts:

- System ID — The system ID is any 6 bytes that are unique in a given area or level. The system ID defaults to the baseMacAddress of the chassis but you can configure a non-default value. The system ID must use a unicast MAC address; do not use a multicast MAC address. A MAC address that has the low order bit 1 set in the highest byte is a multicast MAC address. For example, the following are multicast MAC addresses: x1xx.xxxx.xxxx, x3xx.xxxx.xxxx, x5xx.xxxx.xxxx, x7xx.xxxx.xxxx, x9xx.xxxx.xxxx, xBxx.xxxx.xxxx, xDxx.xxxx.xxxx, and xFxx.xxxx.xxxx.
- Manual area — The manual area or area ID is up to 13 bytes long. The first byte of the area number (for example, 49) is the Authority and Format Indicator (AFI). The next bytes are the assigned domain (area) identifier, which is up to 12 bytes (for example, 49.0102.0304.0506.0708.0910.1112). IS-IS supports a maximum of three manual areas, but the switch software only supports one manual area.
- NSEL — The last byte (00) is the n-selector. In this implementation, this part is automatically attached. There is no user input accepted.

The Network Entity Title (NET) is the combination of all three global parameters.

All routers have at least one manual area. Typically, a Level 1 router does not participate in more than one area.

The following are the requirements for system IDs:

- All IS-IS enabled routers must have one manual area and a unique system ID.
- All routers in the same area must have the same area ID.
- All routers must have system IDs of the same length (6 bytes).
- All IS-IS enabled routers must have a unique nickname.

#### **PSNP interval**

You can change the PSNP interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

### CSNP periodic and interval rate

You can configure the CSNP periodic and interval rate. A longer interval reduces overhead, while a shorter interval speeds up convergence.

### Parameters for the link state packet (LSP)

LSPs contain vital information about the state of adjacencies, which must be exchanged with neighboring IS-IS systems. Routers periodically flood LSPs throughout an area to maintain synchronization. You can configure the LSP to reduce overhead or speed up convergence.

The following list describes IS-IS parameters related to LSPs:

- The **max-lsp-gen-interval** is the time interval at which the generated LSP is refreshed. The default is 900 seconds with a range of 30 to 900.
- The **retransmit-lsp-interval** is the minimum amount of time between retransmission of an LSP. When transmitting or flooding an LSP an acknowledgement (ACK) is expected. If the ack is not received within **retransmit-lsp-interval**, the LSP is re-transmitted. The default is 5 seconds with a range of 1 to 300.

### Point-to-point mode

All SPBM links are point-to-point links. The switch does not support broadcast links.

### IS-IS interface authentication

Configure IS-IS interface authentication to improve security and to guarantee that only trusted routers are included in the IS-IS network. Interface level authentication only checks the IIH PDUs. If the authentication type or key in a received IIH does not match the locally-configured type and key, the IIH is rejected. By default, authentication is disabled.

You can use either one of the following authentication methods:

- Simple password authentication — Uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.
- MD5 authentication — Creates a Message Digest (MD5) key.
- SHA-256 — Adds a Hash-based Message Authentication Code (HMAC) digest to each IS-IS Hello packet.

#### Important

If the `.isis_md5key.txt` and `.isis_simplekey.txt` are missing, IS-IS adjacencies cannot be established.

### Password considerations

To reset the authentication password type, you must set the type to none.

The switch software supports only interface level authentication. The switch software does not support area level or domain level authentication.

### SHA-256 considerations

IS-IS Hello packets are sent periodically to discover IS-IS neighbors, and to establish and maintain IS-IS adjacencies. If you enable SHA-256 authentication, the switch adds an HMAC-SHA256 digest to each Hello packet.

#### Note

The interfaces used to make the adjacencies must have SPBM configured.

The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet.

Directly connected switches must share the same key (secret), which can have a maximum length of 16 characters.

### Hellos

To update the identities of neighboring routers, you can configure the:

- Interface Hello interval
- Interface Hello multiplier

#### Interface Hello interval

IS-IS uses Hello packets to initialize and maintain adjacencies between neighboring routers.

You can configure the interface level Hello interval to change how often Hello packets are sent out from an interface level.

#### Hello multiplier

You can configure the Hello multiplier to specify how many Hellos the switch must miss before it considers the adjacency with a neighboring switch down. By default, the hold (wait) time is the Hello interval multiplied by the Hello multiplier. By default, if the Hello interval is 9 and the Hello multiplier is 3, the hold time is 27. If the Hello multiplier is increased to 10, the hold time is increased to 90.

#### Link metric

You can configure the link metric to overwrite the default metric value. By configuring the metric, you can specify a preferred path. Low cost reflects high-speed media, and high cost reflects slower media. For the wide metric, the value ranges from 1 to 16,777,215.

- The switch only supports the wide metric.
- The total cost of a path equals the sum of the cost of each link.

- The default value for wide metrics is 10.

**Note**

When multiple paths exist to reach a node, the path with the lowest sum of metrics of the individual links is chosen. If the sum of the paths are the same, the one with the lowest number of hops is chosen. If the number of hops is the same as well, then the tie-breaking is done by the system ID.

For the primary BVLAN, the path that has a node with the lowest system ID is chosen.

Whereas, for the secondary BVLAN, the path that has a node with the highest system ID is chosen.

**Disabling IS-IS**

You can disable IS-IS globally or at the interface level. If IS-IS is globally disabled, then all IS-IS functions stop. If IS-IS is enabled at the global level and disabled at one of the interface levels, then IS-IS continues on all other interfaces.

**Overload bit**

The overload bit is sent by a node in LSP updates to inform other devices, whether to use that node to pass transit traffic. For example, when an LSP with an overload bit is received, the device ignores that LSP in its SPF calculation to avoid sending transit traffic through the overloaded node; however the overloaded node can still receive traffic destined to itself.

The overload bit is turned on by default on bootup, and cleared after 20 seconds. You can use the **overload-on-startup** parameter to control the time before the overload bit is cleared after bootup, as this setting is user configurable.

You can permanently set the overload bit using the **overload** parameter. If this is configured, the overload bit will not be cleared after bootup and it will be sent in all LSP updates. If the overload bit is set permanently, other devices do not include this node for use as a transit node in IS-IS computations. By default, the **overload** parameter is set to false.

The **overload** and **overload-on-startup** parameters are two independent settings and are configured under the `router isis` configuration mode in the CLI.

*SPBM B-VLAN*

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

**Note**

SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.

This VLAN is used for both control plane traffic and dataplane traffic.

**Note**

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source address learning is disabled
- Unknown MAC discard is disabled

You cannot add ports to a B-VLAN manually, IS-IS enabled ports are automatically added to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

### *Pre-populated FIB*

An Ethernet network usually learns MAC addresses as frames are sent through the switch. This process is called reverse learning and is accomplished through broadcast.

SPBM does not allow any broadcast flooding of traffic on the B-VLAN in order to prevent looping accomplished through flooding packets with unknown destinations (although multicast traffic is supported). As such, MAC addresses must be distributed within SPBM. This is accomplished by carrying the necessary B-MAC addresses inside the IS-IS link state database. To that end, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. This functionality enables the powerful end-point-provisioning of SPBM.

These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB) to maximize efficiency and to allow Reverse Path Forwarding Check (RPFC) to operate properly.

### *RPFC*

A loop prevention mechanism is required at Layer 2 to stop wayward traffic from crippling the network. Reverse Path Forwarding Check (RPFC) is the chosen method of suppressing loop traffic with SPBM. RPFC was originally designed for IP traffic at Layer 3 where it checks the source address of the packet against the routing entry in the routing table. The source address must match the route for the port it came in on otherwise the packet is illegitimate and therefore dropped.

With SPBM, the node matches the source B-MAC address against the ingress port to establish validity. If the frame is not supposed to come in that port, it is immediately suppressed imposing a guaranteed loop control. If there is no VLAN FDB entry to the source MAC address with the outgoing port as the ingress port, the frame will be dropped.

### *SPBM Unicast FIB*

#### **Unicast FIB**

The unicast computation runs a single Dijkstra (unlike all pair Dijkstras for multicast). SPBM produces only one Shortest Path First (SPF) tree and the tree is rooted on the computing node.

The unicast computation generates an entry for each node in the network. The Destination Address (DA) for that entry is the system-id of the node. In addition, if a node advertises MAC addresses other

than the system-id, each MAC address has an entry in the unicast FIB table, and the shortest path to that MAC should be exactly the same as the path to the node.

Unicast FIB entries are installed to the vlan-fdb table.

The following text shows an example of the unicast FIB.

```
Switch:1# show isis spbm unicast-fib
```

SPBM UNICAST FIB ENTRY INFO					
DESTINATION ADDRESS	BVLAN	SYSID	HOST-NAME	OUTGOING INTERFACE	COST
00:80:2d:35:93:df	10	0080.2d35.93df	86-10	MLT-32	0
00:80:2d:35:93:df	11	0080.2d35.93df	86-10	MLT-32	0
00:80:86:10:86:20	11	0080.2d35.93df	86-10	MLT-32	0
00:e0:7b:84:57:df	10	00e0.7b84.57df	86-30	1/12	0
00:e0:7b:84:57:df	11	00e0.7b84.57df	86-30	1/12	0

## SPBM Restrictions

### RSTP and MSTP

The following list identifies restrictions and limitations associated with RSTP and MSTP:

- RSTP mode does not support SPBM.
- A C-VLAN-level loop across SPBM NNI ports cannot be detected and needs to be resolved at the provisional level.
- SPBM NNI ports are not part of the Layer 2 VSN C-VLAN, and BPDUs are not transmitted over the SPBM tunnel. SPBM can only guarantee loop-free topologies consisting of the NNI ports. You should always use Simple Loop Prevention Protocol (SLPP) in an SMLT environment.

#### Note

Deploy SLPP on C-VLANs to detect loops created by customers in their access networks. However, SLPP is not required on B-VLANs, and it is not supported. The B-VLAN active topology is controlled by IS-IS that has loop mitigation and prevention capabilities built into the protocol.

- SPB internally uses spanning tree group (STG) 63 or Multiple Spanning Tree Instance (MSTI) 62. STG 63 or MSTI 62 cannot be used by another VLAN or MSTI. For non-SPB customer networks, if you use STG 63 or MSTI 62 in the configuration, you must delete STG 63 or MSTI 62 before you can configure SPBM.
- You must configure SPBM B-VLANs on all devices in the same MSTP region. MSTP requires this configuration to generate the correct digest.
- Configure the SPBM B-VLANs to use matching VLAN IDs.

### Best Practices for SPB Regarding MSTP

Use NNI ports exclusively to transport traffic for SPB-based services and not be configured as members of any VLANs other than SPB B-VLANs. In releases that do not support `nni-mstp`, when an SPBM IS-IS interface is created on an NNI port or an MLT, MSTP is automatically disabled for MSTI-62 on the port/MLT. However, MSTP is not automatically disabled on NNI ports for the CIST (default MSTI). In releases that support the `boot config flags nni-mstp` command, the default behavior of the MSTP NNI

ports is that CIST is disabled automatically on the NNI and the NNI ports cannot be members of any VLANs other than B-VLANs. The default boot config flags `nni-mstp` must be set to `false` (which is the default). The following example shows the command to disable the MSTP on the NNI ports.

```
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#no spanning-tree mstp
```

### Coexistence of MSTP and SPB-Based Services on NNI Ports

In releases that do not support `nni-mstp` boot configuration, you can support the coexistence of non-SPB based services on the NNI ports, by adding NNI ports as members of VLANs, except for B-VLANs. These other VLANs rely on the use of MSTP for Loop prevention. The network operator must carefully consider the implications of keeping MSTP enabled on the NNI ports because any MSTP topology changes detected on the NNI ports impacts all services and causes most dynamically learned information on the UNI side to be flushed and relearned. This includes, but is not limited to, all customer MAC and ARP records. This can also cause all the UNI ports on a BEB to be temporarily put into a spanning-tree blocking state before transitioning to a forwarding state again. The net result is that MSTP topology changes on the NNI ports adversely impact traffic for SPB-based services. Therefore, the NNI ports be used exclusively for SPB traffic.

### SPBM IS-IS

The following list identifies restrictions and limitations associated with SPBM IS-IS:

- The switch does not support IP over IS-IS as defined by RFC 1195. IS-IS protocol is only to facilitate SPBM.
- The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The CLI command **show isis int-12-cont1-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.
- The IS-IS standard defines wide (32bit ) metrics and narrow (8 bits) metrics. The switch supports the wide metric.
- IS-IS enabled ports cannot be added to an MLT. The switch does not support this configuration.

### SPBM NNI SMLT

The switch does not support NNI on SMLT links.

### VLACP

VLACP is generally used when a repeater or switch exists between connected switches to detect when a connection is down even when the link LED is lit. If you configure VLACP on an SPBM link that is also an IST link, during a connection fail over (where the link LED stays lit) the IS-IS hellos time out first (after 27 seconds, using default values) and take down the IS-IS adjacency. IS-IS then calculates the new shortest path and fails over the SPBM traffic. 90 seconds after the connection failure (using default values), VLACP goes down but the IST link was already taken down by IS-IS.

In this scenario, there is no data traffic impact because IS-IS can find another path in the SPBM network before VLACP goes down.

### SNMP Traps

On each SPBM peer, if you configure the SPBM B-VLANs to use different VLAN IDs, for example, VLAN 10 and 20 on one switch, and VLAN 30 and 40 on the second, the system does not generate a trap

message to alert of the mismatch because the two switches cannot receive control packets from one another. Configure the SPBM B-VLANs to use matching VLAN IDs.

### System MTU

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

### IP Multicast over Fabric Connect

IP multicast over Fabric Connect cannot connect to existing Protocol Independent Multicast (PIM) networks that connect to SPB originated streams or that add PIM network streams into the SPB network. SPB-PIM Gateway (SPB-PIM GW), however, provides multicast interdomain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this interdomain communication across a special Gateway VLAN. The Gateway VLAN communicates with the PIM network through the PIM protocol messaging and translates the PIM network requirements into SPB language, and vice versa. For more information about SPB-PIM GW, see [SPB-PIM Gateway configuration](#) on page 3045.

### Other

The following list identifies other restrictions or considerations:

- You cannot use 3.33.33 as the SPB nickname because of a conflict with reserved IPv6 Ethernet multicast address 33:33:xx:xx:xx:xx.
- The software does not support I-SID filters.
- You cannot enable C-VLAN and B-VLAN on the same port.
- To ensure proper cleanup of MAC tables after you run the **no spbm** command, save the configuration, and then reboot the switch.

## Network Load Balancing (NLB)

**Table 118: Network Load Balancing product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
Network Load Balancing (NLB) - multicast operation	5520 Series	VOSS 8.2.5
	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

**Table 118: Network Load Balancing product support (continued)**

Feature	Product	Release introduced
Network Load Balancing (NLB) - unicast operation	5520 Series	VOSS 8.2.5
	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

NLB is a clustering technology available with Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of mission critical, IP based services, such as Web, VPN, streaming media, and firewalls. NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

### *SPBM Script*

**Table 119: run spbm installation script product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
run spbm installation script	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 8.0
	XA1400 Series	Not Supported

You can use a CLI script to quickly configure the SPB and IS-IS infrastructure to enable Fabric Connect on a switch. You can use the SPB script, rather than manually configure the minimum SPBM and IS-IS parameters.

You can use the command **run spbm** to quickly configure the following:

- Configure the SPB Ethertype.
- Create an SPB instance.
- Create an SPBM backbone VLAN and associate it to the SPB instance.
- Create an SPBM secondary backbone VLAN and associate it to the SPB instance.
- Add an SPB nickname.
- Create a manual area.
- Enable IS-IS on one of the switch interfaces.
- Enable IS-IS globally.
- Configure the IS-IS system name.
- Configure the IS-IS system ID.

The following table displays the default values applied if you use the **run spbm** command. The SPB script creates some of the default values based on the MAC address of the switch, including the nickname and System ID value.

Parameter	Default values
Ethertype	0x8100
Primary BVLAN	4051
Secondary BVLAN	4052
Manual area	49.0000
Nickname	Derived from the chassis MAC
System name	Derived from the command line prompt
System ID value	Derived from the chassis MAC, using a different algorithm from that for the Nickname

#### Note

The SPB script only creates the SPBM instance, VLAN, or other parameters if they do not already exist. For example, if the SPBM instance and VLAN already exist, the SPB script does not create them. If the SPB script cannot create one of the parameters because the parameter is already configured, the script stops and an error message displays.

*Layer 2 Video Surveillance install script***Table 120: Layer 2 Video Surveillance install script product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
Layer 2 Video Surveillance install script	5520 Series	Not Supported
	VSP 4450 Series	VOSS 6.1
	VSP 4900 Series	VOSS 8.1 To support this feature, VIM installation is mandatory in VSP4900-48P.
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The Layer 2 Video Surveillance install script pre-configures configuration parameters for video surveillance solutions. With this script, a technician can quickly and easily deploy a typical video surveillance network that supports up to 2000 IP cameras, a recording solution, systems management, and viewing stations.

The install script uses best practices for converged solutions and provides redundant paths for all video traffic. The script configures the basic deployment of Shortest Path Bridging (SPB) and uses Layer 2 VSNs to enable full multicast capabilities between all IP subnets and VLANs.

**Configuration Parameters**

The syntax of the install script command is `run vms layer-2 switch <5-99>` where the switch value (between 5 and 99) is a user-defined variable. The install script uses this switch value to configure the camera IP zone for the switch and to specify a unique SPB nickname, system-id, and IP source value.

The install script configures the following major parameters and populates the `xx` with the user-defined variable for the switch value:

- IP Loopback Interface Address: 192.168.0.xx (Management IP address on the switch.)
- IP-Source Address: 192.168.0.xx (IS-IS source IP address for the switch.)
- VLAN ID: 200 (On hardware platforms that only have NNI links, there is no need to create a surveillance VLAN.)
- System ID: 0011.0011.07xx (SPB system-id of switch)
- Nickname: 0.07.xx (SPB Nickname for switch)
- SPB Manual Area ID: 49.0001
- Backbone VLAN IDs: 4051 and 4052 (with 4051 as Primary)

- SPB Multicast: enabled
- SFP and SFP+ ports: (Define all ports as NNI links.)

**Note**

The install script does not configure DHCP Relay parameters.

**Optional `syntax` Parameter**

The install script requires that the switch be in the factory default state. The script prompts you to confirm this, but it does not check if you did so. The script continues running commands even if some of the commands in the script fail, and the failure of script commands is not evident by the script completion message.

The syntax of the install script command is: `run vms layer-2 switch <5-99> [syntax]`. The optional `syntax` parameter prints out all the commands run by the script onto the console. If you do not use the `syntax` parameter, you will not see an error message when a command fails to run.

**Important**

Use the `syntax` parameter to display all the commands run by the script and show any errors that the script encounters. This is the only way to ensure that all configurations are configured without error.

**Configuration Filename**

Upon successful completion of the install script, the switch configuration is saved with a filename based on the switch value used when the script was run. The switch primary boot config file flags are updated with the new filename.

For example, if you use 6 as the switch value, the command `run vms layer-2 switch 6` results in a switch configuration filename of `vms-layer2-switch-6.cfg`.

If you run the install script with the `syntax` parameter, you will see the pre-install command output:

- `save config file pre_vms_layer2_install.cfg`
- `Save config to file /intflash/pre_vms_layer2_install.cfg successful.`

and the completed install script output:

- `save config file vms-layer2-switch-6.cfg`
- `Save config to file /intflash/vms-layer2-switch-6.cfg successful.`

*IS-IS external metric*

The software supports the IS-IS external metric to differentiate between internal and external routes with Accept Policies.

With this feature you can use IS-IS to:

- change the external metric-type of a route when redistributing it from another protocol to IS-IS through route redistribution using a route-map.
- change the external metric-type of a route when accepting a remote IS-IS route with the help of IS-IS accept policies using a route-map.

- match the external metric-type when redistributing IS-IS routes into other protocols using the match option in the route-map.
- match the external metric-type when accepting a remote IS-IS route with the help of IS-IS accept policies by using a route-map
- process the external metric-type in the route selection process.

The IS-IS metric type can also be set using the base redistribute command without using the route-map.

### SPB Ethertype

The switch aligns the SPB ethertype to BCB's locally configured SPB ethertype. The BCBs mark the BTAG Ethertype of a transit MAC-in-MAC packet to match its locally configured value when it exits on a different NNI port, even if the BTAG Ethertype on the incoming packet (CFM or SPB) does not match its configured value.

#### Note

ISIS Hello packets are always marked with 0x8100 ethertype, and do not change according to the BCB's locally configured values.

### Equal Cost Multipath Pathlist with Fabric Connect

**Table 121: ECMP Pathlist with Fabric Connect product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
ECMP Pathlist with Fabric Connect (IS-IS routes)	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.1.5
	VSP 4900 Series	VOSS 8.1.5
	VSP 7200 Series	VOSS 8.1.5
	VSP 7400 Series	VOSS 8.1.5
	VSP 8200 Series	VOSS 8.1.5
	VSP 8400 Series	VOSS 8.1.5
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.1.5

If you use Equal Cost Multipath (ECMP) in a Shortest Path Bridging (SPB) scenario, the Intermediate System-to-Intermediate System (IS-IS) protocol sends multiple routes with the same destination to the routing manager. IS-IS can add up to eight equal cost routes with the same destination to the routing table and the router uses one route for traffic forwarding based on load management. Use the ECMP

Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

**Note**

Different hardware platforms can support a different number of ECMP paths. For more information about the maximum number of ECMP paths supported on the switch, see the scaling information in [Release Notes for VOSS](#).

For information about how to configure ECMP Pathlist, see [Configure ECMP](#) on page 1764 and [Configure ECMP](#) on page 1789.

*FAN Transit*

Fabric Area Network (FAN) transit refers to the ability of a switch to forward traffic between SPB nodes participating in a FAN. The switch is neither a part of the FAN nor does it originate or sink FAN traffic. It only forwards the traffic between the FAN end-points.

For information on how to verify the functioning of a transit switch within a FAN, see [Troubleshooting FAN Transit](#) on page 3747.

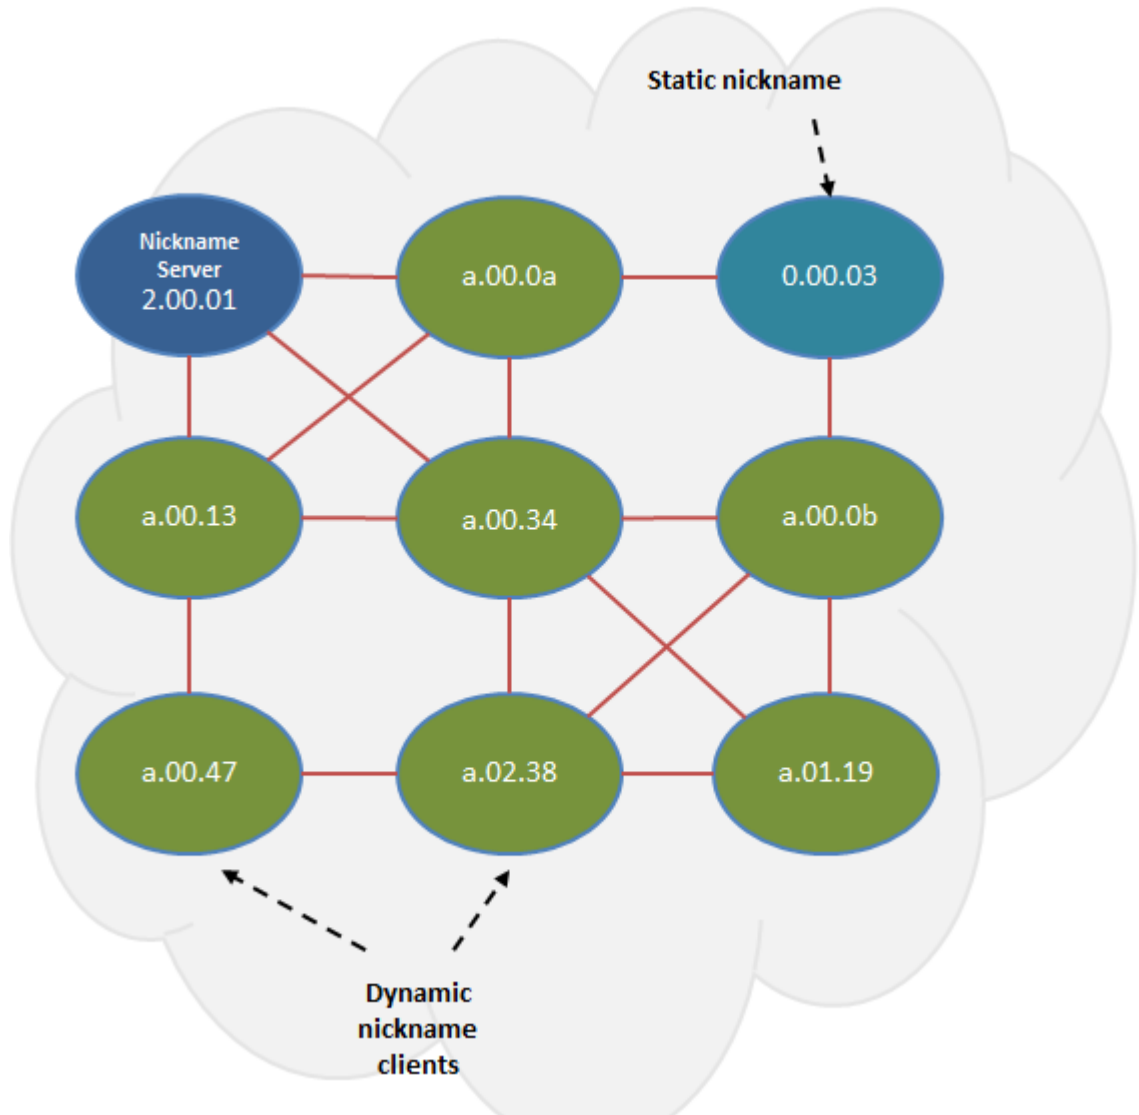

*Dynamic Nickname Assignment*

**Table 122: Dynamic Nickname Assignment product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .

	VSP 8200 Series	VOSS 8.3
	VSP 8400 Series	VOSS 8.3
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Dynamic Nickname Assignment is a service that provides unique nicknames to compatible switches across a Fabric Area Network (FAN).

You can configure a node in a FAN as a nickname server. The nickname server cannot be started until you configure it with a static nickname. As a best practice, configure at least two nickname servers in a FAN to provide redundancy.

#### Note

You must configure the nickname server with a static nickname that is outside any configured dynamic nickname server range in the network.

The nickname server interrogates FAN nodes that have been assigned a dynamic nickname to avoid nickname duplication.

A client joining the dynamic FAN in factory default mode initially does not have a nickname, and issues a broadcast soliciting a valid nickname assignment. The nickname server receives the request and

responds with a nickname assignment offer. The client then explicitly requests the particular nickname offered and the nickname server sends an acknowledgment.

The client maintains the nickname in persistent memory regardless of whether the active nickname server is the same server that originally provided the nickname. The client generates a trap and notifies the user if it is unable to receive a nickname from the server. When IS-IS starts up, it issues a trap if a client does not have a nickname and clears the trap when the client receives a nickname from the nickname server.

A client rebooting or reconnecting to the FAN requests the same nickname assignment it had before reboot. If the requested nickname is within the nickname server's configured range of nicknames and is still available, the server acknowledges the nickname. If the requested nickname is outside of the nickname server's configured range or if the nickname has been assigned to another client, the request is denied by the nickname server and the client must request a new nickname.

### Static and Dynamic Nickname Servers

You can use static nickname assignment and Dynamic Nickname Assignment in the same FAN.

You can configure Dynamic Nickname Assignment using one of the following methods:

- Configure an allocation range from within A.00.00 to F.FF.FF. Nickname allocation ranges for this method are as follows:

Range value	Range for nickname allocation
A	A.00.00 to A.FF.FF
B	B.00.00 to B.FF.FF
C	C.00.00 to C.FF.FF
D	D.00.00 to D.FF.FF
E	E.00.00 to E.FF.FF
F	F.00.00 to F.FF.FF

- Configure a range prefix that can use a range from with 0.00.00 to F.FF.FF. This method increases granularity, providing 256 groups that cover the entire range of 0.00.00 to F.FF.FF instead of the ranges in the preceding table.

#### Note

Regardless of the method you use to configure Dynamic Nickname Assignment, you must configure the nickname server with a static nickname that is outside any configured dynamic nickname server range in the network.

Do not use nicknames from the dynamic nickname range when you assign nicknames statically. However, if there are existing nodes in the network with static nicknames in the dynamic nickname range, it is not a requirement to change their nickname assignment. If a node is assigned a dynamic nickname that is being used in the network, duplicate nickname protection is initiated. If the node that has the dynamic nickname loses the nickname election, it requests a different nickname from the nickname server. If a node with a static nickname loses the nickname election, IS-IS is disabled on that node and you must manually re-assign the nickname and re-enable IS-IS.

You can configure nicknames from a dynamic range if the nickname server is not started.

#### Note

You must disable Dynamic Nickname Assignment before you can change the nickname allocation range.

### Debugging

A node must be a member of a FAN to host Dynamic Nickname Assignment applications. FAN connectivity enables the exchange of information between nickname clients and servers, such as nickname requests or nickname assignments. You can use Connectivity Fault Management (CFM) to debug connectivity issues or isolate faults. For more information about CFM, see [Connectivity Fault Management](#) on page 3553.

### Dynamic Nickname Assignment Considerations

Consider the following information when implementing this feature:

- You must configure a nickname server to attribute unique nicknames to clients based on established policies.
- You can configure multiple nickname servers in a FAN to provide resiliency. If you configure multiple nickname servers, you must ensure that the ranges for nickname allocation do not overlap.
- Dynamic Nickname Assignment is not supported in a FAN that contains ERS 4900 or ERS 5900 products, or on products running VOSS releases prior to 7.0.

### *MSTP-Fabric Connect Multi Homing*

**Table 123: MSTP-Fabric Connect Multi Homing product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
MSTP-Fabric Connect Multi Homing	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 7.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 7.0
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The MSTP-Fabric Connect Multi Homing feature allows MSTP or RSTP network to be multi-homed into a Fabric Connect network, providing a loop-free topology. MSTP-Fabric Connect Multi Homing enables an

MSTP network to be multihomed into the SPB Fabric network through single node-to-multiple nodes or multiple nodes-to-multiple nodes.

### Important

You must enable MSTP-Fabric Connect Multi Homing before you establish multihoming with an MSTP network.

MSTP-Fabric Connect Multi Homing uses I-SID 16777003. The switch creates this I-SID automatically and it cannot be modified.

MSTP-Fabric Connect Multi Homing is supported on SPBM mode only.

## Fabric Extend

	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.0.50

Some hardware platforms support Fabric Extend natively. You can use these switches in a main office of a hub and spoke deployment or to connect one Data Center to another Data Center.

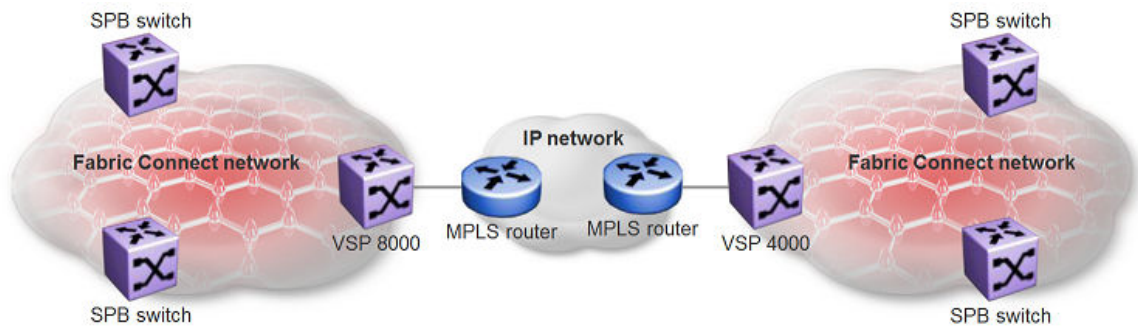

The VSP 4450 Series also supports Fabric Extend, but the switch must be connected to an Open Networking Adapter (ONA) because the VSP 4450 Series does not support Fabric Extend natively. The ONA enables the VSP 4450 Series to support Fabric Extend. The VSP 4450 Series uses the ONA to encapsulate Fabric Connect traffic. For example, you can use the VSP 4450 Series in a branch office of a hub and spoke deployment.

**Note**

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

Fabric Extend enables Enterprises to extend the Fabric Connect technology over Layer 2 or Layer 3 core networks. The *logical IS-IS interface*, which is discussed in detail later in this chapter, is the mechanism that enables Fabric Extend to connect SPB fabric nodes. Logical IS-IS interfaces create virtual tunnels and encapsulate SPB traffic by adding a Virtual Extensible LAN (VXLAN) header to SPB packets.

The following figure illustrates two Fabric Connect “islands” separated by a third-party core IP network. The IP network could be third-party equipment in an enterprise or a service provider’s infrastructure such as an MPLS VPN service.

**Figure 53: Fabric Connect networks connected by an IP network**

The following figure illustrates how Fabric Extend enables you to connect the fabric islands to create ONE Fabric Connect network. This figure shows a layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbones.

**Figure 54: Single Fabric Connect Domain realized using Fabric Extend**

The following figure shows a layer 2 core network where Fabric Extend can transport SPBM packets over a layer 2 MPLS VPLS or PBB E-LINE service by creating layer 3 tunnels over a layer 2 third party network.

**Figure 55: Fabric Extend over VLAN tunnels**

*What are the advantages of connecting Fabric Connect networks?*

**Fabric Connect** is an Ethernet-based, industry-standard (IEEE 802.1aq) networking virtualization solution. With Fabric Connect, you can have thousands of virtualized service instances at any point in the network. Other Fabric Connect advantages include rapid time to service, Layer 2 and Layer 3 Unicast and IP Multicast virtualization, and scalable IP multicast. But the most significant advantage of Fabric Connect is that you provision services at the network edge *only*, not the core.

The **Fabric Extend** feature enables you to *extend* the Fabric Connect model. This allows Enterprises to extend Fabric Connect technology over Layer 2 and Layer 3 core networks. The interconnection of Fabric Connect deployments can be over any IP-based network whether it's a campus backbone, Data Center, or a MAN/WAN IP MPLS network.

### *Fabric Extend and ONA*

Some hardware platforms support Fabric Extend natively on any of its physical ports. However, the VSP 4450 Series requires an Open Networking Adapter (ONA) to enable this functionality. The ONA is the Fabric Extend packet encapsulation engine for the VSP 4450 Series. The ONA / VSP 4450 Series combination can also provide enhanced features such as IP fragmentation and reassembly on Fabric Extend tunnels.

#### **Note**

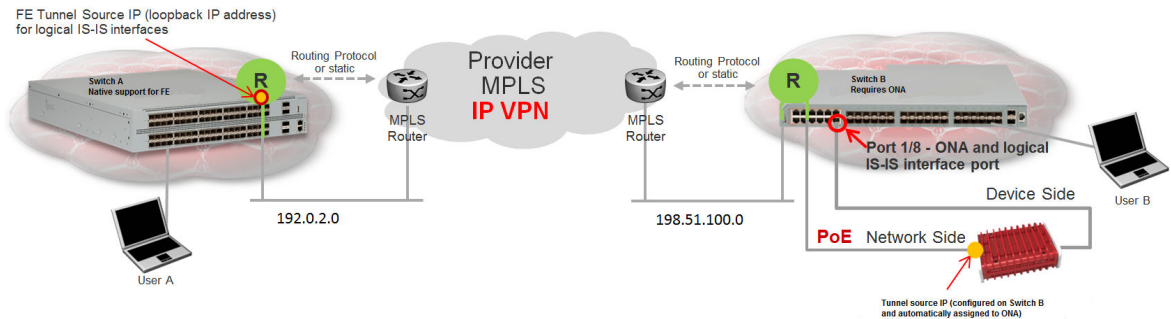

In a Layer 2 core Fabric Extend solution, the VSP 4450 Series does not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

The VSP 4450 Series manages the ONA in the following ways:

- Controls and provisions the ONA.
- If PoE capable, the VSP 4450 Series supplies power to the ONA. (The ONA also supports an optional wall unit power adapter.)
- Transports traffic to and from the ONA over 1 GbE ports and sets QoS appropriately to the ONA's.
  - The ONA 1101GT can support basic Fabric Extend at line rate 1G traffic from the VSP 4450 Series at 1500 byte packet sizes.
  - Oversubscription of the ONA's packet engine may result if packets are smaller than 1500 bytes or if you enable enhanced features such as fragmentation and reassembly of packets. This results in packet drop starting with lower QoS queued packets consistent with PCP and DSCP markings on packets received from the VSP 4450 Series. For more details on the ONA 1101GT forwarding performance, see [ONA Considerations](#) on page 924.

The ONA can operate in different modes. Fabric Extend is Operational Mode 1. To enable Fabric Extend, use the ONA's Manual Configuration menu to change the Operational Mode parameter to 1. For more information, refer to the manual that ships with the ONA.

In the following figure, the VSP 8200 Series is in a Fabric Connect network and is configured with Fabric Extend (FE). The VSP 4450 Series is also in a Fabric Connect network and is configured with SPB. The VSP 8200 Series and the VSP 4450 Series use industry-standard VXLAN tunnels to create a flow for FE traffic between the VSP 8200 Series and the ONA attached to the VSP 4450 Series.

**Figure 56: Fabric Extend traffic flow**

The following flow occurs when User A sends a packet to User B:

- The VSP 8200 Series receives the packet and encapsulates it with a MAC-in-MAC header.
- The VSP 8200 Series sends the MAC-in-MAC-encapsulated packet over the VXLAN tunnel to the VSP 4450 Series.
- The VSP 4450 Series receives the packet and sends it to the ONA network port.
- The ONA decapsulates the packet by removing the VXLAN header and sends the MAC-in-MAC packet header out the ONA device port back to the VSP 4450 Series.
- The VSP 4450 Series decapsulates the MAC-in-MAC header and forwards the packet to User B.

The following flow occurs when User B sends a packet to User A:

- The VSP 4450 Series receives the packet and sends it to the ONA over the ONA device port with MAC-in-MAC encapsulation.
- The ONA encapsulates the packet with a VXLAN header.
- The ONA then sends the packet out the ONA network port and back to the VSP 4450 Series.
- The VSP 4450 Series sends the VXLAN-encapsulated packet over the Routed IP network to the VSP 8200 Series.

**Note**

To interoperate with the VSP 8200 Series, you must set the MTU on the VSP 4450 Series/ONA combination to 1950 bytes.

- The VSP 8200 Series decapsulates the packet by removing the VXLAN header and the MAC-in-MAC header, and then forwards it to User A.

**Note**

Connect the ONA as shown with two ports to the VSP 4450 Series. You cannot connect the ONA directly to the IP core infrastructure.

### Logical IS-IS interface

The logical IS-IS interface is the mechanism that enables Fabric Extend to connect SPB fabric nodes.

Logical IS-IS interfaces perform the following functions depending on the type of core network:

- In a Layer 3 core network, logical IS-IS interfaces create virtual IP tunnels and encapsulate SPB traffic by adding a Virtual Extensible LAN (VXLAN) header to SPB packets.

- In a Layer 2 core network, logical IS-IS interfaces do not use VXLAN. The tunnels are point-to-point VLAN connections so there is no need to encapsulate a VXLAN header to SPB packets. The logical IS-IS interfaces translate the Backbone VLAN IDs (B-VIDs) and maps them to each of the branch provider VIDs.

Fabric Extend uses virtual tunnels in Layer 3 core solutions to connect SPB fabric nodes. These nodes can stretch over IP routed campus networks, service provider Layer 2 core networks, or service provider Layer 3 core networks such as IP MPLS VPNs.

#### Note

VLACP cannot be used on logical IS-IS interface connections.

### Layer 2 core network

If the service provider has a Layer 2 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> vid <list of vlans> primary-vid <vlanId> port
<slot/port> Mlt <mltId> [name <name>]
```

- `vid <list of vlans>` should have two VLANs, not more than two or less than two. The VID range is <2-4059>. You do not have to configure the VIDs as platform VLANs.
- `primary-vid` should be included in `vid <list of vlans>`.
- Each logical interface must have a unique set of VIDs for each port or MLT. The same VIDs however, can be reused across a different set of ports or MLTs.
- Logical interface VIDs and BVLANS cannot be the same.
- Configuring the same VIDs as primary and secondary is not allowed.
- The `port/MLT` on which the Layer 2 core IS-IS logical interface is configured cannot be part of any other user configured VLANs.
- Cannot delete an MLT that is configured as a logical interface tunnel MLT.
- A logical interface consists of a port/MLT and a list of VLANs, where port/MLT is the physical connectivity to the Layer 2 core network and VLANs are the list of VLANs used to transport/bridge IS-IS control packets and Mac-in-Mac data traffic.
- VXLAN headers are not used in Layer 2 core Fabric Extend solutions.
- IS-IS control packets are not encapsulated before they are sent over a logical interface. Instead, the VLAN in the outer Ethernet header (SPB primary bvid) is replaced by the user configured logical interface VLAN.
- Spanning tree is disabled by default on **port/MLT** on which a Layer 2 core logical IS-IS interface is configured.

### Layer 3 core network

If the service provider has a Layer 3 core network, note the following points:

- The syntax for configuring a logical interface is:

```
logical-intf isis <id> dest-ip <destIpAddress> [name <name>]
```

- A logical IS-IS interface points to a remote BEB destination IP address.

- Port and VlanId are not needed to create a logical IS-IS interface, instead they can be retrieved from the next hop of destination IP address.
- IS-IS control packets (IS-IS hello, LSDB, CSNP, PSNP) are encapsulated with a VXLAN header and sent over a logical IS-IS interface.

### *IPsec Compression*

IPsec compression reduces the size of the IP datagram to improve the communication performance between hosts connected behind XA1400 Series Backbone Edge Bridges (BEB).

#### **Tip**

As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms.

The following list identifies how you can implement IPsec compression:

- You can configure IPsec compression for each logical-interface.
- You can configure multiple IPsec Fabric Extend adjacencies with or without compression at the same time.
- You must enable IPsec compression on both BEBs to use IPSEC compression for an FE adjacency.
- You can change the IPsec compression configuration for a logical interface only if IPsec is disabled on the logical interface.

For configuration information, see the following tasks:

- [Configure Fabric Extend Over IPsec](#) on page 1007 (using CLI)
- [Configure Fabric Extend Logical Interfaces](#) on page 1085 (using EDM)

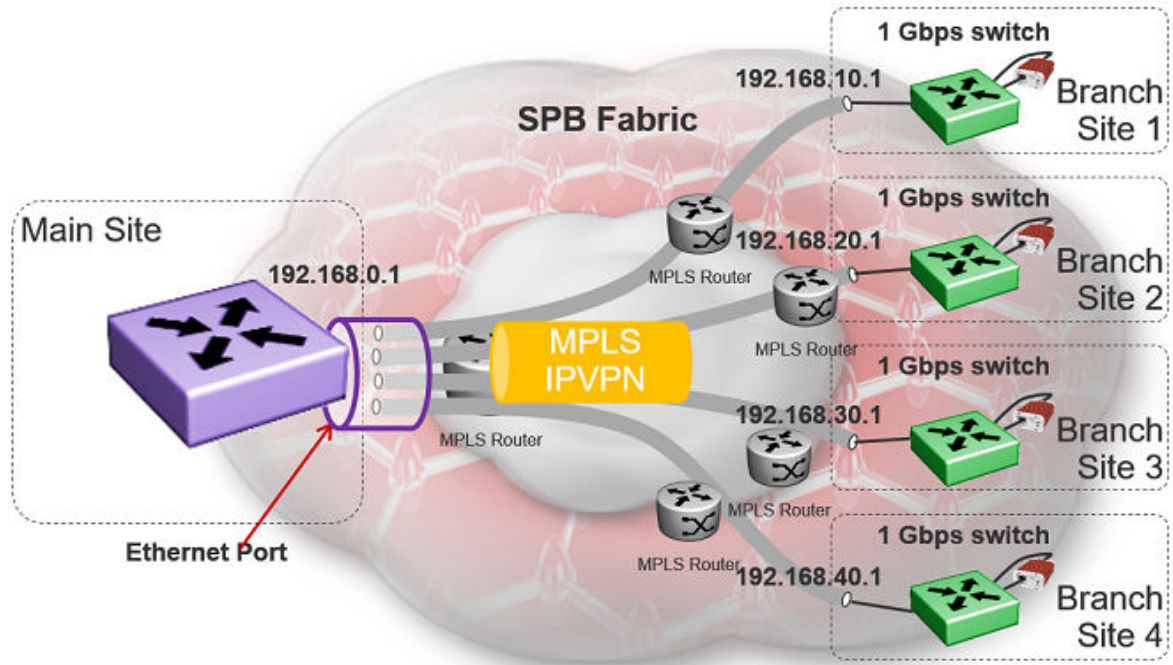

### *Types of Fabric Extend Deployments*

As the number of Fabric Connect networks increased, the need to connect those networks became more and more desirable. Fabric Extend solves the problem of going beyond the Ethernet Fabric Connect connections to include the following IP routed wide area network (WAN) and campus solutions:

1. Fabric Extend over an MPLS IP-VPN provider WAN
2. Fabric Extend over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (ELAN) provider network
3. Fabric Extend over an IP campus network
4. Fabric Extend over an MPLS Pseudo-Wire or Ethernet Virtual Private Line (E-Line) provider network
5. Fabric Extend over IPsec

#### **Fabric Extend over an MPLS IP-VPN provider WAN**

The most common Fabric Extend deployment is a hub and spoke topology that connects the Main office over a service provider's MPLS IP VPN to multiple Branch offices. The following figure illustrates how the hub device on the main site establishes virtual tunnels with all of the spoke devices in the same domain. In this scenario, the traffic flows are bidirectional: from hub-to-spoke and spoke-to-hub.

**Figure 57: Fabric Extend IP VPN Deployment Option**

**Note**

If fragmentation and reassembly is required, you must have a 1 Gbps switch/ONA combination on the main site as well.

**Fabric Extend over an MPLS VPLS/P2P-VPLS/E-LINE/P2P-VLAN provider network**

Where the above hub and spoke deployment is over a Layer 3 MPLS IP-VPN, the following VPLS deployment is over a Layer 2 segment. This type of hub and spoke deployment extends the fabric over an MPLS Virtual Private LAN Service (VPLS) or Provider Backbone Bridging (PBB) Ethernet LAN (E-LINE) network. In this scenario, the SPB nodes are connected with a point-to-point Ethernet link.

**Figure 58: Fabric Extend VPLS Deployment Option**

#### Fabric Extend over an IP campus network

Some customers do not want to migrate their infrastructures to SPB immediately. They want to keep their existing IP core network and deploy SPB on the edge. In this scenario, Fabric Extend supports a fabric overlay on top of the existing campus infrastructure.

The following figure illustrates how this deployment supports any-to-any traffic with full-mesh tunnels between fabric nodes. The fabric nodes serve as campus switches, support routing into the IP infrastructure, and provide an overlay fabric that enables all fabric benefits.

**Figure 59: Fabric Extend Full Mesh Campus Deployment Option**

#### Fabric Extend over an MPLS PWE3/E-Line provider network

The following hub and spoke deployment over an MPLS Pseudowire or Ethernet Virtual Private Line (E-Line) uses service provider VLAN tunnels. Because you can map many (VID, port/mlt list) sets to an I-SID, this gives Service Providers the flexibility to let more than one customer use the same VLAN with different I-SIDs.

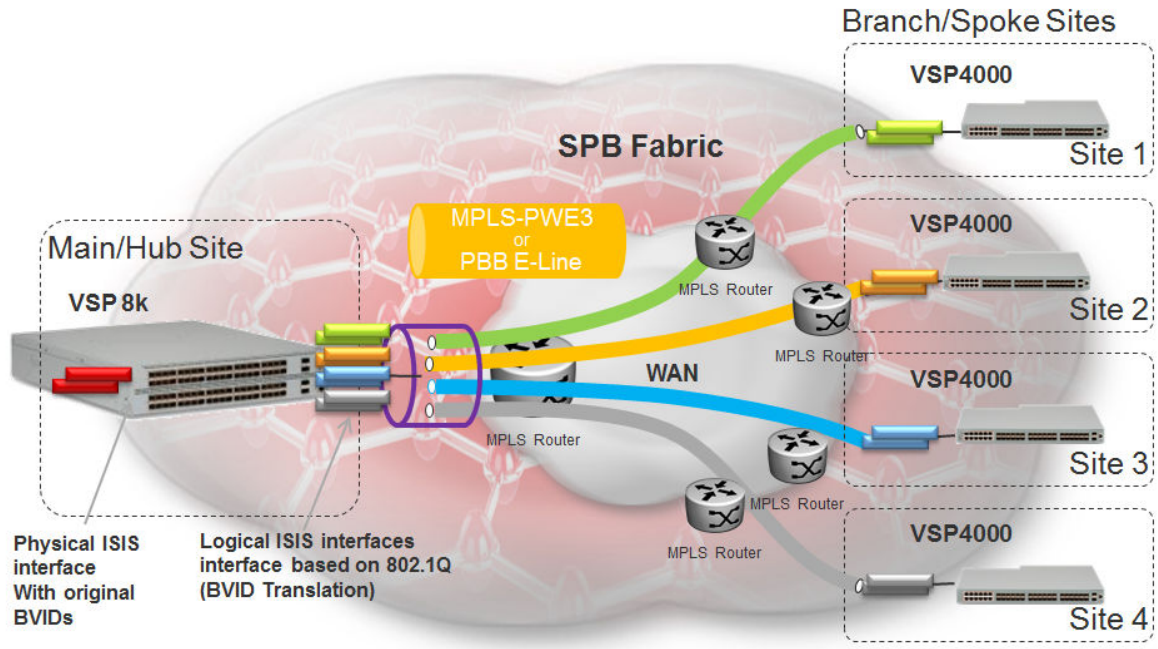

#### Note

The VSP 4450 Series switches in this type of deployment do not require an ONA because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

The following figure illustrates how two dedicated Backbone VLAN IDs (B-VIDs) are mapped from the hub to spoke sites. Logical IS-IS interfaces translate the B-VIDs and maps them to each of the branch provider VLANs.

For a detailed configuration example showing logical interfaces using B-VID translation to two different logical VLAN IDs, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

**Figure 60: Fabric Extend Pseudowire Deployment Option**

**Fabric Extend over IPsec**

The Fabric Extend over IPsec hub and remote deployment uses service provider VLAN tunnels and IPsec to provide permanent connections between locations. It is best used for site-to-site connections, such as connecting remote sites to the core network. Since IPsec works at the network layer, this type of configuration is not limited or dedicated to a particular application.

**Note** FE over IPsec connectivity requires an XA1400 Series device on each end of the FE tunnel.

The following figure illustrates how the FE over IPsec deployment supports the site-to-site connections. It shows a Layer 3 core network where Fabric Extend uses IP tunneling by adding a VXLAN header to the SPBM packets. This can be over a third party IPv4 transport network such as MPLS IP-VPN or in a Campus IP backbone.

**Figure 61: Fabric Extend over IPsec Deployment Option**

### *Fabric Extend View in EFO*

The Fabric Extend view within Extreme Fabric Orchestrator (EFO) provides a graphical management interface for administrators to configure and monitor fabric extensions.

**Note**

Although the Fabric Extend view is not required, as a best practice, include this element in your Fabric Extend solution.

Every Fabric Extend network deployment involves creating numerous bidirectional tunnels. The Fabric Extend view in EFO automates the provisioning of these tunnels by creating *Fabric Extend domains*. When you add nodes to a Fabric Extend domain, the Fabric Extend view automatically creates tunnels between the nodes belonging to the same domain. The Fabric Extend view also ensures error-free bidirectional tunnel provisioning and decommissioning, if required.

**Fabric Extend view functions**

Fabric Extend view provides the following functions:

- Graphically represents the Fabric Connect “islands”
- Identifies Fabric Extend capable switches
- Graphically represents virtual Fabric Extend links and status
- Provides an easy way to group a set of switches into a Fabric Extend domain
- Provides an easy way to configure point-to-point fabric extensions

**Fabric Extend domains**

There are two types of Fabric Extend domains:

- **Mesh** – This type of domain creates full-mesh tunnels between all nodes. If you add a switch to a mesh domain, the Fabric Extend view automatically builds Fabric Extend tunnels to all the other switches in the domain.
- **Hub-and-Spoke** – This type of domain identifies each node as either a hub or a spoke.
  - Hub nodes automatically establish bidirectional tunnels with all spoke nodes in the domain.
  - Spoke nodes automatically establish bidirectional tunnels only with the hub nodes in the domain.

**Point-to-Point tunnels**

You can use Fabric Extend view to provision your own tunnels between Fabric Extend-capable nodes. You must specify the tunnel configuration for both ends of the tunnels.

### *Fabric Extend Tunnel MTU*

You can configure a unique MTU value for each Fabric Extend (FE) tunnel on a XA1400 Series device. You can configure each ISIS logical interface with a unique MTU value for each FE tunnel in the VXLAN interface to improve fragmentation and reassembly in WAN connectivity over MPLS IP VPN and internet-based connections through a NAT router.

Fragmentation and reassembly is based on the MTU value configured for each FE tunnel. You can change the MTU configuration at any time for each FE tunnel. The supported MTU range is 750 to 9000, and the default MTU value is 1950.

#### Note

FE Tunnel MTU is an optional configuration.

For example, if you configure an FE tunnel with an MTU of 900, and a packet size of 1950 is received on UNI with the destination on the FE tunnel, the system fragments the original 1950-sized packet into the three packets (900, 900, 150) with a packet size equal to or less than 900. The system transmits the three fragmented packets over the ISIS logical interface of the FE tunnel. After the packets are received at the destination, the system performs the packet reassembly (900, 900, 150) into the 1950-sized packet.

### Fabric Extend Tunnel MTU Considerations

Consider the following interactions between route MTU and FE Tunnel MTU configurations:

- If route MTU is not configured, the MTU value for each FE tunnel is applicable to ingress and egress traffic on the tunnel.
- If route MTU is configured, the MTU value for each FE tunnel is applicable for ingress traffic on the tunnel. The route MTU value applies to all egress traffic.

#### Note

System MTU maximum is a separate configuration. You can configure a system maximum MTU size of 1522, 1950, or 9022. The default value is 1950.

### Fabric Extend Considerations

Review the following restrictions, limitations, and behavioral characteristics that are associated with Fabric Extend.

#### Note

If your Fabric Extend configuration includes a VSP 4450 Series/ONA combination, see [ONA Considerations](#) on page 924 for more information.

- **Tunnel source IP**

Fabric Extend supports the tunnel source IP address using a brouter port interface, a CLIP IP, or a VLAN IP.

The following table shows lists the product support.

Product	Tunnel source IP		
	Brouter port	CLIP IP	VLAN IP
VSP 4450 Series	Yes	Yes	Yes
VSP 4900 Series	Yes	Yes	Yes
5520 Series	Yes	Yes	Yes
VSP 7200 Series	Yes	Yes	Yes

Product	Tunnel source IP		
	Brouter port	CLIP IP	VLAN IP
VSP 7400 Series	Yes	Yes	Yes
VSP 8200 Series	Yes	Yes	Yes
VSP 8400 Series	Yes	Yes	Yes
VSP 8600 Series	Not supported	Not supported	Not supported
XA1400 Series	Yes	Yes	Yes

- Extreme Fabric Orchestrator (EFO) —The Fabric Extend view within EFO is not required, but should be used.
- **Tunnel failover time**—With IS-IS interface default values, tunnel failure detection can take up to 27 seconds. You can reduce the IS-IS interface hello timers to speed up logical link failure detection, but be careful to avoid link flapping due to values that are too low.

#### Note

If the number of IS-IS interfaces on a node is greater than 100, it is a good practice to set the hello timer not lower than 5 seconds.

- **ACL Filters over VXLAN**—IP filters configured to match IP header fields in the headers of VXLAN encapsulated packets, work only when the switch acts as a transit router and does not participate in the initiation or termination of VXLAN traffic.
- **VLACP**—VLACP is not supported over logical IS-IS interfaces.
- **CFM CCM**—CFM Continuity Check Messages are not supported over logical IS-IS interfaces.
- **CFM traceroute and tracemroute**—If CFM packets transit over a layer 3 tunnel (that is the CFM packets ingress a Fabric Extend layer 3 core tunnel and egress through another layer 3 core tunnel), the transit SPBM nodes do not display as intermediate hops in the output for CFM **12 traceroute** and **12 tracemroute**.

This is because the CFM packets are encapsulated in the outer layer 3 header as part of VXLAN encapsulation, and the transit SPBM nodes cannot look into the payload of the VXLAN packet and send a copy of the CFM packet to local CPU for processing.

- **CFM L2 ping**—CFM L2 ping to MCoSPB source mac is not supported and can fail if they are reachable via Fabric Extend tunnel.
- **MACsec**—Switch-based MAC Security (MACsec) encryption is Layer 2 so it cannot be used with Fabric Extend IP, which is Layer 3.
- **MTU minimum in Layer 2 Pseudowire core networks**—Service provider Layer 2 connections must be at least 1544 bytes. In this type of deployment the tunnels are point-to-point VLAN connections that do not require VXLAN encapsulation. The default MTU value is 1950.
- **Logical IS-IS interfaces**—Layer 2 core and Layer 3 core logical IS-IS interfaces are not supported on the same switch at the same time.
- **Fragmentation/reassembly**—There is no fragmentation/reassembly support in Layer 2 core solutions.

If a tunnel was initially UP between a VSP 4450 Series and another VOSS switch with MTU 1950 and then the VSP 4450 Series was later configured for fragmentation, the following behavior occurs:

- If the ONA MTU is less than 1594, the tunnel to the VOSS switch will go DOWN.

- If the ONA MTU is 1594 and above, the tunnel will stay UP, but any fragmented packets received from the VSP 4450 Series will be lost at the VOSS switch site.

Fragmented traffic can only be sent with an XA1400 Series or VSP 4450 Series/ONA combination on both ends with the same MTU configured on each end.

- **RFC4963 and RFC4459 considerations:**

The ONA 1101GT provides for the IP MTU of the Network port to be reduced from the default setting of 1950 bytes to 1500 bytes or lower. The MTU reduction feature with Fabric Extend is provided to facilitate the connection of two Fabric Connect networks over an IP network with any MTU without requiring end stations on the networks to reduce their MTU. The ONA 1101GT with the IP MTU of the network port set to 1500 bytes will fragment Fabric Extend VXLAN tunnel packets exceeding 1500 bytes. The ONA 1101GT will also reassemble fragmented Fabric Extend VXLAN tunnel packets at the tunnel termination point. The IP fragmentation and reassembly RFC 791 describes the procedure for IP fragmentation, and transmission and reassembly of datagrams and RFC4963 and RFC4459 detail limitations and network design considerations when using fragmentation to avoid out of order packets and performance degradation.

Factors that can impact performance are —

- The link speed per VXLAN IP address should be slower than 1G to avoid reassembly context exhaustion.
- ECMP and link aggregation algorithms in the IP core should be configured not to use UDP port hashing that could send IP fragments after the first fragment on different paths causing out of order packets. This is due to the fact that subsequent fragments do not have UDP port information.

### Important

Different MTU sizes on each end can result in traffic drops.

- **Layer 2 logical IS-IS interfaces**—Layer 2 logical IS-IS interfaces are created using VLANs. Different Layer 2 network Service Providers can share the same VLAN as long as they use different ports or MLT IDs.

### Note

Exception: Layer 2 logical IS-IS interfaces are not supported on XA1400 Series.

- **MTU minimum in Layer 3 core networks**—Service provider IP connections must be at least 1594 bytes to establish IS-IS adjacency over FE tunnels. The 1594 bytes includes the actual maximum frame size with MAC-in-MAC and VXLAN headers. If this required MTU size is not available, a log message reports that the IS-IS adjacency was not established. MTU cannot be auto-discovered over an IP tunnel so the tunnel MTU will not be automatically set. The default MTU value is 1950.

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The XA1400 Series and VSP 4450 Series/ONA combination supports fragmentation and reassembly, but you must have either an XA1400 Series or VSP 4450 Series with ONAs at BOTH ends of the IP WAN connection.

- **IP Shortcuts**—The tunnel destination IP cannot be reachable through an IP Shortcuts route.

**Important**

If you enable IP Shortcuts and you are using the GRT as the tunnel source VRF, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you enable IP Shortcuts and you are using a VRF as the tunnel source VRF, this is not an issue.

- **Layer 3 over Layer 2 Limitation**—The VOSS switches require a single next hop (default gateway) for all tunnels.
  - Over a layer 3 core network, on a given outgoing port or MLT, there is no issue as the one router next hop can support multiple VXLAN tunnels to one or more remote sites.
  - For layer 3 tunneling over a layer 2 core, the VOSS switch without any specific configuration supports only one Fabric Extend tunnel to one remote site. The workaround for this single next hop issue is to create an additional VRF, VLAN, and loopback interface.

For a configuration example of this workaround, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

**Note**

This limitation does not apply to VSP 4450 Series.

- You cannot establish a Virtual IST (vIST) session over a logical IS-IS interface. IST hellos cannot be processed or sent over a logical IS-IS interface if that is the only interface to reach BEBs in vIST pairs.

Assume that vIST is established over a regular NNI interface and the NNI interface goes down. If the vIST pairs are reachable through a logical IS-IS interface, then the vIST session goes down in up to 240 seconds (based on the IST hold down timer). During this time, the error message `IST packets cannot be sent over Fabric Extend tunnels, vist session may go down` is logged.

**Caution**

Expect traffic loss when the vIST session is down or when the error message is being logged.

- **Port Mirroring Resources:**

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these

applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

#### Important

- To enable any one of the above applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.
  - The VSP 8600 uses the four reserved resources for port mirroring and ACLs that have a mirroring action. For the other applications, this restriction does not apply because the VSP 8600 uses mirroring resources that do not come out of the four reserved port mirroring resources.
- **Fabric Extend over IPsec limitations**
    - Fabric Extend over IPsec is only supported on XA1400 Series devices.
    - Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
    - IKEv2 protocol key exchange only.
    - IPsec support is only added for Fabric Extend tunnels.
    - IPsec is not supported for regular layer 3 routed packets.

#### *ONA Considerations*

Review the following restrictions, limitations, and behavioral characteristics that are associated with the ONA.

#### **ONA Network port requirements**

The following are **Network** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Network port should not be part of any static/LACP MLT configurations.
- The ONA Network port should be part of a VLAN that belongs to the GRT.
- The ONA Network port that is configured on the switch cannot be tagged. It must be an Access port.

#### **ONA Device port requirements**

The following are **Device** port mandatory requirements for configuring Fabric Extend on the VSP 4450 Series:

- The ONA Device port should not be part of any static/LACP MLT, VLAN, or brouter configurations.
- The ONA Device port should not be configured as an access port. It is automatically configured as a trunk port when the **ip-tunnel-source-address** command is configured.
- The ONA Device port has to be connected directly to the VSP 4450 Series node where the FE tunnels originate.

#### **Layer 3 and Layer 2 ONA requirements**

An ONA is required for Fabric Extend Layer 3 core solutions. An ONA is *not* required in Layer 2 core solutions because the tunnels are point-to-point VLAN connections, not VXLAN. Therefore, there is no need for an ONA to encapsulate a VXLAN header to SPB packets.

### DHCP server

ONAs require access to a local DHCP server to automatically configure IP addresses. Configure an untagged ONA management VLAN to where the ONA is connected with its network side interface. If DHCP is used, a DHCP relay configuration needs to be added to the ONA network side port in order for the ONA to get an IP address assigned from a DHCP server. Alternatively, you can manually configure its IP address and other required settings with the ONA Manual Configuration menu.

### IP tunnel source address

Before the ONA can get an IP tunnel source address from the VSP 4450 Series, the following steps must be taken:

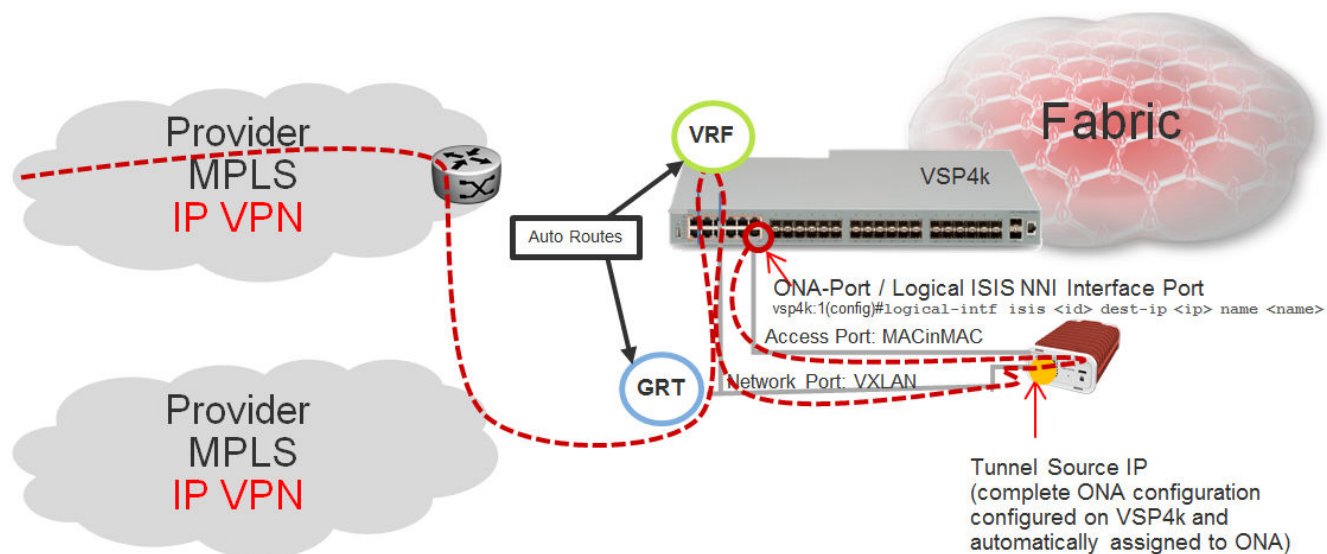

- Connect the Device and Network ports on the ONA to the VSP 4450 Series.
- Make sure that the ONA is connected to a DHCP server. If a DHCP server is unavailable, statically configure an IP tunnel source address on the ONA.
- Create a Management VLAN on the ONA that includes the Network port.
- Designate the Device port for the IP tunnel source address in the configuration file.

The syntax for the IP tunnel source address is: **ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu\_value>] [vrf WORD<1-16>]**.

### Automatic routing of VXLAN packets on the VSP 4450 Series

If you configure an IP tunnel source address in a VRF instead of a GRT, then the VSP 4450 Series automatically routes VXLAN packets from the ONA network port into the VRF configured as part of the IP tunnel source. Although the ONA network port is a part of the management VLAN that is in the GRT, for VXLAN encapsulated packets, the VSP 4450 Series automatically routes the packets into the VRF in which the tunnel source IP address is configured. This is done using a filter rule that the VSP 4450 Series software automatically sets up that filters based on whether the incoming port is equal to the ONA network port and the packet has a VXLAN header.

The Management VLAN on the VSP 4450 Series that is used to communicate with the ONA must always be in a GRT and must not be a part of the IP tunnel source VRF.

**Figure 62: Autorouting between GRT and VRF**

### ONA Gateway

The ONA gateway has to be a local IP address on the ONA Management VLAN. The ONA gateway IP address must be the same as the local IP address of the VSP 4000 connected to the ONA.

#### Note

Extreme does not support ONA gateway IP addresses that are not local to the VSP 4450 Series. For example, you cannot use a VRRP IP address configured in a switch cluster for the ONA gateway.

### Maximum MTU

The ONA supports a maximum transmission unit (MTU) size of 1950 bytes. For the VSP 4450 Series to work with a switch that supports Fabric Extend natively, the MTU size must be left at the default setting of 1950. If the core network does not support jumbo frames, the VSP 4450 Series with ONA must be used on all sites.

### Fragmentation and reassembly

If the maximum MTU size has to be fewer than 1594 bytes, then you require fragmentation and reassembly of packets. The VSP 4450 Series with ONAs support fragmentation and reassembly, but you must have VSP 4450 Series switches with ONAs at BOTH ends of the IP WAN connection.

### QoS priority queues

The ONA 1101GT implements both Layer 2 and Layer 3 QoS. Specifically, it implements IEEE 802.1Q VLAN TCI PCP (Priority Code Point) and IETF IPv4 DSCP (Differentiated Services Code Point). These are implemented in hardware with the limitation that there are four Weighted Random Early Detection (WRED) priority queues, numbered 4 (highest) to 7 (lowest). The following tables show the mappings from the PCP and DSCP values in the packet to the priority queue.

The hardware puts each packet in 1 of the 4 HW queues in the following order:

1. If a packet is a tagged VLAN packet, the PCP field determines the priority queue. (Ethertypes 0x8100 and 0x88a8 identify tagged VLAN packets.)
2. If the packet is an IPv4 packet, the DSCP field determines the priority queue.
3. Use the highest priority queue (4).

The HW QoS is always enabled, and the CP to priority queue mappings are static.

The following table defines the 3 bit VLAN PCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest priority.

**Table 125: VLAN PCP to queue mapping**

VLAN PCP	Queue Number
0	7
1	7
2	6
3	6
4	5
5	5
6	4
7	4

The following table defines the 6 bit IPv4 DSCP value to queue number mapping. The queues are numbered 4..7 with 4 being the highest priority and 7 the lowest.

**Table 126: IPv4 DSCP to queue mapping**

IPv4 DSCP	VLAN PCP	Queue Number
0	1	7
1	1	7
2	1	7

## Fabric Attach

**Table 127: Fabric Attach product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
Fabric Attach	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.0
	VSP 8400 Series	VOSS 5.0
	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Supported

With Fabric Attach, network edge devices that do not support Shortest Path Bridging (SPB), MAC-in-MAC encapsulation (802.1ah) or service identifiers (I-SIDs) can take advantage of SPB infrastructure. To

attach to an SPB network, edge devices signal an SPB-aware FA Server to automatically configure the I-SIDs. The edge devices can then utilize existing SPB features across the fabric and leverage SPB infrastructure capabilities without manual configuration. Fabric Attach uses the IEEE 802.1AB Logical Link Discovery Protocol (LLDP) to signal a desire to join the SPB network.

FA uses the client-server model. An initial handshake occurs between the FA Server and the FA Client. After the discovery phase is complete, the FA Server accepts requests (from FA Clients) to add the C-VID (VLAN ID) and I-SID elements in the SPB network, and also automatically configures the necessary C-VID and I-SID. The FA Server then responds with an acknowledgement of whether the request succeeded. FA Clients can also be aggregated into a proxy device that handles the handshakes and requests on behalf of many clients, to the server. All of the discovery handshakes and I-SID mapping requests are then transferred using LLDP Type, Length, Value (TLV) fields.

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP Protocol Data Units (PDU).

### *FA Zero Touch Client Attachment*

**Table 128: Fabric Attach Zero Touch Client Attachment product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
Fabric Attach Zero Touch Client Attachment	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	VSP 8600 6.3
	XA1400 Series	Not Supported

FA Zero Touch Client Attachment eases the configuration process on FA-capable devices by automating specific configuration tasks required for FA functionality.

#### Note

Only the base functionality of Zero Touch Client Attachment is supported.

After you initially configure Zero Touch Client Attachment on the FA Server, the settings are exported to receiving FA devices, where the required configuration tasks are automatically performed.

Base Zero Touch Client Attachment operation is tightly coupled with FA operation. Although you can enable or disable Zero Touch Client Attachment separately from FA, the feature is dependant on data that is only available during exchanges between the FA Server and FA Proxies, after a primary FA Server has been selected. By default, base Zero Touch Client Attachment support is enabled.

Base Zero Touch Client Attachment operation, when enabled, extracts management VLAN data from the primary FA Server advertisements and uses this data to update the in-use management VLAN if applicable. An FA Client can also utilize FA-provided management VLAN data after the FA Proxy or Server is discovered.

Zero Touch is active when the following criteria are met:

- On an FA Proxy:
  - Zero Touch Client Attachment is enabled
  - Fabric Attach is enabled
  - A primary FA Server is discovered and selected
- On an FA Server:
  - Zero Touch Client Attachment is enabled
  - FA is enabled
  - FA Proxies or FA Clients are discovered

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

#### Note

You must enable Base Zero Touch **auto-client attach** and define the target Fabric Attach client in order to initiate Zero Touch Client Attachment processing.

FA Signaling generated by an FA Proxy or Server contains management VLAN data. If the management VLAN advertised by the primary FA Server differs from the management VLAN currently configured on the FA Proxy, Zero Touch Client Attachment initiates the following:

- VLAN creation — If the FA Server-specified management VLAN does not exist on the FA Proxy, Zero Touch Client Attachment creates a port-based VLAN.
- Management VLAN update — The created port-based VLAN becomes the designated management VLAN for the FA Proxy. No operations related to the previous management VLAN, such as port membership updates or VLAN deletion, are performed.
- Port VLAN membership update (FA Proxy/Server) — If required, Zero Touch Client Attachment updates the port VLAN membership to ensure that the uplink port through which the primary FA Server is accessed is a member of the management VLAN, for network accessibility.
- Port Default VLAN (PVID) update — The port-based PVID is automatically updated based on the VLAN ID value.

- Port Default Priority update — The default 802.1p user priority for the port is updated based on the specified port priority value of the Zero Touch client (range is 0–7).
- Zero Touch Client Specification removal — All Zero Touch client-related settings are updated based on the FA client discovery. Deleting a Zero Touch client specification or disabling any related Zero Touch option does not result in the immediate removal of any previously applied settings.

**Note**

The FA Proxy does not update the acquired management VLAN if the primary FA Server is lost. This data is updated if the management VLAN advertised by the current primary FA Server changes or if another primary FA Server is selected and new management VLAN data is advertised by the server.

Management VLAN and port membership updates performed by Zero Touch are maintained in non-volatile storage and are restored following a system reset. You must remove or update these configuration settings if they are deemed unnecessary at a later time.

- IP Address Source Mode Update — Updates the IP address source mode of the receiving device to DHCP-When-Needed, to initiate DHCP-based IP address acquisition if necessary.
- Automation of the FA Client Port Mode — Automates the configuration of EAP port modes based on the type of discovered FA Clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- ZTC Installation — Initiates ZTC installation on applicable ports on the receiving device. Applies to FA Proxy and, in a limited manner, to FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto Trusted FA Client Port Mode — Initiates automatic QoS interface class update based on the type of discovered FA clients. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports.
- Auto PVID FA Client Port Mode — Initiates automatic port PVID, port management VLAN membership and port tagging mode based on the type of discovered FA device. Applies to FA Proxy and FA Server devices. Automated configuration is applied only to FA-enabled ports. This configuration is incompatible with the automatic FA Client Port Mode and ZTC Automatic attach options.

### *Fabric Attach Components*

FA components dynamically communicate with each other using FA signaling.

**FA Signaling**

FA has defined organizational specific TLVs within the standard LLDP protocol, to exchange messages and data amongst components of an FA solution. The FA TLVs facilitate handshaking and authentication, processing of requests for the creation of services, and providing responses on whether the requests succeeded. In addition, these services are deleted when the service requests are terminated, or when the authentication criteria are no longer valid. All components that participate in FA must be able to send, receive, and interpret the FA TLVs.

**FA Components**

FA includes the following network elements as components:

- FA Server:

An SPB-capable switch at the edge of a Fabric Connect cloud.

An FA Server receives requests from FA Clients or FA Proxies to create services with specific I-SID-to-VLAN bindings. The FA Server completes the association between conventional networks and fabric-based virtual service networks. For more details on the operation of an FA Server, see [Fabric Attach Server](#) on page 933.

- FA Proxy:

A network switch that supports the definition of I-SID-to-VLAN assignments and has the ability to advertise these assignments for possible use by an FA Server. FA Proxy switches also support the client mode for directly attached users or end devices. Typically, FA Proxies support downstream FA Client devices, while being directly connected to an upstream FA Server device.

- FA Client:

A network attached end-point device that advertises I-SID-to-VLAN binding requests for service creation, to an FA Proxy or an FA Server. FA Clients use FA signaling to automatically attach to fabric services.

### *Fabric Attach Server*

#### **FA Server operation**

In an FA solution, the FA Server performs the role of connecting FA Clients and FA Proxies to the SPB fabric, with minimal configuration. As part of the discovery handshake between the FA Server and client or proxy devices, LLDP PDUs are exchanged. Using standard LLDP, the FA Server learns neighbors, that include the proxy and client devices. In addition, the FA Server transmits organizational-specific element-discovery TLVs that are used by the client or proxy device to recognize its attachment to the FA Server.

**Figure 63: Fabric Attach Server connecting client or proxy devices to the Fabric network**

After the initial discovery handshake is complete, the client or proxy device transmits I-SID-to-VLAN assignment mapping requests to the FA Server to join the SPB fabric. These requests include the C-VID (VLAN ID) and the I-SID that the client or proxy device needs to join. The FA Server then creates the requested C-VID and I-SID on its device. It then responds with a PDU (containing the FA-specific TLV) to indicate whether the request succeeded. The I-SID thus created is a ELAN I-SID with endpoints of type Switched UNI. After I-SID creation, the I-SID is also advertised to the SPB network by IS-IS.

The traffic that is sent to or received from the SPB cloud is MAC-in-MAC (MiM) encapsulated. The FA Server, being SPB-capable, decapsulates the MiM traffic. If the I-SID matches the I-SID created on behalf of the client or proxy, the FA Server sends the traffic to that client or proxy and passes it on the C-VID that it expects.

### FA Server configuration

An FA Server can be configured at two levels—global and interface.

Configuration at the global level enables or disables FA on the entire switch. However, for attachment of clients or proxy devices, you must also configure FA at the interface level. Interfaces can be ports (including channelized ports), MLTs, SMLT or LACP MLTs. Enabling FA on an interface also enables transmission of LLDP packets that contain the FA-specific TLVs.

When you disable FA on an interface, LLDP transmission automatically stops on that interface.

#### Caution

Disabling FA or IS-IS triggers a flush of FA information on the switch. Disabling FA at the global level flushes all FA element-discovery information and mappings. Disabling at the interface level flushes element-discovery information and mappings associated with that interface.

#### Important

The only provisioning mode supported on the FA Server is SPB.

### *FA Proxies and FA Clients*

The configuration mode of FA Proxies and FA Clients is not supported. However, in an FA solution, the FA Server interacts with FA Proxies and FA Clients by accepting LLDP PDUs (containing FA TLVs) and using them to automatically create Switched UNI I-SIDs and endpoints, based on the mapping requests contained in those TLVs. For more information, see [FA TLVs](#) on page 934.

### *Fabric Attach operation*

The following sections detail FA operation.

### FA TLVs

FA leverages LLDP to discover directly connected FA peers and to exchange information associated with FA amongst those peers. FA information is transmitted using company-specific proprietary organizational Type, Length, Value (TLV) fields within LLDP Protocol Data Units (PDU). The following section describes the TLVs for FA.

FA uses two TLVs:

- FA Element TLV
- FA Assignment TLV

#### FA Element TLV

The FA Element TLV is used by FA elements to advertise Fabric Attach capabilities. This data forms the basis for FA element discovery and is used in the initial handshake between the FA Server and a client or proxy device.

TLV Type [127]	TLV Length [50 octets]	OUI [00-04-0D]	Subtype [11]	HMAC-SHA Digest	Element Type	State	Mgmt VLAN	Rsvd	System ID
7 bits	9 bits	3 octets	1 octet	32 octets	6 bits	6 bits	12 bits	1 octet	10 octets

**Figure 64: FA Element TLV format**

**Table 129: FA Element TLV field descriptions**

Field	Description
TLV Type	Indicates whether the discovered element is a client or a proxy device.
OUI and Subtype	The information in these fields is used in LLDP packet handling.
HMAC-SHA Digest	<p>Data integrity and source validation is supported through the use of the HMAC-SHA256 message authentication. This field supports a digest exchange between the source and destination devices. Symmetric private keys are used for digest generation. The HMAC-SHA256 generated digest size is 32 octets.</p> <p>The HMAC-SHA256 digest is computed starting with the Element Type data, that is, it starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing commences. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b> If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA Element TLV is discarded before it is processed by the system operating in secure mode.</p>

**Table 129: FA Element TLV field descriptions (continued)**

Field	Description
Element Type	<p>Indicates the supported element type. The primary element types are the FA Server, FA Proxy and FA Client.</p> <p>An FA Server is an SPB capable device that accepts externally generated I-SID-to-VLAN assignments. An FA Proxy is a non-SPBM device that supports I-SID-to-VLAN assignment definitions and advertises these assignments for possible use by an FA Server. An FA Client, also a non-SPBM device, advertises I-SID-to-VLAN assignments to a directly connected FA Proxy or an FA Server. Both tagged and untagged FA Client connections are supported.</p> <p>The list of supported element types and their values are:</p> <ul style="list-style-type: none"> <li>• FA Element Type - Other (1)</li> <li>• FA Server (2)</li> <li>• FA Proxy (3)</li> <li>• FA Server No Authentication (4)</li> <li>• FA Proxy No Authentication (5)</li> <li>• FA Client - Wireless Access Point Type 1, which directly attaches to the SPBM network.</li> <li>• FA Client - Wireless Access Point Type 2, which is tunneled to a controller.</li> <li>• FA Client - Switch (8)</li> <li>• FA Client - Router (9)</li> <li>• FA Client - IP Phone (10)</li> <li>• FA Client - IP Camera (11)</li> <li>• FA Client - IP Video (12)</li> <li>• FA Client - Security Device (13)</li> <li>• FA Client - Virtual Switch (14)</li> <li>• FA Client - Server/Endpoint (15)</li> </ul>
State	<p>Indicates the link tagging requirements in FA Client-sourced frames. This field also indicates the current provisioning mode.</p> <p>The Link VLAN Tagging bit (bit 1) has one of the following values:</p> <ul style="list-style-type: none"> <li>• 0 – indicates that all traffic on the link is tagged. In this case, all discovered FA Clients are treated as tagged.</li> <li>• 1 – indicates that traffic on the link is either tagged or untagged. Here, all discovered FA Clients are treated as untagged.</li> </ul> <p>The automatic provisioning mode bits (bits 2 and 3) always have the value 1 for SPB provisioning. The switch only supports the SPB provisioning mode.</p>
Mgmt VLAN	<p>When you configure a management VLAN on the FA Server, it is included in this field in FA Server or FA Proxy sourced frames, and is used to support management VLAN auto-configuration on the downstream proxy and client devices.</p>
System ID	<p>This field contains connection information that a TLV recipient can use to enforce connectivity restrictions.</p> <p>It contains the system MAC address (6 octets) for MLT configurations and the virtual BMAC address for vIST and SMLT configurations. It also contains information on the connection type such as MLT or SMLT.</p>

**Limitations**

- The FA Element TLV exists only once in an LLDP PDU and is included in all PDUs when the FA service is enabled.

- The maximum length of the FA Element TLV is 56 bytes.

#### FA I-SID-to-VLAN Assignment TLV

The FA I-SID-to-VLAN Assignment TLV is used by FA Clients to distribute I-SID-to-VLAN assignments that need to be supported by an FA Proxy or an FA Server.

TLV Type [127]	TLV Length [41-506 octets]	OUI [00-04-0D]	Subtype [12]	HMAC-SHA Digest	Assignment Status	VLAN	I-SID
7 bits	9 bits	3 octets	1 octet	32 octets	4 bits	12 bits	3 octets

**Figure 65: FA Assignment TLV format**

#### FA I-SID-to-VLAN Assignment TLV fields

Some fields are common to both the FA Element and FA Assignment TLVs. The following fields are specific only to the FA Assignment TLV.

TLV Field	Description
HMAC-SHA Digest	<p>The HMAC-SHA256 digest is computed for the series 1 to 94 of I-SID-to-VLAN assignments, that is, the data for the digest computation starts at zero-based byte 38 of the TLV. The digest is then placed in the HMAC-SHA256 Digest field in the TLV prior to transmission. Upon receipt, the digest is again computed for the series 1 to 94 of I-SID-to-VLAN assignments in the received TLV and the resulting digest is compared against the received digest. If the received digest is the same as the newly computed digest, the TLV is considered valid and processing can commence. If the comparison fails, the TLV is discarded and processing is terminated.</p> <p><b>Caution:</b> If FA communication occurs between non-secure systems, the HMAC-SHA256 Digest data must always be zero. If one system operates in secure mode and the other operates in non-secure mode, the FA I-SID-to-VLAN Assignment TLV is discarded before it is processed by the system operating in secure mode.</p>
Assignment status	Indicates whether the FA Server accepted or rejected the I-SID-to-VLAN mapping request from a client or proxy device.
VLAN	Indicates the C-VID value advertised by the client or proxy device in the FA I-SID-to-VLAN mapping request.
I-SID	<p>Indicates the I-SID that is advertised by a client or proxy device in the FA I-SID-to-VLAN mapping request. This I-SID is used to create a Switched UNI (ELAN) I-SID.</p> <p><b>Note:</b> This I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.</p>

#### Limitations

- The FA I-SID-to-VLAN Assignment TLV is included in an LLDP PDU only if the FA Server and proxy or client devices are directly connected to each other.
- This TLV can exist only once in an LLDP PDU.

- The size limit of this TLV is 511 bytes. This limits the maximum number of I-SID-to-VLAN assignments supported in an LLDP PDU to 94.
- For an FA I-SID-to-VLAN Assignment TLV to be processed, the FA Element TLV must also be present in the LLDP PDU.

### FA Element Discovery

The first stage of establishing FA connectivity is element discovery.

On an FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface. After FA is enabled, the FA Server begins transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices.

An FA Server can communicate with multiple different FA Client and FA Proxy devices.

### FA data processing

In the following FA deployment, a client device (Client 1) attaches to the FA Server (FA Server 1) using a proxy device. Another client device (Client 2) attaches to the FA Server (FA Server 2) at the other edge of the network. The following section describes how data is processed when data traffic is transmitted from Client 1 to Client 2.

When Client 1 successfully attaches to FA Server 1, FA Server 1 creates a unique I-SID-to-VLAN mapping for Client 1 on its device. This mapping contains the I-SID and C-VID advertised by Client 1, using the FA Assignment TLV. For example, assume that Client 1 advertises I-SID 200 and C-VID 250.

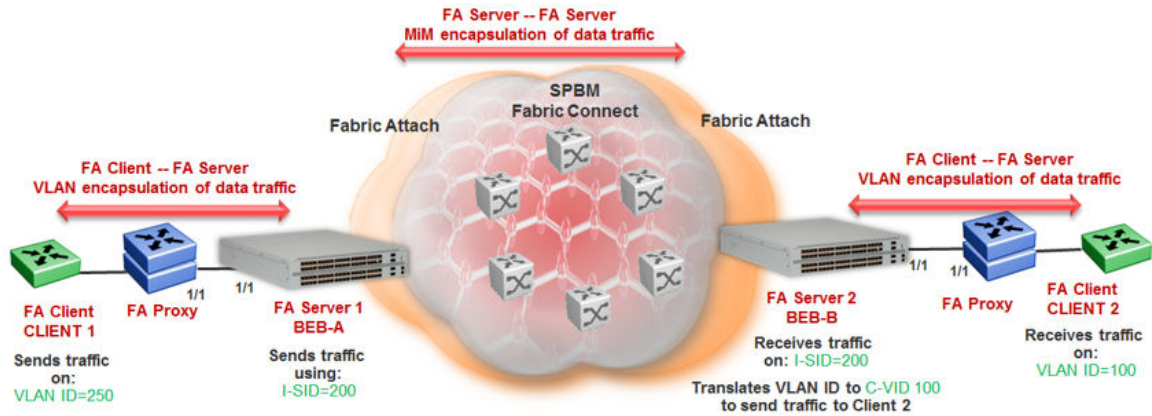

Similarly, when Client 2 attaches to FA Server 2, FA Server 2 creates an I-SID-to-VLAN mapping for Client 2 on its device with, for example, I-SID 200 and C-VID 100. This is depicted in the following figure.

**Figure 66: Learning of I-SID-to-VLAN mappings**

When data traffic ingresses FA Server 1 at the FA-enabled port 1/1, it contains the C-VID of Client 1, which is, 250. The data is VLAN-encapsulated at this stage. As traffic egresses FA Server 1 into the SPB cloud, it is encapsulated with the ELAN I-SID created on FA Server 1 on behalf of Client 1, that is I-SID 200. The traffic is now MiM encapsulated with I-SID 200.

The following figure depicts VLAN encapsulation of data traffic from the FA Client to the FA Server (at either end of the SPB cloud) and its MiM encapsulation as it traverses the SPB cloud.

**Figure 67: Data encapsulation – VLAN encapsulation and MiM encapsulation**

As traffic exits the SPB cloud and ingresses the remote FA Server 2, it continues to be MiM encapsulated with I-SID 200.

At FA Server 2, the MiM traffic is decapsulated. Since the I-SID in the data packet matches the I-SID created on its device on behalf of Client 2, FA Server 2 prepares to send traffic to Client 2. At this stage, to successfully transmit the data traffic to Client 2, FA Server 2 must additionally know the C-VID that Client 2 expects traffic on. This information is obtained from the I-SID-to-VLAN mapping on FA Server 2 created on behalf of Client 2, which is C-VID 100. Thus FA Server 2 translates the C-VID in its data packets to this VLAN ID, and then passes it on to Client 2.

The following figure depicts the typical MiM encapsulation of a data packet. The B-DA and B-SA components indicated the system ID of the FA Server running SPB.

**Figure 68: MiM encapsulation**

## FA Server and I-SID-to-VLAN Assignments

FA Client or FA Proxy devices advertise I-SID-to-VLAN assignments to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. All communication between FA Proxies or Clients and the FA Server is using LLDP. Successful assignments result in the creation of a Switched UNI I-SIDs and endpoints based on the mapping requests.

The FA Server rejects I-SID-to-VLAN assignment requests if:

- FA is not configured properly on the port or MLT.
- Router IS-IS is disabled.

### Note

For Fabric Attach to operate properly and for the FA Server to accept I-SID-to-VLAN assignment requests, IS-IS must be enabled.

The following error message is logged immediately after IS-IS is disabled, and appears only once in the log file. It does not appear again when an assignment request is made from the FA Proxy.

```
CP1 [12/04/15 00:33:49.733:UTC] 0x00374589 00000000
GlobalRouter FA INFO Fabric Attach Assignments will be rejected
since ISIS is disabled.
```

- The C-VID and I-SID are not within the supported range.

Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported. The value 4096 indicates that the port is untagged. An I-SID value of 0 is not supported on the FA Server.

- The I-SID is already assigned to an IP VPN.

The system displays the error message `I-SID is already assigned to an IPVPN`.

- The I-SID is already in use for SPB multicast.

The system displays the error message `SPB Multicast is enabled, ISID 16000000 and greater reserved for dynamic data-isid's used to carry Multicast traffic over SPB`.

- The I-SID has a value that is reserved for internal use.
- The I-SID cannot be used in an IS-IS accept policy.
- The I-SID is associated with a platform VLAN and that VLAN is used as a private VLAN (that is, has a secondary VLAN specified).
- The I-SID is already in use for Transparent Port UNI.
- The port that receives the I-SID-to-VLAN assignment is a member of an MLT, but FA is not successfully enabled on that MLT interface.
- There is a resource error on the FA Server system, such as lack of memory.
- The number of I-SID-to-VLAN assignments on a port exceeds the maximum limit which is 94.
- The number of I-SIDs on the switch exceeds the maximum limit.
- The same endpoint is configured on more than one I-SID.
- The port or MLT is associated with more than one C-VID in the same I-SID.

When the FA Server rejects I-SID-to-VLAN assignments, aside from viewing the log file, you can use trace to troubleshoot the cause of rejection.

For an example on troubleshooting rejection of I-SID-to-VLAN assignments on the FA Server and for more information on using trace, see [Troubleshooting Fabric Attach](#) on page 3738.

## FA management

You can configure a management I-SID on an FA-enabled port or MLT. This I-SID includes an optional C-VID parameter, which is a VLAN ID that is locally significant to the port or MLT and does **not** represent a platform VLAN.

Depending on whether the C-VID value is specified, the behavior is as follows:

- If the C-VID value is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN ID for management traffic on the FA Server uplink.

Different hardware platforms support different customer C-VID ranges.

- If the C-VID value is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

If you do not configure a management I-SID, the FA Server transmits a management VLAN ID value of 0 in the FA Element TLV. A client/proxy that receives the FA Element TLV retains the initial management configuration (if any) on its device.

Limitations of FA management I-SIDs

- A management I-SID value of 0 is not supported on the FA Server.
- You cannot enable BPDU on a management I-SID.

FA management configuration considerations

A Switched UNI I-SID that is created when an FA assignment is learned on a port or MLT, is uniquely identified by a tuple comprising of one of the combinations of (port, I-SID and C-VID) or (MLT ID, I-SID and C-VID). When you configure FA management, similar tuples are used. You can configure FA management on an FA-enabled port or MLT on which FA assignment mappings are learned, as long as the FA management tuple exactly matches the tuple created by the learned FA mapping.

The following scenarios describe the behavior when you configure FA management on a port or MLT that also receives learned FA mappings, but the tuples do not match.

- **Scenario 1:** You attempt to configure FA management on a port or MLT where an FA assignment mapping is already learned.

For example, consider an FA-enabled port 1/1 on which an assignment mapping is learned, with I-SID 100 and C-VID 20. You can configure FA management on port 1/1 as long as the I-SID and C-VID values exactly match that of the learned FA mapping. However, if you attempt to configure FA management on the port with a different I-SID and C-VID value, the configuration is not successful and an error message displays.

- **Scenario 2:** An FA assignment mapping is learned on a port or MLT that already has FA management configured.

For example, consider that FA management is configured on port 1/1. If an FA assignment mapping is learned on the port with the same I-SID and C-VID values as that of the FA management configuration, then the mapping is accepted. Otherwise the mapping is rejected.

### FA message authentication and integrity protection

For the security of FA communication in terms of data integrity and authenticity, a keyed-hash message authentication code can be transmitted within every FA TLV.

It protects the I-SID-to-VLAN assignment exchanges between the FA Server and FA Proxy. The standard HMAC-SHA256 algorithm calculates the message authentication code (digest) involving a cryptographic hash function (SHA-256) in combination with a shared secret key. The key is symmetric, that is, it is known by both the source and destination parties.

By default, on the FA Server, message authentication is enabled at the interface level and a default key is defined to provide secure communication.

You can configure a different authentication key on an interface (port or MLT) on the FA Server, to authenticate a client on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server. For an FA Client to authenticate and attach to the FA Server, the authentication key must match on both the client and the server. In general, the FA authentication key must match between two FA components exchanging FA TLVs through LLDP.

When you enable FA message authentication, the message authentication key (default or configured) generates a Hash-based Message Authentication Code (HMAC) digest that is included in FA I-SID-to-VLAN Assignment TLV. Upon receipt, the HMAC digest is recomputed for the TLV data and compared against the digest included in the TLV. If the digests are the same, the data is valid. If the digests are not the same, the data is considered invalid and is ignored.

The FA secure communication setting (enabled/disabled) and the symmetric key data are maintained across resets and restored during FA initialization.

### *Fabric Attach and Switched UNI*

With the C-VLAN UNI feature, I-SID-to-VLAN mappings must be unique across the network. With the Transparent Port UNI (ELAN Transparent) feature, you can map an entire port or MLT to an I-SID.

With the Switched UNI feature, you can associate many different C-VID/port or C-VID/MLT list combinations to a single I-SID.

### Switched UNI and FA

FA brings the capability of automatically creating Switched UNI I-SIDs on a switch, without manual intervention. The I-SIDs thus created are ELAN I-SIDs with endpoints of type Switched UNI, and are by default for Layer 2. MAC learning takes place and there is an any-to-any relationship. For Layer 3 participation, you must configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping.

#### Note

The number of Switched UNI I-SIDs created are different for different product families. For more information, see [Release Notes for VOSS](#).

**Limitations of FA-created Switched UNI I-SIDs**

- An FA-created Switched UNI I-SID is always ELAN.
- You cannot enable BPDU on an FA-created Switched UNI I-SID.
- The ELAN I-SIDs created are by default for Layer 2. For Layer 3 participation, you must manually configure a platform VLAN with the same I-SID value as that of the I-SID in a learned FA mapping. You can configure the platform VLAN with the same VLAN ID as that of the C-VID, or use a different value.
- The Switched UNI (ELAN) I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or a T-UNI.
- You cannot change from one UNI type to another dynamically. The I-SID must be deleted and created with the new UNI type (Customer VLAN (C-VLAN), Transparent Port user-network-interface (T-UNI), ELAN).
- If the port is a member of an MLT, you must add the entire MLT to the C-VID.
- The port is always in the forwarding state.
- You cannot associate a port or MLT with more than one C-VID in the same I-SID.
- The same C-VID, port or MLT cannot be a member of more than one I-SID. Different hardware platforms support different customer C-VID ranges. The value 4095 is not supported and cannot be configured. The value 4096 indicates that the port is untagged.
- An I-SID value of 0 is not supported on the FA Server.

*Fabric Attach deployment scenarios*

Fabric Attach is typically deployed in the access layer(s) of a Fabric Connect network.

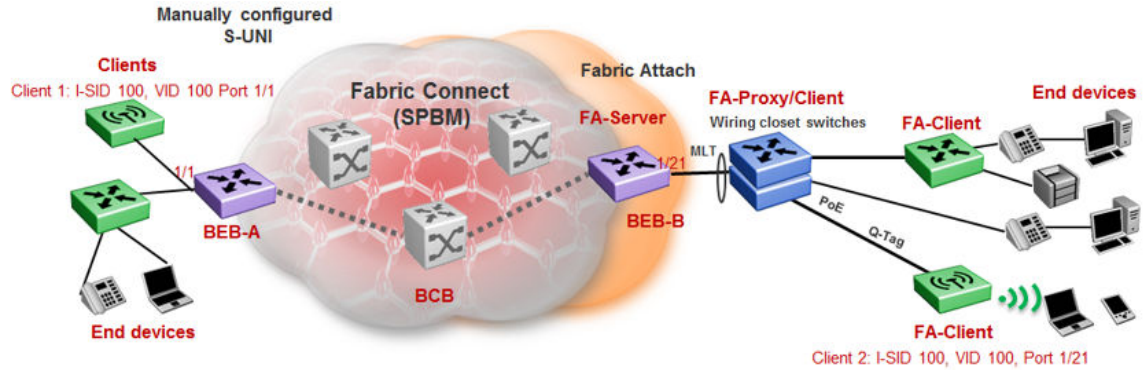

Fabric Attach, when used with a Fabric Connect solution, provides the same capabilities at the access layer, but those services and policies are now mapped across the entire network end-to-end. FA makes user and end device attachment simple and creates network configuration and sets up resources only when needed.

An FA Server can be connected to FA Client or FA Proxy devices on three types of interfaces, namely, a port, MLT or an SMLT. The following sections discuss FA in SMLT and non-SMLT deployments.

**FA and Switched UNI in non-SMLT deployments**

The following deployment shows an SPBM network in which one edge has manually configured Switched UNI I-SIDs and the other edge has Fabric Attach (FA). At the FA edge, the I-SIDs are learned using FA TLVs and are automatically created on the FA Server as ELAN I-SIDs with Switched UNI endpoints.

This deployment demonstrates that the FA-created I-SIDs can communicate with any other I-SID (manually created Switched UNI or a C-VLAN with an I-SID), on the local switch or across the SPBM fabric, as long as the I-SID values are the same.

BEB-B is a switch acting as the FA Server with an NNI interface to the SPBM cloud. FA Client and FA Proxy devices send I-SID-to-VLAN mapping requests to the FA Server on the respective FA-enabled ports, using LLDP TLVs. This enables the I-SID endpoints to communicate with the SPB cloud.

If several clients are aggregated in an MLT, at least one of the ports must send the mapping requests for the FA Server to create the I-SID endpoints for that MLT. For example, let Client 2 be a wireless FA Client (such as a WLAN 9100 AP device) on port 1/21, that sends an FA mapping request for I-SID 100 and C-VID (VLAN ID) 100. The FA Server (BEB-B) creates the requested I-SID 100 on its device, and advertises it to the SPB cloud.

BEB-A has manually configured Switched UNI endpoints, one of which is Client 1 (connected at port 1/1) using the same I-SID value 100.

With this setup, data traffic can freely flow between Client 1 and Client 2 through the two BEBs and the BCB.

Thus the Switched UNI I-SIDs learned using FA TLVs on one edge of the Fabric Connect (SPBM) network can communicate with the manually created I-SIDs on the other edge, as long as they both have the same value.

### FA and Switched UNI in SMLT deployments

The following examples discuss FA in dual-homed and single-homed SMLT deployments.

#### Fabric Attach in a dual-homed SMLT deployment

The following section describes FA in a dual-homed SMLT deployment. A pair of switches that operate as IST peers act as the FA Server. An FA Proxy (typically a wiring closet switch or an access switch) is connected to FA Clients and in turn to end devices. The FA Clients or FA Proxies advertise I-SID-to-VLAN mappings namely the interface C-VID and the I-SID to the FA Server switches. Both switches receive the mapping information using LLDP TLVs. The switch that learns the mapping first from the LLDP TLV considers the I-SID endpoint to be discovered locally, and creates the I-SID on its device. It then sends the mapping information to its peer switch. When the peer switch receives the mapping

across IST in a new SMLT message, it too creates the I-SID and endpoint on its device. This I-SID however, is considered to be discovered remotely, because the data was synchronized from its peer.

#### Note

- For the peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration must be the same on both peers.
- For successful FA operation, configuration of FA message authentication and the authentication key must be the same on both peers.
- For successful operation in Layer 3, a platform VLAN must be configured on both peers. This is necessary for proper MAC learning.

**Figure 69: FA in a dual-homed SMLT deployment**

In the above example deployment, BEB-A and BEB-B are IST peers collectively acting as the FA Server. FA TLVs sent from the clients (through the proxy) are learned on FA-enabled ports on BEB-A and BEB-B. When BEB-A learns the mapping for the first time on its port, it creates an I-SID on its device. This is considered locally discovered. In addition, it sends an SMLT message to its peer BEB-B, which also creates the I-SID on its device. This time, the I-SID is considered remotely discovered. Similarly, if BEB-B receives a mapping from a client for the first time, it creates an I-SID (locally discovered) and also sends an IST message to its peer to create an I-SID (remotely discovered).

Irrespective of whether the I-SID creation on the FA peers is triggered by a local TLV event or by messaging from the IST peer, they can both receive data traffic. Thus in a dual-homed SMLT deployment, any I-SID can be learned irrespective of whether it is discovered locally, discovered remotely or both.

#### Note

- On the IST peers, if an FA TLV is learned on a port or normal MLT (instead of the admin SMLT), only the I-SID is sent to the peer switch.

### Fabric Attach in a single-homed SMLT deployment

In the single-homed SMLT, as shown in the following deployment, the FA Server creates either a locally discovered I-SID (if received from a client using FA TLVs) or a remotely discovered I-SID (if synchronized from its IST peer), but not both.

**Figure 70: Fabric Attach in a single-homed SMLT deployment**

### *Fabric Attach Considerations*

Review the following restrictions, limitations, and behavioral characteristics for Fabric Attach.

- IS-IS and FA must be globally enabled on the FA Server, for FA to operate successfully.
- Static MAC, Static ARP and configuration of a static IGMP group are not supported on FA-enabled ports.
- An FA port cannot be a BROUTER port.
- You cannot enable FA on an existing Transparent Port UNI or a C-VLAN UNI port.
- On VSP 8600 Series, you also cannot enable FA on an existing Switched UNI.
- FA I-SID-to-VLAN assignment mapping requests from a client or proxy device can be accepted or rejected by the FA Server.
- On an FA-enabled port or MLT, you must first disable LACP before you change the LACP key.
- You can only enable VLACP on an FA enabled MLT; VLACP is not supported on FA enabled non-MLT ports.
- On VLACP enabled ports, FA and LLDP signaling run independent of the VLACP state. Therefore, requests and responses are exchanged between the FA Server and client or proxy devices even if VLACP is operationally down. However, forwarding of data traffic is dependent on VLACP being operationally up on the port.

For example, if VLACP is enabled on the FA Server side of the link but not on the proxy or the client side, the FA Server learns the I-SID-to-VLAN assignment mappings and creates the required I-SIDs on its device. However, data traffic is not forwarded on the port until VLACP is operationally up.

- On VSP 4450 Series, you cannot use a port designated as a Fabric Extend tunnel source, configured using the command **ip-tunnel-source-address**, for Fabric Attach.
- FA uses the virtual MAC to create the FA system ID when the FA is on an SMLT. If you delete the SPBM instance, then this information is no longer available. Therefore, you must delete the FA on SMLT before deleting the SPBM instance.

- You cannot enable FA and Endpoint Tracking simultaneously on the same interface.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN-ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

## Endpoint Tracking

**Table 130: Endpoint Tracking product support**

Feature	Product	Release introduced
For configuration details, see <a href="#">VOSS User Guide</a> .		
Endpoint Tracking	5520 Series	VOSS 8.2.5
	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	VOSS 8.1.1
	VSP 7400 Series	VOSS 8.1.1
	VSP 8200 Series	VOSS 8.1.1
	VSP 8400 Series	VOSS 8.1.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

### *Endpoint Tracking Overview*

Endpoint Tracking provides dynamic assignment of virtual machines (VMs) to IP subnets as they attach to a Shortest Path Bridging (SPB) cloud. Deployment scenarios include VMs connecting to DvR Leaf nodes, or regular SPBM deployments.

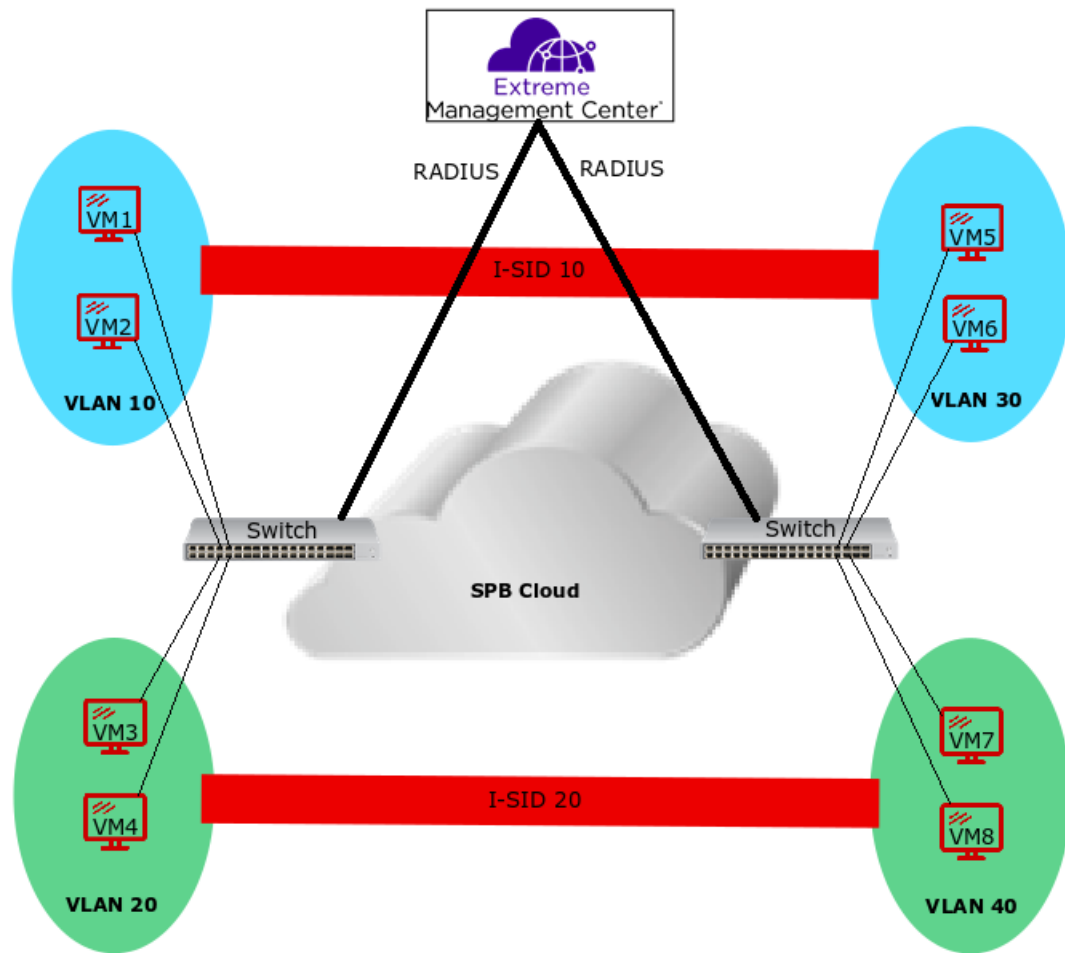

Extreme Management Center is integral to the Endpoint Tracking solution. Extreme Management Center delivers automation; there is no need to manually configure server VLANs on data center access switches. Additionally, Extreme Management Center provides the ability to see what VM MACs exist, and where they are located.

Extreme Management Center's ExtremeConnect module integrates with third-party virtualization software (such as VMware or Microsoft HyperV) and communicates with the ExtremeControl module to automatically extract all of the VM MACs (including VLAN assignment for each MAC) and then automatically create all of the necessary authentication profiles, rules and mappings.

When the switch detects a new VM on a port, it sends a RADIUS request to Extreme Management Center. ExtremeConnect checks with VCenter for the Port Group, VLAN ID, and I-SID information that corresponds with the VM, communicates with the ExtremeControl module for the RADIUS authentication, and sends the RADIUS response back to the switch with the VLAN:I-SID binding information. Based on the binding, the switch then automatically creates a dynamic Switched UNI (S-UNI). Dynamic S-UNIs are not saved into the configuration file.

### *Typical Endpoint Tracking Implementation Example*

The following example shows a typical implementation of Endpoint Tracking and the dynamic I-SID assignment process, as provisioned in Extreme Management Center.

**Figure 71: Endpoint Tracking Example**

The sequence within and among the four example VLANs in this configuration is as follows:

1. The RADIUS server authenticates VM1, and the switch automatically creates a Switched UNI with VLAN 10 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM2, which uses the same Switched UNI.
2. Similarly, on the other side of the SPB cloud, the RADIUS server authenticates VM5 and the switch automatically creates a Switched UNI with VLAN 30 and I-SID 10 binding, (using the outbound attributes received from the RADIUS server). Subsequently, the server authenticates VM6, which uses the same Switched UNI.
3. The same sequence occurs for VMs 3 and 4, and PCs 7 and 8, with the first authentication in each VLAN providing the outbound RADIUS attributes needed for the creation of a Switched UNI for that VLAN.
4. The final result is that VMs 1, 2, 5, and 6 can access each other on I-SID 10, and VMs 3, 4, 7, and 8 can access each other on I-SID 20.

#### *Static S-UNIs and Visibility Mode*

Endpoint Tracking can also be used in cases where static S-UNIs are configured on Endpoint Tracking-enabled ports. In this case, the MACs are allowed by default on the static S-UNI. However, by default, the

MACs learned on a static S-UNI are not learned at the Endpoint Tracking level. Endpoint Tracking Visibility Mode allows tracking of MACs that are learned on static S-UNIs. This implies that a binding is created for these MACs, but these bindings do not create dynamic S-UNIs, they are used for tracking purposes only.

### *Interface Support*

Endpoint Tracking is supported on Ethernet ports, MLTs, and SMLTs.

If the switch is a Virtual IST (vIST) peer, the dynamic Switched UNI is synchronized to its vIST peer as follows:

- If the MAC is learned on an SMLT UNI interface, all Switched UNI information is synchronized to the vIST peer.
- If the MAC is learned on a non-SMLT UNI interface, only the I-SID is synchronized to the vIST peer.

### *VM Moves and VLAN:I-SID Bindings*

When a VM moves to a new switch within a network (with no change to the VLAN segment), the new switch triggers a new RADIUS authentication, which points that VM MAC to the new switch, and new bindings are applied on the new switch. The old switch detects that the VM MAC is moved and automatically deletes the old binding, if the old binding has not already aged out.

However, if a VM remains attached to the same (previously authenticated) switch, but the VLAN segment is changed, you must push a reauthentication request from Extreme Management Center to force the required binding updates. For more information about managing binding updates using RADIUS Change-of-Authorization (CoA) functionality, see [Extreme Management Center Integration](#) on page 949.

### *Operational Considerations*

Consider the following when implementing Endpoint Tracking:

- A RADIUS server used for Endpoint Tracking provides authorization only; no accounting processes are supported. Although accounting is enabled by default for all RADIUS servers, it is not currently supported for use with Endpoint Tracking, even if left enabled.
- Fabric Attach is not supported on ports or MLT/SMLTs that have Endpoint Tracking enabled.

### *Extreme Management Center Integration*

Endpoint Tracking integrates with Extreme Management Center ExtremeConnect and ExtremeControl modules. The ExtremeConnect module offers API integration with third party products, such as VMware or Microsoft HyperV, from which VM endpoint information is extracted and automatically converted into usable policies for use in the ExtremeControl module, which acts as a RADIUS server for authorizing Endpoint Tracking MACs.

The following diagram illustrates an example of Extreme Management Center interaction with a switch for Endpoint Tracking:

**Figure 72: Extreme Management Center Endpoint Tracking Interaction Example**

### RADIUS Server Attributes

The RADIUS attributes to configure in either standard or custom Extreme Management Center RADIUS profiles for Endpoint Tracking depend on your deployment and traffic type:

- For tagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use only the **FA-VLAN-ISID** attribute.
- For tagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use only the **Tunnel-Private-Group-ID** attribute.
- For untagged traffic, if the RADIUS server provides both the VLAN ID and I-SID value, use the **FA-VLAN-ISID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- For untagged traffic, if the RADIUS server provides only the VLAN ID (and you are therefore using an I-SID offset value), use the **Tunnel-Private-Group-ID** and **Egress-VLANID** or **Egress-VLAN-name** attributes.
- Use the **Session-Timeout** attribute to override the default timeout period of 24 hours, which is amount of time, in seconds, between a MAC address authentication and the deletion of that MAC address from the Endpoint Tracking binding table.

All other RADIUS attributes are ignored.

### Managing Binding Updates using RADIUS Change-of-Authorization

Endpoint Tracking uses RADIUS RFC 5176 Change-of-Authorization (CoA) functionality to enable forced VLAN:I-SID binding updates.

For example, when a VLAN segment is changed on a VM that resides on a previously authenticated switch, that VM requires a new VLAN:I-SID binding to reflect the new VLAN segment. Because the switch has previously been authenticated, you must force a new authentication request to update the binding information.

Using ExtremeControl, you can manually push a reauthentication request for the VM MAC. This action sends a disconnect-request from the RADIUS server to the switch, which deletes the old binding. When the switch detects the VM again, a new RADIUS authentication request is sent from the switch to the RADIUS server, resulting in updated binding information upon successful authentication.

For more information about RADIUS Dynamic Session Change Support (RFC 5176), see [RADIUS Fundamentals](#) on page 2593.

Deployment Examples

Endpoint Tracking deployment scenarios include Distributed Virtual Routing (DvR) deployments, or regular SPBM deployments.

The following example illustrates a DvR deployment:

**Figure 73: DvR Topology Example**

The following example illustrates a regular SPBM deployment:

**Figure 74: SPBM Cloud Example**

### Configuration Fundamentals

#### Extreme Management Center Configuration

To configure Endpoint Tracking, you must perform the following:

- Using the ExtremeConnect component, configure and manage your third-party virtualization platform.
- Using the ExtremeControl component, configure and manage the RADIUS server used for Endpoint Tracking authentication.

For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.

#### Switch Configuration

To configure Endpoint Tracking, you must perform the following:

- Add, configure, and enable the RADIUS server host as configured in the Extreme Management Center to function as the switch authentication server for Endpoint Tracking. Ensure that you select **endpoint-tracking** for the **used-by** variable. Add, configure and enable the RADIUS dynamic-

server client. For information about adding a RADIUS server host and a RADIUS dynamic-server client to the switch, see [RADIUS](#) on page 2590.

- Optionally configure a global I-SID offset value.

When you provision the Endpoint Tracking RADIUS server in Extreme Management Center, you choose which outbound attributes the RADIUS server includes in each authentication response. If you always include an I-SID value in those outbound attributes, you do not need to configure an I-SID offset value on the switch.

For MACs that do not receive an I-SID attribute from the RADIUS server, use Auto-ISID-Offset functionality. The configured I-SID offset value is used to calculate an I-SID value for a switched UNI when no I-SID value is provided by the RADIUS server in the outbound attributes. In that case, the I-SID value is calculated as follows:

$I\text{-SID} = \text{VLAN ID} + \text{configured I-SID offset value}$ .

- After optionally configuring a global I-SID offset value, enable Endpoint Tracking globally on the switch.
- Create and enable Endpoint Tracking on each interface. Ensure that you have deleted any existing VLAN bindings on the interfaces, as the Endpoint Tracking bindings are dynamic.

CLI commands provide the functionality to separate the creation, deletion, enabling, and disabling of Endpoint Tracking on interfaces. For example, if you want to flush all VLAN:I-SID bindings on a port, you can disable (but not delete) Endpoint Tracking on that port, keeping the port distinct from other ports where Endpoint Tracking is not yet created.

## SPBM and IS-IS infrastructure configuration using CLI

This section provides procedures to configure SPBM and IS-IS using Command Line Interface (CLI).

### Important

The **spbm-config-mode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### *Running the SPBM script*

Use the following procedure to run the SPBM script to automate the minimum required SPBM and IS-IS parameters to allow Fabric Connect to operate on the switch.

### **Before You Begin**

- Enable SPBM before running the SPBM script.
- Delete existing IS-IS interfaces before running this script. See [Removing specific IS-IS and MLT interfaces](#) on page 957 for information on removing IS-IS interfaces.

### **About This Task**

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script. The default values are given in square

brackets. You may input your values at the prompt or if you wish to accept the default values, press **Enter**. This command first accepts all values and then removes existing SPBM configurations before configuring the entered values.

### Note

This process causes the SPBM traffic to flap temporarily.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Run the SPBM script:

```
run spbm
```

### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

## Example

Run the SPBM script:

```
Switch:1(config)# run spbm
```

```

*** This script will guide you through configuring the ***
*** switch for optimal operation SPB. ***
*** ----- ***
*** The values in [] are the default values, you can ***
*** input alternative values at any of the prompts. ***
*** If you wish to terminate or exit this script ***
*** enter ^C <control-C> at any prompt. ***
*** NOTE: THE COMMAND WILL TEMPORARILY FLAP IS-IS,SPBM ***

SPB Ethertype <0x8100,0x88a8> [0x8100]:
SPB primary BVLAN 2-4059 [4051]:300
SPB secondary BVLAN 2-4059 [4052]:400

ISIS MLT interface <MLT ID LIST>[:]:1
Enable CFM SPBM (y/n) [n]:y
Enter CFM SPBM MEPID <1-8191> [1]:2
Enter CFM SPBM level <0-7> [4]:4

****CONFIGURATION IN PROGRESS****
SPBM enabled globally
```

```
SPBM instance 1 configured
SPBM BVLANS configured
SPBM SMLT configured
SPBM multicast enabled globally
IP shortcuts configured
SPBM SMLT configured
IS-IS enabled
IS-IS on port 1/5 configured
IS-IS on port 1/6 configured
IS-IS on MLT 1 configured
CFM SPBM configured
****SCRIPT EXECUTION COMPLETE****
```

### Remove Existing SPBM Configuration

Use the following procedure to remove existing SPBM configurations, disable CFM, and return the CFM MEP-ID and level configurations to default values.

#### Before You Begin

- Enable SPBM before running this script.
- If the switch uses Zero Touch Fabric Configuration, you must run the following commands before you perform this procedure:
  - **no auto-sense onboarding i-sid**
  - **no vlan i-sid <1-4059>**

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run the script:
 

```
run spbm clean
```

#### Note

If the script causes a configuration conflict or cannot run a command, an error message displays and the script stops.

3. To ensure proper cleanup of MAC tables, save the configuration, and then reboot the switch.

#### Example

Run the script:

```
Switch:1(config)#no auto-sense onboarding i-sid
Switch:1(config)#no vlan i-sid
Switch:1(config)#run spbm clean
The following will delete all SPBM and interfaces and default the CFM configurations. Do
you want to continue? <y/n>[n]:y

Switch:1(config)#no router isis enable
Switch:1(config)#interface gigabitethernet 1/10
Switch:1(config-if)#no isis
Switch:1(config-if)#interface gigabitethernet 1/11
Switch:1(config-if)#no isis
Switch:1(config-if)#configure terminal
```

```

Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no vlan 4051
Switch:1(config)#no vlan 4052
Switch:1(config)#router isis
Switch:1(config-isis)#no spbm 1
Switch:1(config-isis)#router isis
Switch:1(config-isis)#no ip-source-address
Switch:1(config-isis)#no system-id
Switch:1(config-isis)#no manual-area 49.0000
Switch:1(config-isis)#no cfm spbm enable
Switch:1(config)#cfm spbm level 4
Switch:1(config)#cfm spbm mepid 1
Switch:1(config)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#

SPBM configurations have been removed

```

### Configuring the IS-IS port interfaces using SPBM script

Use the following procedure to run the SPBM script to configure the IS-IS port interfaces. As this command does not flap IS-IS or SPBM, it is particularly effective to use this command when SPBM is already configured and you require to configure additional ports or MLTs. Running the `run spbm interface` command does not alter existing IS-IS or SPBM configurations.

#### About This Task

You can use this procedure to quickly configure the minimum SPBM and IS-IS parameters. However, a manual procedure is available instead of using this script.

#### Note

You must enable SPBM before running the SPBM script.

#### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Run the SPBM script:  

```
run spbm interface
```

#### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

#### Example

Run the SPBM script:

```

Switch:1(config)# run spbm interface

*** This script will guide you through configuring the ***
*** switch for optimal operation SPB. ***
*** ----- ***

```

```

*** The values in [] are the default values, you can ***
*** input alternative values at any of the prompts. ***
*** If you wish to terminate or exit this script ***
*** enter ^C <control-C> at any prompt. ***

ISIS port interfaces <a/b,c/d> []:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
IS-IS on port 1/2 configured
IS-IS on port 1/4 configured
IS-IS on port 1/8 configured
IS-IS on MLT-1 configured

```

### Removing specific IS-IS and MLT interfaces

Use the following procedure to remove specific IS-IS ports and MLT interfaces when you get the error IS-IS SPBM interfaces have been configured. Please delete these interfaces.

#### About This Task

This procedure removes existing IS-IS ports and MLT interfaces. You can choose which port and MLT interfaces need to be removed. This command does not alter the other SPBM or IS-IS configurations.

#### Note

You must enable SPBM before running the SPBM script.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Run the script:
 

```
run spbm interface clean
```

#### Note

If the script causes a configuration conflict or cannot execute a command, an error message displays and the script stops.

#### Example

Run the spbm interface clean script:

```
Switch:1(config)# run spbm interface clean
```

```

*** This script will guide you through deleting the ***
*** IS-IS SPBM interfaces. ***
*** -----
*** The values in [] are the default values. ***
*** If you wish to terminate or exit this script ***
*** enter ^C <control-C> at any prompt. ***

ISIS port interfaces to be deleted <a/b,c/d>[]:1/2,1/4,1/8
ISIS MLT interface <MLT ID LIST> []:1
IS-IS port 1/2 deleted

```

```
IS-IS port 1/4 deleted
IS-IS port 1/8 deleted
** 3 IS-IS port interfaces deleted **
MLT 1 deleted
** 1 IS-IS MLTs deleted **
```

### Configuring minimum SPBM and IS-IS parameters

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to enable SPBM operation on the switch.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable SPBM globally:
 

```
spbm
```
3. Enter IS-IS Router Configuration mode:
 

```
router isis
```
4. Create the SPBM instance (only one SPBM instance is supported):
 

```
spbm <1-100>
```
5. Add the SPBM B-VLAN to the SPBM instance:
 

```
spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]
```
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):
 

```
spbm <1-100> nick-name <x.xx.xx>
```

#### Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxx>, only one manual area is supported.):
 

```
manual-area <xx.xxxx.xxxx...xxx>
```
8. Exit IS-IS Router Configuration mode to Global Configuration mode:
 

```
exit
```
9. Create the SPBM backbone VLAN (B-VLAN):
 

```
vlan create <2-4059> type spbm-bvlan
```
10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:
 

```
interface {GigabitEthernet {slot/port [/sub-port] [-slot/port [/sub-port]] [,...]} | mlt <1-512> }
```

11. Configure an IS-IS interface on the selected ports or MLTs:
  - a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```
  - b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```
  - c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```
12. Enable interface.
13. Exit Interface Configuration mode:

```
exit
```
14. Enable IS-IS globally:

```
router isis enable
```
15. Display the SPBM configurations:

```
show isis spbm
```
16. Display the global IS-IS configuration:

```
show isis
```
17. Display the interface IS-IS configuration:

```
show isis interface
```

### Example

```
Switch> enable

Switch# configure terminal

Switch(config)# spbm

Switch(config)# router isis

Switch(config-isis)# spbm 1

Switch(config-isis)# spbm 1 b-vid 4051,4052 primary 10

Switch(config-isis)# spbm 1 nick-name 1.11.16

Switch(config-isis)# manual-area c0.2000.000.00

Switch(config-isis)# exit

Switch(config)# interface GigabitEthernet 1/21

Switch(config-if)# isis

Switch(config-if)# isis spbm 1

Switch(config-if)# isis enable

Switch(config-if)# exit
```

Switch(config)# vlan create 4051 type spbm-vlan

Switch(config)# vlan create 4052 type spbm-vlan

Switch(config)# router isis enable

Switch(config)# show isis spbm

```
Switch:1(config)#show isis spbm

**Variable definitions**

The following table defines parameters for the **isis** command.

Variable	Value
<i>enable</i>	Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface.
<i>spbm</i> <1-100>	Enable the SPBM instance on the IS-IS interfaces.

The following table defines parameters for the **manual-area** command.

Variable	Value
<xx.xxx.xxx...xxx>	Specifies the IS-IS manual-area (1-13 bytes in the format <xx.xxx.xxx...xxx>). Only one manual area is supported. For IS-IS to operate, you must configure at least one area. Use the no option to delete the manual area.

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Creates the SPBM instance. Only one SPBM instance is supported.
<i>b-vid</i> {<vlan-id [-vlan-id] [,...]}>	Sets the IS-IS SPBM instance data VLANs. Use the no option to remove the specified B-VLAN from the SPBM instance.
<i>nick-name</i> <x.xx.xx>	Specifies a nickname for the SPBM instance globally. The value is 2.5 bytes in the format <x.xx.xx>. Use the no or default options to delete the configured nickname.
<i>primary</i> <1-4059>	Sets the IS-IS instance primary data B-VLAN.

The following table defines parameters for the **vlan create** command.

Variable	Value
<2-4059>	Specifies the VLAN ID. Creates an SPBM Backbone VLAN (B-VLAN). You can optionally specify a name for the SPBM B-VLAN.
<i>type {port-mstprstp protocol-mstprstp spbm-bvlan}</i>	Specifies the type of VLAN created. <ul style="list-style-type: none"> <li>port-mstprstp — Create a VLAN by port.</li> <li>protocol-mstprstp — Create a VLAN by protocol.</li> <li>spbm-bvlan — Create an SPBM-BVLAN.</li> </ul>

### Job aid

#### Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

#### Note

To check the age out time, use the **show isis lsdbs sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

### Configuring minimum SPBM and IS-IS parameters using auto-nni command

Use the following procedure to configure the minimum required SPBM and IS-IS parameters using the **auto-nni** command to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface.

This procedure is only for the port interface. The **auto-nni** command is not supported on the MLT interface and the Fabric Extend Logical Interface.

#### About This Task

The **auto-nni** command provides a quick and simple way to configure the IS-IS interface. You can use the **auto-nni** command instead of the following existing IS-IS commands on the physical (port) interface:

- **isis**
- **isis spbm instance**

- **isis enable**

The existing commands are still available and you have the option to use the new command or the three existing commands. If you need to modify any of the default parameters under **isis** or **isis spbm instance**, use **isis** and **isis spbm instance** constructs even if you created the interface with the **auto-nni** command.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable SPBM globally:  

```
spbm
```
3. Enter IS-IS Router Configuration mode:  

```
router isis
```
4. Create the SPBM instance (only one SPBM instance is supported):  

```
spbm <1-100>
```
5. Add the SPBM B-VLAN to the SPBM instance:  

```
spbm <1-100> b-vid {<vlan-id [-vlan-id] [,...]} [primary <1-4059>]
```
6. Configure the system nickname (2.5 bytes in the format <x.xx.xx>):  

```
spbm <1-100> nick-name <x.xx.xx>
```

#### Note

Although it is not strictly required for SPBM operation, you should change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch (Log on to IS-IS Router configuration mode and use the `system-id <xxxx.xxxx.xxxx>` command). This helps to recognize source and destination addresses for troubleshooting purposes.

7. Configure an IS-IS manual area (1-13 bytes in the format <xx.xxxx.xxxx...xxx>. Only one manual area is supported.):  

```
manual-area <xx.xxxx.xxxx...xxx>
```
8. Exit IS-IS Router Configuration mode to Global Configuration mode:  

```
exit
```
9. Create the SPBM backbone VLAN (B-VLAN):  

```
vlan create <2-4059> type spbm-bvlan
```
10. Enter Interface Configuration mode, by specifying the ports or MLTs that are going to link to the SPBM network:  

```
interface {GigabitEthernet {slot/port [/sub-port] [-slot/port [/sub-port]] [,...]} | mlt <1-512> }
```
11. Configure an IS-IS interface on the selected ports.  

```
auto-nni
```
12. Enable interface.

13. Exit Interface Configuration mode:  

```
exit
```
14. Enable IS-IS globally:  

```
router isis enable
```
15. Display the SPBM configurations:  

```
show isis spbm
```
16. Display the global IS-IS configuration:  

```
show isis
```
17. Display the interface IS-IS configuration:  

```
show isis interface
```

**Example**

```
Switch> enable

Switch# configure terminal

Switch(config)# spbm

Switch(config)# router isis

Switch(config-isis)# spbm 1

Switch(config-isis)# spbm 1 b-vid 10,20 primary 10

*Configure I-SIDs for Private VLANs***Before You Begin**

- A private VLAN must be created. For more information about creating private VLANs, see [Create a Private VLAN](#) on page 3829.

**About This Task**

Assign one I-SID for each private VLAN.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Assign the I-SID to the primary and secondary VLAN.
 

```
vlan i-sid <1-4059> <0-16777215> [force]
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan i-sid 5 75
Switch:1(config)#show vlan private-vlan
=====
 PRIVATE VLAN
=====
Primary Primary Secondary Secondary
VLAN ISID VLAN ISID

5 75 6 75
```

**Variable Definitions**

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<1-4059>	Specifies the VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
<i>force</i>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

### Displaying global SPBM parameters

Use the following procedure to verify the proper global SPBM configuration.

#### Procedure

1. Display the SPBM configuration:  

```
show isis spbm
```
2. You can also use the following command to identify SPBM VLANs. For *spbm-bvlan*, the attribute `TYPE` displays *spbm-bvlan* instead of *byport*. For private VLANs, the attribute `TYPE` displays *private* instead of *byport*.  

```
show vlan basic
```

#### Example

```
Switch# show isis spbm

### Job aid

The following table describes the fields in the output for the **show isis spbm** command.

Parameter	Description
SPBM INSTANCE	Indicates the SPBM instance identifier. You can only create one SPBM instance.
B-VID	Indicates the SPBM B-VLAN associated with the SPBM instance.
PRIMARY VLAN	Indicates the primary SPBM B-VLAN.
NICK NAME	Indicates the SPBM node nickname. The nickname is used to calculate the I-SID multicast MAC address.
LSDB TRAP	Indicates the status of the IS-IS SPBM LSDB update trap on this SPBM instance. The default is disable.
IP	Indicates the status of SPBM IP shortcuts on this SPBM instance. The default is disable.
IPv6	Indicates the status of SPBM IPv6 shortcuts on this SPBM instance. The default is disable.
MULTICAST	Indicates if SPBM multicast is enabled. The default is disabled.
SPB-PIM-GW	Indicates if SPB PIM Gateway is enabled. The default is disabled.
STP-MULTI HOMING	Indicates if MSTP-Fabric Connect Multi Homing is enabled. The default is disabled.
SMLT-SPLIT-BEB	Specifies whether the switch is the primary or secondary vIST peer.
SMLT-VIRTUAL-BMAC	Specifies a virtual MAC address that can be used by both peers.
SMLT-PEER-SYSTEM-ID	Specifies the vIST peer system ID.

### Displaying global IS-IS parameters

Use the following procedure to display the global IS-IS parameters.

#### Procedure

1. Display IS-IS configuration information:  
`show isis`
2. Display the IS-IS system-id:  
`show isis system-id`
3. Display IS-IS net info:  
`show isis net`

**Example**

```
Switch# show isis
=====
 ISIS General Info

**Job aid**

The following sections describe the fields in the outputs for the global IS-IS show commands.

show isis

The following table describes the fields in the output for the **show isis** command.

Parameter	Description
AdminState	Indicates the administrative state of the router.
RouterType	Indicates the router Level: I1, I2, or I1/2.
System ID	Indicates the system ID.
Max LSP Gen Interval	Indicates the maximum time between LSP updates in seconds.
Metric	Indicates if the metric is narrow or wide.
Overload-on-startup	Indicates the IS-IS overload-on-startup value in seconds. The overload-onstartup value is used as a timer to control when to send out Link State Packets (LSPs) with the overload bit cleared after IS-IS startup. The default value is 20 seconds.
Overload	Indicates if there is an overload condition.
Csnp Interval	Indicates the interval between CSNP updates in seconds.
PSNP Interval	Indicates the interval between PSNP updates in seconds.
Rxmt LSP Interval	Indicates the received LSP time interval.
spf-delay	Indicates an SPF delay in milliseconds. The default value is 100 milliseconds.
Router Name	Indicates the IS-IS name of the router.
ip source-address	Indicates the IP source address used for SPBM IP shortcuts.
ipv6 source-address	Indicates the IPv6 source address used for SPBM IP shortcuts.
ip tunnel source-address	Indicates the IP tunnel source address used for SPBM Fabric Extend.
Tunnel vrf	Indicates the name of the vrf that contains the tunnel endpoints.
ONA Port	Indicates the port to which the ONA device is attached.  <b>Note:</b> The ONA port parameter is applicable only to the VSP 4450 Series.
ip tunnel mtu	Indicates the maximum size of a packet that can be transmitted through the IP tunnel.
Num of Interfaces	Indicates the number of interfaces on the router.
Num of Area Addresses	Indicates the number of area addresses on the router.
Num of Summary Address	Indicates the summary of the addresses on router.
inband-mgmt-ip	Indicates the DvR management IP address for this node, in the DvR domain.  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.
backbone	Indicates whether this node is part of the DvR backbone.

Parameter	Description
Dynamically Learned Area	For Fabric Area Network (FAN) members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.
FAN Member	Indicates whether the node is a member of the FAN.

show isis system-id

The following table describes the fields in the output for the **show isis system-id** command.

Parameter	Description
SYSTEM-ID	Shows the system ID. Output from this show command is from the global IS-IS configuration of the system ID. There is one system ID configured. The system ID is 6 bytes in length.

show isis net

The following table describes the fields in the output for the **show isis net** command.

Parameter	Description
NET	Shows the NET address. Output from this command is from the global IS-IS configuration of the manual area and the configuration of the system ID. There is only one manual areas defined and only one system ID. The manual area is from 1-13 bytes in length. The system ID is 6 bytes in length.

### Displaying IS-IS areas

Use the following procedure to display IS-IS areas.

#### Procedure

Use the following procedure to display IS-IS areas.

```
show isis manual-area
```

#### Example

```
Switch# show isis manual-area
=====
 ISIS Manual Area Address
=====
AREA ADDRESS

c0.2000.0000.00
```

#### Job aid

The following table describes the fields in the output for the **show isis manual-area** command.

Parameter	Description
AREA ADDRESS	Shows the manual areas defined. There can only be one area. Use the same manual area across the entire SPBM cloud. The manual area can be from 1-13 bytes in length.

### Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

#### Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual B-MAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual B-MAC.

When using a manually configured system-id value, the SMLT Virtual B-MAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of a Layer 2 VSN. Also, if a Layer 2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Disable IS-IS on the switch:
 

```
no router isis enable
```
3. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
4. Specify the system ID of the vIST peer, so that if it goes down, the local peer can take over forwarding for the failed peer:
 

```
spbM <1-100> smlt-peer-system-id <xxxx.xxxx.xxxx>
```
5. Configure the virtual B-MAC, which is shared and advertised by both peers:
 

```
spbM <1-100> smlt-virtual-bmac <0x00:0x00:0x00:0x00:0x00:0x00>
```
6. Exit to Global Configuration mode:
 

```
exit
```

7. Enable IS-IS on the switch:

```
router isis enable
```

8. Display the SPBM SMLT configuration:

```
show isis spbm
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

- Disable IS-IS on the switch:

```
Switch:1(config)#no router isis enable
```

- Enter the IS-IS Router Configuration mode:

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 smlt-peer-system-id 0018.b0bb.b3df
Switch:1(config-isis)#spbm 1 smlt-virtual-bmac 00:14:c7:e1:33:e0
Switch:1(config-isis)#router isis enable
```

```
Switch:1(config-isis)#show isis spbm
```

```
=====

```

Total Num of SPBM instances: 1

```

### Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<code>smlt-peer-system-id</code> <xxxx.xxxx.xxxx>	Specifies the IS-IS SPBM peer system ID. SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
<code>smlt-virtual-bmac</code> <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies a virtual MAC address that can be used by both peers. SMLT virtual B-MAC is an optional configuration.  <b>Note:</b> <ul style="list-style-type: none"> <li>If SMLT virtual B-MAC is not configured, the system derives SMLT virtual B-MAC from the configured SMLT peer system ID and the nodal MAC of the device (IS-IS system ID). The system compares the nodal MAC of the device with the SMLT peer system ID configured and takes the small one, plus 0x01, as the SMLT virtual B-MAC.</li> <li>The system also derives SMLT split BEB from the SMLT peer system ID and nodal MAC of the device. The device with the lower system ID is primary, the device with the higher system ID is secondary.</li> </ul>

### Configuring optional SPBM parameters

Use the following procedure to configure optional SPBM parameters.

#### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the SPBM ethertype:
 

```
spbm ethertype {0x8100 | 0x88a8}
```
- Configure the optional link-state database (LSDB) trap global parameter. To configure this parameter, you must globally disable IS-IS on the switch:
  - Disable IS-IS on the switch:
 

```
no router isis enable
```
  - Enter IS-IS Router Configuration mode:
 

```
router isis
```
  - Enable a trap when the SPBM LSDB changes:
 

```
spbm <1-100> lsdb-trap enable
```
  - Enable IS-IS on the switch:
 

```
router isis enable
```
  - Exit IS-IS Router Configuration mode:
 

```
exit
```

4. Configure the optional SPBM interface parameters. To configure these parameters, you must disable IS-IS on the interface:
  - a. Specify an SPBM interface to configure:

```
interface {GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | mlt <mltid> }
```
  - b. Disable IS-IS on the interface:

```
no isis enable
```
  - c. Configure SPBM instance interface-type on IS-IS interface. SPBM supports only pt-pt:

```
isis spbm <1-100> interface-type {broadcast|pt-pt}
```
  - d. Configure the SPBM instance level 1 metric on the IS-IS interface:

```
isis spbm <1-100> ll-metric <1-16777215>
```
  - e. Enable IS-IS on the switch:

```
isis enable
```

### Example

```
Switch> enable
Switch# configure terminal
Switch(config)# spbm ethertype 0x8100
Switch(config-isis)# no router isis enable
Switch(config)# router isis
Switch(config-isis)# spbm 1 lsdB-trap enable
Switch(config-isis)# router isis enable
Switch(config-isis)# exit
Switch(config)# interface gigabitEthernet 1/7
Switch(config-if)# no isis enable
Switch(config-if)# isis spbm 1 interface-type pt-pt
Switch(config-if)# isis spbm 1 ll-metric 500
Switch(config-if)# isis enable
```

### Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<code>ethertype {0x8100   0x88a8}</code>	Configures the SPBM ethertype. The default value is 0x8100.
<code>&lt;1-100&gt; lsdb-trap enable</code>	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disabled. Use the <b>no</b> or <b>default</b> options to disable LSDB traps.

The following table defines parameters for the **isis spbm** command.

Variable	Value
<code>&lt;1-100&gt; interface-type {broadcast pt-pt}</code>	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT. SPBM only supports the point-to-point (pt-pt) interface type. The default is pt-pt. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of pt-pt.
<code>&lt;1-100&gt; ll-metric &lt;1-16777215&gt;</code>	Configures the SPBM instance ll-metric on the IS-IS interface located on the specified port or MLT. The default value is 10. Use the <b>no</b> or <b>default</b> options to set this parameter to the default.

### Configuring optional IS-IS global parameters

Use the following procedure to configure optional IS-IS global parameters.

#### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable
configure terminal
router isis
```
2. Configure optional IS-IS global parameters:
  - a. Specify the Complete Sequence Number Packet (CSNP) interval in seconds:
 

```
csnp-interval <1-600>
```
  - b. Configure the router type globally:
 

```
is-type {11|112}
```
  - c. Configure the maximum level, in seconds, between generated LSPs by this Intermediate System:
 

```
max-lsp-gen-interval <30-900>
```
  - d. Configure the IS-IS metric type:
 

```
metric {narrow|wide}
```
  - e. Set or clear the overload condition:
 

```
overload
```
  - f. Configure the overload-on-startup value in seconds:
 

```
overload-on-startup <15-3600>
```

- g. Configure the Partial Sequence Number Packet (PSNP) in seconds:  
psnp-interval <1-120>
- h. Configure the minimum time between retransmission of an LSP:  
retransmit-lsp-interval <1-300>
- i. Configure the SPF delay in milliseconds:  
spf-delay <0-5000>
- j. Configure the name for the system:  
sys-name WORD<0-255>
- k. Configure the IS-IS system ID for the switch:  
system-id <xxxx.xxxx.xxxx>

**Example**

```
Switch> enable

Switch# configure terminal

Switch(config)# router isis

Switch(config-isis)# csnp-interval 10

Switch(config-isis)# is-type 11

Switch(config-isis)# max-lsp-gen-interval 800

Switch(config-isis)# metric wide

Switch(config-isis)# overload

Switch(config-isis)# overload-on-startup 30

Switch(config-isis)# psnp-interval 10

Switch(config-isis)# retransmit-lsp-interval 10

Switch(config-isis)# default sys-name

Switch(config-isis)# spf-delay 200

Switch(config-isis)# default system-id
```

## Variable definitions

The following table defines parameters for the **csnp-interval** command.

Variable	Value
<1-600>	Specifies the CSNP interval in seconds. This is a system level parameter that applies for level 1 CSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 10. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 10.

The following table defines parameters for the **is-type** command.

Variable	Value
{11 112}	Sets the router type globally: <ul style="list-style-type: none"> <li>• 11: Level-1 router type</li> <li>• 112: Not valid.</li> </ul> The default value is 11. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 11.

The following table defines parameters for the **max-lsp-gen-interval** command.

Variable	Value
<30-900>	Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate System. The default value is 900 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 900.

The following table defines parameters for the **metric** command.

Variable	Value
{narrow wide}	Specifies the IS-IS metric type. Only wide is supported. The default value is wide. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of wide.

The following table defines parameters for the **overload** command.

Variable	Value
overload	Sets or clears the overload condition. The default value is disabled. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of disabled.

The following table defines parameters for the **overload-on-startup** command.

Variable	Value
<15–3600>	Specifies the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup. The default value is 20. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 20.

The following table defines parameters for the **psnp-interval** command.

Variable	Value
<1–120>	Specifies the PSNP interval in seconds. This is a system level parameter that applies for level 1 PSNP generation on all interfaces. A longer interval reduces overhead, while a shorter interval speeds up convergence. The default value is 2. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 2.

The following table defines parameters for the **retransmit-lsp-interval** command.

Variable	Value
<1–300>	Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for Level1 retransmission of LSPs. The default value is 5 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 5.

The following table defines parameters for the **spf-delay** command.

Variable	Value
<0–5000>	Configures the delay, in milliseconds, to pace successive Shortest Path First (SPF) runs. The timer prevents more than two SPF runs from being scheduled back-to-back. The mechanism for pacing SPF allows two back-to-back SPF runs. The default value is 100 milliseconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 100 milliseconds.

The following table defines parameters for the **sys-name** command.

Variable	Value
WORD<0–255>	Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value (host name).  <b>Note:</b> No consistency checks appear when you edit sys-name.

The following table defines parameters for the **system-id** command.

Variable	Value
<xxxxx.xxxxx.xxxxx>	Specifies the IS-IS system ID for the switch. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value (node BMAC).

## Job aid

### Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

### Note

To check the age out time, use the **show isis lsdbsysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

## Configuring optional IS-IS interface parameters

Use the following procedure to configure optional IS-IS interface parameters.

### Important

Save your configuration using **save config** for the updates to be available after reboot. Saving the configuration also ensures that any authentication keys (passwords) specified during the configuration are properly encrypted.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional IS-IS interface parameters:

- a. Specify the authentication type used for IS-IS hello packets on the interface:

```
isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
```

- b. If you select `simple` as the `hello-auth` type, you must also specify a key value but the key-id is optional:

```
isis hello-auth type simple key WORD<1-16> [key-id <1-255>]
```

- c. If you select `hmac-md5` or `hmac-sha-256`, you must also specify a key value. The key-id is optional:

```
isis hello-auth type hmac-md5 key WORD<1-16> [key-id <1-255>]]
```

```
isis hello-auth type hmac-sha-256 key WORD<1-16> [key-id <1-255>]]
```

- d. Configure the level 1 IS-IS designated router priority:

```
isis [l1-dr-priority <0-127>]
```

### Note

This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.

- e. Configure the level 1 hello interval:

```
isis [l1-hello-interval <1-600>]
```

- f. Configure the level 1 hello multiplier:

```
isis [l1-hello-multiplier <1-600>]
```

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch(config):1# interface gigabitethernet 1/1
```

```
Switch(config-if):1# isis
```

```
Switch(config-if):1# isis hello-auth type hmac-md5 key test
```

```
Switch(config-if):1# isis ll-dr-priority 100
Switch(config-if):1# isis ll-hello-interval 20
Switch(config-if):1# isis ll-hello-multiplier 10
Switch(config):1# save config
```

**Variable definitions**

The following table defines parameters for the **isis** command.

Variable	Value
<pre>hello-auth type {none  simple hmac-md5 hmac- sha-256}} [key [key WORD&lt;1- 16&gt;] [key-id &lt;1-255&gt;]</pre>	<p>Specifies the authentication type used for IS-IS hello packets on the interface. <b>type</b> can be one of the following:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b> Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default is none. Use the <b>no</b> or <b>default</b> options to set the hello-auth type to none.</p>
<pre>ll-dr-priority &lt;0-127&gt;</pre>	<p>Configures the level 1 IS-IS designated router priority to the specified value. The default value is 64. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 64.</p> <p><b>Note:</b> This parameter is not used for SPBM because SPBM only runs on point-to-point interfaces. This parameter is for designated router election on a broadcast LAN segment, which is not supported.</p>

Variable	Value
<code>l1-hello-interval &lt;1-600&gt;</code>	Configures the level 1 hello interval. The default value is 9 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 9 seconds.
<code>l1-hello-multiplier &lt;1-600&gt;</code>	Configures the level 1 hello multiplier. The default value is 3 seconds. Use the <b>no</b> or <b>default</b> options to set this parameter to the default value of 3 seconds.

*Displaying IS-IS interface parameters*

Use the following procedure to display the IS-IS interface parameters.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Display IS-IS interface configuration and status parameters (including adjacencies):  
`show isis interface [l1|l2|l1l2]`
3. Display IS-IS interface authentication configuration:  
`show isis int-auth`
4. Display IS-IS interface timers:  
`show isis int-timers`
5. Display IS-IS circuit level parameters:  
`show isis int-ckt-level`

**Example**

```
Switch:1# show isis interface
=====
 ISIS Interfaces
=====
IFIDX TYPE LEVEL OP-STATE ADM-STATE ADJ UP-ADJ SPBM-L1-METRIC

Mlt2 pt-pt Level 1 UP UP 1 1 10

=====
 ISIS Circuit level parameters
=====
IFIDX LEVEL DIS CKTID

Mlt2 Level 1 1
Port1/21 Level 1 2

```

### Variable definitions

The following table defines parameters for the **show isis interface** command.

Variable	Value
<i>[11, 12, 112]</i>	Displays the interface information for the specified level: I1, I2, or I12.

### Job aid

The following sections describe the fields in the outputs for the IS-IS interface show commands.

show isis interface

The following table describes the fields in the output for the **show isis interface** command.

Parameter	Description
IFIDX	Indicates the interface index for the Ethernet or MLT interface.
TYPE	Indicates the type of interface configured (only pt-pt is supported).
LEVEL	Indicates the level of the IS-IS interface (Level 1 [default] or Level 2).
OP-STATE	Shows the physical connection state of the interface.
ADM-STATE	Shows the configured state of the interface.
ADJ	Shows how many adjacencies are learned through the interface.
UP-ADJ	Shows how many adjacencies are active through the interface.
SPBM-L1-METRIC	Indicates the SPBM instance Level 1 metric on the IS-IS interface.

show isis int-auth

The following table describes the fields in the output for the **show isis int-auth** command.

Parameter	Description
IFIDX	Shows the interface index for the Ethernet or MLT interface.
AUTH-TYPE	Shows the type of authentication configured for the interface. Types include: <ul style="list-style-type: none"> <li>• none for no authentication.</li> <li>• simple for a simple password.</li> <li>• hmac-md5 for MD5 encryption.</li> <li>• hmac-sha-256 for SHA-256 encryption.</li> </ul>
AUTH-KEYID	Shows the authentication password configured for the interface. If the KeyId is not configured, the value is 0.
AUTH-KEY	Shows the HMAC-MD5 key needed for encryption. This is used only for HMAC-MD5.

show isis int-timers

The following table describes the fields in the output for the **show isis int-timers** command.

Parameter	Description
IFIDX	Indicates the interface index for the Ethernet or MLT interface.
LEVEL	Indicates the IS-IS interface level.
HELLO INTERVAL	Indicates the interval at which a Hello packet is sent to the IS-IS network.
HELLO MULTIPLIER	Indicates the multiplier that is used in conjunction with the Hello Interval.
HELLO DR	Indicates the interval at which a Hello packet is sent to the IS-IS network if the router is a designated router (DIS).

show isis int-ckt-level

The following table describes the fields in the output for the **show isis int-ckt-level** command.

Parameter	Description
IFIDX	Shows the interface index for the ethernet or MLT interface.
LEVEL	Shows the level of the IS-IS interface (Level 1 [default] or Level 2).
DIS	Shows the Designated Intermediate System (DIS) of the circuit.
CKT ID	Displays the CKT ID.

*Display the IP unicast FIB, unicast FIB, and unicast tree*

### About This Task

In SPBM, Backbone MAC (B-MAC) addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS Type-Length-Value (TLV) that advertises the Service Instance Identifier (I-SID)

and B-MAC information across the network. Each node has a System ID, which also serves as B-MAC of the switch. These B-MAC addresses are populated into the SPBM Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allow Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **show isis spbm ip-unicast-fib** or **show isis spbm ipv6-unicast-fib** command displays all of the IS-IS routes in the IS-IS LSDB. The IP ROUTE PREFERENCE column in the show output displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies enable you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SPBM IP unicast FIB:

- For IPv4:

```
show isis spbm ip-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-mac]
```

- For IPv6:

```
show isis spbm ipv6-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-mac]
```

3. Display the SPBM unicast FIB:

```
show isis spbm unicast-fib [b-mac <0x00:0x00:0x00:0x00:0x00:0x00>] [vlan <1-4059>] [summary]
```

4. Display the SPBM unicast tree:

```
show isis spbm unicast-tree <1-4059> [destination <xxxx.xxxx.xxxx>]
```

## Examples

```
Switch# show isis spbm ip-unicast-fib
```

```

## Variable Definitions

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

Variable	Value
<i>all</i>	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances.  <b>Note:</b> If you use the command <b>show isis spbm ip-unicast-fib</b> the device displays only GRT entries. The command shows IP routes from remote Backbone Edge Bridges (BEBs).
<i>id &lt;1-16777215&gt;</i>	Displays IS-IS SPBM IP unicast Forwarding Information Base (FIB) information by Service Instance Identifier (I-SID) ID.
<i>spbm-nh-as-mac</i>	Displays the next hop B-MAC of the IP unicast FIB entry.

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

Variable	Value
<i>all</i>	Displays entries for the Global Routing Table (GRT) and all Virtual Routing and Forwarding (VRF) instances.  <b>Note:</b> If you use the command <b>show isis spbm ipv6-unicast-fib</b> the device displays only GRT entries. The command shows IPv6 routes from remote Backbone Edge Bridges (BEBs).
<i>id &lt;1-16777215&gt;</i>	Displays IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information by Service Instance Identifier (I-SID) ID.
<i>spbm-nh-as-mac</i>	Displays the next hop as MAC of the IPv6 unicast FIB entry.

The following table defines parameters for the **show isis spbm unicast-fib** command.

Variable	Value
<i>b-mac</i> <i>&lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</i>	Displays the FIB for the specified B-MAC.
<i>vlan &lt;1-4059&gt;</i>	Displays the FIB for the specified SPBM VLAN.
<i>summary</i>	Displays a summary of the FIB.

The following table defines parameters for the **show isis spbm unicast-tree** command.

Variable	Value
<1-4059>	Specifies the SPBM B-VLAN ID.
<i>destination</i> <xxxx.xxxx.xxxx>	Displays the unicast tree for the specified destination.

### Job Aid

The following sections describe the fields in the outputs for SPBM unicast FIB and unicast tree show commands.

show isis spbm ip-unicast-fib

The following table describes the fields in the output for the **show isis spbm ip-unicast-fib** command.

Parameter	Description
VRF	Specifies the VRF ID of the IP unicast FIB entry, 0 indicates NRE.
VRF ISID	Specifies the I-SID of the IP unicast FIB entry.
DEST ISID	Specifies the destination I-SID of the IP unicast FIB entry.
Destination	Specifies the destination IP address of the IP unicast FIB entry.
NH BEB	Specifies the next hop B-MAC of the IP unicast FIB entry.
VLAN	Specifies the VLAN of the IP unicast FIB entry.
OUTGOING INTERFACE	Specifies the outgoing port of the IP unicast FIB.
SPBM COST	Specifies the B-MAC cost of the IP unicast FIB entry.
PREFIX COST	Specifies the prefix cost of the IP unicast FIB entry.
PREFIX TYPE	Specifies the prefix type of the IP unicast FIB entry.
IP ROUTE PREFERENCE	Specifies the IP route preference of the IP unicast FIB entry.

show isis spbm ipv6-unicast-fib

The following table describes the fields in the output for the **show isis spbm ipv6-unicast-fib** command.

Parameter	Description
VRF	Specifies the VRF ID of the IPv6 unicast FIB entry, 0 indicates NRE.
VRF ISID	Specifies the I-SID of the IPv6 unicast FIB entry.
DEST ISID	Specifies the destination I-SID of the IPv6 unicast FIB entry.
Destination	Specifies the destination IPv6 address of the IPv6 unicast FIB entry.
NH BEB	Specifies the next hop B-MAC of the IPv6 unicast FIB entry.
VLAN	Specifies the VLAN of the IPv6 unicast FIB entry.

Parameter	Description
OUTGOING INTERFACE	Specifies the outgoing port of the IPv6 unicast FIB.
SPBM COST	Specifies the B-MAC cost of the IPv6 unicast FIB entry.
PREFIX COST	Specifies the prefix cost of the IPv6 unicast FIB entry.
METRIC TYPE	Specifies the metric type. Specifies an internal or an external metric. For internal metric type, the cost of the external routes is equal to the sum of all internal costs and the external cost. For external metric type, the cost of the external routes is equal to the external cost alone. The default is internal.

show isis spbm unicast-fib

The following table describes the fields in the output for the **show isis spbm unicast-fib** command.

Parameter	Description
DESTINATION ADDRESS	Indicates the destination MAC Address of the unicast FIB entry.
BVLAN	Indicates the B-VLAN of the unicast FIB entry.
SYSID	Indicates the destination system identifier of the unicast FIB entry.
HOST-NAME	Indicates the destination host name of the unicast FIB entry.
OUTGOING INTERFACE	Indicates the outgoing interface of the unicast FIB entry.
COST	Indicates the cost of the unicast FIB entry.

### Displaying IS-IS LSDB and adjacencies

Use the following procedure to display the IS-IS LSDB and adjacencies.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS LSDB:
 

```
show isis lsdb [level {l1|l2|l12}] [sysid <xxxx.xxxx.xxxx>] [lspid <xxxx.xxxx.xxxx.xx-xx>] [tlv <1-236>] [detail]
```
3. Display IS-IS adjacencies:
 

```
show isis adjacencies
```
4. Clear IS-IS LSDB:
 

```
clear isis lsdb
```

#### Example

```
Switch:1# show isis lsdb

## Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
<i>detail</i>	Displays detailed information.
<i>level {l1 l2 l12}</i>	Displays the LSDB for the specified level: l1, l2, or l12.
<i>local</i>	Displays IS-IS local LSDB information.
<i>sysid &lt;xxxx.xxxx.xxxx&gt;</i>	Displays the LSDB for the specified system ID.

Variable	Value
<i>lspid</i> <xxxx.xxxx.xxxx.xx-xx>	Displays the LSDB for the specified LSP ID.
<i>tlv</i> <1-236>	Displays the LSDB by TLV type.

The following table defines parameters for the **clear isis** command.

Variable	Value
<i>lsdb</i>	Clears the IS-IS Link State Database (LSDB). The command clears learned LSPs only. The command does not clear local generated LSPs. As soon as the platform clears the LSDB the LSP synchronization process starts immediately and the LSDB synchronizes with its neighbors.

### Job Aid

The following sections describe the fields in the outputs for the IS-IS LSDB and adjacencies show commands.

show isis lsdb

The following table describes the fields in the output for the **show isis lsdb** command.

Parameter	Description
LSP ID	Indicates the LSP ID assigned to external IS-IS routing devices.
LEVEL	Indicates the level of the external router: I1, I2, or I12.
LIFETIME	Indicates the maximum age of the LSP. If the max-lsp-gen-interval is set to 900 (default) then the lifetime value begins to count down from 1200 seconds and updates after 300 seconds if connectivity remains. If the timer counts down to zero, the counter adds on an additional 60 seconds, then the LSP for that router is lost. This happens because of the zero age lifetime, which is detailed in the RFC standards.
SEQNUM	Indicates the LSP sequence number. This number changes each time the LSP is updated.
CHKSUM	Indicates the LSP checksum. This is an error checking mechanism used to verify the validity of the IP packet.
HOST-NAME	Indicates the hostname listed in the LSP. If the host name is not configured, then the system name is displayed.

show isis adjacencies

The following table describes the fields in the output for the **show isis adjacencies** command.

Parameter	Description
INTERFACE	Indicates the interface port, MLT, or logical interface on which IS-IS exists.
L	Indicates the level of the adjacent router.

Parameter	Description
STATE	Indicates the state of IS-IS on the interface (enabled [UP] or disabled [DOWN]). The state is non-configurable.
UPTIME	Indicates the length of time the adjacency has been up in ddd hh:mm:ss format.
PRI	Indicates the priority of the neighboring Intermediate System for becoming the Designated Intermediate System (DIS).
HOLDTIME	Indicates the calculated hold time for the Hello (hello multiplier x hello interval); if the route is determined to be a designated router, then the product is divided by 3.
SYSID	Indicates the adjacent system ID of the router.
HOST-NAME	Indicates the hostname listed in the LSP. If the host name is not configured, then the system name is displayed.
STATUS	Indicates if the adjacency is active.

### Displaying IS-IS Statistics and Counters

Use the following procedure to display the IS-IS statistics and counters.

#### Procedure

1. Display IS-IS system statistics:  
`show isis statistics`
2. Display IS-IS interface counters:  
`show isis int-counters`
3. Display IS-IS level 1 control packet counters:  
`show isis int-l1-ctrl-pkts`

#### Note

The switch uses level 1 IS-IS. The switch does not support level 2 IS-IS. The command **show isis int-l2-ctrl-pkts** is not supported because the IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1.

4. Clear IS-IS statistics:

```
clear isis stats [error-counters] [packet-counters]
```

#### Example

```
Switch:1# show isis statistics
=====
 ISIS System Stats
=====
LEVEL CORR AUTH AREA MAX SEQ SEQ NUM OWN LSP BAD ID PART LSP DB
 LSPs FAILS DROP EXCEEDED SKIPS PURGE LEN CHANGES OLOAD

Level-1 0 0 0 0 1 0 0 0 0 0

Switch:1# show isis int-counters
=====
 ISIS Interface Counters
=====
```

```

IFIDX LEVEL AUTH ADJ INIT REJ ID LEN MAX AREA LAN DIS
 FAILS CHANGES FAILS ADJ

Mlt2 Level 1-2 0 1 0 0 0 0 0
Port1/21 Level 1-2 0 1 0 0 0 0 0

Switch:1# show isis int-l1-cntl-pkts
=====
 ISIS L1 Control Packet counters
=====
IFIDX DIRECTION HELLO LSP CSNP PSNP

Mlt2 Transmitted 13346 231 2 229
Mlt2 Received 13329 230 1 230
Port1/21 Transmitted 13340 227 2 226
Port1/21 Received 13335 226 1 227

```

**Variable Definitions**

The following table defines parameters for the **clear isis stats** command.

Variable	Value
<i>error-counters</i>	Clears IS-IS stats error-counters.
<i>packet-counters</i>	Clears IS-IS stats packet-counters.

**Job Aid**

show isis statistics

The following table describes the fields in the output for the **show isis statistics** command.

Parameter	Description
LEVEL	Shows the level of the IS-IS interface.
CORR LSPs	Shows the number of corrupted LSPs detected.
AUTH FAILS	Shows the number of times authentication has failed on the global level.
AREA DROP	Shows the number of manual addresses dropped from the area.
MAX SEQ EXCEEDED	Shows the number of attempts to exceed the maximum sequence number.
SEQ NUM SKIPS	Shows the number of times the sequence number was skipped.
OWN LSP PURGE	Shows how many times the local LSP was purged.
BAD ID LEN	Shows the number of ID field length mismatches.
PART CHANGES	Shows the number of partition link changes.
LSP DB OLOAD	Show the number of times the switch was in the overload state.

show isis int-counters

The following table describes the fields in the output for the **show isis int-counters** command.

Parameter	Description
IFIDX	Shows the interface index for the Ethernet or MLT interface.
LEVEL	Shows the level of the IS-IS interface.
AUTH FAILS	Shows the number of times authentication has failed per interface.
ADJ CHANGES	Shows the number of times the adjacencies have changed.
INIT FAILS	Shows the number of times the adjacency has failed to establish.
REJ ADJ	Shows the number of times the adjacency was rejected by another router.
ID LEN	Shows the ID field length mismatches.
MAX AREA	Shows the maximum area address mismatches.
LAN DIS CHANGES	Shows the number of times the DIS has changed.

```
show isis int-ll-cntl-pkts
```

The following table describes the fields in the output for the **show isis int-ll-cntl-pkts** command.

Parameter	Description
IFIDX	Shows the interface index for the Ethernet or MLT interface.
DIRECTION	Shows the packet flow (Transmitted or Received).
HELLO	Shows the amount of interface-level Hello packets.
LSP	Shows the amount of LSP packets.
CSNP	Shows the amount of CSNPs.
PSNP	Shows the amount of PSNPs.

### *Run the Layer 2 Video Surveillance install script*

Use the following procedure to run the Layer 2 Video Surveillance install script.

#### **Before You Begin**

The switch must be in the factory default state. When you start the install script, the switch displays a prompt to remind you to do this.

#### **Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

2. Run the install script:

```
run vms layer-2 switch <5-99> [syntax]
```

The script uses the value that you assign to the switch number (between 5 and 99) to seed unique values in the configuration script.

### Examples

The following example shows the complete output of the install script without the `syntax` parameter. As you can see, there is no indication that the script encountered any errors.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

Previous configurations stored in pre_vms_layer2_install.cfg
New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg
*** VMS Layer-2 script execution complete ***
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

The following example displays the output of the script using the `syntax` parameter. This example is only a small sample of the output, but it shows how the script reports warnings and errors it encounters.

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)# run vms layer-2 switch 6 syntax

Do you want to execute the run vms layer-2 script? Device needs to be in factory default
state. (y/n) ? y

Switch:1(config)# save config file pre_vms_layer2_install.cfg
File [/intflash/pre_vms_layer2_install.cfg] already existing,CP-1: Save config to file /
intflash/pre_vms_layer2_install.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/vms-layer2-switch-6.cfg".

Switch:1(config)# spbm
Switch:1(config)# spbm ethertype 0x8100
Switch:1(config)# router isis
Switch:1(config-isis)# spbm 1

Error: ISIS - IS-IS is enabled, runtime change not allowed.

Switch:1(config)# exit

Switch:1(config)# save config file vms-layer2-switch-6.cfg
File [/intflash/vms-layer2-switch-6.cfg] already existing,CP-1: Save config to file /
intflash/vms-layer2-switch-6.cfg successful.

Switch:1(config)# boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
Switch:1(config)#
Previous configurations stored in pre_vms_layer2_install.cfg
New VMS configurations stored in new primary config file vms-layer2-switch-6.cfg
*** VMS Layer-2 script execution complete ***
```

```
Switch:1(config)#boot config choice primary config-file /intflash/vms-layer2-switch-6.cfg
```

## Variable Definitions

The following table defines parameters for the **run vms layer-2 switch** command.

Variable	Value
<5-99>	Specifies a switch value, which is then used as a common element to configure switch parameters such as nickname, VLAN ID, SPB and IP parameters. This switch value is also used in the name of the saved configuration file. For example, <b>6</b> is the switch value in <code>vms-layer2-switch-6.cfg</code>
<i>syntax</i>	Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters.  <b>Note:</b> The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch.

### *Suspend Duplicate System ID Detection When Replacing a Switch*

When a switch is replaced and the original system ID and nickname is used, you must wait up to 20 minutes for the LSPs with the original system to age out. This is due to duplicate system ID and nickname detection. However, you can suspend duplicate detection on the replacement switch so that you can bring the switch into the network immediately.

#### About This Task

To temporarily disable duplicate detection on the replacement switch, perform the following steps:

#### Procedure

1. Copy the configuration file of the original switch to the replacement switch.
2. Power up the replacement switch while it is not connected to the SPB network, that is, NNI ports are not connected.
3. Disable IS-IS on the original switch, or remove the switch from the network.
4. On the replacement switch, enter the following Global Configuration command to suspend duplicate detection for up to 21 minutes:  

```
isis dup-detection-temp-disable
```
5. To check the remaining time, use the `show isis dup-detection-temp-disable remaining time` command.
6. Remove the original switch from the network.
7. Connect the replacement switch to the network.

*Configure Dynamic Nickname Assignment***About This Task**

Use this procedure to specify a nickname allocation range for Dynamic Nickname Assignment.

**Note**

You must disable Dynamic Nickname Assignment before you can change the nickname allocation range.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the Dynamic Nickname Assignment nickname allocation:  

```
spbm nick-name server {range <a-f> | prefix x.xx.xx}
```
3. Enable Dynamic Nickname Assignment:  

```
spbm nick-name server
```
4. Verify the configuration:  

```
show spbm
```

**Examples**

Configure a nickname allocation range:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm nick-name server range b
```

Dynamic Nickname Assignment configuration values and their associated behavior are shown in the following output from the **show spbm** command:

```
Switch:1>show spbm
 spbm : enable
 ethertype : 0x8100
 nick-name server : disable
 nick-name allocation : static
 nick-name server range : B.00.00-B.FF.FF
```

Configure a nickname allocation prefix:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm nick-name server prefix C.30.00
```

## Variable Definitions

The following table defines parameters for the **spbm nick-name server** command.

Variable	Value
<code>prefix x.xx.xx</code>	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.FF.FF.
<code>range &lt;a-f&gt;</code>	Specifies the nickname server allocation range. The default range is <b>a</b> (A.00.00 to A.FF.FF).

### Displaying Dynamic Nickname Assignment

#### About This Task

Use this procedure to display the current status and values for Dynamic Nickname Assignment.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display Dynamic Nickname Assignment configuration values.

```
show spbm
```

#### Example

```
Switch:1>show spbm
 spbm : enable
 ethertype : 0x8100
 nick-name server : disable
 nick-name allocation : static
 nick-name server range : B.00.00-B.FF.FF
```

### Enabling MSTP-Fabric Connect Multi Homing

#### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

#### About This Task

Perform this procedure to enable MSTP-Fabric Connect Multi Homing for a specific SPBM instance.

#### Before You Begin

You must configure a nickname for the specific SPBM instance on which you enable MSTP-Fabric Connect Multi Homing.

#### Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

2. Enable MSTP-Fabric Connect Multi Homing on a specified SPBM instance:

```
spbm <1-100> stp-multi-homing enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 stp-multi-homing enable
```

### Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Specifies the IS-IS SPBM instance ID to create an SPBM instance.
<i>stp-multi-homing enable</i>	Enables MSTP-Fabric Connect Multi Homing on the specific SPBM instance. The default is disabled.

### Determine the Root Bridge in an MSTP-Fabric Connect Multi Homing Configuration

Identify the root bridge by determining where the Common and Internal Spanning Tree (CIST) regional root MAC address is learned for the STP-reserved I-SID. Check which MAC address has the same first five octets as the CIST regional root MAC address.

### About This Task

When you enable MSTP-Fabric Connect Multi Homing, you can use the following two commands to determine which BEB is the root bridge:

- **show spanning-tree mstp status**
- **show i-sid mac-address-entry 16777003**

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the CIST regional root:
 

```
show spanning-tree mstp status
```
3. Determine which MAC address has the same first five octets as seen in the CIST regional root MAC address:
 

```
show i-sid mac-address-entry 16777003
```

### Example

In the following example, bold text identifies the relevant information in the command output. In the output of the second command, the DEST-MAC shows 10:cd:ae:6e:d8:84, which is the system ID of the CIST regional root BEB, and the system name is BEB-1000.

```
Switch:1>show spanning-tree mstp status
=====
MSTP Status
=====

Bridge Address : b0:ad:aa:4d:b8:00
```

```

Cist Root : 80:00:10:cd:ae:6e:d8:00
Cist Regional Root : 80:00:10:cd:ae:6e:d8:00
Cist Root Port : fabric
Cist Root Cost : 0
Cist Regional Root Cost : 2000000
Cist Instance Vlan Mapped : 1-1024
Cist Instance Vlan Mapped2k : 1025-2048
Cist Instance Vlan Mapped3k : 2049-3072
Cist Instance Vlan Mapped4k : 3073-4050,4053-4059
Cist Max Age : 20 seconds
Cist Forward Delay : 15 seconds

```

```
Switch:1>show i-sid mac-address-entry 16777003
```

```

=====
I-SID Fdb Table
=====

## Fabric Extend configuration using the CLI

The following sections provide procedural information you can use to configure Fabric Extend (FE) using the Command Line Interface (CLI).

### Configure Fabric Extend

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office. This is a typical deployment. However, if your deployment creates tunnels between two switches that support Fabric Extend natively, then repeat those steps and ignore the steps for switches that require an ONA.

#### Note

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

### Before You Begin

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

#### Note

Product Notice: Except VSP 8600 Series, all product series support a VLAN IP as the Fabric Extend tunnel source IP address.

For information about product support, see [Fabric Extend Considerations](#) on page 920.

If using the tunnel originating address on the **GRT**, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

#### Note

A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you **MUST** exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a **VRF**, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the VRF.
- Remote management of the VSP 4450 Series is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

### About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note that the VSP 4450 Series source address command is different than other platforms. Also note that the logical interface commands are different between Layer 2 and Layer 3 networks.

### Procedure

The following steps are for platforms that support FE natively:

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```
3. Enter Global Configuration mode:

```
exit
```

4. Use one of the following commands to create a logical IS-IS interface:
  - In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`
  - In a network with a Layer 2 Core, enter `logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059> port <slot/port> mlt <mltId> [name WORD<1-64>] [mtu <750-9000>]`

**Note**

The primary VLAN ID (**primary-vid**) must be one of the VLANs in the **vid <list of vids>**.

The following steps are for platforms that require an ONA to support FE:

**Note**

The interface VLAN connecting to the ONA network port is always in the GRT and the member port that the VLAN is part of is always an access port.

5. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
6. Configure the IP tunnel source address on the port that connects to the Device side of the ONA:
 

```
ip-tunnel-source-address <A.B.C.D> port <slot/port> [mtu <mtu_value>]
[vrf WORD<1-16>]
```
7. Exit back into Global Configuration mode:
 

```
exit
```
8. Use one of the following commands to create a logical IS-IS interface:
  - In a network with a Layer 3 Core, enter:
 

```
logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>]
```
  - In a network with a Layer 2 Core, enter:
 

```
logical-intf isis <1-255> vid <list of vids> primary-vid <2-4059>
port <slot/port> mlt <mltId> [name WORD<1-64>]
```

**Note**

The primary VLAN ID (**primary-vid**) must be one of the VLANs in the **vid <list of vids>**.

## Variable Definitions

The following table defines parameters for the **ip-tunnel-source-address** command.

To delete an IS-IS IP tunnel source address, use the **no ip-tunnel-source-address** option.

#### Note

The `port` parameter is for the VSP 4450 Series only.

Variable	Value
<code>&lt;A.B.C.D&gt;</code>	Specifies the IS-IS IPv4 tunnel source address, which can be a brouter interface IP, a CLIP IP, or a VLAN IP.
<code>port &lt;slot/port&gt;</code>	Specifies the port that is connected to the ONA's Device port.
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the VRF name associated with the IP tunnel.
<code>mtu &lt;mtu_value&gt;</code>	Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch. This parameter only applies to an ONA configuration.

The following table defines parameters for the **logical-intf isis** command, depending on whether you have a Layer 2 or Layer 3 core.

To delete a logical IS-IS interface, use the **no logical-intf isis** option.

**Table 131: Layer 2 core**

Variable	Value
<code>&lt;1-255&gt;</code>	Specifies the index number that uniquely identifies this logical interface.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the physical port that the logical interface is connected to in a Layer 2 network.
<code>vid &lt;list of vids&gt;</code>	Specifies the list of VLANs that are associated with this logical interface.
<code>primary-vid &lt;2-4059&gt;</code>	Specifies the primary tunnel VLAN ID associated with this Layer 2 IS-IS logical interface.
<code>mlt &lt;mltId&gt;</code>	Specifies the MLT ID that the logical interface is connected to in a Layer 2 network.

**Table 131: Layer 2 core (continued)**

Variable	Value
<code>name WORD&lt;1-64&gt;</code>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<code>mtu&lt;750-9000&gt;</code> <b>Note:</b> Exception: only supported on XA1400 Series.	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

**Table 132: Layer 3 core**

Variable	Value
<code>&lt;1-255&gt;</code>	Specifies the index number that uniquely identifies this logical interface.
<code>dest-ip &lt;A.B.C.D&gt;</code>	Specifies the tunnel destination IP address of the remote BEB.
<code>name WORD&lt;1-64&gt;</code>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<code>mtu&lt;750-9000&gt;</code> <b>Note:</b> Exception: only supported on XA1400 Series.	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

### Configure Fabric Extend Over IPsec

**Note**

This procedure only applies to XA1400 Series.

Use the following procedure to configure Fabric Extend (FE) over IPsec.

**Before You Begin**

The tunnel source IP address can be a brouter port IP, a CLIP IP, or a VLAN IP.

**About This Task**

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

For information about how to configure an IPsec NAT-T Responder, see [IPsec configuration using CLI](#) on page 1687.

**Procedure****Switch A Steps**

1. Enter IS-IS Router Configuration mode:  
`enable`  
  
`configure terminal`  
  
`router isis`
  2. Configure the IP tunnel source address:  
`ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]`
  3. Enter Global Configuration mode:  
`exit`
  4. Use one of the following commands to create a logical IS-IS interface:
    - In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`
  5. Configure an IS-IS interface on the selected ports or MLTs:
    - a. Create an IS-IS circuit and interface on the selected ports or MLTs:  
`isis`
    - b. Enable the SPBM instance on the IS-IS interfaces:  
`isis spbm <1-100>`
    - c. Enable the IS-IS circuit/interface on the selected ports or MLTs:  
`isis enable`
  6. Configure the IPsec authentication method:  
`ipsec auth-method <pre-share |rsa-sig>`
  7. Create the authentication key, if using a pre-shared key:  
`auth-key WORD<1-32>`
  8. Configure IPsec encryption key length for FE tunnel.  
`ipsec encryption-key-length <128 | 256>`
-  **Note**
- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.
9. (Optional) Enable IPsec compression on the logical interface:  
`ipsec compression`  
  
By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.
  10. Enable IPsec on the logical interface:  
`ipsec`
  11. Exit interface configuration mode:  
`exit`

### Switch B Steps

12. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

13. Configure the IP tunnel source address:

```
ip-tunnel-source-address <A.B.C.D> [vrf WORD<1-16>]
```

14. Enter Global Configuration mode:

```
exit
```

15. Use one of the following commands to create a logical IS-IS interface:

- In a network with a Layer 3 Core, enter `logical-intf isis <1-255> dest-ip <A.B.C.D> [name WORD<1-64>] [mtu <750-9000>]`

16. Configure an IS-IS interface on the selected ports or MLTs:

- a. Create an IS-IS circuit and interface on the selected ports or MLTs:

```
isis
```

- b. Enable the SPBM instance on the IS-IS interfaces:

```
isis spbm <1-100>
```

- c. Enable the IS-IS circuit/interface on the selected ports or MLTs:

```
isis enable
```

17. Configure the IPsec authentication method:

```
ipsec auth-method <pre-share |rsa-sig>
```

18. Create the authentication key, if using a pre-shared key:

```
auth-key WORD<1-32>
```

19. Configure IPsec encryption key length for FE tunnel.

```
ipsec encryption-key-length <128 | 256>
```

#### Note

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

20. (Optional) Enable IPsec compression on the logical interface:

```
ipsec compression
```

By default, IPsec compression is disabled. If you enable it, you must enable it on both ends of the adjacency.

21. Enable IPsec on the logical interface:

```
ipsec
```

22. Exit interface configuration mode:

```
exit
```

## Variable Definitions

The following table defines parameters to configure Fabric Extend (FE) over IPsec on a device.

The following table defines parameters for the **ip-tunnel-source-address** command.

Variable	Value
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be a router IP, a CLIP IP, or a VLAN IP.
vrf WORD<1-16>	Specifies the VRF name associated with the IP tunnel.

**Table 133: Layer 3 core**

Variable	Value
<1-255>	Specifies the index number that uniquely identifies this logical interface.
<A.B.C.D>	Specifies the IS-IS IPv4 tunnel source address, which can be either a router interface IP or a CLIP IP.
name WORD<1-64>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
mtu <750-9000>	Specifies the Maximum Transmission Unit (MTU) size of each packet. The default MTU value is 1950.

The following table defines parameters for the **isis** command.

Variable	Value
enable	Enables or disables the IS-IS circuit/interface on the specified port or MLT. The default is disabled. Use the no option to disable IS-IS on the specified interface.
spbm <1-100>	Enable the SPBM instance on the IS-IS interfaces.

The following table defines parameters for the **auth-key** command.

Variable	Value
WORD<1-32>	Specifies the authentication key on the assigned logical interface if using a pre-shared key. Use the no option to disable the authentication key on the specified interface.

The following table defines parameters for the **ipsec** command.

Variable	Value
auth-method <pre-share   rsa-sig>	Configures the authentication method for IPsec. The default is a pre-shared key. Use <i>rsa-sig</i> to use an installed digital certificate instead.
encryption-key-length <128   256>	Specifies the IPsec encryption key length for FE tunnel, which is 128 bit or 256 bit. The default IPsec encryption key length value is 128 bit.

## Adjust the TCP Maximum Segment Size

### Note

This procedure only applies to XA1400 Series.

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. By default, this functionality is enabled and auto-derived.

### Tip

As a best practice, turn off this enhancement on the head-end side and keep this enabled only at the branch side.

## About This Task

The MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) greater than or equal to 1500 is configured. The functionality is inactive if no FE tunnels with MTU greater than or equal to 1500 are configured. Deleting the last tunnel with MTU greater than or equal to 1500 results in the functionality becoming inactive.

The switch can auto-derive the MSS value based of the tunnel MTUs or you can manually configure the MSS value. The formula for the auto-derived value is  $\min(\text{Tunnels MTUs}) - 250\text{B}$  (size for VXLAN + MIM + IPSEC + IP+TCP headers). If you configure multiple FE tunnels with MTU greater than or equal to 1500, then the switch uses the lowest of all tunnel MTUs to auto-derive the TCP MSS adjust value. The same value applies to all TCP syn packets that transmit NNI to UNI and UNI to NNI.

The switch does not support different TCP adjust MSS values if you configure different FE tunnel MTUs on different tunnels.

If you configure FE tunnels and regular NNIs on the same adjacency, then the TCP adjust MSS value applies to all TCP packets traversing across regular NNIs and FE tunnels.

## Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Use one of the following commands to configure the MSS adjustment functionality as required:
  - a. Configure an explicit MSS adjust value:

```
ip tcp adjust-mss mss <500-1250>
```
  - b. Disable MSS adjustment explicitly:

```
no ip tcp adjust-mss
```
  - c. Disable a configured MSS adjustment value and return to the auto-derived value:

```
no ip tcp adjust-mss mss
```
3. Verify the configuration:

```
show isis tcp adjust-mss
```

## Example

Configure an MSS value of 1100 and verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router isis
Switch:1(config-isis)#ip tcp adjust-mss mss 1100

Switch:1>show isis tcp adjust-mss
=====
 ISIS TCP Adjust MSS
=====
ENABLE STATUS TCP MSS TCP MSS
 TYPE VALUE

TRUE ACTIVE MANUAL-CONFIG 1100
```

### Displaying Fabric Extend over IPsec tunnel status

Use the following procedure to display the Fabric Extend over IPsec tunnel status on the switch.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Fabric Extend over IPsec tunnel status:

```
show io logical-intf-ipsec
```

Example of a Fabric Extend over IPsec tunnel status.

```
Switch:1> show io logical-intf-ipsec
bash-4.3# ipsec status | grep ESTABLISHED
ipsecl-192.0.2.192[12]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.192[192.0.2.192]
ipseco-192.0.2.182[11]: ESTABLISHED 13 hours ago,
192.0.2.193[192.0.2.193]...192.0.2.182[192.0.2.182]
```

### Configure BFD on a Fabric Extend Tunnel

#### About This Task

Use the following procedure to configure BFD on a Fabric Extend Tunnel.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable BFD:
 

```
router bfd enable
```
3. In the VLAN Interface Configuration mode, you can enable BFD:
 

```
ip bfd enable
```
4. In the Loopback Interface Configuration mode, you can enable BFD:
 

```
ip bfd enable
```

5. Enable BFD on an IS-IS Logical Interface:

```
logical-intf isis <1-255> bfd enable
```

### Example

Enable BFD on a Fabric Extend tunnel:

```
Switch:1>enable
Switch:1#config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd enable
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip bfd enable
Switch:1(config-if)#logical-intf isis 1
Switch:1(config-isis-1-1.2.3.5)#bfd enable
```

### Display IS-IS Logical Interfaces

Use the following procedure to display the Intermediate-System-to-Intermediate-System (IS-IS) logical interfaces configured on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interfaces:

```
show isis logical-interface [name | ipsec | shaper | mtu]
```

### Examples

Example of a Layer 2 Core

```
Switch:1> show isis logical-interface
=====
ISIS Logical Interfaces
=====
IFIDX NAME ENCAP L2_INFO TUNNEL L3_TUNNEL_NEXT_HOP_INFO
 TYPE TYPE PORT/MLT VIDS (PRIMARY) DEST-IP PORT/MLT VLAN VRF

1 -- L2-P2P-VID Port2/40 101,201 (101) -- -- -- --
2 -- L2-P2P-VID Port1/3 102,202 (102) -- -- -- --

2 out of 2 Total Num of Logical ISIS interfaces
=====
```

Example of a Layer 3 Core

```
Switch:1> show isis logical-interface
=====
ISIS Logical Interfaces
=====
IFIDX NAME ENCAP L2_INFO TUNNEL L3_TUNNEL_NEXT_HOP_INFO
 TYPE TYPE PORT/MLT VIDS (PRIMARY) DEST-IP PORT/MLT VLAN VRF

1 SPBoIP_T1 IP -- -- 41.41.41.41 MLT10 2 vrf24
2 SPBoIP_T2 IP -- -- 42.42.42.42 MLT10 2 vrf24
3 SPBoIP_4K5 IP -- -- 187.187.187.187 MLT10 2 vrf24

3 out of 3 Total Num of Logical ISIS interfaces
=====
```

Example showing the status of BFD configurations on the IS-IS Logical interface

```
Switch:1> show isis logical-interface
=====
ISIS Logical Interfaces
=====
IFIDX NAME ENCAP L2_INFO TUNNEL L3_TUNNEL_NEXT_HOP_INFO BFD
 TYPE PORT/MLT VIDS (PRIMARY) DEST-IP PORT/MLT VLAN VRF STATUS

1 tunnel01 IP -- -- 198.51.100.1 Port1/2 123 vrf30 disabled
2 tunnel102 IP -- -- 198.51.100.2 Port1/3 345 vrf20 disabled

2 out of 2 Total Num of Logical ISIS interfaces
=====
```

Example showing the full IS-IS logical interface name

The command **show isis logical-interface** truncates the IS-IS logical interface name to the first 16 characters. To view the entire name (up to a maximum of 64 characters), use the command **show isis logical-interface name**.

```
Switch:1> show isis logical-interface name
=====
ISIS Logical Interface name
=====
ID NAME

1 SPBoIP_T1
2 SPBoIP_T2
3 SPBoIP_4K5

```

1 out of 1 Total Num of Logical ISIS interfaces

```

Display the IS-IS logical interface egress shaping rate values. This command displays interfaces with egress shaping rates configured.

```
Switch:1>show isis logical-interface shaper
```

```
=====
ISIS Logical Interface Egress Shaping Rate
=====
ID NAME service-rate (Mbps)

1 remotel 135
2 remote2 120
3 remote3 178

3 out of 3 Total Num of Logical ISIS interfaces

```

Example showing the IS-IS logical interfaces mtu values

This command displays the Maximum Transmission Unit (MTU) size for each logical interface.

```
Switch:1>show isis logical-interface mtu
```

```
=====
ISIS Logical Interface Mtu
=====
ID NAME MTU

1 SPBoIP_T1 751
2 SPBoIP_T2 1000
3 SPBoIP_4K5 1950

3 out of 3 Total Num of Logical ISIS interfaces

```

## Job Aid

The following table describes the fields in the output for the **show isis logical interface** command.

Parameter	Description
BFD STATUS	Specifies the status of BFD on this logical interface. The status can be enabled or disabled.
IFIDX	Specifies an index value for this logical interface.
NAME	Specifies the administratively assigned name of this logical interface, which can be up to 16 characters.
ENCAP TYPE	Specifies whether the encapsulation type for the logical interface is Layer 2 (L2-P2P-VID) or Layer 3 (IP).
L2_INFO PORT/MLT	Specifies the port or MLT that the logical interface is connected to in an L2 network.
L2_INFO VLAN	Specifies the list of VLANs that are associated with this L2 logical interface.
TUNNEL DEST-IP	Specifies the destination IP address for the logical interface.

Parameter	Description
L3_TUNNEL_NEXT_HOP_INFO PORT/MLT	Specifies the outgoing interface (port or MLT) for VXLAN traffic.
L3_TUNNEL_NEXT_HOP_INFO VLAN	Specifies the outgoing VLAN interface for VXLAN traffic.
L3_TUNNEL_NEXT_HOP_INFO VRF	Specifies the name of the VRF that this L3 logical interface is configured on.

### Variable Definitions

The following table defines parameters for the **show isis logical-interface** command.

Variable	Value
name	Displays the full name of the IS-IS logical interface (up to a maximum of 64 characters).
ipsec	Displays the IS-IS logical interface ID and IPsec authentication key.
shaper	Displays the IS-IS logical interface egress shaping rate values. Only interfaces that have egress shaping rates configured display.

### Display BFD Fabric Extend Neighbor Information

#### About This Task

Use this procedure to display BFD Fabric Extend neighbors.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:

```
show ip bfd neighbors vrf WORD<1-16>
```

#### Example

```
Switch:1>show ip bfd neighbors vrf vrf30
=====
 BFD Session - VRF vrf30
=====
MY_DISC YOUR_DISC NEXT_HOP STATE MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME
REMOTE_STATE APP RUN

1 1 192.0.2.11 UP 3 200 200 1000 600
UP ISIS ISIS

1 out of 1 BFD session displayed

```

*Configure Global Source IP Address for IPsec Tunnel***About This Task**

Perform this procedure to configure the global source IP address for IPsec tunnel on the switch.

**Note**

Product Notice: This procedure only applies to XA1400 Series switches.

**Procedure**

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the source IP address for IPsec tunnel:
 

```
ipsec tunnel-source-address {A.B.C.D}
```

**Note**

You must configure the source IP address for IPsec tunnel on the same VRF as the source address for IP tunnel.

**Example**

Configuring source IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#ipsec tunnel-source-address 192.0.2.10
```

**Variable Definitions**

The following table defines the variable for **ipsec tunnel-source-address** command.

Variable	Value
{A.B.C.D}	Specifies the global IP address for IPsec tunnel, which is configured on the same VRF as the source address for IP tunnel.

*Configure Destination IP Address for IPsec Tunnel***About This Task**

Perform this procedure to configure the destination IP address for the IPsec tunnel on a specific IS-IS logical interface on the switch.

**Note**

Product Notice: This procedure only applies to XA1400 Series switches.

**Procedure**

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```

2. Configure destination IP address for IPsec tunnel:

```
ipsec tunnel-dest-ip {A.B.C.D}
```

**Example**

Configuring destination IP address for IPsec tunnel.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#logical-intf isis 1
Switch:1(config-isis-1-192.0.2.25)ipsec tunnel-dest-ip 192.0.2.30
```

**Variable Definitions**

The following table defines the variable for **ipsec tunnel-dest-ip** command.

Variable	Value
{A.B.C.D}	Specifies destination IP address for the IPsec tunnel on a specific IS-IS logical interface.

**Fabric Attach Configuration using the CLI**

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using the Command Line Interface (CLI). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using CLI](#) on page 2113.

*Configuring Fabric Attach globally*

For proper operation, FA must be enabled at both the global level and at the interface level on the FA Server. By default, FA is globally enabled. However, FA is disabled by default at the interface level and must be explicitly enabled on each interface.

Use this procedure to enable Fabric Attach globally on a switch.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable FA:

```
fa enable
```

## 3. (Optional) Disable FA:

```
no fa enable
```

**Caution**

Disabling FA flushes all FA element discovery and mappings.

## 4. View the FA configuration status. Use one of the following commands:

- show fa
- show fa agent

**Example**

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa enable
Switch:1(config)#show fa

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm

Switch:1(config)#show fa agent

=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

*Configuring Fabric Attach discovery timeout*

Use this procedure to configure the Fabric Attach discovery time-out.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure the FA discovery time-out in seconds:
 

```
fa discovery-timeout <45-480>
```

**Note**

The discovery time-out must be greater than or equal to the assignment time-out.

- (Optional) Configure the default FA discovery time-out:

```
default fa discovery-timeout
```

### Example

Configure the FA discovery time-out.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa discovery-timeout 50
```

Verify the configuration.

```
Switch:1(config)#show fa

=====
 Fabric Attach Configuration
=====
 FA Service : enabled
 FA Element Type : server
FA Assignment Timeout : 45
FA Discovery Timeout : 50
FA Provision Mode : spbm
```

### Variable definitions

The following table defines parameters for the **fa discovery-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach discovery time-out in seconds. The default value is 240 seconds.

### Configuring Fabric Attach assignment timeout

Use this procedure to configure the Fabric Attach assignment time-out.

#### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the FA assignment time-out in seconds:
 

```
fa assignment-timeout <45-480>
```

#### Note

The assignment time-out must be less than or equal to the discovery time-out.

- (Optional) Configure the default FA assignment time-out value:

```
default fa assignment-timeout
```

## Example

Configure the FA assignment time-out:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#fa assignment-timeout 50
```

Verify the configuration:

```
Switch:1(config)#show fa

=====
 Fabric Attach Configuration
=====

 FA Service : enabled
 FA Element Type : server
 FA Assignment Timeout : 50
 FA Discovery Timeout : 240
 FA Provision Mode : spbm
```

## Variable definitions

The following table defines parameters for the **fa assignment-timeout** command.

Variable	Value
<45-480>	Specifies the Fabric Attach assignment time-out in seconds. The default value is 240 seconds.

### *Enabling Fabric Attach on an interface*

Use this procedure to enable Fabric Attach on an interface (port, static MLT or LACP MLT). Enabling FA on an MLT enables FA on all ports of the MLT. If your platform supports channelization, FA can also be enabled on channelized ports.

### **Before You Begin**

Verify that FA is enabled globally on the switch.

### **About This Task**

Enabling FA on a port or MLT is necessary for element discovery.

On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on the desired port or MLT interface. FA is successfully enabled on an MLT only if all ports of the MLT have FA successfully enabled. Enabling FA automatically configures LLDP on all ports. Tagging is configured and spanning tree is disabled.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable FA on the interface:

```
fa enable
```

3. (Optional) Disable FA on the interface:

```
no fa enable
```

### Caution

Disabling FA flushes all FA element discovery and I-SID-to-VLAN mappings associated with the interface.

4. View the FA configuration status:

```
show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port
<{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}>]
```

## Example

Enable FA on a port:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA on an MLT:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#
```

Verify that FA is enabled on the interfaces.

#### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and appears encrypted on the output.

```
Switch:1(config)#show fa interface

=====
Fabric Attach Interfaces

```

### Variable definitions

The following table defines parameters for the `show fa interface` command.

Variable	Value
disabled-auth	Displays the FA interfaces (port or MLT) that have authentication disabled.
enabled-auth	Displays the FA interfaces (port or MLT) that have authentication enabled.

Variable	Value
<1-512>	The valid range for MLT ID. Displays FA configuration on the specified MLT interface.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays FA configuration on the specified port.

### Configuring FA message authentication on an interface

Use this procedure to configure FA message authentication on an interface (port or MLT).

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure FA message authentication on a port or MLT:

```
[default] [no] fa message-authentication
```

#### Note

When FA is enabled, message authentication is enabled by default. The authentication key is set to the default value and appears encrypted on the output.

#### Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#
```

Enable message authentication on a port.

```
Switch:1(config)#interface gigabitEthernet 1/2

Switch:1(config-if)#fa message-authentication
Switch:1(config-if)#show fa interface port 1/2
```

```

### Configuring the FA authentication key on an interface

On the FA Server, you can configure an authentication key on an interface (port, static MLT or LACP MLT), to authenticate a client or proxy device on that interface. The authentication key is stored in encrypted form when you save configuration on the FA Server.

## Before You Begin

Ensure that:

- On the FA Server, FA is enabled globally and also on the interface.
- FA message authentication is enabled on the interface.

### Note

By default, enabling FA enables message authentication. The authentication key is set to the default value and appears encrypted on the output.

## About This Task

Use this procedure to configure an FA authentication key on a specified port or on all ports of an MLT, on the switch. If you do not configure an authentication key, the default value is used. If you specify a key, the default value is overridden and is stored in encrypted format in a separate file other than the configuration file, when you execute the `save config` command.

### Caution

For an FA Client or an FA Proxy device to successfully authenticate and attach to the FA Server, the authentication key must match on both the client and the server. If the authentication key is changed on the FA Server switch, it must correspondingly be changed on the FA Client or Proxy attached to it, for FA to operate properly.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA authentication key:

```
fa authentication-key WORD<0-32>
```

3. (Optional) Configure the default FA authentication key:

```
default fa authentication-key
```

## Example

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
```

Enable FA and message authentication on a port. Configure the authentication key `phone-network` on the port.

```
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa enable
Switch:1(config-if)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key phone-network
Switch:1(config-if)#exit
Switch:1(config)#
```

Enable FA and message authentication on an MLT. Configure the authentication key `client-network` on the MLT.

```
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#fa message-authentication
Switch:1(config-mlt)#fa authentication-key client-network
```

Verify configuration of the FA authentication key. The authentication key appears encrypted on the output.

```
Switch:1(config-if)#show fa interface

## Variable Definitions

The following table defines parameters for the **fa authentication-key** command.

Variable	Value
WORD<0-32>	Specifies the authentication key on the port or MLT.

## Configure FA Management on a Port or MLT

Use this procedure to configure a management I-SID on an FA enabled port or MLT on the switch.

### Before You Begin

Ensure that the port or MLT is enabled for Fabric Attach.

### About This Task

This command applies to all traffic sent or received on a port or MLT, carrying the VLAN ID specified using the `c-vid` parameter. This parameter is optional.

Depending on whether the `c-vid` parameter is specified or not, the behavior is as follows:

- If the `c-vid` parameter is specified, the FA Server transmits this VLAN ID as the management VLAN in the FA Element TLV. A client or proxy receiving this TLV uses this VLAN-ID for management traffic on the FA Server uplink.
- If the `c-vid` parameter is not specified, the FA Server transmits a management VLAN with a VLAN ID value of 4095 in the FA Element TLV. A client or proxy receiving this TLV uses **untagged** traffic for network management on the FA Server uplink.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the FA management I-SID:

```
fa management i-sid <i-sid><c-vid>
```

### Important

If you do not specify a C-VID value, the port or MLT is **untagged**.

3. Delete FA management I-SID on a port or MLT using one of the following commands:

- `default fa management i-sid`
- `no fa management i-sid`

4. Verify configuration of FA management on the port or MLT, using the following commands:

- `show i-sid <i-sid>`
- `show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show mlt i-sid [<1-512>]`

## Examples

The following example demonstrates configuring FA management on the port 1/2.

Configure FA management on port 1/2:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#fa management i-sid 101 c-vid 101
Switch:1(config-if)#show i-sid 101
=====
Isid Info
```

```
=====
```

ISID ID	ISID TYPE	VLANID	PORT INTERFACES	MLT INTERFACES	ORIGIN	ISID NAME
101	ELAN	3	-	-	CONFIG	EXTRSERVER_101

```
=====
```

The following example demonstrates the configuring of Origin as "auto-sense".

```
Switch:1(config-if)#show i-sid 500

```

The following example demonstrates configuring FA management on an MLT.

Configure FA management on MLT 10.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#fa management i-sid 101
```

Verify configuration of FA management on the MLT. Since the C-VID is not specified, the MLT is displayed as untagged.

```
Switch:1(config-mlt)#show i-sid 101
=====
 Isid Info
=====
ISID ISID PORT MLT ORIGIN ISID
ID TYPE VLANID INTERFACES INTERFACES

101 ELAN 3 - u:10 CONFIG EXTRSERVER_101
```

An FA management I-SID can have a platform VLAN associated with it. For Layer 3 support on the management I-SID, you must create a platform VLAN by port and associate the platform VLAN with the management I-SID. The C-VID can be of the same value or of a different value than that of the platform VLAN.

If the management I-SID matches one of the FA Switched UNI (ELAN) I-SIDs (as displayed by the command `show i-sid elan`), then the platform VLAN is automatically associated with the FA enabled interface (port or MLT).

In the following example, for Layer 3 support, create a platform VLAN 3 and associate it with the management I-SID 101.

```
Switch:1(config-if)#vlan create 3 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 3 101
Switch:1(config)#show i-sid
=====
=
 Isid Info
=====
=

```

## Variable Definitions

The following table defines parameters for the **fa management** command.

Variable	Value
<code>i-sid &lt;i-sid&gt;</code>	Specifies the management I-SID. Different hardware platforms support different customer I-SID ranges. To see the available range for the switch, use the CLI Help.
<code>&lt;c-vid&gt;</code>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.  <b>Important:</b> If you do not specify a C-VID value, the port or MLT is <b>untagged</b> .

### Viewing Fabric Attach global configuration status

Use this procedure to display the Fabric Attach global configuration status on a switch.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display the FA configuration status using one of the following commands:
  - `show fa`
  - `show fa agent`

#### Example

Sample output for the **show fa** command:

```
Switch:1#show fa
=====
 Fabric Attach Configuration
=====
 FA Service : enabled
 FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

Sample output for the **show fa agent** command:

```
Switch:1#show fa agent
=====
 Fabric Attach Configuration
=====
 FA Service : enabled
 FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

### Viewing Fabric Attach interface configuration

Use this procedure to view FA interface configuration.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View all FA interfaces (ports and MLTs):

```
show fa interface
```

3. To view FA interface configuration on ports, use one of the following commands:

- View FA configuration on all ports:

```
show fa interface port
```

- View FA configuration on a specific port, enter:

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

4. To view FA interface configuration on MLTs, use one of the following commands:

- View FA configuration on all MLTs:

```
show fa interface mlt
```

- View FA configuration on a specific MLT:

```
show fa interface mlt [<1-512>]
```

#### Example

The following example displays sample outputs for the **show fa interface** command.

```
Switch:1>en
Switch:1#show fa interface

=====

### Variable definitions

The following table defines parameters for the `show fa interface port` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,sport/sport). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the `show fa interface mlt` command.

Variable	Value
<code>&lt;1-512&gt;</code>	The valid range for MLT ID.

### Viewing Fabric Attach Discovered Elements

Use this procedure to view Fabric Attach discovered elements.

#### About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or FA Proxies. Standard LLDPs allow neighbors to be learned. With the help of organizational-specific element discovery TLVs, the client or proxy recognizes that it has attached to the FA Server. Only after the discovery handshake is complete, an FA Client or FA Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric network through the FA Server.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```

2. Display FA discovered elements:

```
show fa elements
```

3. Display FA discovered elements on a specific port:

```
show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

**Example**

The following example displays the sample output for the `show fa elements` command.

```
Switch:1#show fa elements

=====
Fabric Attach Discovery Elements
=====
PORT TYPE MGMT ELEM ASGN
VLAN STATE SYSTEM ID AUTH AUTH

NA= Not Authenticated, N= None

2 out of 2 Total Num of fabric attach discovery elements displayed
```

**Variable definitions**

The following table defines parameters for the `show fa elements` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

*Viewing Fabric Attach I-SID-to-VLAN Assignments*

Use this procedure to display the I-SID-to-VLAN assignments advertised by an FA Client or an FA Proxy, to be supported on the FA Server. These assignments can be accepted or rejected by the FA Server. An

assignment that is successfully accepted by the FA Server results in the creation of a Switched UNI I-SID on the interface.

### Before You Begin

Verify that IS-IS and SPBM are properly configured on the FA Server switch.

- Verify SPBM configuration using the command **show running-config module spbm**.
- Verify IS-IS configuration using one of the following commands:
  - **show isis**
  - **show isis interface**
  - **show isis adjacency**
  - **show isis lsdb**

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display FA I-SID-to-VLAN assignments:

```
show fa assignment
```

3. Display FA I-SID-to-VLAN assignments on specific ports:

```
show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

### Example

The following example displays a sample output for the `show fa assignment` command.

#### Note

The state of I-SID-to-VLAN assignments on a client or proxy device is pending until it is changed by the FA Server to `active` or `reject`.

```
Switch:>en
Switch:1#show fa assignment
=====
 Fabric Attach Assignment Map
=====
Interface I-SID Vlan State Origin

1/1 2 2 active proxy
1/2 3 3 active proxy
1/2 4 4 active proxy
1/3 5 5 reject proxy

4 out of 4 Total Num of fabric attach assignment mappings displayed

```

## Variable definitions

The following table defines parameters for the **show fa assignment** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Viewing Fabric Attach Statistics

If FA discovery fails, use this procedure to display FA statistics to determine if FA discovery TLVs were processed. You can also view the FA assignment statistics to determine the number of FA assignments that were accepted or rejected by the FA Server.

You can view the statistics at either the global level or at the port (interface) level.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View global level FA statistics:  
show fa statistics [summary]
3. View FA statistics at the slot/port level:  
show fa statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

#### Note

If a slot is removed from the switch chassis, the FA statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

4. (Optional) Clear FA statistics:  
clear fa statistics [summary] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

### Examples

Viewing FA discovery and assignment statistics:

```
Switch:1>en
Switch:1#show fa statistics
```

```
=====

## Variable Definitions

The following table defines parameters for the **show fa statistics** command.

Variable	Value
summary	Displays a summary of Fabric Attach element discovery and assignment statistics at the global level.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Displaying Learned LLDP Neighbors

Use this procedure to verify details of the LLDP neighbors learned.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Verify details of LLDP neighbors learned:  
show lldp neighbor
3. Verify details of LLDP neighbors learned on a specific port:  
show lldp neighbor port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*

### Example

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors. Switch A, which is the FA Server is an VSP 7200 Series switch (model 7254XSQ) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples shows neighbor discovery on non-channelized and channelized ports (if your platform supports channelization).

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

```

SwitchA:1>en
SwitchA:1#show lldp neighbor

```

```

## Variable Definitions

The following table defines parameters for the **show lldp neighbor** command.

Variable	Value
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. Displays LLDP neighbor information on the specified port.

### Display Switched UNI (ELAN) I-SID Information

Use this procedure to display information on FA-created Switched UNI (ELAN) I-SIDs.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display all Switched UNI (ELAN) I-SIDs:
 

```
show i-sid elan
```

3. Display ELAN I-SID information on an MLT:

```
show mlt i-sid [<1-512>]
```

#### Note

Viewing ELAN I-SID information on an MLT is useful to understand the origin of the I-SID when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

4. Display ELAN I-SID information on ports:

```
show interfaces gigabitEthernet i-sid [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

#### Examples

Display information on all Switched UNI (ELAN) I-SIDs.

The following sample output displays, for example, the I-SID information on one of the peer switches of the FA Server, in a dual-homed SMLT configuration.

```
Switch:1>enable
Switch:1#show i-sid elan

=====
Isid Info

All 6 out of 6 Total Num of Elan i-sids displayed

ORIGIN Legend:
C: manually configured; D: discovered by FA or EPT
M: FA management; E: discovered by EAP; A: auto-sense
```

```
l: discover by local switch r: discover by remote VIST switch
```

### Note

The I-SID TYPE field displays once for each I-SID. The I-SID TYPE of an I-SID that is either learned through FA mapping assignments or configured as an FA management I-SID, is always ELAN. If a platform VLAN has the same I-SID value as that of the I-SID in an FA mapping assignment or in an FA management I-SID configuration, then the platform VLAN is associated with the I-SID endpoint and appears in the VLANID column.

Display MLT I-SID information for MLT 1.

In this sample output, the ORIGIN field indicates the origin of the I-SID endpoint.

```
Switch:1>show mlt i-sid

### Variable Definitions

The following table defines parameters for the **show i-sid** command.

Variable	Value
elan	Displays all ELAN I-SIDs.

The following table defines parameters for the **show mlt i-sid** command.

Variable	Value
<1-512>	The valid range for MLT ID.

The following table defines parameters for the **show interfaces gigabitEthernet i-sid** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Enabling or disabling FA Zero Touch Client Attachment

Use this procedure to enable or disable the global FA Zero Touch Client Attachment feature on an FA Proxy or Server. By default, FA Zero Touch Client Attachment support is enabled.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable an FA Zero Touch client:

```
fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|phone|
router|security-device|srvr-endpt|switch|video|virtual-switch|wap-
type1|wap-type2> i-sid <1-15999999>
```

3. Disable an FA Zero Touch client:

```
no fa zero-touch-client standard <camera|ona-sdn|ona-spb-over-ip|
phone|router|security-device|srvr-endpt|switch|video|virtual-switch|
wap-type1|wap-type2>
```

#### Example

```
Switch:1(config)# fa zero-touch-client standard camera i-sid 1003
Switch:1(config)# no fa zero-touch-client standard camera
```

## Variable definitions

The following table defines parameters for the **fa zero-touch-client standard** command.

Variable	Value
<i>camera</i>	Specify element type to match camera.
<i>ona-sdn</i>	Specify element type to match ona-sdn.
<i>ona-spb-over-ip</i>	Specify element type to match ona-spb-over-ip.
<i>phone</i>	Specify element type to match phone.
<i>router</i>	Specify element type to match router.
<i>security-device</i>	Specify element type to match security-device.
<i>svr-endpt</i>	Specify element type to match svr-endpt.
<i>switch</i>	Specify element type to match switch.
<i>video</i>	Specify element type to match video.
<i>virtual-switch</i>	Specify element type to match virtual-switch.
<i>wap-type1</i>	Specify element type to match wap-type1.
<i>wap-type2</i>	Specify element type to match wap-type2.

## Displaying FA Zero Touch Client Attachment

Use this procedure to display the Zero Touch Client Attachment data you have configured on an FA Server.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display Zero Touch Client Attachment data:  
show fa zero-touch-client

### Example

The following example displays sample output for the **show fa zero-touch-client** command.

```
Switch:1#show fa zero-touch-client
=====
Fabric Attach Zero Touch Client
=====
Type Description I-SID VLAN

6 wap-type1 11111 123
11 camera 2000 200
17 ona-spb-over-ip 40001 4001

3 out of 3 Total Num of Fabric Attach Zero Touch Client entries displayed
=====
```

## Configure Endpoint Tracking Using CLI

The following sections provide procedural information to configure Endpoint Tracking using CLI.

### *Configure Endpoint Tracking Interfaces*

Create and enable Endpoint Tracking on ports and MLT/SMLT interfaces. Creating, deleting, enabling, and disabling Endpoint Tracking on interfaces can be accomplished as separate steps using this procedure.

#### **Before You Begin**

- In Extreme Management Center, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center.

#### **About This Task**

Configure ports and MLT/SMLT interfaces to function as Switched UNI interfaces, and then create and enable Endpoint Tracking on those interfaces.

#### **Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

#### **Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Flex UNI on the interface:

```
flex-uni enable
```

3. Create and enable Endpoint Tracking:

- Create Endpoint Tracking on the interface:

```
endpoint-tracking
```

- Create and enable Endpoint Tracking on the interface:

```
endpoint-tracking enable
```

#### **What to Do Next**

Configure Endpoint Tracking globally on the switch.

## Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

### Before You Begin

- In Extreme Management Center, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center.
- Create and enable Endpoint Tracking on interfaces.

### About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:
 

```
endpoint-tracking auto-isid-offset <0-15995903>
endpoint-tracking auto-isid-offset enable
```
3. Enable Endpoint Tracking globally on the switch:
 

```
endpoint-tracking enable
```

### Variable Definitions

The following table defines parameters for the **endpoint-tracking auto-isid-offset** command.

Variable	Value
<code>&lt;0-15995903&gt;</code>	The I-SID offset value. The default is 15990000.
<code>enable</code>	Enables or disables I-SID offset value globally on the switch. The default is disabled.

### Configure Endpoint Tracking Visibility Mode

Configure Endpoint Tracking visibility mode on the switch.

#### Before You Begin

- In Extreme Management Center, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center.
- Create and enable Endpoint Tracking on interfaces.
- Enable Endpoint Tracking globally on the switch.

#### About This Task

Enable visibility mode to allow MAC learning on static S-UNIs for Endpoint Tracking.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable Endpoint Tracking visibility mode on the switch:  
`endpoint-tracking visibility-mode`

### Display Endpoint Tracking Configuration Information

Perform this procedure to display configuration information for Endpoint Tracking.

#### About This Task

Perform this procedure to display global, interface and binding information for Endpoint Tracking.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global status of Endpoint Tracking on the switch, and the configured I-SID offset value, if applicable:  
`show endpoint-tracking`
3. Display the status of all interfaces that have Endpoint Tracking created:  
`show endpoint-tracking interfaces [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]][, ...]] | [mlt <1-512>]]`
4. Display a summary of the VLAN:I-SID binding information for all ports, or MLT/SMLT interfaces:  
`show endpoint-tracking bindings summary`
5. Display the VLAN:I-SID binding information for the switch, for ports, or for MLT/SMLT interfaces:  
`show endpoint-tracking bindings [gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]][, ...]] | [mlt <1-512>]]`

## Example

The following example displays all of the Endpoint Tracking configuration information for a switch.

```
Switch:1>show endpoint-tracking
=====
Endpoint Tracking Configuration
=====

endpoint tracking status : ENABLED
auto-isid-offset value : 15990000
auto-isid-offset enabled : ENABLED
visibility-mode status : ENABLED

Switch:1>show endpoint-tracking interfaces
=====
Endpoint Tracking Interfaces
=====

PORT
NUM INDEX STATUS

1/1 192 Enabled
1/10 201 Enabled

1/10 201 00:00:00:00:1b:02 accept 27 15990027 autoconfig 0 day(s), 00:01:40 0 day(s), 00:00:00
1/10 201 00:00:00:00:1b:03 accept 27 15990027 autoconfig 0 day(s), 00:01:40 0 day(s), 00:00:00
1/10 201 00:00:00:00:1b:04 accept 27 15990027 autoconfig 0 day(s), 00:01:40 0 day(s), 00:00:00
1/10 201 00:00:00:00:1b:05 accept 27 15990027 autoconfig 0 day(s), 00:01:40 0 day(s), 00:00:00

5 out of 5 Total Num of Endpoint Tracking bindings displayed.
```

## Variable Definitions

The following table defines parameters for the **show endpoint-tracking bindings** command.

Variable	Value
gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
MLT <1-512>	Specifies the MLT ID.
summary	Provides a summary of the total number and status of bindings for all interfaces.

## IS-IS external metric configuration using the CLI

This section provides procedures for IS-IS external metric configuration.

### Matching metric type for IS-IS routes

#### About This Task

Use this procedure to match the external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing IS-IS routes into other protocols.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

#### Procedure

1. Enter Route-Map Configuration mode:
 

```
enable

configure terminal

route-map WORD<1-64> <1-65535>
```
2. Match IS-IS metric type:
 

```
match metric-type-isis {any|internal|external}
```
3. Permit the route policy action:
 

```
permit
```
4. Enable the route policy
 

```
enable
```

## Example

Match metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Match metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Match metric type to redistribute IS-IS routes into some other protocol (OSPF,RIP,BGP)

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router bgp
Switch:1(router-bgp)# redistribute isis route-map rol
Switch:1(router-bgp)# exit
Switch:1(config)# ip bgp apply redistribute
```

## Variable definitions

The following table defines parameters for the **match metric-type-isis** command.

Variable	Value
metric-type-isis {any internal  external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> <li>• internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>• external – permits or denies routes that originate from an external routing protocol domain.</li> <li>• any – permits or denies both internal routes as well as external routes.</li> </ul>

## Setting metric type for IS-IS routes

### About This Task

Use this procedure to set the IS-IS external metric-type by using a route-map for any of the following cases:

- accepting a remote IS-IS route with the help of IS-IS accept policies.
- redistributing routes from other protocols into IS-IS.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the route-map configuration mode in the CLI.

## Procedure

1. Enter Route-Map Configuration mode:  
enable  
  
configure terminal  
  
route-map *WORD*<1-64> <1-65535>
2. Set IS-IS metric type:  
set metric-type-isis {any|internal|external}
3. Permit the route policy action:  
permit
4. Enable the route policy  
enable

## Example

Set metric type for IS-IS routes:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
```

Set metric type for IS-IS routes in accept policies:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# set metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# accept route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply accept
```

Set metric type to redistribute routes from other protocols into IS-IS:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# route-map rol 10
Switch:1(route-map)# match metric-type-isis internal
Switch:1(route-map)# permit
Switch:1(route-map)# enable
Switch:1(route-map)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute bgp route-map rol
Switch:1(config-isis)# exit
Switch:1(config)# isis apply redistribute
```

## Variable definitions

The following table defines parameters for the **set metric-type-isis** command.

Variable	Value
metric-type-isis {any internal external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> <li>internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>external – permits or denies routes that originate from an external routing protocol domain.</li> <li>any – permits or denies both internal routes as well as external routes.</li> </ul>

*Setting metric type for IS-IS routes using global redistribute command*

### About This Task

Use this procedure to set the IS-IS external metric-type using the global redistribute command for the following cases redistributing routes from other protocols into IS-IS.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must log on to the IS-IS router configuration mode in the CLI.

### Procedure

- Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
- Set IS-IS metric type using global redistribute command:

```
redistribute direct metric-type {internal|external}
```
- Enable the route policy

```
redistribute direct enable
```

### Example

Set metric type for IS-IS routes using global redistribute command:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# router isis
Switch:1(config-isis)# redistribute direct metric-type internal
Switch:1(config-isis)# redistribute direct enable
```

### Variable definitions

The following table defines parameters for the **redistribute direct metric-type** command.

Variable	Value
metric-type {internal external}	Specifies the IS-IS metric type. <ul style="list-style-type: none"> <li>• internal – permits or denies routes that are internal to the IS-IS domain.</li> <li>• external – permits or denies routes that originate from an external routing protocol domain.</li> </ul>

## SPBM and IS-IS infrastructure configuration using EDM

This section provides procedures to configure basic SPBM and IS-IS infrastructure using Enterprise Device Manager (EDM).

### Important

The **EnableSpbmConfigMode** boot flag must be enabled (default) before you can configure SPBM or IS-IS. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

### Configuring required SPBM and IS-IS parameters

#### About This Task

Use the following procedure to configure the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

#### Procedure

1. Configure SBPM B-VLANs:

#### Note

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

- a. In the navigation pane, expand **Configuration > VLAN > VLANs**.
  - b. Click the **Basic** tab.
  - c. Click **Insert**.
  - d. In the **type** field, click **spbm-bvlan**.
  - e. Click **Insert**.
2. Enable SPBM globally:
    - a. In the navigation pane, expand **Configuration > IS-IS**.
    - b. Click **SPBM**.
    - c. Click the **Globals** tab.
    - d. In the **GlobalEnable** field, select **enable** to enable SPBM globally.
    - e. Click **Apply**.

3. Create an SPBM instance:

**Note**

Only one SBPM instance is supported.

- a. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
  - b. Click the **SPBM** tab.
  - c. Click **Insert** to create an SPBM instance.
  - d. In the **Id** field, specify the SPBM instance ID.
  - e. In the **NodeNickName** field, specify the node nickname (valid value is 2.5 bytes in the format <x.xx.xx>).
  - f. In the **Vlans** field, specify the IDs of the SPBM B-VLANs to add to the SPBM instance.
  - g. In the **PrimaryVlan** field, specify which of the SPBM B-VLANs specified in the previous step is the primary B-VLAN.
  - h. Click **Insert**.
4. Create a manual area:

**Note**

Only one manual area is supported.

- a. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
  - b. Click the **Manual Area** tab.
  - c. Click **Insert**.
  - d. Specify the Manual Area address (a valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>).
  - e. Click **Insert**.
5. Update the default IS-IS system ID to a recognizable address:
- a. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
  - b. Click the **Globals** tab.
  - c. In the **SystemId** field, update the default B-MAC value to a recognizable address.

**Note**

Although it is not strictly required for SPBM operation, you must change the IS-IS system ID from the default B-MAC value to a recognizable address to easily identify a switch. This helps to recognize the source and destination addresses for troubleshooting purposes.

- d. In the **AdminState** field, click **on**.
  - e. Click **Apply**.
6. Create an IS-IS circuit and enable SPBM on the circuit:
- a. In the navigation pane, expand **Configuration > IS-IS**.
  - b. Click the **Interfaces** tab.
  - c. Click **Insert** to create an IS-IS circuit.
  - d. In the **IfIndex** field, specify the port or MLT on which to create the IS-IS circuit.
  - e. Click **Insert**.
  - f. Select the newly created IS-IS circuit entry, and click **SPBM**.

- g. In the **Interfaces SPBM** tab, click **Insert**.
- h. In the **State** field, select **enable**.
- i. Click **Insert**. This enables the SPBM instance on the IS-IS circuit.
- j. Navigate back to the **Interfaces** tab.
- k. In the **AdminState** field for the IS-IS circuit entry, select **on** to enable the IS-IS circuit.
- l. Click **Apply**.

### SPBM Field Descriptions

#### Note

The following tables list the minimum required SPBM and IS-IS parameters to allow SPBM to operate on the switch. For more detailed information on all of the parameters see the procedures that follow. For more information on how to configure VLANs, see [VLAN Configuration using EDM](#) on page 3858.

Use the data in the following table to use the **VLANs Basic** tab.

Name	Description
<b>Type</b>	Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>

Use the data in the following table to use the **SPBM Globals** tab.

Name	Description
<b>GlobalEnable</b>	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
<b>GlobalEtherType</b>	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
<b>NicknameServerEnable</b> <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Enables or disables the nickname server. The default is disabled.
<b>NicknameDynamicAllocationStatus</b> <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Displays the Dynamic Nickname Allocation service operational status. This value is read-only.

Name	Description
<b>NicknameServerRange</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname allocation range for Dynamic Nickname Assignment. Select <b>none</b> to use the range 0.00.00-0.0F.FF. The default is rangeA (A.00.00 to A.FF.FF).
<b>NicknameServerPrefix</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.FF.FF.

Use the data in the following table to use the **SPBM** tab.

Name	Description
<b>Id</b>	Specifies the SPBM instance ID. Only one SPBM instance is supported.
<b>NodeNickName</b>	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
<b>PrimaryVlan</b>	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
<b>Vlans</b>	Specifies the SPBM B-VLANs to add to the SPBM instance.
<b>LsdbTrap</b>	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
<b>IpShortcut</b>	Enables or disables SPBM IP shortcut state. The default is disable.
<b>SmltSplitBEB</b>	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
<b>SmltVirtualBmac</b>	Specifies a virtual MAC address that can be used by both peers.
<b>SmltPeerSysId</b>	Specifies the system ID of the SPBM SMLT for this SPBM instance.
<b>Mcast</b>	Specifies if IP multicast over SPBM is enabled. The default is disabled.
<b>McastFwdCacheTimeout</b>	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
<b>Ipv6Shortcut</b>	Enables or disables SPBM IPv6 shortcut state. The default is disable.
<b>McastSpbPimGwControllerEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
<b>McastSpbPimGwGatewayEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.

Name	Description
<b>StpMultiHoming</b>	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
<b>BVlanOrigin</b>  <b>Note:</b> Exception: not supported on XA1400 Series and VSP 8600 Series.	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

Use the data in the following table to use the **IS-IS Manual Area** tab.

Name	Description
<b>AreaAddr</b>	Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area.

Use the data in the following table to use the **IS-IS Globals** tab.

Name	Description
<b>AdminState</b>	Specifies the global status of IS-IS on the switch: on or off. The default is off.
<b>SystemId</b>	Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>.  <b>Important:</b> After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 962.

Use the data in the following table to use the **IS-IS Interfaces** tab.

Name	Description
<b>Index</b>	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
<b>AdminState</b>	Specifies the administrative state of the circuit: on or off.

Use the data in the following table to use the **IS-IS Interfaces SPBM** tab.

Name	Description
<b>State</b>	Specifies whether the SPBM interface is enabled or disabled.

### Job aid

#### Important

After you have configured the SPBM nickname and enabled IS-IS. To maintain the same nickname with a different system ID, perform the following steps:

1. Disable IS-IS.
2. Change the system ID.
3. Change the nickname to a temporary one.
4. Enable IS-IS.
5. Wait up to 20 minutes for the LSPs with the original system ID to age out.

#### Note

To check the age out time, use the **show isis lsdb sysid <original-sys-id>** command on any of the other SPB nodes in the network. When there is no output from this command, proceed to the next step. The time left (in seconds) for the LSPs to age out is shown under the column **LIFETIME**.

6. Disable IS-IS.
7. Change the nickname to the original nickname.
8. Enable IS-IS.

### Displaying SPBM and IS-IS summary information

Use the following procedure to view a summary of SPBM and IS-IS protocol information.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Protocol Summary** tab.

### Protocol Summary field descriptions

Use the data in the following table to use the **Protocol Summary** tab.

Name	Description
<b>Globals ISIS</b>	
<b>AdminState</b>	Indicates the global status of IS-IS on the switch.
<b>SystemId</b>	Indicates the IS-IS system ID for the switch. Valid value is a 6-byte value in the format <xxxx.xxxx.xxxx>

Name	Description
<b>HostName</b>	Indicates a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.
<b>Globals SPBM</b>	
<b>GlobalEnable</b>	Indicates whether SPBM is enabled or disabled at the global level.
<b>NodeNickName</b>	Indicates the nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
<b>PrimaryVlan</b>	Indicates the primary VLAN ID for this SPBM instance.
<b>SmltSplitBEB</b>	Indicates whether the switch is the primary or secondary IST peer.
<b>ISIS Interfaces</b>	
<b>Circuit Index</b>	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This is for SNMP Indexing purposes only and need not have any relation to any protocol value.
<b>IfIndex</b>	Indicates the interface to which this circuit corresponds.
<b>AdminState</b>	Indicates the administrative state of the circuit: on or off.
<b>OperState</b>	Indicates the operational state of the circuit: up or down.
<b>ISIS Adjacency View</b>	
<b>Circuit Index</b>	Displays the identifier of this IS-IS circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
<b>AdjIndex</b>	Displays a unique value identifying the IS adjacency from all other such adjacencies on this circuit. This value is automatically assigned by the system when the adjacency is created
<b>AdjIfIndex</b>	Indicates the interface to which this circuit corresponds.
<b>AdjState</b>	Indicates the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>
<b>AdjNeighSysID</b>	Indicates the system ID of the neighboring Intermediate System.
<b>AdjHostName</b>	Indicates the host name listed in the LSP, or the system name if the host name is not configured.

*Displaying the SPBM I-SID information*

Use the following procedure to display the SPBM Service Instance Identifier (I-SID) information. The SPBM B-MAC header includes an I-SID with a length of 24 bits. This I-SID can be used to identify and transmit any virtualized traffic in an encapsulated SPBM frame.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **I-SID** tab.

**I-SID field descriptions**

Use the data in the following table to use the **I-SID** tab.

Name	Description
<b>SysId</b>	Indicates the system identifier.
<b>Vlan</b>	Indicates the B-VLAN where this I-SID was configured or discovered.
<b>Isid</b>	Indicates the IS-IS SPBM I-SID identifier.
<b>NickName</b>	Indicates the nickname of the node where this I-SID was configured or discovered.
<b>HostName</b>	Indicates the host name listed in the LSP, or the system name if the host name is not configured.
<b>Type</b>	Indicates the SPBM I-SID type; either configured or discovered.

*Displaying Level 1 Area information*

Use the following procedure to display Level 1 area information. IS-IS provides support for hierarchical routing, which enables you to partition large routing domains into smaller areas. IS-IS uses a two-level hierarchy, dividing the domain into multiple Level 1 areas and one Level 2 area. The Level 2 area serves as backbone of the domain, connecting to all the Level 1 areas.

**Important**

The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **L1 Area** tab.

**L1 Area field descriptions**

Use the data in the following table to use the **L1 Area** tab.

Name	Description
<b>AreaAddr</b>	Specifies an area address reported in a Level 1 link-state packets (LSP) generated or received by this Intermediate System.

### Configuring SMLT parameters for SPBM

Use the following procedure to configure the required Split MultiLink Trunking (SMLT) parameters to allow SPBM to interoperate with SMLT on the switch.

#### Note

- The assignment of primary and secondary roles to the vIST peers is automatic. The switch with the lower system ID (between the two vIST peers) is primary, and the switch with the higher system ID is secondary when default system-id values are being used.
- SMLT peer system ID is part of the required configuration. You must configure the SMLT peer system ID as the nodal MAC of the peer device. In the IS-IS network, the nodal MAC of devices should be eight apart from each other.
- When using the default hardware assigned system-id value, the SMLT Virtual BMAC is automatically derived by comparing the system-id values of the two vIST peers. A value of 0x01 plus the lower of the two system-id values is used as the SMLT Virtual BMAC.

When using a manually configured system-id value, the SMLT Virtual BMAC must also be manually configured.

- An I-SID must be assigned to every VLAN that is a member of an L2 VSN. Also if an L2 VSN is created on one vIST Peer, it must also be created on the other vIST peer.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **SPBM** tab.
3. Use the **SmltSplitBEB** field to see whether the switch is the primary or secondary vIST peer. This field cannot be modified.
4. Use the **SmltVirtualBmac** field to specify a virtual MAC address that can be used by both peers.
5. Use the **SmltPeerSysId** field to specify the vIST peer B-MAC address.
6. Click **Apply**.

### Enabling or disabling SPBM at the global level

Use the following procedure to enable or disable SPBM at the global level. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Globals** tab.
4. To enable or disable SPBM, click **enable** or **disable** in the **GlobalEnable** field.

5. To configure the global ethertype value, click the desired option in the **GlobalEtherType** field.
6. Click **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>GlobalEnable</b>	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
<b>GlobalEtherType</b>	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
<b>NicknameServerEnable</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Enables or disables the nickname server. The default is disabled.
<b>NicknameDynamicAllocationStatus</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Displays the Dynamic Nickname Allocation service operational status. This value is read-only.
<b>NicknameServerRange</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname allocation range for Dynamic Nickname Assignment. Select <b>none</b> to use the range 0.00.00-0.0F.FF. The default is rangeA (A.00.00 to A.FF.FF).
<b>NicknameServerPrefix</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.FF.FF.

### Configuring SPBM parameters

Use the following procedure to configure SPBM global parameters. SPBM uses the Intermediate-System-to-Intermediate-System (IS-IS) link state routing protocol to provide a loop free Ethernet topology that creates a shortest path topology from every node to every other node in the network based on node MAC addresses.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **SPBM** tab.
4. To create an SPBM instance, click **Insert**.

5. Configure the SPBM parameters.
6. Click **Apply**.

### SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
<b>Id</b>	Specifies the SPBM instance ID. Only one SPBM instance is supported.
<b>NodeNickName</b>	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
<b>PrimaryVlan</b>	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
<b>Vlans</b>	Specifies the SPBM B-VLANs to add to the SPBM instance.
<b>LsdbTrap</b>	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
<b>IpShortcut</b>	Enables or disables SPBM IP shortcut state. The default is disable.
<b>SmltSplitBEB</b>	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
<b>SmltVirtualBmac</b>	Specifies a virtual MAC address that can be used by both peers.
<b>SmltPeerSysId</b>	Specifies the system ID of the SPBM SMLT for this SPBM instance.
<b>Mcast</b>	Specifies if IP multicast over SPBM is enabled. The default is disabled.
<b>McastFwdCacheTimeout</b>	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
<b>Ipv6Shortcut</b>	Enables or disables SPBM IPv6 shortcut state. The default is disable.
<b>McastSpbPimGwControllerEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
<b>McastSpbPimGwGatewayEnable</b>	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.
<b>StpMultiHoming</b>	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
<b>BVlanOrigin</b>	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.
<b>Note:</b> Exception: not supported on XA1400 Series and VSP 8600 Series.	

*Displaying SPBM nicknames*

Use the following procedure to display SPBM nicknames.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Nick Names** tab.

**Nickname field descriptions**

Use the data in the following table to use the **NickName** tab.

Name	Description
<b>Level</b>	Indicates the level at which this LSP appears.
<b>ID</b>	Indicates the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.
<b>LifetimeRemain</b>	Indicates the remaining lifetime in seconds for the LSP.
<b>NickName</b>	Indicates the nickname for the SPBM node.
<b>HostName</b>	Indicates the hostname listed in the LSP, or the system name if the host name is not configured.

*Configuring interface SPBM parameters*

Use the following procedure to configure SPBM interface parameters.

**Procedure**

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Interfaces SPBM** tab.
4. Configure the SPBM interface parameters.
5. Click **Apply**.

**Interfaces SPBM Field Descriptions**

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
<b>Index</b>	Specifies an Index value for the SPBM interface.
<b>SpbmId</b>	Specifies the SPBM ID.
<b>State</b>	Specifies whether the SPBM interface is enabled or disabled.
<b>Type</b>	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported.

Name	Description
<b>L1Metric</b>	Configures the SPBM instance l1-metric on the IS-IS interface located on the specified port or MLT. The default value is 10.
<b>Origin</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

### Configuring SPBM on an interface

Use the following procedure to configure SPBM on an interface.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Click the **SPBM** button.
5. In the **Interfaces SPBM** tab, click **Insert**.
6. Click **Insert**.

#### SPBM field descriptions

Use the data in the following table to use the **Interfaces SPBM** tab.

Name	Description
<b>Index</b>	Specifies an Index value for the SPBM interface.
<b>SpbmId</b>	Specifies the SPBM ID.
<b>State</b>	Specifies whether the SPBM interface is enabled or disabled.
<b>Type</b>	Configures the SPBM instance interface-type on the IS-IS interface located on the specified port or MLT: ptpt or bcast. Only the point-to-point (ptpt) interface type is supported.
<b>L1Metric</b>	Configures the SPBM instance l1-metric on the IS-IS interface located on the specified port or MLT. The default value is 10.
<b>Origin</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the source of the SPBM instance configuration, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

### Displaying the IP unicast FIB

Use the following procedure to display the IP unicast Forwarding Information Base (FIB). The tab shows IP routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

The **IP Unicast FIB** tab displays all of the IS-IS routes in the IS-IS LSDB. The Preference column in the **IP Unicast FIB** tab displays the IP route preference.

Routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. IS-IS accept policies allow you to change the route preference for incoming routes. If the same route is learned from multiple sources with different route preferences, then the routes are not considered equal cost multipath (ECMP) routes. The route with the lowest route preference is the preferred route. In Layer 2, in the event of a tie-break between routes from multiple sources, the tie-breaking is based on cost and hop count.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **IP Unicast FIB** tab.

### IP Unicast FIB field descriptions

Use the data in the following table to use the **IP Unicast FIB** tab.

Name	Description
<b>Vrfid</b>	Specifies the VRF ID of the IP unicast FIB entry, 0 indicates NRE.
<b>DestinationIpAddrType</b>	Specifies the address type of the destination IP address.
<b>DestinationIpAddr</b>	Specifies the destination IP Address of the IP unicast FIB entry.
<b>DestinationMask</b>	Specifies the destination IP mask of the IP unicast FIB entry
<b>NextHopBmac</b>	Specifies the nexthop B-MAC of the IP unicast FIB entry.
<b>DestId</b>	Specifies the destination ISID of the IP unicast FIB entry.
<b>Vlan</b>	Specifies the VLAN of the IP unicast FIB entry.
<b>Isid</b>	Specifies the I-SID of the IP unicast FIB entry.
<b>NextHopName</b>	Specifies the nexthop hostname of the IP unicast FIB entry.

Name	Description
<b>OutgoingPort</b>	Specifies the outgoing port of the IP unicast FIB entry.
<b>PrefixCost</b>	Specifies the prefix cost of the IP unicast FIB entry.
<b>SpbmCost</b>	Specifies the B-MAC cost of the IP unicast FIB entry.
<b>Preference</b>	Specifies the IP Route preference of the IP unicast FIB entry
<b>MetricType</b>	Specifies the IP Metric Type of the IP unicast FIB entry.

### Displaying the IPv6 unicast FIB

Use the following procedure to display the IPv6 unicast Forwarding Information Base (FIB). The tab shows IPv6 routes from remote Backbone Edge Bridges (BEBs)

In SPBM, each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB). When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

I-SIDs are only used for virtual services (Layer 2 VSNs and Layer 3 VSNs). If you only enable IP Shortcuts on the Backbone Edge Bridges, I-SIDs are never exchanged in the network as IP Shortcuts allows for Global Routing Table (GRT) IP networks to be transported across IS-IS.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **IPv6 Unicast FIB** tab.

### IPv6 Unicast FIB Field Descriptions

Use the data in the following table to use the **IPv6 Unicast FIB** tab.

Name	Description
<b>Vrfid</b>	Specifies the VRF ID of the IPv6 unicast FIB entry, 0 indicates NRE.
<b>DestinationIpAddrType</b>	Specifies the address type of the destination IPv6 address.
<b>DestinationIpAddr</b>	Specifies the destination IPv6 Address of the IPv6 unicast FIB entry.
<b>DestinationMask</b>	Specifies the destination IPv6 mask of the IPv6 unicast FIB entry
<b>NextHopBmac</b>	Specifies the nexthop B-MAC of the IPv6 unicast FIB entry.
<b>DestIsid</b>	Specifies the destination I-SID of the IPv6 unicast FIB entry.
<b>Vlan</b>	Specifies the VLAN of the IPv6 unicast FIB entry.
<b>Isid</b>	Specifies the I-SID of the IPv6 unicast FIB entry.
<b>NextHopName</b>	Specifies the nexthop hostname of the IPv6 unicast FIB entry.

Name	Description
<b>OutgoingPort</b>	Specifies the outgoing port of the IPv6 unicast FIB entry.
<b>PrefixCost</b>	Specifies the prefix cost of the IPv6 unicast FIB entry.
<b>SpbmCost</b>	Specifies the B-MAC cost of the IPv6 unicast FIB entry.
<b>MetricType</b>	Specifies the Metric Type of the IPv6 unicast FIB entry.

### Displaying the unicast FIB

Use the following procedure to display the unicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Unicast FIB** tab.

### Unicast FIB field descriptions

Use the data in the following table to use the **Unicast FIB** tab.

Name	Description
<b>SysId</b>	Specifies the system ID of the node where the unicast FIB entry originated.
<b>Vlan</b>	Specifies the VLAN of the unicast FIB entry.
<b>DestinationMacAddr</b>	Specifies the destination MAC Address of the unicast FIB entry.
<b>OutgoingPort</b>	Specifies the outgoing port of the unicast FIB entry.
<b>HostName</b>	Specifies the host name of the node where unicast FIB entry originated.
<b>Cost</b>	Specifies the cost of the unicast FIB entry.

### Displaying LSP summary information

Use the following procedure to display link-state packet (LSP) summary information. Link State Packets (LSP) contain information about the state of adjacencies or defined and distributed static routes. Intermediate System to Intermediate System (IS-IS) exchanges this information with neighboring IS-IS routers at periodic intervals.

## Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **LSP Summary** tab.

### LSP Summary field descriptions

Use the data in the following table to use the **LSP Summary** tab.

Name	Description
<b>Level</b>	Specifies the level at which this LSP appears.
<b>ID</b>	Specifies the 8 byte LSP ID, consisting of the SystemID, Circuit ID, and Fragment Number.
<b>Seq</b>	Specifies the sequence number for this LSP.
<b>Checksum</b>	Specifies the 16 bit Fletcher Checksum for this LSP.
<b>LifetimeRemain</b>	The remaining lifetime in seconds for this LSP.
<b>HostName</b>	The hostname listed in LSP, or the system name if host name is not configured.

### Displaying IS-IS adjacencies

Use the following procedure to display IS-IS adjacency information. The platform sends IS-IS Hello (IIH) packets to discover IS-IS neighbors and establish and maintain IS-IS adjacencies. The platform continues to send IIH packets to maintain the established adjacencies. For two nodes to form an adjacency the B-VLAN pairs for the primary B-VLAN and secondary B-VLAN must match.

## Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Adjacency** tab.

### Adjacency field descriptions

Use the data in the following table to use the **Adjacency** tab.

Name	Description
<b>Interface</b>	Specifies the IS-IS interface on which the adjacency is found.
<b>Level</b>	Indicates the level of the IS-IS interface (Level 1 [default] or Level 2).
<b>State</b>	Specifies the state of the adjacency: <ul style="list-style-type: none"> <li>• down</li> <li>• initializing</li> <li>• up</li> <li>• failed</li> </ul>

Name	Description
<b>LastUpTime</b>	Indicates when the adjacency most recently entered the state <b>up</b> , measured in hundredths of a second since the last re-initialization of the network management subsystem. Displays 0 if the adjacency has never been in state <b>up</b> .
<b>NeighPriority</b>	Specifies the priority of the neighboring Intermediate System for becoming the Designated Intermediate System.
<b>HoldTimer</b>	Specifies the holding time in seconds for this adjacency. This value is based on received IS-IS Hello (IIH) PDUs and the elapsed time since receipt.
<b>NeighSysID</b>	Specifies the system ID of the neighboring Intermediate System.
<b>AdjHostName</b>	Specifies the host name listed in the LSP, or the system name if host name is not configured.
<b>ParallelActive</b>	Specifies if the current adjacency among all the parallel adjacencies between two nodes is active. <ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>

### Configuring IS-IS global parameters

Use the following procedure to configure IS-IS global parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. From the **Globals** tab, configure the global IS-IS parameters.
4. Click **Apply**.

#### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AdminState</b>	Specifies the global status of IS-IS on the switch: on or off. The default is off.
<b>LevelType</b>	Sets the router type globally: <ul style="list-style-type: none"> <li>• level1: Level-1 router type</li> <li>• level1and2: Level-1/2 router type is not supported.</li> </ul> The default value is level1.

Name	Description
<b>SystemId</b>	<p>Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format &lt;xxxx.xxxx.xxxx&gt;.</p> <p><b>Important:</b> After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 962.</p>
<b>MaxLspGenInt</b>	<p>Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate system. The value must be greater than any value configured for RxmtLsplnt. The default value is 900 seconds.</p>
<b>Csnplnt</b>	<p>Specifies the Complete Sequence Number Packet (CSNP) interval in seconds. This is a system level parameter that applies for L1 CSNP generation on all interfaces. The default value is 10.</p>
<b>RxmtLsplnt</b>	<p>Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for L1 retransmission of LSPs. The default value is 5 seconds.</p>
<b>PSNPInterval</b>	<p>Specifies the Partial Sequence Number Packet (PSNP) interval in seconds. This is a system level parameter that applies for L1 PSNP generation on all interfaces. The default value is 2.</p>
<b>SpfDelay</b>	<p>Specifies the SPF delay in milliseconds. This value is used to pace successive SPF runs. The timer prevents two SPF runs from being scheduled very closely. The default value is 100 milliseconds.</p>
<b>HostName</b>	<p>Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.</p>
<b>IpSourceAddress</b>	<p>Specifies IP source address for SPBM IP shortcuts.</p>
<b>Ipv6SourceAddressType</b>	<p>Click <b>ipv6</b> to use IPv6 addresses.</p>
<b>Ipv6SourceAddress</b>	<p>Specifies IPv6 source address for SPBM IP shortcuts.</p>
<b>IpTunnelSourceAddress</b>	<p>Specifies the IS-IS IP tunnel source address.</p>

Name	Description
<b>IpTunnelVrf</b>	Specifies the VRF name associated with the IP tunnel.
<b>MgmtIpAddr</b>	Specifies the DvR management IP address for this node, in the DvR domain.
<b>BackboneEnable</b>	Select to enable this node to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the network.
<b>FanMember</b>	Specifies whether the node is a member of the Fabric Area Network (FAN) .
<b>DynamicallyLearnedArea</b>	For FAN members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.
<b>TcpAdjustMssEnable</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. By default, this functionality is enabled and auto-derived.
<b>TcpAdjustMssStatus</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Displays the activation status of the MSS adjustment functionality. The MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) greater than or equal to 1500 is configured.
<b>TcpAdjustMssType</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Displays if the MSS adjustment value is manually configured or auto-derived.
<b>TcpAdjustMssValue</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Configures the MSS adjustment value.

### Configuring system-level IS-IS parameters

Use the following procedure to configure system-level IS-IS parameters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
2. Click the **System Level** tab.
3. Configure the IS-IS system level parameters.
4. Click **Apply**.

#### System Level field descriptions

Use the data in the following table to use the **System Level** tab.

Name	Description
<b>Index</b>	Specifies the level: I1 or I2. Only I1 is supported.
<b>State</b>	Specifies the state of the database at this level. The value 'off' indicates that IS-IS is not active at this level. The value 'on' indicates that IS-IS is active at this level, and not overloaded. The value 'waiting' indicates a database that is low on an essential resources, such as memory. The administrator may force the state to 'overloaded' by setting the object <b>SetOverload</b> . If the state is 'waiting' or 'overloaded', you originate LSPs with the Overload bit set.
<b>SetOverload</b>	Sets or clears the overload condition. The possible values are true or false. The default value is false.
<b>SetOverloadUntil</b>	Sets the IS-IS overload-on-startup value in seconds. The overload-on-startup value is used as a timer to control when to send out LSPs with the overload bit cleared after IS-IS startup.  <b>Note:</b> If you configure <b>SetOverloadUntil</b> to a number other than zero, then the overload bit is set at this level when the <b>AdminState</b> variable goes to the state 'on' for this Intermediate System. After the <b>SetOverloadUntil</b> seconds elapse, the overload flag remains set if the implementation runs out of memory or if you configured it manually using <b>SetOverload</b> to true. If <b>SetOverload</b> is false, the system clears the overload bit after <b>SetOverloadUntil</b> seconds elapse, if the system has not run out of memory.  The default value is 20.
<b>MetricStyle</b>	Specifies the IS-IS metric type. Available values are narrow, wide or both. Only wide is supported.

### Displaying IS-IS system statistics

Use the following procedure to display Intermediate-System-to-Intermediate-System (IS-IS) system statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **Stats**.
3. Click the **System Stats** tab.

#### System Stats field descriptions

Use the data in the following table to use the **System Stats** tab.

Name	Description
<b>CorrLSPs</b>	Indicates the number of corrupted in-memory link-state packets (LSPs) detected. LSPs received from the wire with a bad checksum are silently dropped and not counted.
<b>AuthFails</b>	Indicates the number of authentication key failures recognized by this Intermediate System.
<b>LSPDbaseOloads</b>	Indicates the number of times the LSP database has become overloaded.
<b>ManAddrDropFromAreas</b>	Indicates the number of times a manual address has been dropped from the area.
<b>AttmptToExMaxSeqNums</b>	Indicates the number of times the IS has attempted to exceed the maximum sequence number.
<b>SeqNumSkips</b>	Indicates the number of times a sequence number skip has occurred.
<b>OwnLSPPurges</b>	Indicates the number of times a zero-aged copy of the system's own LSP is received from some other node.
<b>IDFieldLenMismatches</b>	Indicates the number of times a PDU is received with a different value for ID field length to that of the receiving system.
<b>PartChanges</b>	Indicates partition changes.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/sec</b>	Displays the average value for each second.
<b>Minimum/sec</b>	Displays the minimum value for each second.
<b>Maximum/sec</b>	Displays the maximum value for each second.
<b>LastVal/sec</b>	Displays the last value for each second.

### Configuring IS-IS interfaces

Use the following procedure to configure IS-IS interfaces. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Configure the IS-IS interface parameters.
5. Click **Apply**.

#### Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>Index</b>	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
<b>IfIndex</b>	Specifies the interface on which the circuit is configured (port or MLT).
<b>Type</b>	Specifies the IS-IS circuit type. Only the point-to-point (PtToPt) interface type is supported.
<b>AdminState</b>	Specifies the administrative state of the circuit: on or off.
<b>OperState</b>	Specifies the operational state of the circuit.
<b>AuthType</b>	<p>Specifies the authentication type:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• simple: If selected, you must also specify a key value but the key id is optional. Simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet.</li> <li>• hmac-md5: If selected, you must also specify a key value, but the key-id is optional. MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. There is an optional key ID.</li> <li>• hmac-sha-256: If selected, you must also specify a key value, but the key-id is optional. With SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. If the digests match, the packet is accepted. If the digests do not match, the receiving switch discards the packet. There is an optional key ID.</li> </ul> <p><b>Note:</b> Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate IS-IS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default is none.</p>
<b>AuthKey</b>	Specifies the authentication key.

Name	Description
<b>KeyId</b>	Specifies the authentication key ID.
<b>LevelType</b>	Specifies the router type globally: <ul style="list-style-type: none"> <li>level1: Level-1 router type</li> <li>level1and2: Level-1/2 router type. This type is not supported.</li> </ul> The default value is level1.
<b>NumAdj</b>	Specifies the number of adjacencies on this circuit.
<b>NumUpAdj</b>	Specifies the number of adjacencies that are up.
<b>AutoNniEnable</b>	Enable to have the node create an IS-IS interface, attach the interface to an SPBM instance, and then enable IS-IS on the port interface. This field displays on the Insert Interfaces dialog box and applies to port interfaces only.
<b>Origin</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the origin of the IS-IS circuit configuration on the port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

### Configuring IS-IS interface level parameters

Use the following procedure to configure IS-IS interface level parameters. SPBM uses IS-IS to discover network topology, build shortest path trees between network nodes, and communicate network information in the control plane.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces Level** tab.
4. Configure the IS-IS interface level parameters.
5. Click **Apply**.

#### Interfaces Level Field Descriptions

Use the data in the following table to use the **Interfaces Level** tab.

Name	Description
<b>Index</b>	The identifier of this circuit, unique within the Intermediate System. This value is for SNMP Indexing purposes only and need not have any relation to any protocol value.
<b>Level</b>	Specifies the router type globally: <ul style="list-style-type: none"> <li>l1: Level1 router type</li> <li>l12: Level1/Level2 router type. This type is not supported.</li> </ul> The default value is l1.

Name	Description
<b>ISPriority</b>	Specifies an integer sub-range for IS-IS priority. The default is 64.
<b>HelloTimer</b>	Configures the level 1 hello interval. Specifies the maximum period, in milliseconds, between IS-IS Hello Packets (IIH) PDUs on multiaccess networks at this level for LANs. The value at Level1 is used as the period between Hellos on Level1/Level2 point to point circuits. Setting this value at Level 2 on an Level1/Level2 point-to-point circuit results in an error of InconsistentValue. The default value is 9000 milliseconds or 9 seconds.
<b>HelloMultiplier</b>	Configures the level 1 hello multiplier. The default value is 3 seconds.
<b>DRHelloTimer</b>	Indicates the period, in milliseconds, between Hello PDUs on multiaccess networks when this Intermediate System is the Designated Intermediate System. The default is 3.

### Displaying IS-IS interface counters

Use the following procedure to display IS-IS interface counters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **Stats**.
3. Click the **Interface Counters** tab.

#### Interface Counters field descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
<b>Index</b>	Shows a unique value identifying the IS-IS interface.
<b>Level</b>	Shows the type of circuit that discovered the interface counters. The point to point Hello PDU includes both L1 and L2, and IS from a single adjacency on point to point links, therefore combining counts on point to point links into one group.
<b>AdjChanges</b>	Shows the number of times an adjacency state change has occurred on this circuit.
<b>InitFails</b>	Shows the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures. Failures to form an adjacency are counted by isisCircRejAdjs.
<b>RejAdjs</b>	Shows the number of times an adjacency has been rejected on this circuit.
<b>IDFieldLenMismatches</b>	Shows the number of times an IS-IS control PDU with an ID field length different to that for this system has been received.

Name	Description
<b>MaxAreaAddrMismatches</b>	Shows the number of times an IS-IS control PDU with a max area address field different to that for this system has been received.
<b>AuthFails</b>	Shows the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
<b>LANDesISChanges</b>	Shows the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.

### Displaying IS-IS interface control packets

Use the following procedure to display IS-IS interface control packets.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **Stats**.
3. Click the **Interface Control Packets** tab.

#### Interface Control Packets field descriptions

Use the data in the following table to use the **Interface Control Packets** tab.

Name	Description
<b>Index</b>	Shows a unique value identifying the Intermediate-System-to-Intermediate-System (IS-IS) interface.
<b>Direction</b>	Indicates whether the switch is sending or receiving the PDUs.
<b>Hello</b>	Indicates the number of IS-IS Hello frames seen in this direction at this level.
<b>LSP</b>	Indicates the number of IS-IS LSP frames seen in this direction at this level.
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packets (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNP) frames seen in this direction at this level.

### Graphing IS-IS interface counters

Use the following procedure to graph IS-IS interface counters.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Select an existing interface.
5. Click the **Graph** button.

### Interface Counters field descriptions

The following table describes the fields in the **Interface Counters** tab.

Name	Description
<b>InitFails</b>	Indicates the number of times initialization of this circuit has failed. This counts events such as PPP NCP failures.
<b>RejAdjs</b>	Indicates the number of times an adjacency has been rejected on this circuit.
<b>IDFieldLenMismatches</b>	Indicates the number of times an Intermediate-System-to-Intermediate-System (IS-IS) control PDU with an ID field length different from that for this system has been received.
<b>MaxAreaAddrMismatches</b>	Indicates the number of times an IS-IS control PDU with a max area address field different from that for this system has been received.
<b>AuthFails</b>	Indicates the number of times an IS-IS control PDU with the correct auth type has failed to pass authentication validation.
<b>LANDesISChanges</b>	Indicates the number of times the Designated IS has changed on this circuit at this level. If the circuit is point to point, this count is zero.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

### Graphing IS-IS interface sending control packet statistics

Use the following procedure to graph IS-IS interface receiving control packet statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Select an existing interface.
5. Click the **Graph** button.
6. Click the **Interface Sending Control Packets** tab.

### Interface Sending Control Packets field descriptions

The following table describes the fields in the **Interface Sending Control Packets** tab.

Name	Description
<b>Hello</b>	Indicates the number of IS-IS Hello (IIH) PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on L1 or L1L2 circuits, and at L2 otherwise.
<b>LSP</b>	Indicates the number of IS-IS LSP frames seen in this direction at this level.
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

### Graphing IS-IS interface receiving control packet statistics

Use the following procedure to graph IS-IS interface sending control packet statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Interfaces** tab.
4. Select an existing interface.
5. Click the **Graph** button.
6. Click the **Interface Receiving Control Packets** tab.

#### Interface Receiving Control Packets field descriptions

The following table describes the fields in the **Interface Receiving Control Packets** tab.

Name	Description
<b>Hello</b>	Indicates the number of IS-IS Hello PDUs seen in this direction at this level. Point-to-Point IIH PDUs are counted at the lowest enabled level: at L1 on L1 or L1L2 circuits, and at L2 otherwise.
<b>LSP</b>	Indicates the number of IS-IS link-state packet (LSP) frames seen in this direction at this level.
<b>CSNP</b>	Indicates the number of IS-IS Complete Sequence Number Packet (CSNP) frames seen in this direction at this level.
<b>PSNP</b>	Indicates the number of IS-IS Partial Sequence Number Packets (PSNPs) seen in this direction at this level.

Name	Description
<b>AbsoluteValue</b>	Displays the counter value.
<b>Cumulative</b>	Displays the total value since you opened the Stats tab.
<b>Average/Sec</b>	Displays the average value for each second.
<b>Minimum/Sec</b>	Displays the minimum value for each second.
<b>Maximum/Sec</b>	Displays the maximum value for each second.
<b>Last Val/Sec</b>	Displays the last value for each second.

### Configuring an IS-IS Manual Area

Use the following procedure to configure an IS-IS manual area.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **IS-IS**.
3. Click the **Manual Area** tab.
4. Click **Insert**.
5. Specify an Area Address in the **AreaAddr** field, and click **Insert**.

#### Manual Area field descriptions

Use the data in the following table to use the **Manual Area** tab.

Name	Description
<b>AreaAddr</b>	Specifies the IS-IS manual area. Valid value is 1-13 bytes in the format <xx.xxxx.xxxx...xxxx>. Only one manual area is supported. Use the same manual area across the entire SPBM cloud. For IS-IS to operate, you must configure at least one manual area.

### Configure Dynamic Nickname Assignment

#### About This Task

Use this procedure to enable Dynamic Nickname Assignment and specify a nickname allocation range.

#### Note

You must disable Dynamic Nickname Assignment before you can change the nickname allocation range.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **Globals** tab.
4. To enable the Nick-name server, select **enable** in the **NicknameServerEnable** field.

- In the **NicknameServerRange** field, select the nickname server allocation range or in **NicknameServerPrefix**, type a prefix.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>GlobalEnable</b>	Enables or disables SPBM globally. The default is disabled. To ensure proper cleanup of MAC tables after you disable SPBM, save the configuration, and then reboot the switch.
<b>GlobalEtherType</b>	Specifies the global ethertype value as 0x8100 or 0x88a8. The default value is 0x8100.
<b>NicknameServerEnable</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Enables or disables the nickname server. The default is disabled.
<b>NicknameDynamicAllocationStatus</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Displays the Dynamic Nickname Allocation service operational status. This value is read-only.
<b>NicknameServerRange</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname allocation range for Dynamic Nickname Assignment. Select <b>none</b> to use the range 0.00.00-0.0F.FF. The default is rangeA (A.00.00 to A.FF.FF).
<b>NicknameServerPrefix</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series or XA1400 Series.	Specifies the nickname server allocation prefix. x.xx.xx uses the form X.X0.00 from 0.00.00 to F.F0.00. A group, X.X0.00 to X.XF.FF, can provide up to 4,096 nicknames. The default nickname allocation range is A.00.00-A.FF.FF.

## Fabric Extend Configuration using EDM

The following sections provide procedural information you can use to configure Fabric Extend (FE) using Enterprise Device Manager (EDM).

For information about how to configure an IPsec NAT-T Responder, see [IPsec configuration using EDM](#) on page 1710.

### *Configure Fabric Extend Tunnels*

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office. This is a typical deployment. However, if your deployment creates tunnels between two switches that

support Fabric Extend natively, then repeat those steps and ignore the steps for switches that require an ONA.

**Note**

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

**Before You Begin**

The tunnel source IP address can be either a brouter port IP, a CLIP IP, or a VLAN IP.

**Note**

Product Notice: Except VSP 8600 Series, all product series support a VLAN IP as the Fabric Extend tunnel source IP address.

If using the tunnel originating address on the GRT, Fabric Extend has the following requirements:

- The tunnel source IP address must be on the GRT, not on a VRF.

**Note**

A best practice is to use separate IP addresses for the SPBM IP Shortcuts **ip-source-address** command and the Fabric Extend **ip-tunnel-source-address** command. However, if you want these IP addresses to be the same, you **MUST** exclude the **ip-source-address** address with an IS-IS accept policy. You cannot use the redistribute command with a route map exclusion.

Specify a CLIP interface to use as the source address for SPBM IP shortcuts.

- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.

If you are using the tunnel originating address on a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the VRF.
- Remote management of the VSP 4450 Series is possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

**About This Task**

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

Note that the VSP 4450 Series source address command is different than other platforms. Also note that the logical interface commands are different between Layer 2 and Layer 3 networks.

**Procedure**

The following steps are for platforms that support FE natively:

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select the **Globals** tab.
4. In the **IpTunnelSourceAddress** field, enter the IP tunnel source address.
5. If you are using a VRF, select **IpTunnelVrf** field.

6. Select **Apply**.

The following steps are for platforms that require an ONA to support FE:

**Note**

The interface VLAN connecting to the ONA network port is always in the GRT and the member port that the VLAN is part of is always an access port.

7. In the navigation pane, expand **Configuration > IS-IS**.
8. Select **IS-IS**.
9. Select the **Globals** tab.
10. In the **IpTunnelSourceAddress** field, enter the IP tunnel source address.
11. In the **IpTunnelPort** field, select the physical port that the logical interface is connected to in an L2 network.
12. If you are using a VRF, select its name from the list for **IpTunnelVrf**.
13. In the **IpTunnelMtu** field, enter a value between 750 and 1950 to specify the size of the maximum transmission unit (MTU).
14. Select **Apply**.

### Fabric Extend Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>IpTunnelSourceAddress</b>	Specifies the IS-IS IPv4 tunnel source address.
<b>IpTunnelPort</b>	Specifies the physical port that the logical interface is connected to in an L2 network. The parameter is for the VSP 4450 Series only.
<b>IpTunnelVrf</b>	Specifies the VRF name associated with the IP tunnel.
<b>IpTunnelMtu</b>	Specifies the size of the maximum transmission unit (MTU). The default is 1950. This parameter applies to an ONA configuration only.

### Configure Fabric Extend Logical Interfaces

Use the following procedure to configure Fabric Extend (FE) between a Main office to a Branch office. This is a typical deployment. However, if your deployment creates tunnels between two switches that support Fabric Extend natively, repeat those steps and ignore the steps for switches that require an ONA.

**Note**

VRF is an optional parameter. If a VRF is not configured, then FE uses the GRT.

## About This Task

Configuring Fabric Extend consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

### Note

The VSP 4450 Series source address command is different than other platforms. The logical interface commands are different between Layer 2 and Layer 3 networks.

## Procedure

The following steps are for platforms that support FE natively:

1. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
2. Select the **Logical Interfaces** tab.
3. Select **Insert**.
4. In the **Id** field, enter the index number that uniquely identifies this logical interface.
5. In the **Name** field, enter the name of this logical interface.
6. In the **Type** field, select the type of core network that the tunnel will traverse. If it is a Layer 2 Core, select **layer2**. If it is a Layer 3 Core, select **ip**.

### Note

Different fields will be available depending on the type of core network you select.

7. To enable BFD, select **enable** in the **BFDEnable** field.
8. For a Layer 2 Core, configure the following fields:

### Note

This step does not apply to XA1400 Series.

- a. In the **DestIfIndex** field, select the ellipsis (...) to select the physical port that the logical interface connects to or enter the name of the MLT.
- b. In the **Vids** field, enter the list of VLANs for this logical interface.
- c. In the **PrimaryVid** field, enter the primary tunnel VLAN ID.

### Note

The primary VLAN ID must be one of the VLANs listed in the **Vids** field.

9. For a Layer 3 Core, complete the following field:
  - a. In the **DestIPAddr** field, enter the destination IP address for the logical interface.
10. (Optional) In the **IpssecCompression** field, select whether to enable compression for a Fabric Extend over IPsec connection.

### Note

This step only applies to XA1400 Series.

11. In the **IpsecEnable** field, select whether to enable a Fabric Extend over IPsec connection for the logical interface.

**Note**

This step only applies to XA1400 Series.

12. Select the IPsec authentication method.

**Note**

This step only applies to XA1400 Series.

13. (Optional) For a pre-shared key, in the **AuthenticationKey** field, enter the authentication key to secure your Fabric Extend over IPsec connection for the logical interface.

**Note**

This step only applies to XA1400 Series.

14. In the **ShapingRate** field, enter the value in Mbps of the shaper used for Egress Tunnel Shaping.

**Note**

This step only applies to XA1400 Series.

15. In the **Mtu** field, enter a value to specify the size of the maximum transmission unit (MTU).

16. In the **EncryptionKeyLength** field, select the IPsec encryption key length.

**Note**

This step only applies to XA1400 Series.

- You cannot change the encryption key length when IPsec is enabled on the FE tunnel.

17. In the **IpsecTunnelDestAddress** field, enter the destination IP address for the IPsec tunnel.

**Note**

This step only applies to XA1400 Series.

18. Select **Insert**.

The following steps are for platforms that require an ONA to support FE:

**Note**

The interface VLAN connecting to the ONA network port is always in the GRT, and the member port that the VLAN is part of is always an access port.

19. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.

20. Select the **Logical Interfaces** tab.

21. Select **Insert**.

22. In the **Id** field, enter the index number that uniquely identifies this logical interface.

23. In the **Name** field, enter the name of this logical interface.

24. In the **Type** field, select the type of core network that the tunnel will traverse. If it is a Layer 2 Core, select **layer2**. If it is a Layer 3 Core, select **ip**.

**Note**

Different fields will be available depending on the type of core network you select.

25. For a Layer 2 Core, complete the following fields:

- a. In the **DestIfIndex** field, select the ellipsis (...) to select the physical port that the logical interface connects to or enter the name of the MLT.
- b. In the **Vids** field, enter the list of VLANs for this logical interface.
- c. In the **PrimaryVid** field, enter the primary tunnel VLAN ID.

**Note**

The primary VLAN ID must be one of the VIDs listed in the **Vids** field.

26. For a Layer 3 Core, configure the following field:

- a. in the **DestIPAddr** field, enter the destination IP address for the logical interface.

27. In the **IpssecEnable** field, select whether to enable a Fabric Extend over IPsec connection for the logical interface.

28. In the **AuthenticationKey** field, enter the authentication key to secure your Fabric Extend over IPsec connection for the logical interface.

29. In the **ShapingRate** field, enter the value in Mbps of the shaper used for Egress Tunnel Shaping.

30. Select **Insert**.

### Logical Interfaces Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

Name	Description
<b>Id</b>	Specifies the index number that uniquely identifies this logical interface. This field displays on the <b>Insert Logical Interfaces</b> dialog only.
<b>IfIndex</b>	Specifies the index number that uniquely identifies this logical interface. This field is read-only. This field displays on the <b>Logical Interfaces</b> tab only.
<b>Name</b>	Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.
<b>Type</b> <b>Note:</b> Exception: Type Layer 2 is not supported on XA1400 Series.	Specifies the type of logical interface to create: <ul style="list-style-type: none"> <li>• Specify <b>layer 2</b> for a Layer 2 core network that the tunnel will traverse.</li> <li>• Specify <b>ip</b> for a Layer 3 core network that the tunnel will traverse.</li> </ul>
<b>DestIPAddr</b>	Specifies the destination IP address for the IP-type logical interface.

Name	Description
<b>DestIfIndex</b> <b>Note:</b> Exception: Not supported on XA1400 Series.	Specifies the physical port or MultiLink Trunking (MLT) that the Layer 2 logical interface is connected to.
<b>Vids</b> <b>Note:</b> Exception: Not supported on XA1400 Series.	Specifies the list of VLANs that are associated with this logical interface.
<b>PrimaryVid</b> <b>Note:</b> Exception: Not supported on XA1400 Series.	Specifies the primary tunnel VLAN ID associated with this L2 Intermediate-System-to-Intermediate-System (IS-IS) logical interface.
<b>CircIndex</b> <b>Note:</b> Exception: Not supported on XA1400 Series.	Identifies the IS-IS circuit created under the logical interface. This field displays on the <b>Logical Interfaces</b> tab only.
<b>NextHopVrf</b> <b>Note:</b> Exception: Not supported on XA1400 Series.	Identifies the next-hop VRF name to reach the logical tunnel destination IP. This field displays on the <b>Logical Interfaces</b> tab only.
<b>IpssecEnable</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies whether the logical interace should use IPsec.
<b>AuthenticationKey</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies the authentication key of this logical interface, which can be up to 32 characters.
<b>ShapingRate</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies the value, in Mbps, of the Egress Tunnel Shaper applied to the logical interface.
<b>Mtu</b>	Specifies the Maximum Transmission Unit (MTU) size for each logical interface. The default MTU value is 1950.

Name	Description
<b>EncryptionKeyLength</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies the IPsec encryption key length for FE tunnel, which can be 128 bit or 256 bit. The default value is len128bit.
<b>IpsecTunnelDestAddress</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies the destination IP address for the IPsec tunnel.
<b>BfdEnable</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series or VSP 4450 Series.	Enables or disables BFD on an IS-IS Logical Interface.
<b>IpsecResponderOnly</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies whether the device is a Responder device in an IPsec Network Address Translation Traversal (NAT-T) connection.
<b>IpsecRemoteNatIPAddr</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Specifies the public IP address of the NAT router connected to the Responder device in an IPsec NAT-T connection.
<b>IpsecAuthMethod</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Configures the IPsec authentication method for the tunnel as either a pre-shared key or RSA signature for digital certificates. The default is pre-shared key.
<b>IpsecCompression</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Reduces the size of the IP datagram to improve the communication performance between hosts connected behind Backbone Edge Bridges (BEB).  <b>Tip:</b> As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms.

*Adjust the TCP Maximum Segment Size*

**Note**

This procedure only applies to XA1400 Series.

Adjust the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. By default, this functionality is enabled and auto-derived.

#### Tip

As a best practice, turn off this enhancement on the head-end side and keep this enabled only at the branch side.

### About This Task

The MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) greater than or equal to 1500 is configured. The functionality is inactive if no FE tunnels with MTU greater than or equal to 1500 are configured. Deleting the last tunnel with MTU greater than or equal to 1500 results in the functionality becoming inactive.

The switch can auto-derive the MSS value based of the tunnel MTUs or you can manually configure the MSS value. The formula for the auto-derived value is  $\min(\text{Tunnels MTUs}) - 250B$  (size for VXLAN + MIM + IPSEC + IP+TCP headers). If you configure multiple FE tunnels with MTU greater than or equal to 1500, then the switch uses the lowest of all tunnel MTUs to auto-derive the TCP MSS adjust value. The same value applies to all TCP syn packets that transmit NNI to UNI and UNI to NNI.

The switch does not support different TCP adjust MSS values if you configure different FE tunnel MTUs on different tunnels.

If you configure FE tunnels and regular NNIs on the same adjacency, then the TCP adjust MSS value applies to all TCP packets traversing across regular NNIs and FE tunnels.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > .**
2. Select **IS-IS**.
3. Select the **Globals** tab.
4. Select the **TcpAdjustMssEnable** field to enable this functionality.
5. (Optional) Enter a value in the **TcpAdjustMssValue** field.
6. Select **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AdminState</b>	Specifies the global status of IS-IS on the switch: on or off. The default is off.
<b>LevelType</b>	Sets the router type globally: <ul style="list-style-type: none"> <li>• level1: Level-1 router type</li> <li>• level1and2: Level-1/2 router type is not supported.</li> </ul> The default value is level1.

Name	Description
<b>SystemId</b>	<p>Specifies the IS-IS system ID for the switch. Valid value is a 6-byte value in the format &lt;xxxx.xxxx.xxxx&gt;.</p> <p><b>Important:</b> After you have configured the SPBM nickname and enabled IS-IS, if you require a change of the system ID, you must also change the nickname. However, for naming convention purposes or configuration purposes, you may not want to change the nickname. To maintain the same nickname with a different system ID, see <a href="#">Job aid</a> on page 962.</p>
<b>MaxLspGenInt</b>	<p>Specifies the maximum interval, in seconds, between generated LSPs by this Intermediate system. The value must be greater than any value configured for RxmtLsplnt. The default value is 900 seconds.</p>
<b>Csnplnt</b>	<p>Specifies the Complete Sequence Number Packet (CSNP) interval in seconds. This is a system level parameter that applies for L1 CSNP generation on all interfaces. The default value is 10.</p>
<b>RxmtLsplnt</b>	<p>Specifies the minimum time between retransmission of an LSP. This defines how fast the switch resends the same LSP. This is a system level parameter that applies for L1 retransmission of LSPs. The default value is 5 seconds.</p>
<b>PSNPInterval</b>	<p>Specifies the Partial Sequence Number Packet (PSNP) interval in seconds. This is a system level parameter that applies for L1 PSNP generation on all interfaces. The default value is 2.</p>
<b>SpfDelay</b>	<p>Specifies the SPF delay in milliseconds. This value is used to pace successive SPF runs. The timer prevents two SPF runs from being scheduled very closely. The default value is 100 milliseconds.</p>
<b>HostName</b>	<p>Specifies a name for the system. This may be used as the host name for dynamic host name exchange in accordance with RFC 2763. By default, the system name comes from the host name configured at the system level.</p>
<b>IpSourceAddress</b>	<p>Specifies IP source address for SPBM IP shortcuts.</p>
<b>Ipv6SourceAddressType</b>	<p>Click <b>ipv6</b> to use IPv6 addresses.</p>
<b>Ipv6SourceAddress</b>	<p>Specifies IPv6 source address for SPBM IP shortcuts.</p>
<b>IpTunnelSourceAddress</b>	<p>Specifies the IS-IS IP tunnel source address.</p>

Name	Description
<b>IpTunnelVrf</b>	Specifies the VRF name associated with the IP tunnel.
<b>MgmtIpAddr</b>	Specifies the DvR management IP address for this node, in the DvR domain.
<b>BackboneEnable</b>	Select to enable this node to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the network.
<b>FanMember</b>	Specifies whether the node is a member of the Fabric Area Network (FAN) .
<b>DynamicallyLearnedArea</b>	For FAN members, specifies the IS-IS area that is dynamically learned from the neighbor's Hello PDU if the node does not have the IS-IS manual area configured.
<b>TcpAdjustMssEnable</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. By default, this functionality is enabled and auto-derived.
<b>TcpAdjustMssStatus</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Displays the activation status of the MSS adjustment functionality. The MSS adjustment functionality only activates when at least one FE tunnel with a maximum transmission unit (MTU) greater than or equal to 1500 is configured.
<b>TcpAdjustMssType</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Displays if the MSS adjustment value is manually configured or auto-derived.
<b>TcpAdjustMssValue</b> <b>Note:</b> Exception: Only supported on XA1400 Series.	Configures the MSS adjustment value.

### *Display the Logical Interface Next Hop*

Use the following procedure to display the next hop for the logical interface.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS > IS-IS**.
2. Select the **Logical Interfaces NextHop** tab.

#### **Logical Interfaces NextHop field descriptions**

Use the data in the following table to use the **Logical Interfaces NextHop** tab.

Name	Description
<b>Id</b>	Shows a unique value that identifies the logical interface tunnel.
<b>Ip</b>	Shows a unique value that identifies the next hop IP address of the logical interface tunnel.
<b>DestIfIndex</b>	Shows the next hop destination interface index to reach the next hop IP of the logical interface tunnel.
<b>DestVid</b>	Shows the next hop destination VLAN ID to reach the next hop IP of the logical interface tunnel.

## Fabric Attach configuration using the EDM

The following sections provide procedural information you can use to configure Fabric Attach (FA) and Logical Link Discovery Protocol (LLDP) using Enterprise Device Manager (EDM). For information about LLDP related to FA, see [Link Layer Discovery Protocol configuration using EDM](#) on page 2133.

### Configure Fabric Attach Globally

Use this procedure to configure FA globally or view existing FA global configuration.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Globals** tab.
4. To enable or disable the Fabric Attach service, click **enabled** or **disabled** in the **Service** field.

#### Caution

Disabling FA flushes all FA element discovery and mappings.

5. View the element type in the **ElementType** field.

#### Note

The only supported element type is **faServer** (FA Server).

6. To specify the assignment time-out, enter a time-out value in seconds in the **AsgnTimeout** field.
7. View the provision mode in the **ProvisionMode** field.

#### Note

The supported provision mode is **spbm**.

8. To specify the discovery time-out, enter a time-out value in seconds in the **DiscTimeout** field.
9. To clear the FA statistics, select the **Clear FA Statistics** checkbox.
10. To clear the error counters, select the check boxes **ClearErrorCounters** and/or **ClearGlobalErrorCounters**.
11. Click **Apply**.

### Fabric Attach Globals Field Descriptions

Use the data in the following table to use the **Fabric Attach Globals** tab.

Name	Description
<b>Service</b>	Enables or disables Fabric Attach service globally. The default is enable.
<b>ElementType</b>	Specifies the Fabric Attach element type. The supported element type is Fabric Attach Server.
<b>AsgnTimeout</b>	Specifies the Fabric Attach assignment time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.
<b>ProvisionMode</b>	Specifies the Fabric Attach provision mode. The supported provision mode is SPB.
<b>DiscTimeout</b>	Specifies the Fabric Attach discovery time-out in seconds. The range is 45 to 480 seconds. The default is 240 seconds.
<b>Clear FA Statistics</b>	Clears Fabric Attach statistics.
<b>ClearGlobalErrorCounters</b>	Clears Fabric Attach global error counters. Disabled by default.

### Configure Fabric Attach I-SID-to-VLAN Assignments

Use this procedure to view or configure FA I-SID-to-VLAN assignment information.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Assignment** tab.
4. If you make configuration changes, click **Apply** to save changes.

### Assignments Field Descriptions

Use the data in the following table to use the **Assignments** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface identifier of the I-SID-to-VLAN assignment.
<b>Isid</b>	Specifies the I-SID value of the I-SID-to-VLAN assignment.
<b>Vlan</b>	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.
<b>State</b>	Specifies the current state of the I-SID-to-VLAN assignment. It can be one of the following values: <ul style="list-style-type: none"> <li>• Other</li> <li>• Pending</li> <li>• Active</li> <li>• Rejected</li> </ul>
<b>Origin</b>	Specifies the origin information of the I-SID-to-VLAN assignment.

### Configure Fabric Attach Interface-level Settings

Use this procedure to configure FA interface-level settings or view existing interface-level settings.

You can enable Fabric Attach on a port, static MLT or an LACP MLT. Enabling FA on a port not only enables tagging but also disables spanning tree on that port. Enabling FA on an MLT enables FA on all ports of the MLT. When FA is enabled on ports in an MLT or LACP MLT, tagging is enabled and spanning tree is disabled on all those ports.

### Before You Begin

Ensure that FA is enabled globally on the switch.

### About This Task

Enabling FA on a port or MLT is necessary for element discovery. On the FA Server, FA is enabled globally by default. However, you must explicitly enable FA on a desired port or MLT interface, following which the FA Server can begin transmitting LLDP PDUs that contain the element discovery TLVs. This information is received by FA Client and FA Proxy devices which in turn also transmit their FA capabilities and settings. After the element handshake completes, the FA Server receives I-SID-to-VLAN assignment mappings from the connected client or proxy devices, on that port or MLT.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Ports** tab.

The FA interface-level settings are displayed.

4. To modify existing settings, double-click on the fields on this window. After making the required changes, click **Apply** to save your changes.
5. To configure FA on a new port or MLT interface:
  - a. Click **Insert**.

The **Insert Ports** dialog box appears.
  - b. To configure FA on a port, enter a port number in the format slot/port[/sub-port], or click **Port** to select from a list of available ports.
  - c. To configure FA on an MLT, enter an MLT ID or click **Mlt** to select from a list of configured MLTs.

#### Note

FA is successfully enabled on the MLT, only if all ports of the MLT have FA successfully enabled. Enabling FA enables LLDP on all ports. Tagging is enabled and spanning tree is disabled.

- d. Click **Insert** to save your changes.
6. To remove (delete) FA on a port or MLT:
    - a. In the content pane, select a port or MLT from the list.
    - b. Click **Delete**.

#### Caution

Removing FA on an interface flushes all FA element discovery and I-SID-to-VLAN mappings associated with that interface.

## Ports Field Descriptions

Use the data in the following table to use the **Ports** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface (port or MLT) on which Fabric Attach is configured.
<b>State</b>	Specifies the current state of the Fabric Attach port. It is either enabled or disabled. This field indicates whether LLDP PDUs (that include FA TLVs) are generated on the port (enabled) or not (disabled).
<b>MsgAuthStatus</b>	Specifies the Fabric Attach message authentication status on the port. It is either enabled or disabled.
<b>MsgAuthKey</b>	Specifies the Fabric Attach message authentication key for the associated port. The maximum length of this key is 32 characters.
<b>MgmtIsid</b>	Specifies the Fabric Attach management I-SID for the associated port. The range is 0 to 16777215. A zero value indicates that the management I-SID is not specified for the interface.
<b>MgmtCvid</b>	Specifies the Fabric Attach management customer VLAN ID (C-VID) for the interface. A zero value indicates that no C-VID is specified for the interface. Using the maximum configuration value for your switch indicates the port is untagged. Platform support determines the C-VID range.
<b>Origin</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the origin of Fabric Attach port, either manually configured through CLI or EDM or dynamically configured through Auto-sense.

### Viewing Fabric Attach discovered elements

Use this procedure to view discovered Fabric Attach elements.

#### About This Task

When FA is enabled on an FA Server switch, LLDP PDUs are exchanged between the FA Server and FA Clients or Proxies. Standard LLDPs allow neighbors to be learned. In addition, organizational specific element discovery TLVs allow the Client or Proxy to recognize that it has attached to an FA Server. Only after the discovery handshake is complete, an FA Client or Proxy can transmit I-SID-to-VLAN assignments to join the SPB Fabric through the FA Server.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Elements** tab.

### Elements field descriptions

Use the data in the following table to use the **Elements** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface (port or MLT) at which the Fabric Attach element was discovered.
<b>ElementType</b>	Specifies the element type of the discovered Fabric Attach element, as advertised using LLDP. The supported element type is the Fabric Attach Server.
<b>ElementVlan</b>	Specifies the VLAN ID of the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementId</b>	Specifies the system ID of the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementState</b>	Specifies the state flag data associated with the discovered Fabric Attach element, as advertised using LLDP.
<b>ElementOperAuthStatus</b>	Specifies the authentication status of the discovered Fabric Attach element.
<b>ElementAsgnsOperAuthStatus</b>	Specifies the authentication status of remote assignments.
<b>ElementAuth</b>	Specifies the discovered element authentication status.
<b>AsgnsAuth</b>	Specifies the assignment authentication status.

### Viewing FA statistics

Use this procedure to view FA statistics.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. In the content pane, click the **Stats** tab.

### Stats field descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
<b>PortIndex</b>	Specifies the port for which the FA statistics are displayed.
<b>DiscElemReceived</b>	Specifies the number of element discoveries received on the port.
<b>AsgnReceived</b>	Specifies the number of remote assignments received on the port.
<b>AsgnAccepted</b>	Specifies the number of remote assignments accepted on the port.
<b>AsgnRejected</b>	Specifies the number of remote assignments rejected on the port.
<b>AsgnExpired</b>	Specifies the number of remote assignments that have expired, on the port.
<b>AuthFailed</b>	Specifies the number of authentications that have failed on the port.

Name	Description
<b>DiscElemExpired</b>	Specifies the number of discovery elements that have expired on the port.
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that are deleted on the port.
<b>AsgnDeleted</b>	Specifies the number of remote assignments deleted on the port.
<b>AsgnAuthFailed</b>	Specifies the number of remote assignment authentications that failed on the port.

### *View Global FA Statistics Graphically*

Use this procedure to view the global FA statistics graphically.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Graph**.
2. Click **Chassis**.
3. Click the **Fabric Attach** tab.
4. To view a graphical representation of the statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
5. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
6. Click **Export**, to export the statistical data to a file.
7. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

#### **Fabric Attach field descriptions**

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
<b>DiscElemReceived</b>	Specifies the number of discovery elements received globally.
<b>AsgnReceived</b>	Specifies the number of remote I-SID-to-VLAN assignments received globally.
<b>AsgnAccepted</b>	Specifies the number of remote I-SID-to-VLAN assignments accepted globally.
<b>AsgnRejected</b>	Specifies the number of remote I-SID-to-VLAN assignments rejected globally.
<b>AsgnExpired</b>	Specifies the number of remote I-SID-to-VLAN assignments that expired globally.
<b>AuthFailed</b>	Specifies the number of authentications that failed globally.
<b>DiscAuthFailed</b>	Specifies the number of discovery authentications that failed globally.
<b>DiscElemExpired</b>	Specifies the number of discovery elements that expired globally.

Name	Description
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that were deleted globally.
<b>AsgnDeleted</b>	Specifies the number of remote assignments that were deleted globally.

### View FA Port Statistics Graphically

Use this procedure to view the FA port statistics graphically.

#### Before You Begin

Ensure that a switch port is selected in the **Device Physical View** tab.

#### Procedure

1. In the navigation pane, expand **Graph > Port**.
2. Click the **Fabric Attach** tab.  
The FA port statistics are displayed.
3. To view a graphical representation of the port statistics, select a row and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
5. Click **Export**, to export the statistical data to a file.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

#### Fabric Attach Field Descriptions

Use the data in the following table to use the **Fabric Attach** tab.

Name	Description
<b>DiscElemReceived</b>	Specifies the number of discovery elements received on a given port.
<b>AsgnReceived</b>	Specifies the number of remote I-SID-to-VLAN assignments received on a given port.
<b>AsgnAccepted</b>	Specifies the number of remote I-SID-to-VLAN assignments accepted on a given port.
<b>AsgnRejected</b>	Specifies the number of remote I-SID-to-VLAN assignments rejected on a given port.
<b>AsgnExpired</b>	Specifies the number of remote I-SID-to-VLAN assignments that expired on a given port.
<b>AuthFailed</b>	Indicates the number of received TLVs for which authentication was attempted and failed on the identified port.
<b>DiscElemExpired</b>	Specifies the number of discovery elements that expired on a given port.
<b>DiscElemDeleted</b>	Specifies the number of discovery elements that were deleted on a given port.

Name	Description
<b>AsgnDeleted</b>	Specifies the number of remote assignments that were deleted on a given port.
<b>AsgnAuthFailed</b>	Specifies the number of remote assignment authentications that failed on a given port.

### *Inserting a Zero Touch Client*

Use this procedure to insert a FA Zero Touch Client.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Fabric Attach**.
3. Click the **Zero Touch Client Auto Attach** tab.
4. Click **Insert**.  
The **Insert Zero Touch Client** dialog box appears.
5. In the **Type** field click the ellipsis and select a client. Click **Ok** to select the client or **Refresh** to update the list.
6. In the **Isid** field enter the ISID value.  
The ISID value is between 0 and 16777214.
7. Click **Insert**.

### *Configure FA Zero Touch Client Auto Attach*

Use this procedure to configure FA Zero Touch Client auto attach.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Fabric Attach**
3. Select the **Zero Touch Client Auto Attach** tab.  
From the Zero Touch Client Auto Attach tab you can configure a number of auto attach settings.
4. Select **Insert**.
5. In the **Type** field, select the ellipsis and select a client.
6. Select **Ok** to select the client or **Refresh** to update the list.
7. In the **Isid** field enter the ISID value.
8. Select **Insert**.
9. (Optional) To **Delete** a FA Zero Touch client select it from the auto attach table and select **Delete**.

## Zero Touch Client Auto Attach Field Descriptions

Use the data in the following table to use the **Zero Touch Client Auto Attach** tab

Field	Description
<b>Type</b>	This column describes the type of client assigned to auto attach. Available FA client types are: <ul style="list-style-type: none"> <li>• Wireless AP (Type 1)</li> <li>• Wireless AP (Type 2)</li> <li>• Switch</li> <li>• Router</li> <li>• IP Phone</li> <li>• IP Camera</li> <li>• IP Video</li> <li>• Security Device</li> <li>• Virtual Switch</li> <li>• Server Endpoint</li> <li>• ONA (SDN)</li> <li>• ONA (spbOIP)</li> </ul>
<b>Vlan</b>	Specifies the VLAN ID component of the I-SID-to-VLAN assignment.
<b>Isid</b>	Specifies the I-SID value of the I-SID-to-VLAN assignment.

## Configure Endpoint Tracking Using EDM

The following sections provide procedural information to configure Endpoint Tracking using Enterprise Device Manager (EDM).

### *Configure Endpoint Tracking Interfaces*

Configure ports and MLT/SMLT interfaces for Endpoint Tracking.

#### **Before You Begin**

- In Extreme Management Center, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center.

#### **About This Task**

Enable Endpoint Tracking on ports or MLT/SMLT interfaces.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Interface** tab.
4. Select **Insert**.
5. Select **Port** or **Mlt**, select the slot and port number or MLT ID, and select **OK**.
6. Select **InterfaceEnable**.

7. Select **Insert**.
8. Select **Apply**.

### What to Do Next

Configure Endpoint Tracking globally on the switch.

### Interface Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>InterfaceIndex</b>	Specifies the interface index of the selected port or MLT.
<b>InterfaceEnable</b>	Enables Endpoint Tracking on the selected port or MLT.

### Configure Endpoint Tracking Globally

Configure Endpoint Tracking globally on the switch.

#### Before You Begin

- In Extreme Management Center, configure your third-party virtualization platform, and the RADIUS server used for Endpoint Tracking authentication. For information about configuring Extreme Management Center, see the Extreme Management Center documentation at <https://www.extremenetworks.com/support/documentation/>.
- On the switch, add and configure the RADIUS server as configured in Extreme Management Center.
- Create and enable Endpoint Tracking on interfaces.

#### About This Task

Optionally, if the RADIUS outbound attributes do not include an I-SID value, configure an I-SID offset value, and globally enable I-SID offset for Endpoint Tracking. The I-SID offset value is used to calculate an I-SID value for a switched UNI if no I-SID value is provided by the RADIUS server. In that case, the I-SID value is calculated as follows: I-SID = VLAN ID + configured I-SID offset value.

After optionally configuring an I-SID offset value, enable Endpoint Tracking globally on the switch.

#### Note

If you have previously enabled Endpoint Tracking globally and want to change the currently configured I-SID offset value, you must disable Endpoint Tracking globally, change the I-SID value, and then re-enable Endpoint Tracking globally.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Globals** tab.
4. (Optional) Configure an I-SID offset value, and enable I-SID offset globally on the switch:  
Enter a value into the **AutolsidOffset** field and select **AutolsidOffsetEnable**.
5. Select **GlobalEnable**.

6. Select **Apply**.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AutolSidOffset</b>	The I-SID offset value. The default is 15990000.
<b>AutolSidOffsetEnable</b>	Enables or disables I-SID offset value globally on the switch. The default is disabled.
<b>GlobalEnable</b>	Enables or disables Endpoint Tracking globally on the switch. The default is disabled.
<b>VisibilityEnable</b>	Enables or disables visibility mode for Endpoint Tracking. The default is disabled.

### Display Binding Information

Display Endpoint Tracking binding information.

### About This Task

Display all VLAN:I-SID binding information on the switch for Endpoint Tracking.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Endpoint Tracking**.
3. Select the **Binding** tab.

### Binding Field Descriptions

Use the data in the following table to use the **Binding** tab.

Name	Description
<b>IfIndex</b>	Specifies the interface index of the selected port or MLT.
<b>MacAddress</b>	Specifies the MAC address that corresponds to the VLAN:I-SID binding.
<b>Status</b>	Specifies the Endpoint Tracking data binding status as follows: <ul style="list-style-type: none"> <li>• pending: indicates that a request has been sent to the RADIUS server</li> <li>• accept: indicates that the RADIUS server has successfully returned the request</li> <li>• reject: indicates that the RADIUS server has rejected the request</li> <li>• timeout: indicates that the RADIUS server request has timed out. The entry is deleted if it remains in this state for 15 minutes.</li> <li>• serverNotConfigured: indicates that the RADIUS server is not configured for Endpoint Tracking. The entry is deleted if it remains in this state for 15 minutes.</li> </ul>
<b>VlanId</b>	Specifies the VLAN ID.
<b>Isid</b>	Specifies the I-SID value, either provided by the RADIUS server, or calculated using the VLAN ID plus the configured I-SID offset value.

Name	Description
<b>IsidSource</b>	Specifies whether the I-SID value is provided by the RADIUS server (radius), or calculated using the VLAN ID plus the configured endpoint-tracking offset value (autoconfig).
<b>Timeout</b>	Specifies the timeout period that is applied to the MAC in the bindings table when the MAC is aged out. If the MAC is in timeout state (there is no response from the RADIUS server), the timeout triggers immediately with a 15 minute period. Otherwise, the default timeout is one day, and triggers the moment the MAC ages out from the VLAN/ISID bridge forwarding database (FDB) table. The default timeout of one day can be overridden by the RADIUS server if the Session-Timeout attribute is configured and returned.
<b>TimeRemaining</b>	Specifies the time remaining until the Endpoint Tracking data binding entry expires.

## SPBM configuration examples

This section provides configuration examples to configure basic SPBM and IS-IS infrastructure.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Basic SPBM configuration example

The following figure shows a sample greenfield deployment for SPBM.

**Figure 75: Greenfield SPBM deployment**

#### Note

For migration purposes, SPBM can coexist with existing SMLT configurations.

### Ethernet and MLT configuration

The following sections show the steps required to configure the Ethernet and MLT interfaces in this example.

#### SwitchC

```
PORT CONFIGURATION - PHASE 1
interface GigabitEthernet 1/30
```

```
encapsulation dot1q
exit
```

### SwitchG

```
PORT CONFIGURATION - PHASE 1

interface GigabitEthernet 1/5
encapsulation dot1q
exit

MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/21-1/22
mlt 1 encapsulation dot1q
```

### SwitchD

```
MLT CONFIGURATION

mlt 1 enable
mlt 1 member 1/20,1/30
mlt 1 encapsulation dot1q
```

### IS-IS SPBM global configuration

The following figure shows the IS-IS area information added to the network.

**Figure 76: IS-IS SPBM global**

The following sections show the steps required to configure the global IS-IS SPBM parameters in this example.

### SwitchC

```
enable
configure terminal
prompt SwitchC

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1
```

```
spbm 1 nick-name f.30.13
spbm 1 b-vid 20

ISIS CONFIGURATION

is-type l1
manual-area 30.0000
sys-name SwitchC
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan
```

### SwitchG

```
enable
configure terminal
prompt SwitchG

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1
spbm 1 nick-name f.30.10
spbm 1 b-vid 20

ISIS CONFIGURATION

is-type l1

sys-name SwitchG
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan
```

### SwitchD

```
enable
configure terminal
prompt SwitchD

BOOT CONFIGURATION

spbm
spbm ethertype 0x8100

ISIS SPBM CONFIGURATION

router isis
spbm 1
spbm 1 nick-name f.30.14
spbm 1 b-vid 20
```

```

ISIS CONFIGURATION

is-type l1
manual-area 30.0000
sys-name SwitchD
exit
router isis enable

VLAN CONFIGURATION

vlan create 20 name "B-VLAN" type spbm-bvlan

```

### IS-IS SPBM Interface Configuration

The following figure shows the IS-IS area information and interfaces in the network.

**Figure 77: IS-IS SPBM interface**

The following sections show the steps required to configure the IS-IS SPBM interfaces in this example.

#### SwitchC

```

PORT CONFIGURATION - PHASE II

interface GigabitEthernet 1/30
isis
isis spbm 1
isis enable
exit

```

#### SwitchG

```

PORT CONFIGURATION - PHASE II

interface GigabitEthernet 1/5
isis
isis spbm 1
isis enable
exit

MLT INTERFACE CONFIGURATION

interface mlt 1
isis
isis spbm 1
isis enable
exit

```

**SwitchD**

```
MLT INTERFACE CONFIGURATION

interface mlt 1
isis
isis spbm 1
isis enable
exit
```

*Verifying SPBM operations*

The following sections show the output from verifying the sample IS-IS SPBM configuration.

## Fabric Extend Configuration Examples

This section provides configuration examples to configure Fabric Extend in the following deployment scenarios.

- [Fabric Extend over IP using the GRT](#) on page 1111
- [Fabric Extend over IP using a VRF](#) on page 1114
- [Fabric Extend over VPLS](#) on page 1117
- [Fabric Extend over Layer 2 Pseudowire](#) on page 1119
- [Fabric Extend with ONAs in the core and branches](#) on page 1121
- [Fabric Extend Over IPsec](#) on page 1124

For more configuration examples, see *Shortest Path Bridging (802.1aq) Technical Configuration Guide*.

### Fabric Extend over IP using the GRT

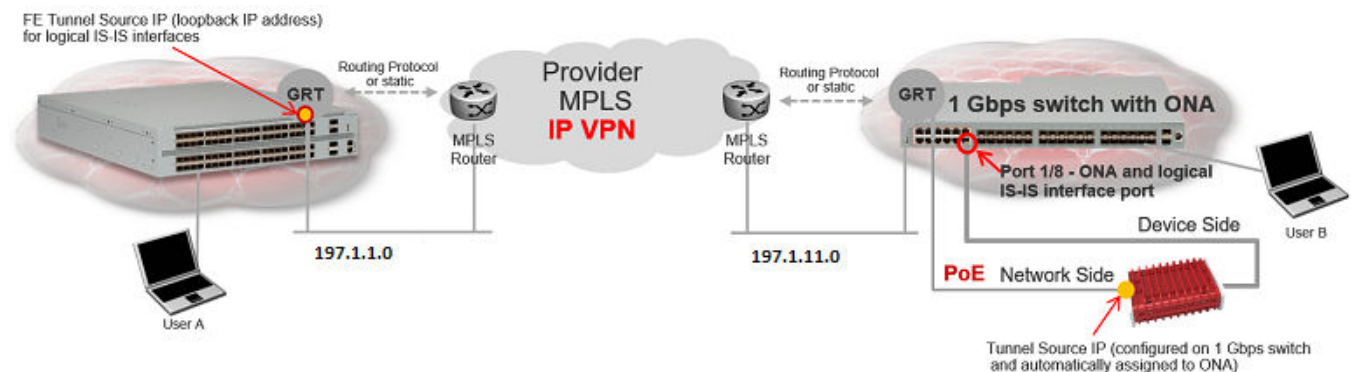

This example shows a typical Fabric Extend deployment with a 10/40/100 Gbps switch in the core and a 1 Gbps switch in one of the branch offices. The 10/40/100 Gbps switch supports Fabric Extend natively and is connected over an IP network to a 1 Gbps switch, which requires an ONA to encapsulate SPB traffic with a VXLAN header. The ONA sets up a bridge between the ONA device-side port and the ONA network-side port. Fabric Extend uses a VXLAN tunnel to send traffic to and from the 10/40/100 Gbps switch through the 1 Gbps switch to the ONA.

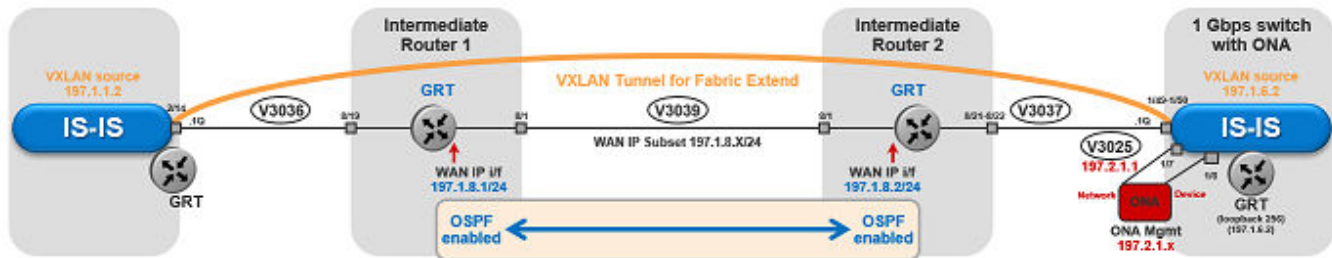

#### Note

- This deployment uses the **GRT** so the tunnel source IP address must be on the GRT, not on a VRF.
- If IP Shortcuts is enabled, you must configure an IS-IS accept policy or exclude route-map to ensure that tunnel destination IP addresses are not learned through IS-IS.
- Add any IP address used for setting up the logical tunnel (such as local network and loopback IP addresses) to the IS-IS accept policy or exclude route-map to prevent these addresses from being advertised into IS-IS.

The following figure shows a sample Fabric Extend deployment over IP using the GRT.

**Figure 78: IP using GRT traffic flow**

**Figure 79: IP (GRT) traffic flow component view**

### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured in the GRT.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept
```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the GRT. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# interface loopback 256
Switch(config-if)# ip address 256 197.1.6.2/255.255.255.0
Switch(config-if)# ip ospf 256
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
```

```

Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

Switch(config)# ip prefix-list "isis-tunnel-addr" 197.1.0.0/16 ge 16 le 32
Switch(config)# route-map "deny-isis-tunnel-network" 1
Switch(route-map)# no permit
Switch(route-map)# enable
Switch(route-map)# match network "isis-tunnel-addr"
Switch(route-map)# match protocol isis
Switch(route-map)# exit

Switch(config)# router isis
Switch(config-isis)# accept route-map "deny-isis-tunnel-network"
Switch(config-isis)# exit
Switch(config)# isis apply accept

```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

**For Intermediate Router 2**

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

*Fabric Extend over IP using a VRF*

This example is the same as the previous IP example except this Fabric Extend deployment uses a VRF instead of the GRT. Because this deployment is using a VRF, Fabric Extend has the following requirements:

- Configure a CLIP and tunnel source IP address on the same VRF.
- Remote management of the 1 Gbps switch is only possible after establishing IP Shortcut over IS-IS. (Alternatively, you can enable GRT-VRF redistribution locally.)

The following figure shows a sample Fabric Extend deployment over IP using a VRF.

**Figure 80: IP using VRF traffic flow**

**Figure 81: IP (VRF) traffic flow component view**

**For 10/40/100 Gbps Switches**

(The tunnel source IP address is configured as a brouter address in the VRF.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

**For 1 Gbps Switches**

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
```

```

Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit

Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit

```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```

Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit

```

#### For Intermediate Router 2

```

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit

```

### Fabric Extend over VPLS

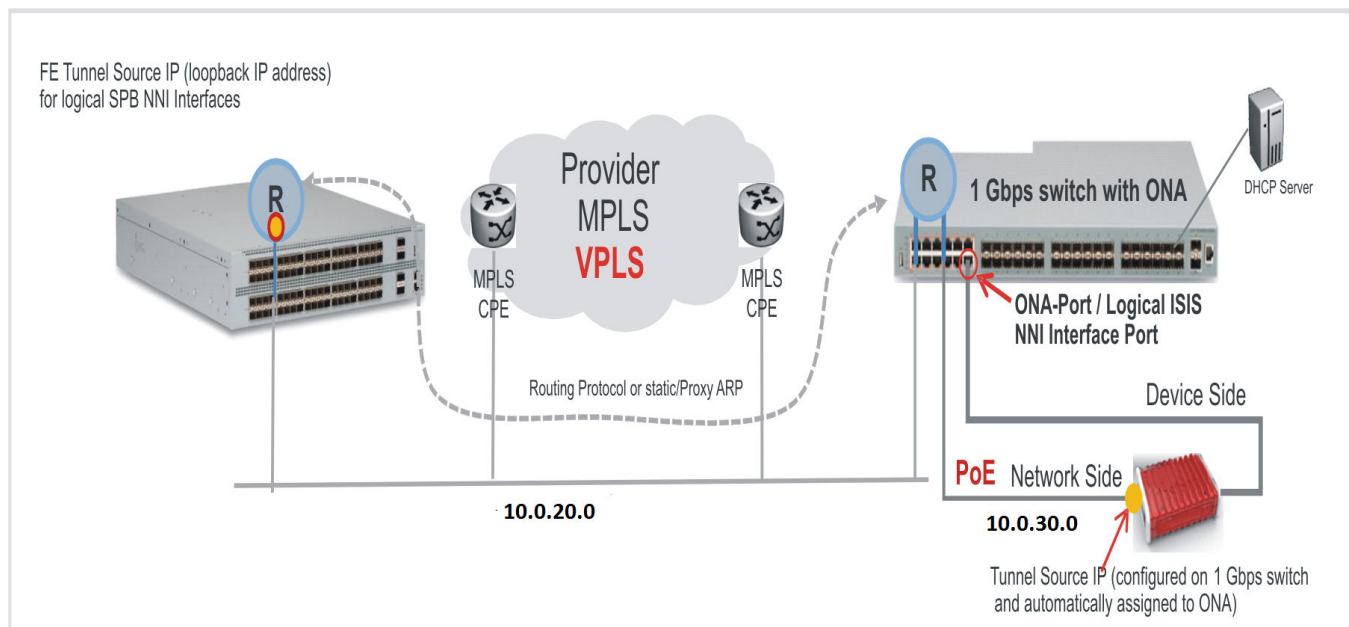

This example shows a Fabric Extend deployment over MPLS Virtual Private LAN Service (VPLS). In this scenario, VPLS emulates a LAN with full mesh connectivity. The SPB nodes connect with point-to-point Ethernet links and also use MPLS for normal forwarding.

#### Note

On the Core side, the 10/40/100 Gbps switches require a single next hop IP address as a default gateway for all tunnels. To ensure the single next hop, VPLS uses a loopback IP address and an additional VRF.

The following figure shows a sample Fabric Extend deployment over VPLS.

**Figure 82: FE over VPLS traffic flow**

#### For 10/40/100 Gbps Switches

(The tunnel source IP address is configured as a brouter address in the VRF.)

```
Switch(config)# interface GigabitEthernet 2/14
Switch(config-if)# no shutdown
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-SP-core"
Switch(config-if)# vrf vrf24
Switch(config-if)# brouter port 2/14 vlan 3036 subnet 197.1.1.2/255.255.255.0 mac-offset 1
Switch(config-if)# no spanning-tree mstp force-port-state enable
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.1.2 vrf vrf24
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.1.6.2)# exit
```

### For 1 Gbps Switches

(The tunnel source address is a CLIP address on the VRF. This address is configured on the 1 Gbps switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface vlan 3037
Switch(config-if)# vrf tunnel
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/7 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/8 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.1.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### For Intermediate Router 1

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit
```

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit
```

### For Intermediate Router 2

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend over Layer 2 Pseudowire

This example shows a Fabric Extend deployment using service provider VLAN tunnels over MPLS Pseudowire. In this scenario, you map two dedicated VLAN IDs (VIDs) from the Hub to the Spoke sites. Then the logical IS-IS interfaces translate the BVIDs to map them to the per branch provider VIDs. Because the tunnels are point-to-point VLAN connections, not VXLAN, there is no need to encapsulate a VXLAN header to SPB packets. Therefore, the 1 Gbps switches in this type of deployment do not require ONAs.

#### Important

10/40/100 Gbps switch — — — — — Core — — — — — 1 Gbps switch

- You cannot have IS-IS in the Core.
- Do not create the two VLANs represented in the logical interface connection on the BEBs. If you do, you will not be able add any Fabric Extend ports to be members of those VLANs. One links the port that is facing the core and those VLANs in the logical interface connection.

The following figure shows a sample Fabric Extend deployment over Pseudowire.

**Figure 83: FE over Pseudowire traffic flow**

**Figure 84: FE over Pseudowire traffic flow component view**

#### For 10/40/100 Gbps Switches

#### Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 port 2/14 name
fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

#### For 1 Gbps Switches

#### Note

Logical interface VLANs cannot be the same as the SPBM B-VLANs and you cannot create these VLANs locally. Use these VLANs for configuring the logical interface only. Once a port is being used for a logical interface it cannot be added to any platform VLAN and spanning tree is automatically disabled on the port.

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 1/49-1/50
Switch(config)# router isis enable

Switch(config)# logical-intf isis 255 vid 200,300 primary-vid 200 mlt 11 name fe_to_Switch
Switch(config-isis-255)# isis
Switch(config-isis-255)# isis spbm 1
Switch(config-isis-255)# isis enable
Switch(config-isis-255)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

#### For Intermediate Router 1

```
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1,8/19
Switch(config)# vlan member add 300 8/1,8/19
```

#### For Intermediate Router 2

```
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# vlan create 200 type port-mstprstp 1
Switch(config)# vlan create 300 type port-mstprstp 1
Switch(config)# vlan member add 200 8/1
Switch(config)# vlan mlt 200 11
Switch(config)# vlan member add 300 8/1
Switch(config)# vlan mlt 300 11
```

### Fabric Extend with ONAs in the core and branches

This example shows a Fabric Extend deployment with 1 Gbps switches in the core of the network and in the branch sites. This type of deployment is not only a lower cost Fabric Extend solution, it also addresses situations where large MTU sizes (over 1594 bytes) are a problem for the Service Provider.

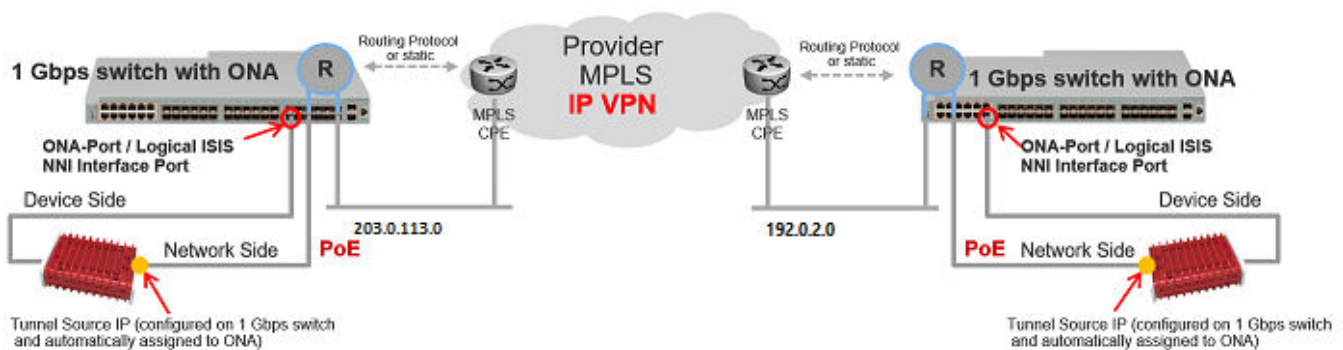

MTU sizes less than 1594 bytes require fragmentation and reassembly of packets and the 1 Gbps switch with ONA supports fragmentation and reassembly. However, you must have 1 Gbps switches with ONAs at BOTH ends of the IP WAN connection.

#### Important

There is no fragmentation/reassembly support in Layer 2 core solutions.

The following figure shows a sample Fabric Extend deployment using VRFs with both switches.

**Figure 85: Fabric Extend traffic flow**

**Figure 86: Fabric Extend traffic flow component view**

### Core switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24
Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.5.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3036 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3036 1/14 portmember
Switch(config)# interface vlan 3036
Switch(config)# vrf vrf24
Switch(config-if)# ip address 197.1.1.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3024 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3024 1/8 portmember
Switch(config)# interface vlan 3024
Switch(config-if)# ip address 197.3.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.3.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.5.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.6.2 name "Tunnel-to-Branch1"
Switch(config-isis-255-197.1.6.2)# isis
Switch(config-isis-255-197.1.6.2)# isis spbm 1
Switch(config-isis-255-197.1.6.2)# isis enable
Switch(config-isis-255-197.2.1.1)# exit
```

### Branch switch configuration

(The tunnel source address is a CLIP address on the VRF. This address is configured on the switch and then automatically assigned to the ONA.)

```
Switch(config)# ip vrf vrf24

Switch(config)# router vrf vrf24
Switch(router-vrf)# ip ospf
Switch(router-vrf)# ip ospf admin-state
Switch(router-vrf)# exit

Switch(config)# interface loopback 256
Switch(config-if)# ip address 197.1.6.2 255.255.255.255 vrf vrf24
Switch(config-if)# ip ospf vrf vrf24
Switch(config-if)# exit

Switch(config)# interface GigabitEthernet 1/7-1/8; enables ports to ONA
Switch(config-if)# no shutdown
Switch(config-if)# exit

Switch(config)# vlan create 3037 name "ospf-intf-SP-core" type port-mstprstp 0
Switch(config)# vlan members 3037 1/49-1/50 portmember
Switch(config)# interface vlan 3037
Switch(config-if)# vrf vrf24
Switch(config-if)# ip address 197.1.11.2 255.255.255.0 0
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3025 name "ONA-Mgmt-vlan" type port-mstprstp 0
Switch(config)# vlan members 3025 1/8 portmember
Switch(config)# interface vlan 3025
Switch(config-if)# ip address 197.2.1.1 255.255.255.0 3
Switch(config-if)# exit

Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 enable
Switch(config)# ip dhcp-relay fwd-path 197.2.1.1 197.10.1.11 mode bootp_dhcp

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 197.1.6.2 port 1/7 vrf vrf24 mtu 1950
Switch(config-isis)# exit
Switch(config)# logical-intf isis 255 dest-ip 197.1.5.2 name "Tunnel-to-HQ"
Switch(config-isis-255-197.1.1.2)# isis
Switch(config-isis-255-197.1.1.2)# isis spbm 1
Switch(config-isis-255-197.1.1.2)# isis enable
Switch(config-isis-255-197.1.1.2)# exit
```

Intermediate routers are typically configured by an Internet service provider (ISP). The following configurations are for reference only.

### Intermediate Router 1 configuration

```
Switch(config)# interface GigabitEthernet 8/19
Switch(config-if)# default-vlan-id 0
Switch(config-if)# name "ospf-intf-from-Headoffice"
Switch(config-if)# no shutdown
Switch(config-if)# brouter port 8/19 vlan 3036 subnet 197.1.1.3/255.255.255.0 mac-offset 2
Switch(config-if)# ip ospf enable
Switch(config-if)# exit

Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
```

```
Switch(config)# ip address 197.1.8.1 255.255.255.0 2
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Intermediate Router 2 configuration

```
Switch(config)# vlan create 3039 name "core-ospf-vlan" type port-mstprstp 0
Switch(config)# vlan members 3039 8/1 portmember
Switch(config)# interface Vlan 3039
Switch(config)# ip address 197.1.8.2 255.255.255.0 0
Switch(config)# ip ospf enable
Switch(config)# exit

Switch(config)# vlan create 3037 name "ospf-intf-from-branch1" type port-mstprstp 0
Switch(config)# vlan members 3037 8/21-8/22 portmember
Switch(config)# mlt 11
Switch(config)# mlt 11 encapsulation dot1q
Switch(config)# mlt 11 mem 8/21-8/22
Switch(config)# mlt 11 vlan 3037
Switch(config)# interface Vlan 3037
Switch(config)# ip address 197.1.11.1 255.255.255.0 5
Switch(config)# ip ospf enable
Switch(config)# exit
```

### Fabric Extend Over IPsec

The following example shows a Fabric Extend deployment using service provider VLAN tunnels and IPsec.

#### Note

Fabric Extend over IPsec limitations:

- Only pre-shared authentication key IPsec parameters are user configurable. Other, third-party solutions are not configurable.
- The key exchange only uses the Internet Key Exchange (IKE) v2 protocol.
- IPsec support is only added for Fabric Extend tunnels.
- IPsec is not supported for regular layer 3 routed packets.

### Global SPBM for Fabric Extend over IPsec Configuration

The global SPBM parameters must be configured before you can configure the Fabric Extend over IPsec tunnel.

#### Note

The **ipsec** command is only available after the **auth-key** command is configured.

```
Switch> enable
Switch# configure terminal

Switch(config)# spbm
Switch(config-isis)# router isis
Switch(config-isis)# spbm 1
Switch(config-isis)# spbm 1 nick-name 1.11.40
Switch(config-isis)# spbm 1 b-vid 2,3 primary 2
Switch(config-isis)# is-type 11
```

```
Switch(config-isis)# manual-area c0.2000.0000.00
Switch(config-isis)# sys-name SwitchB
Switch(config-isis)# exit

Switch(config)# vlan create 2 type spbm-bvlan
Switch(config)# vlan create 3 type spbm-bvlan
Switch(config)# router isis enable
```

### Fabric Extend tunnel and IPsec configuration

Configuring Fabric Extend over IPsec consists of two primary tasks: configuring the tunnel source address and configuring the logical interface. These tasks must be completed on both ends of the tunnel.

```
Switch> enable
Switch# configure terminal

Switch(config)# interface GigabitEthernet 1/1
Switch(config-if)# brouter port 1/1 vlan 2500 subnet 192.0.2.0/255.255.255.0 mac-offset 0
Switch(config-if)# exit

Switch(config)# router isis
Switch(config-isis)# ip-tunnel-source-address 192.0.2.0
Switch(config-isis)# exit

Switch(config)# logical-intf isis 1 dest-ip 198.51.100.0
Switch(config-isis-1-198.51.100.0)# isis
Switch(config-isis-1-198.51.100.0)# isis spbm 1
Switch(config-isis-1-198.51.100.0)# isis enable
Switch(config-isis-1-198.51.100.0)# auth-key 12345678
Switch(config-isis-1-198.51.100.0)# ipsec encryption-key-length 256
Switch(config-isis-1-198.51.100.0)# ipsec
Switch(config-isis-1-198.51.100.0)# exit
```

#### Note

Product Notice: 256-bit IPsec Encryption for Fabric Extend Tunnels is only supported on XA1400 Series devices.

## Fabric Attach configuration examples

This section provides configuration examples to configure Fabric Attach.

### Configuring a Fabric Attach solution

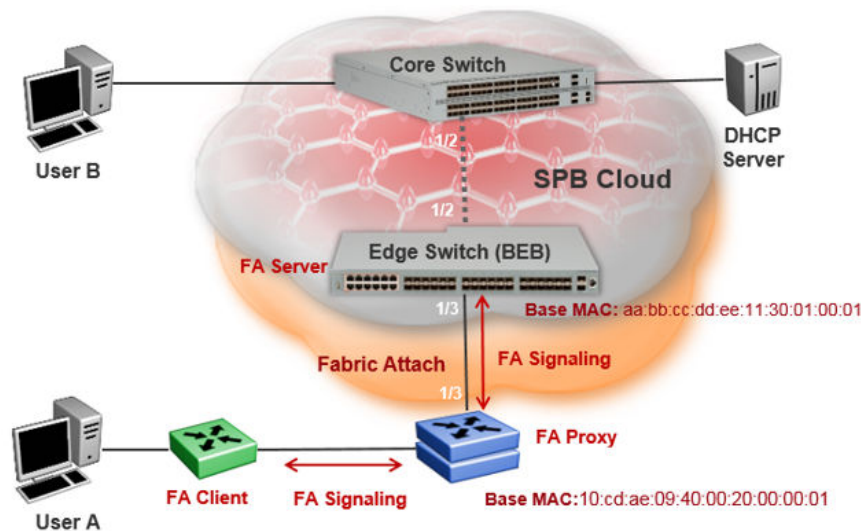

The following section describes a simple configuration example to configure Fabric Attach (FA) at the edge of a Fabric Connect network. This is a typical deployment at its simplest level and is powerful because of its use in conjunction with a Fabric Connect core.

#### About This Task

Configuring FA primarily consists of configuring the FA Server. The FA Server in turn discovers neighboring FA component devices (like the FA Proxies and FA Clients) using FA TLVs within the LLDP PDUs.

In the following deployment, the switch at the edge of the Fabric Connect cloud is configured as the FA Server. On this switch, FA is enabled globally and at the interface (port) level. Another switch,

functioning as the FA Proxy connects to the FA enabled port (1/3) on the FA Server. User A is an end user device that needs to send and receive data traffic from User B (another end user device) across the network.

### Before You Begin

Configure SPBM and IS-IS on the edge and core switches. For more information, see [Configuring minimum SPBM and IS-IS parameters](#) on page 958.

### Procedure

#### Configure the edge switch (BEB) as the FA Server:

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable FA globally:  

```
fa enable
```
3. Enter port interface configuration mode:  

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. Enable FA on the port:  

```
fa enable
```

#### Note

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and appears encrypted on the output.

#### Note

Enabling FA on a port not only enables tagging but also disables spanning tree on that port.

#### Verify global and interface level FA configuration:

5. Verify global configuration of FA using one of the following commands:

- show fa
- show fa agent

6. Verify interface level configuration of FA:

```
show fa interface
```

7. Verify the discovery of clients attaching to the FA Server:

```
show fa elements
```

8. Display the FA I-SID-to-VLAN assignments:

```
show fa assignment
```

To verify I-SID-to-VLAN assignments on a specific port, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

9. Verify creation of Switched UNI (ELAN) I-SIDs:

```
show i-sid elan
```

### Example

#### SPBM and IS-IS configuration on the core and edge switches:

SPBM configuration:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spbm
Switch:1(config)#spbm ethertype 0x8100
```

IS-IS SPBM configuration:

```
Switch:1(config)#router isis
Switch:1(config)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 1.00.01
Switch:1(config-isis)#spbm 1 b-vid 41-42 primary 41
Switch:1(config-isis)#spbm 1 ip enable
```

IS-IS router configuration:

```
Switch:1(config-isis)#router isis
Switch:1(config-isis)#sys-name BEB-Switch
Switch:1(config-isis)#ip-source-address 3.3.3.3
Switch:1(config-isis)#is-type 11
Switch:1(config-isis)#system-id 0001.0001.0001
Switch:1(config-isis)#manual-area c0.2000.000.00
Switch:1(config-isis)#exit
```

Interface (port-level) configuration

```
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#no shutdown
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-isis)#exit
Switch(config)#vlan create 41 type spbm-vlan
Switch(config)#vlan create 42 type spbm-vlan
```

```
Switch(config)#router isis enable
Switch(config)#show isis spbm
```

### Configuration of the edge switch as the FA Server.

Enable FA globally.

```
Switch:1(config)#fa enable
Switch:1(config)#show fa

=====
 Fabric Attach Configuration
=====
 FA Service : enabled
 FA Element Type : server
 FA Assignment Timeout : 240
 FA Discovery Timeout : 240
 FA Provision Mode : spbm
```

Enable FA on the port.

Enabling FA automatically enables message authentication. The authentication key is configured with the default value, which appears in encrypted format in the output.

```
Switch:1(config)#int gigabitEthernet 1/3
Switch:1(config-if)#fa enable
Switch:1(config-if)#show fa interface port 1/3

=====
 Fabric Attach Interfaces
=====
INTERFACE SERVER MGMT MGMT MSG AUTH MSG AUTH
STATUS STATUS ISID CVID STATUS KEY

Port1/3 enabled 0 0 enabled ****

1 out of 1 Total Num of fabric attach interfaces displayed

Switch:1(config-if)#exit
Switch:1(config)#exit
```

Verify that the FA Proxy is discovered by the FA Server.

```
Switch:1(config)#show fa elements

=====
 Fabric Attach Discovery Elements
=====
PORT TYPE MGMT ELEM ASGN
 TYPE VLAN STATE SYSTEM ID AUTH AUTH

1/3 proxy 2 T / S 10:cd:ae:09:40:00:20:00:00:01 AP AP

```

For Layer 3 support, you must configure a platform VLAN. The platform VLAN can have the same value as that of the C-VID or it can have a different value.

In this example, the platform VLAN has the same value as the C-VID.

```

### Configure Fabric Attach in an SMLT

The following example describes FA configuration and behavior in a dual-homed SMLT deployment.

The following figure shows a simple FA solution in a dual-homed SMLT deployment. In this deployment, a pair of BEB switches (BEB A and BEB B) operating as IST peers are configured as the FA Server. An access switch or a wiring closet switch configured as an FA Proxy connects to the FA Server. The FA Proxy advertises I-SID-to-VLAN assignment mappings to the FA Server. Both BEB switches receive the mapping information using LLDP PDUs containing assignment TLVs. The switch that learns the mapping first considers the I-SID to be discovered locally and creates the I-SID on its device. The mapping information is then shared with its IST peer switch. When the peer switch receives the mapping across IST in a new SMLT message, it too creates the I-SID on its device. This I-SID however, is considered to be discovered remotely because it is learnt from synchronization with the peer switch. The mappings can also be learned on the FA Server from both LLDP PDUs and from IST synchronization.

**Figure 87: FA configuration in dual-homed SMLT**

### Before You Begin

Ensure that the proxy device (for example, an access switch) is properly configured for FA. See the corresponding product documentation for information on how to configure FA on the switch.

### Procedure

1. Configure SMLT and vIST on switches BEB A and BEB B.

#### Caution

For the IST peer switches acting as the FA Server to transmit the same FA System ID (based on the virtual MAC), SMLT configuration on both the switches must be the same.

For detailed information on configuring SMLT and vIST, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2254.

### Configure BEB A and BEB B as the FA Server

Perform the following configuration on each switch.

2. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

3. Enable FA globally:

```
fa enable
```

4. Enter MLT interface configuration mode:

```
interface mlt <1-512>
```

5. Enable FA on the MLT:

```
fa enable
```

**Note**

Enabling FA automatically enables message authentication. Also, the authentication key is set to the default value and appears encrypted on the output.

6. (Optional) Configure an FA authentication key with a value different from that of the default value:

```
fa authentication-key [WORD<0-32>]
```

**Caution**

When you configure the FA authentication key, you must configure the same value on both BEB switches in the SMLT.

**Verify global and MLT-level FA configuration on BEB A and BEB B:**

7. Verify global configuration of FA using one of the following commands:

- `show fa`
- `show fa agent`

8. Verify MLT-level (interface-level) configuration of FA:

```
show fa interface
```

**Verify FA discovery on BEB A and BEB B:**

9. Verify discovery of the FA Proxy.

```
show fa elements
```

**View FA I-SID-to-VLAN assignments on BEB A and BEB B:**

10. View the FA I-SID-to-VLAN assignments:

```
show fa assignment
```

To view FA I-SID-to-VLAN assignments on specific ports, enter:

```
show fa assignment {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Verify creation of Switched UNI I-SIDs on BEB A and BEB B:**

## 11. Verify creation of Switched UNI (ELAN) I-SIDs:

- View ELAN I-SID information using `show i-sid elan`.
- View ELAN I-SID information on a specific MLT using `show mlt i-sid [<1-512>]`.

**Note**

Viewing ELAN I-SID information on an MLT is very useful to understand the origin of the I-SID, when multiple client or proxy devices connecting to the FA Server using SMLT MLT advertise the same I-SID-to-VLAN mappings. In the event of a link failure on an MLT, the origin of the I-SID helps determine on which MLT, and thereby from which proxy or client device, the mappings were successfully learnt.

**Examples****SMLT configuration on BEB A and BEB B:**

On BEB A:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config)#smlt
```

On BEB B:

```
Switch:2>en
Switch:2#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:2(config)#interface mlt 1
Switch:2(config)#smlt
```

**vIST configuration on BEB A and BEB B:**

On BEB A:

```
Switch:1(config)#vlan create 2261 type port-mstprstp 0
Switch:1(config)#vlan i-sid 2261 1502261
Switch:1(config)#interface vlan 2261
Switch:1(config)#ip address 192.0.2.0 255.255.255.0 2
```

Configure BEB B (IP address 192.0.2.1) as the IST peer.

```
Switch:1(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:1(config)#show virtual-ist
Switch:1(config)#exit
```

On BEB B:

```
Switch:2(config)#vlan create 2261 type port-mstprstp 0
Switch:2(config)#vlan i-sid 2261 1502261
Switch:2(config)#interface vlan 2261
Switch:2(config)#ip address 192.0.2.1 255.255.255.0 2
```

Configure BEB A (IP address 192.0.2.1) as the IST peer.

```
Switch:2(config)#virtual-ist peer-ip 192.0.2.1 vlan 2261
Switch:2(config)#show virtual-ist
Switch:2(config)#exit
```

**FA configuration on BEB A:**

Enable FA globally and on the MLT:

```
Switch:1(config)#fa enable
Switch:1(config)#show fa
=====
Fabric Attach Configuration
=====
FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240

## Layer 2 VSN configuration fundamentals

This section provides fundamentals concepts for Layer 2 VSN.

### *SPBM L2 VSN*

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the Backbone Edge Bridges (BEBs), customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

In the backbone VLAN (B-VLAN), Backbone Core Bridges (BCBs) forward the encapsulated traffic based on the B-MAC-DA, using the shortest path topology learned using IS-IS.

The following figure shows a sample campus SPBM Layer 2 VSN network.

**Figure 89: SPBM L2 VSN in a campus**

One of the key advantages of the SPBM Layer 2 VSN is that network virtualization provisioning is achieved by configuring only the edge of the network (BEBs). As a result, the intrusive core provisioning that other Layer 2 virtualization technologies require is not needed when new connectivity services are added to the SPBM network. For example, when new virtual server instances are created and need their own VLAN instances, they are provisioned at the network edge only and do not need to be configured throughout the rest of the network infrastructure.

Based on its I-SID scalability, this solution can scale much higher than any 802.1Q tagging based solution. Also, due to the fact that there is no need for Spanning Tree in the core, this solution does not need any core link provisioning for normal operation.

Redundant connectivity between the C-VLAN domain and the SPBM infrastructure can be achieved by operating two SPBM switches in switch clustering (SMLT) mode. This allows the dual homing of any traditional link aggregation capable device into an SPBM network.

### Configuration difference from ERS 8800

One major difference between these VSP switches and the ERS 8800 is how they connect to two SMLT devices.

The ERS 8800 uses an interswitch trunk (IST). The IST connects directly to two SMLT devices with a dedicated MLT and runs IS-IS over it. The dedicated MLT carries the IST control traffic and data traffic during an SMLT failover. This feature dramatically improves resiliency over other methods. However, if the dedicated MLT breaks, then there is no way to communicate between the IST peers, which causes traffic loss.

These VSP switches use a virtual IST (vIST) that eliminates this single point of failure. The vIST feature creates a virtualized IST channel in the SPBM cloud. With vIST, the IST tunnel is always up as long as there is SPBM connectivity between the vIST peers. vIST also interoperates between any two devices that support vIST, and the devices do not have to be the same type of device.

Before you can create a vIST, you must do the following:

- Enable SPBM and IS-IS globally.
- Configure SPBM and IS-IS.
- Create a VLAN (that is not used anywhere else) for each peer.
- Create an I-SID that is not used anywhere else.
- Configure an IP address for the vIST VLAN.
- Configure an L2 VSN by assigning an I-SID to the C-VLAN, which is used by the vIST.

#### Important

- An I-SID must be assigned to every VLAN that is a member of an L2 VSN.
- For proper traffic flow, if an L2 VSN is created on one vIST peer, it must also be created on the other vIST peer.
- For Simplified vIST deployment, if a VLAN is part of an SMLT it must be configured on both the IST peers.

For information about vIST, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2254.

### Fabric Connect Service Types

The Fabric Connect technology delivers Layer 2 and Layer 3 virtualization. These virtualized Layer 2 and Layer 3 instances are referred to as Virtual Service Networks (VSNs). A Service Identifier (I-SID) is used to uniquely distinguish these service instances network-wide, and a User Network Interface (UNI) is the boundary or demarcation point between the “service layer” of traditional networks, that is VLANs and VRFs, and the Fabric Connect “service layer”, that is Layer 2 & Layer 3 VSNs.

- Layer 2 VSNs are virtual broadcast domains interconnecting UNI members that share the same Layer 2 VSN I-SID. MAC learning/aging is applied to all Layer 2 VSNs.
- Layer 3 VSNs are virtual routed Layer 3 networks (Layer 3 VPN) leveraging IS-IS as the routing protocol between VRFs that share the same Layer 3 VSN I-SID.

Fabric Connect uses the User-Network-Interface (UNI) to denote the capabilities and attributes of the service interfaces. Fabric connect devices support the following UNI types:

- VLAN UNI (C-VLAN) — a device-specific VLAN-ID maps to a Layer 2 VSN I-SID – all device physical ports that are associated with the VLAN are therefore associated with the UNI.
- Flex UNI — it has the following sub-types:
  - Switched UNI — a VLAN-ID and a given port (VID, port) maps to a Layer 2 VSN I-SID. With this UNI type, VLAN-IDs can be reused on other ports and therefore mapped to different I-SIDs.
  - Transparent Port UNI — a physical port maps to a Layer 2 VSN I-SID (all traffic through that port, 802.1Q tagged or untagged, ingress and egress is mapped to the I-SID). Note: All VLANs on a Transparent Port UNI interface now share the same single MAC learning table of the Transparent Port UNI I-SID.
- E-Tree UNI — it extends Private VLANs beyond one Switch to form a network-wide E-Tree service infrastructure. An E-Tree UNI is a Layer 2 VSN where broadcast traffic flows from Hub sites to Spokes sites, and from Spokes to Hubs, but not between Spoke sites. E-Tree Hubs can be formed with any VLAN UNI, while E-Tree Spokes must be configured as Private VLAN UNIs.
- Layer 3 VSN UNI — a device-specific VRF maps to an I-SID, and the control plane exchanges the Layer 3 routes belonging to the same I-SID. All VRFs in a network sharing the same Layer 3 I-SID effectively form an Layer 3 VPN. Layer 3 VSNs can be configured to simultaneously support both IP Unicast and IP Multicast.

### Transparent Port UNI

Use a Transparent Port User-Network-Interface (Transparent Port UNI or T-UNI) to map an entire port or an MLT to an I-SID. C-MAC learning is done against the I-SID. T-UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. No VLAN is involved in this process. Devices switch tagged and untagged traffic in the assigned I-SID regardless of the VLAN ID. The T-UNI port or MLT can be either static or LACP and is not a member of any VLAN or Spanning Tree Group (STG). The T-UNI port or MLT is always in the forwarding state.

You can map multiple ports to a T-UNI I-SID. Multiple ports on the same switch and on other BEBs can use the common I-SID to switch traffic.

T-UNI is a point to point service and all traffic that ingress the UNI egress from the remote UNI end-point

For information about QoS re-marking, see [QoS re-marking on a Transparent Port UNI](#) on page 2547.

Transparent

T-UNI is transparent because the MAC learning occurs within the I-SID, and packets that ingress from any CVLAN are processed in an identical manner. Devices switch tagged and untagged traffic in the assigned I-SID. Devices switch control protocols, such as BPDU, LACP, LLDP, and others, in the assigned I-SID, rather than forwarding to the CP.

The service classification of packets that are received on a T-UNI port, is independent of the VLAN ID values present in those packets. All data packets received on a T-UNI port are classified into the same service. When data packets enter and exit the T-UNI service, no VLAN tag modifications are performed on the data packets.

T-UNI based MAC learning

When a packet ingresses a port or MLT associated with a T-UNI I-SID, the system performs MAC lookup based on the I-SID. A packet that ingresses a T-UNI port on a BEB can transfer through the SPB network, or can egress out another T-UNI port configured to the same I-SID.

When a packet ingresses an NNI port, before egressing a T-UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all T-UNI ports.

#### Considerations

Consider the following design requirements when you configure a T-UNI:

- Only E-LAN based T-UNI is supported. All T-UNI I-SID end points for a given I-SID become members of the same shared E-LAN service. If an E-LINE type of service is required, provision T-UNI at the two end points comprising the point-to-point service.
- You cannot configure a T-UNI on the same I-SID as a C-VLAN.
- A port or MLT associated with a T-UNI I-SID cannot be part of any VLAN and does not belong to any STG.
- Ensure that you always associate a T-UNI LACP MLT with a VLAN (even if it is the default VLAN) before adding it to a T-UNI ISID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.
- No Layer 3 processing takes place on packets ingressing on a T-UNI port.
- Pause frames do not switch through the T-UNI I-SID.
- Multiple ports or MLTs can be associated with same T-UNI I-SID.
- One port or MLT cannot be part of multiple T-UNI I-SIDs.
- An ISID mapped to a T-UNI service must not be mapped to any other service, such as L2 VSN and L3 VSN, on any of the remote BEBs in the SPBM network.
- Any Spanning Tree Protocol implementation is disabled on the port or MLT associated with the T-UNI I-SID. The port will always be in a Forwarding state.
- No additional IS-IS TLVs are added to advertise or withdraw T-UNI I-SID services. Extreme Networks makes use of the existing IS-IS TLV-144 and sub TLV-3 to carry I-SID information.
- MACs are learned against the combination of the I-SID and port or MLT.
- The MAC address limit is supported on a per-I-SID basis. For example, the MAC addresses learned on the T-UNI I-SID can be limited.

#### Note

MAC learning limit for T-UNI service is not supported on all hardware platforms.

- Static MAC is not supported for a T-UNI port.
- IP traffic and control packets are transparently bridged over T-UNI endpoints.
- Untagged traffic ingressing on the T-UNI port will use COS 0. B-TAG and I-TAG priorities are derived from the best effort queue that is assigned. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned.
- The 802.1p bits of the incoming traffic are used to derive the B-TAG and I-TAG priorities for tagged traffic.
- LACP, VLACP and LLDP PDUs are extracted to the CP and all other control packets are transparently bridged over the T-UNI port or MLT.

This feature handles control PDUs in the following manner:

All the Layer 2 and Layer 3 control packets are transparently bridged over the T-UNI port or MLT with the exception of LACP, VLACP and LLDP PDUs. LACP PDUs, VLACP PDUs and LLDP PDUs are not transparently bridged over the T-UNI port or MLT if LACP, VLACP or LLDP is enabled on the port or MLT.

- If an LACP MLT is associated with a T-UNI I-SID, LACP PDUs are extracted to CP and processed locally.
- If LACP is not enabled globally and LACP MLT is not associated with the T-UNI I-SID, LACP PDUs are transparently bridged across the T-UNI port or MLT.
- If a VLACP enabled port is added to a T-UNI I-SID, VLACP PDUs are extracted to the CP for local processing. If a port that is not VLACP enabled is added to the T-UNI I-SID, VLACP PDUs are transparently bridged across T-UNI port.
- If a LLDP enabled port is added to a T-UNI I-SID, LLDP PDUs are extracted to the CP for local processing.
- If LLDP is not enabled on the port or MLT interface associated to TUNI ISID , LLDP PDUs are transparently bridged across the T-UNI port or MLT.

The following list of control packet types are transparently bridged across the T-UNI I-SID:

- SLPP
- VRRP
- OSPF
- RIP
- BGP
- ISIS
- CFM
- STP
- SONMP

Use T-UNI when either of the following apply:

- All tagged and untagged traffic on a port must be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

An example of an application for T-UNI is a typical Ethernet provider deployment with port-based classification and transparent forwarding.

### **Transparent Port UNI over vIST**

Virtual IST (vIST) provides the ability to dual-home hosts, servers and other network devices to a pair of Multi-Chassis Link Aggregation (MC-LAG) enabled devices. The MC-LAG nodes appear to the connected devices as one link-aggregated group. So, although the physical connection is spread between two individual network nodes, logically they appear as a single connection.

Transparent Port UNI (T-UNI) over vIST peers extends the capability of dual-home hosts on the SPB cloud to achieve higher network resiliency. The MACs learnt on the T-UNI interface of any one vIST peer is synchronized with the other peer through MAC synchronization.

In the following figure, the T-UNI access switch ACCESS-1 is dual-homed into vIST peer hosts VIST-PEER 1 and VIST-PEER 2. At ACCESS-1, a link aggregation is created to connect to the SPBM cluster. On the VIST peers, an SMLT is created towards ACCESS-1. Depending on the link aggregation hashing logic,

traffic is hashed on to VIST-PEER 1 and VIST-PEER 2. The MACs learnt on the T-UNI interfaces of either host is synchronized with the other host.

**Figure 90: Example of Transparent Port UNI over vIST**

If one of the links between ACCESS-1 and the vIST cluster goes down, all traffic is serviced through the other link. The same applies when any of the vIST peers go down. Since MAC learning on both peers are synchronized, both peers can switch traffic with the same efficiency.

Single-homed T-UNI service on a vIST-enabled node

If you configure a T-UNI service as a single-homed service on a vIST-enabled node, you must configure the same ISID service without port/MLT being mapped to ISID, on the other vIST peer node. Failure to perform this configuration on the vIST peer node can result in the loss of traffic to the single-homed T-UNI service in various scenarios.

## Switched UNI

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Switched UNI summary:

- Switched UNI is a VLAN and ports associated with I-SIDs.
- Local significance on the ports.
- You can re-use the same VLAN to associate different ports with different I-SIDs.
- You can use a different VLAN to the same ports, or you can assign different ports to the same I-SID.
- Supports VLAN mapping on the local switch.
- To accept untagged traffic, the port needs to be configured as untagged-traffic in the I-SID.

Use Switched UNI when either of the following apply:

- Vlan ID (VID) reuse is required. The same VID is used on different broadcast domains (multi-tenant applications).
- Multiple VLANs must be part of the same broadcast domain.
- VID translation is required.

An example of an application for Switched UNI is a typical host and provider deployment, with a port and VID-based classification.

Switched UNI based MAC learning

MAC learning is done on I-SID MAC. When a packet ingresses on a port or MLT which is associated with Switched UNI I-SID, the system performs MAC look up based on the I-SID. Switched UNI operates on Any-To-Any (ELAN) mode, there can be one or more ports associated to a Switched UNI I-SID. A packet that ingresses to a Switched UNI port on a BEB can transfer through the SPBM cloud, or can egress out another Switched UNI port configured to the same I-SID.

When a packet ingresses an NNI port, before egressing a Switched UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all Switched UNI ports in the I-SID.

#### Considerations

Consider the following when you configure a Switched UNI:

- The VLAN tag is removed before the traffic egresses out on the untagged-traffic port or MLT.
- VLAN priority received on the packet is maintained across VLAN IDs.
- Spanning tree is disabled on all Switched UNI ports, and the ports remain in forwarding state.
- The Switched UNI I-SID is advertised to the SPBM cloud.
- The Broadcast and unknown Unicast packets are flooded to all ports in the I-SID.

#### Limitations

- You cannot change from one UNI type to another dynamically. The I-SID has to be deleted and created with new UNI type (Customer VLAN (C-VLAN), Transparent port user-network-interface (T-UNI), ELAN).
- I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.
- If the port is a member of MLT, the entire MLT has to be added to the VID.
- The port is always in the forwarding state.
- The same VID, port, or MLT cannot be member of more than one I-SID.
- Static MAC, Static ARP and static IGMP group are not supported on Switched UNI enabled ports.
- For a Switched UNI endpoint without a platform VLAN on the VSP 7400 Series, when MAC-in-MAC terminated traffic is sent out to the UNI endpoint the packet is re-marked based on existing QoS rules.
- On VSP 8600 Series, dynamically learned Fabric Attach announced VLAN-ISID bindings and manually configured Switched-UNI end-points are not supported on the same interface.

#### BPDU handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

#### Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

### SPBM sample operation—L2 VSN

The following section shows how a SPBM network is established, in this case, a Layer 2 VSN.

1. Discover network topology

**Figure 91: SPBM topology discover**

IS-IS runs on all nodes of the SPBM domain. Since IS-IS is the basis of SPBM, the IS-IS adjacency must be formed first. After the neighboring nodes see hellos from each other they look for the same Level (Level 1) and the same area (for example, Area 2f.8700.0000.00). After the hellos are confirmed both nodes send Link State Protocol Data Units, which contain connectivity information for the SPBM node. These nodes also send copies of all other LSPs they have in their databases. This

establishes a network of connectivity providing the necessary information for each node to find the best and proper path to all destinations in the network.

Each node has a system ID, which is used in the topology announcement. This same System ID also serves as the switch Backbone MAC address (B-MAC), which is used as the source and destination MAC address in the SPBM network.

2. Each IS-IS node automatically builds trees from itself to all other nodes

When the network topology is discovered and stored in the IS-IS link state database (LSDB), each node calculates shortest path trees for each source node. A unicast path now exists from every node to every other node

With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes. Multicast FIB is not produced until Layer 2 VSN services are configured and learned.

3. IS-IS advertises new service communities of interest

When a new service is provisioned, its membership is flooded throughout the topology with an IS-IS advertisement.

**Figure 92: SPBM B-MAC and I-SID population**

BMAC and I-SID information is flooded throughout the network to announce new I-SID memberships. In this case, VLAN 20 is mapped to I-SID 100.

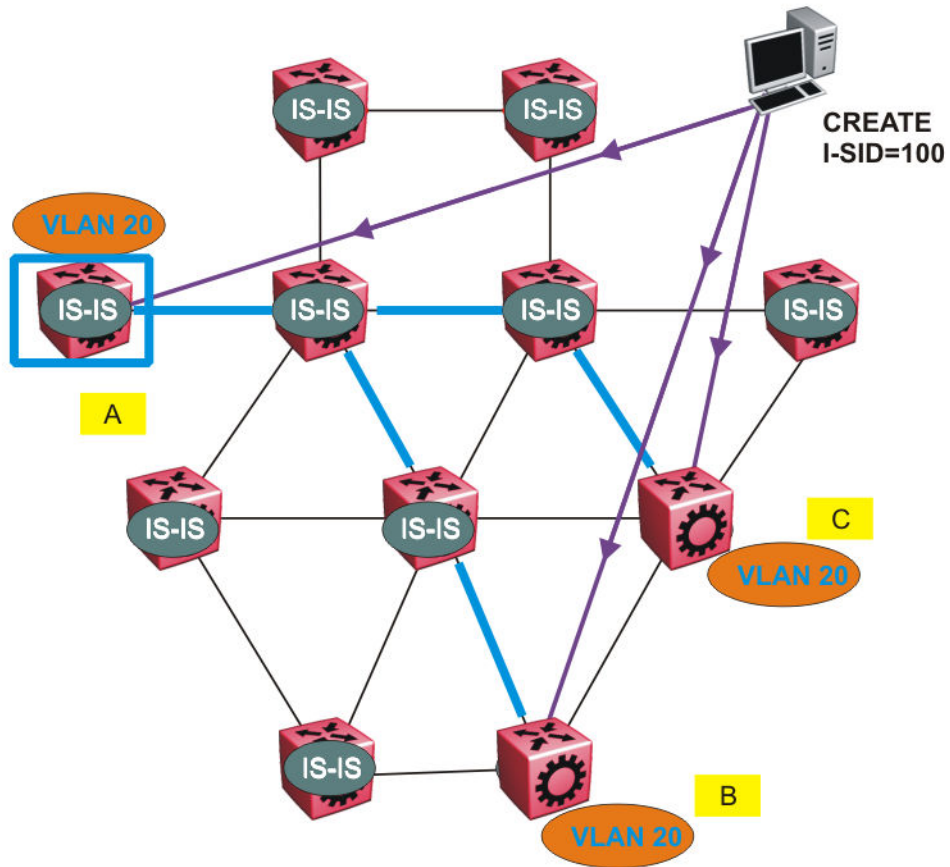

**Note**

I-SIDs are only used for virtual services (Layer 2 and Layer 3 VSNs). If IP Shortcuts only is enabled on the BEBs, I-SIDs are never exchanged in the network as IP Shortcuts allow for IP networks to be transported across IS-IS.

Each node populates its FDB with the BMAC information derived from the IS-IS shortest path tree calculations. Thus there is no traditional flooding and learning mechanism in place for the B-VLAN, but FDBs are programmed by the IS-IS protocol.

- 4. When a node receives notice of a new service AND is on the shortest path, it updates the FDB

In this scenario, where there are three source nodes having a membership on I-SID 100, there are three shortest path trees calculated (not counting the Equal Cost Trees (ECTs)).

**Figure 93: Shortest path tree for source node A**

Figure 94: Shortest path tree for source node B

**Figure 95: Shortest path tree for source node C**

The paths between any two nodes are always the shortest paths. Also, the paths in either direction are congruent, thus a bidirectional communication stream can be monitored easily by mirroring ingress and egress on a link to a network analyzer.

VLAN traffic arriving on switch A and VLAN 20 is forwarded following the blue path, traffic arriving on switch B and VLAN 20 the orange path and on switch C VLAN 20 traffic is following the green path.

If the destination CMAC is unknown at the SPBM ingress node or the traffic is of type broadcast or multicast, then it is flooded to all members of the topology which spans VLAN 20. If the destination CMAC is already known, then the traffic is only forwarded as a unicast to the appropriate destination. In the SPBM domain, the traffic is switched on the BMAC header only. The bridge filtering database (FDB) at the VLAN to I-SID boundary (backbone edge bridge BEB), maintains a mapping between CMACs and corresponding BMACs.

For example, Switch B learns all CMACs which are on VLAN 20 connected to switch A with the BMAC of A in its FDB and the CMACs which are behind C are learned with the BMAC of C.

## Layer 2 VSN configuration using the CLI

This section provides procedures to configure Layer 2 VSNs using the CLI.

### Configure SPBM Layer 2 VSN

SPBM supports Layer 2 Virtual Service Network (VSN) functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM BVLANS.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

### Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

3. Display C-VLAN information:

```
show vlan i-sid
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan i-sid 10 100
Switch:1(config)#show vlan i-sid

Switch:1>show vlan i-sid
=====
 Vlan I-SID
=====
VLAN_ID I-SID I-SID NAME

```

```

1
10 100 Hospital-Server-10
90 1000 ISID-1000

3 out of 3 Total Num of Vlans displayed

```

**Variable Definitions**

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<1-4059>	Specifies the primary VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID).  <b>Note:</b> The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.  This value is the same for the primary and secondary VLANs.
<i>force</i>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

*Configure a Global I-SID Name*

You can configure a service name for I-SIDs, loopback interfaces, and static routes. The service name can be configured before or after the I-SID is created for the following services:

- Layer 2 VSN
- Layer 3 VSN
- ELAN I-SID or Switched UNI I-SID
- ELAN transparent I-SID or Transparent UNI I-SID
- IPv4 and IPv6 static routes
- IPv4 and IPv6 loopback CLIP interface

**Note**

The service name for I-SIDs does not support the following special characters: " " # \$ % ' / [ \ ] ^ { | } ~ @.

By default, the service is named ISID-x, where x correlates to the I-SID number of the service.

#### Note

Product Notice: For XA1400 Series, you can configure a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only.

#### Note

Product Notice: This procedure does not apply to VSP 8600 Series.

### About This Task

Use this procedure to provide a descriptive name for the Service Identifier (I-SID).

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter a name for the global I-SID.  

```
i-sid name <1-6777215> WORD<1-64>
```
3. Display I-SID names for all configured I-SIDs.  

```
show i-sid name
```
4. Display I-SID name by I-SID.  

```
show i-sid name <1-6777215>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#i-sid name 1 ExtremeServer1
Switch:1(config)#i-sid name 20 ExtremeServer7
```

View the configured I-SID names:

```
Switch:1(config)#show i-sid name
=====
I-SID Name
=====
I-SID I-SID NAME TYPE

1 ExtremeServer1 adminName
2 ExtremeServer2 adminName
3 ExtremeServer3 config adminName
4 ISID-4 config
23 ISID-23 config
25 ExtremeServer4 config adminName

Total number of I-SID Name entries: 6.
```

View the configured I-SID by number:

```
Switch:1#show i-sid name 1
=====
I-SID Name
```

```

=====
I-SID I-SID NAME TYPE

1 ExtremeServer1 adminName

Switch:1#show i-sid name 20
=====
 I-SID Name
=====
I-SID I-SID NAME TYPE

20 ExtremeServer7 adminName

```

**Variable Definitions**

Use the data in the following table to use the **i-sid name** command.

Variable	Value
<1-6777215>	Specifies the I-SID number.
WORD<1-64> <b>Note:</b> This parameter does not apply to all hardware platforms.	Specifies the name of the I-SID. The I-SID can be named before or after the I-SID is created. By default, for an I-SID in use, the service is named ISID-x, where x correlates to the I-SID number of the service.

*Displaying C-VLAN I-SID information*

Use the following procedure to display C-VLAN I-SID information.

**Procedure**

1. Display the C-VLAN to I-SID associations:  
show vlan i-sid <1-4059>
2. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  
show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
3. Discover where entries are learned:  
show vlan mac-address-entry [spbm-tunnel-as-mac]
4. Display the VLAN remote MAC table for a C-VLAN:  
show vlan remote-mac-table <1-4059>

**Example**

```

Switch:1>show vlan i-sid
=====
 Vlan I-SID

## Variable definitions

The following table defines parameters for the **show vlan** commands.

Variable	Value
<i>i-sid</i> <1-4059>	Displays I-SID information for the specified C-VLAN.
<i>mac-address-entry</i> [ <i>spbm-tunnel-as-mac</i> ]	Displays the bridging forwarding database. Use the optional parameter, <i>spbm-tunnel-as-mac</i> to display the BMAC in the TUNNEL column. If you do not use this optional parameter, the TUNNEL column displays the host name. If an entry is not learned in the SPBM network, the TUNNEL column will be empty (-).
<i>remote-mac-table</i> <1-4059>	Displays C-VLAN remote-mac-table information.

The following table defines parameters for the **show isis** commands.

Variable	Value
<i>spbm i-sid</i> { <i>all</i>   <i>config</i>   <i>discover</i> }	<ul style="list-style-type: none"> <li>all: displays all I-SID entries</li> <li>config: displays configured I-SID entries</li> <li>discover: displays discovered I-SID entries</li> </ul>
<i>vlan</i> <1-4059>	Displays I-SID information for the specified SPBM VLAN.
<i>id</i> <1-16777215>	Displays I-SID information for the specified I-SID.
<i>nick-name</i> <x.xx.xx>	Displays I-SID information for the specified nickname.

## Job aid

The following sections describe the fields in the outputs for the C-VLAN I-SID show commands.

show vlan i-sid

The following table describes the fields in the output for the **show vlan i-sid** command.

Parameter	Description
VLAN_ID	Indicates the VLAN IDs.
I-SID	Indicates the I-SIDs associated with the specified C-VLANs.

show isis spbm i-sid

The following describes the fields in the output for the **show isis spbm i-sid** command.

Parameter	Description
ISID	Indicates the IS-IS SPBM I-SID identifier.
SOURCE NAME	Indicates the nickname of the node where this I-SID was configured or discovered.  <b>Note:</b> SOURCE NAME is equivalent to nickname.

Parameter	Description
VLAN	Indicates the B-VLAN where this I-SID was configured or discovered.
SYSID	Indicates the system identifier.
TYPE	Indicates the SPBM I-SID type as either configured or discovered.
HOST_NAME	Indicates the host name of the multicast FIB entry.

show vlan mac-address-entry

The following table describes the fields in the output for the **show vlan mac-address-entry** command.

Parameter	Description
VLAN ID	Indicates the VLAN for this MAC address.
STATUS	Indicates the status of this entry: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul>
MAC ADDRESS	Indicates the MAC address.
INTERFACE	Displays the network-to-network (NNI) interface.
SMLT REMOTE	Indicates the MAC address entry for the remote vIST peer.
TUNNEL	Indicates the host name of the remote Backbone Edge Bridge (BEB).

show vlan remote-mac-table

The following table describes the fields in the output for the **show vlan remote-mac-table** command.

Parameter	Description
VLAN	Indicates the VLAN ID for this MAC address.
STATUS	Indicates the status of this entry: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul>
MAC-ADDRESS	Indicates the customer MAC address for which the bridge has forwarding and/or filtering information.
DEST-MAC	Indicates the provide MAC address for which the bridge has forwarding and/or filtering information.
BVLAN	Indicates the B-VLAN ID for this MAC address.

Parameter	Description
DEST-SYSNAME	Indicates the system name of the node where the MAC address entry comes from.
PORTS	Either displays the value 0 or indicates the port in which a frame comes from.
SMLT REMOTE	Indicates the MAC address entry for the remote vIST peer.

### Configuring an SPBM Layer 2 Transparent Port UNI

Use this procedure to configure a Transparent Port UNI or E-LAN Transparent service.

#### Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes creating the SPBM BVLANS.
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

#### Caution

In the case of T-UNI LACP SMLT, before you configure SMLT on switch peers, ensure that the T-UNI LACP MLT on each peer is always associated with a VLAN, even if it is the default VLAN, and that it is added to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

### About This Task

You can configure Transparent Port UNI when either of the following apply:

- You want all tagged and untagged traffic on a port to be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure a Transparent Port UNI (Elan-Transparent based service). Enter:
 

```
i-sid <1-16777215> elan-transparent
```

This command automatically takes you to the Elan-Transparent I-SID Configuration mode.

3. Add ports to the Elan-Transparent based service. Enter:

```
port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

A warning message displays indicating that adding a port to a T-UNI I-SID removes the port from all VLANs. Click **y** when prompted, to continue.

4. Add an MLT to the Elan-Transparent based service. Enter:

```
mlt <1-512>
```

A warning message displays indicating that adding an MLT to a Transparent Port UNI I-SID removes the MLT from all VLANs. Click **y** when prompted, to continue.

5. To verify the Transparent Port UNI configuration, enter:

```
show i-sid <1-16777215>
```

6. To remove ports or MLT from the Elan-Transparent based service, enter one of the following commands:

```
no port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

OR

```
no mlt <1-512>
```

7. To delete the Elan-Transparent based service, enter:

```
no i-sid <1-16777215>
```

### Example

Configure a Transparent Port UNI I-SID (elan-transparent based service).

```
Switch:1(config)#i-sid 3 elan-transparent

Switch:1(elan-tp:3)#port 1/25
Adding Ports to Transparent UNI i-sid removes it from all VLANs.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#

Switch:1(elan-tp:3)#mlt 1
Adding MLTs to Transparent UNI i-sid removes it from all VLANs.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#
```

Verify Transparent Port UNI or Elan-Transparent based service configuration.

```
Switch:1(config)#show i-sid 3

**Variable definitions**

The following table defines parameters for the **i-sid** command.

**Note**

When SPB is enabled, ISID IDs 16000000 (0xF42400) and greater, up to 16,777,215 (0xFFFFF), are reserved for dynamic i-sid allocation and used to support IP Multicast traffic over SPB and other advanced Fabric services.

Variable	Value
<code>i-sid &lt;1-16777215&gt; elan-transparent</code>	Creates an Elan-Transparent based service. The service interface identifier (I-SID) range is 1 to 16777215.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Add ports to the Elan-Transparent based service.
<code>mlt &lt;1-512&gt;</code>	Add MLTs to the Elan-Transparent based service. The MLT range is 1 to 512.

*View all Configured I-SIDs*

Perform this procedure to view all the configured I-SIDs including their types, ports, and MLTs.

**About This Task**

View all configured I-SIDs (both CVLAN and T-UNI). View also the I-SID types and the ports or MLTs that are assigned to each I-SID.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. View all configured I-SIDs. This command displays both CVLAN and T-UNI based I-SIDs.  
`show i-sid`
3. View all T-UNI (Elan-Transparent) I-SIDs.  
`show i-sid [elan-transparent]`
4. View information for a particular T-UNI I-SID.  
`show i-sid [<1-16777215>]`
5. View all IS-IS SPBM I-SID information by I-SID ID:  
`show isis spbm i-sid {all|config|discover} [vlan <2-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]`

**Example**

View all configured I-SIDs.

```
Switch:1#show i-sid

## Variable Definitions

### Note

When SPB is enabled, I-SID IDs 16777216 and greater are reserved for internal I-SID and SPB multicast.

The following table defines parameters for the **show i-sid** command.

Variable	Value
<code>&lt;1-16777215&gt;</code>	Specifies the service interface identifier (ISID).
<code>elan-transparent</code>	Displays only all the Elan-Transparent (T-UNI based) ISIDs.

The following table defines parameters for the **show isis spbm i-sid** command.

Variable	Value
<code>{all config discover}</code>	<ul style="list-style-type: none"> <li>all: displays all I-SID entries</li> <li>config: displays configured I-SID entries</li> <li>discover: displays discovered I-SID entries</li> </ul>
<code>vlan &lt;2-4059&gt;</code>	Displays I-SID information for the specified SPBM VLAN.
<code>id &lt;1-16777215&gt;</code>	Displays I-SID information for the specified I-SID.
<code>nick-name &lt;x.xx.xx&gt;</code>	Displays I-SID information for the specified nickname.

## Job Aid

The following table defines parameters for the **show i-sid** command.

**Table 135: show i-sid**

Field	Description
ISID ID	Specifies the service interface identifier (I-SID)
ISID TYPE	Specifies the type of I-SID
VLANID	Specifies the backbone VLAN

**Table 135: show i-sid (continued)**

Field	Description
PORT INTERFACES	Specifies the port that is assigned to the I-SID
MLT INTERFACES	Specifies the mlt that is assigned to the I-SID
ORIGIN	Specifies how the I-SID is discovered.
ISID NAME	Specifies the name of the I-SID. By default, for an I-SID in use, the service is named ISID-x, where x correlates to the I-SID number of the service.

The following table defines parameters for the **show isis spbm i-sid** command.

**Table 136: show isis spbm i-sid**

Field	Description
ISID	Indicates the IS-IS SPBM I-SID identifier.
SOURCE NAME	Indicates the nickname of the node where this I-SID was configured or discovered. <b>Note:</b> SOURCE NAME is equivalent to nickname.
VLAN	Indicates the B-VLAN where this I-SID was configured or discovered.
SYSID	Indicates the system identifier.
TYPE	Indicates the SPBM I-SID type as either configured or discovered.
HOST_NAME	Indicates the host name of the multicast FIB entry.
ISID NAME	Specifies the configured name for the I-SID.

### Viewing C-MACs Learned on T-UNI Ports for an I-SID

Perform this procedure to view the I-SID bridge forwarding database.

#### About This Task

The **show i-sid mac-address-entry** command displays the C-MACs learned on T-UNI I-SIDs. It also displays the C-MACs learned on T-UNI I-SIDs for a specific I-SID, MAC address, port or port list or remote MAC address.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View C-MACs learned on the T-UNI I-SIDs:

```
show i-sid mac-address-entry [<1-16777215>] [mac
<0x00:0x00:0x00:0x00:0x00:0x00>] [port {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}] [remote]
```

**Example**

View C-MACs learned on all T-UNI I-SIDs.

```
Switch:1#show i-sid mac-address-entry

### Variable Definitions

The following table defines parameters for the **show i-sid mac-address-entry** command.

Variable	Value
<code>&lt;1-16777215&gt;</code>	Displays the MAC address learned on the service interface identifier (ISID).
<code>mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code>	Displays the I-SID FDB details for the specified MAC address.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Displays the MAC address learned on the specified port or port list.
<code>remote</code>	Displays the remote MAC address learned on the I-SID.

### Job Aid

The following table describes the fields in the output for the **show i-sid mac-address-entry** command.

**Table 137: show i-sid**

Field	Description
I-SID	Specifies the service interface identifier (I-SID).
STATUS	Specifies the learning status of the associated MAC.
MAC-ADDRESS	Specifies the MAC address of the port assigned to the specific I-SID or MAC learned on the specific I-SID.
INTERFACE	Specifies the port or MLT on which the MAC is learned for the specific I-SID.
TYPE	Specifies whether the MAC is a Local or IST PEER or a Remote MAC.
DEST-MAC	Specifies the virtual BMAC address or system ID, in MAC format, of the destination node.
BVLAN	Specifies the BVLAN on which the destination node is discovered for the I-SID.
DEST-SYSNAME	Specifies the destination system name.

*Viewing I-SID maximum MAC-limit*

Perform this procedure to view the maximum MAC learning limit information for an I-SID.

**Important**

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

**About This Task**

The total MAC learning limit per switch is 32000. MAC learning on I-SID stops when the maximum limit is reached.

**Procedure**

View the maximum MAC learning limit configured for an I-SID:

```
show i-sid limit-fdb-learning <1-16777215>
```

**Example**

View maximum MAC learning limit for all I-SIDs.

```
Switch:1#show i-sid limit-fdb-learning

=====

## Variable definitions

The following table defines parameters for the **show i-sid limit-fdb-learning** command.

### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

Variable	Value
<i>limit-fdb-learning</i>	Displays the I-SID-based maximum MAC limit information.
<1-6777215>	Displays the service interface identifier (ISID). The ISID range is 1 to 16777215.

## Job aid

The following table describes the fields in the output of the **show i-sid limit-fdb-learning** command.

### Important

The command **show i-sid limit-fdb-learning** is supported only on the VSP 4450 Series.

**Table 138: show i-sid limit-fdb-learning**

Field	Description
ISID ID	Specifies the service interface identifier (ISID)
MAC-LIMIT STATUS	Specifies whether the MAC learning limit is enabled or disabled
MAXMAC COUNT	Specifies the MAC learning limit

## Configure an SPBM Layer 2 Switched UNI on an MLT

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

## About This Task

To configure a Switched UNI on an MLT, you must create a Switched UNI I-SID, and map an MLT to the Switched UNI I-SID.

### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

**Procedure**

1. Enter MLT Interface Configuration mode:

```
enable

configure terminal

interface mlt <1-512>
```

2. Enable S-UNI on MLT:

```
flex-uni enable
```

**Note**

You cannot enable Switched UNI on EAPoL enabled interface.

3. Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

4. Add an MLT to a Switched UNI I-SID:

```
c-vid <c-vid> mlt <1-512>
```

**Note**

You can run this command again to map a Switched UNI MLT to multiple I-SIDs.

5. Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic mlt <1-512> [bpdu enable]
```

6. Display the Switched UNI information:

```
show mlt i-sid
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#mlt 10
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#flex-uni enable
Switch:1(config-mlt)#i-sid 100
Switch:1(elan:100)#c-vid 20 mlt 10
Switch:1(elan:100)#untagged-traffic mlt 10 bpdu enable
Switch:1(elan:100)#show mlt i-sid

=====
 MLT Isid Info
=====

```

```

```

ORIGIN Legend:
C: manually configured; D: discovered by FA or EPT
M: FA management; E: discovered by EAP; A: auto-sense
l: discover by local switch r: discover by remote VIST switch

```

### Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <l-16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid <c-vid> mlt <mlt-id>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic mlt <mlt-id> [bpdu enable]	Add untagged traffic to the Elan-based service.

### Configuring an SPBM Layer 2 Switched UNI on a Port

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

#### Note

EAP and FA can co-exist on the same port. EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port. If EAP is currently enabled, FA can only be enabled if the port is a Flex UNI-enabled port. VSP 4450 Series, VSP 8600 Series, or XA1400 Series do not support EAP and FA on the same port.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

### About This Task

To configure a Switched UNI on a port, you must create a Switched UNI I-SID, and map the port to the Switched UNI I-SID.

#### Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Switched UNI on a port:

```
flex-uni enable
```

### Note

You cannot enable enable EAP on a Switched UNI (S-UNI) on the VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

3. Configure a Switched UNI Service Instance Identifier (I-SID):

```
i-sid <1-16777215> [elan]
```

This command automatically takes you to the Elan I-SID Configuration mode.

4. Add ports to a Switched UNI I-SID:

```
c-vid <c-vid> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

5. Add untagged traffic to a Switched UNI I-SID:

```
untagged-traffic port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} [bpdu enable]
```

6. Display the Switched UNI information:

```
show interface gigabitEthernet i-sid {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/1,1/2
Switch:1(config-if)#flex-uni enable
Switch:1(config-if)#i-sid 100
Switch:1(elan:100)#c-vid 10 port 1/1,1/2
Switch:1(elan:100)#untagged-traffic port 1/1,1/2 bpdu enable
```

### Note

Not all fields are supported on all hardware platforms.

```
Switch:1#show interface gigabitEthernet i-sid
```

```
=====
PORT Isid Info

M: FA management; E: discovered by EAP; A: auto-sense

l: discover by local switch r: discover by remote VIST switch

### Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <1-16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid <c-vid> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic < port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}> [bpdu enable]	Add untagged traffic to the Elan-based service.

#### View All Configured Switched UNI I-SIDs

Perform this procedure to view all the configured Switched UNI I-SIDs including their types, ports, and MLTs.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View all configured CVLAN, T-UNI, and S-UNI based I-SIDs:  
show i-sid
3. View all S-UNI I-SIDs.  
show i-sid [elan]
4. View all associated MLT on the S-UNI I-SID.  
show mlt i-sid [MLT ID <1-512>]

5. View all associated ports on the S-UNI I-SID.  
`show interface gigabitethernet i-sid {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]`
6. View all IS-IS SPBM multicast FIB entries.  
`show isis spbm multicast-fib detail`

**Examples**

View all configured I-SIDs.

```
Switch:1#show i-sid

**Variable Definitions**

The following table defines parameters for the **i-sid** command.

Variable	Value
elan	Displays only all the Elan (S-UNI based) I-SIDs.
MLT ID <1-512>	Specifies the MLT associated with the Switched UNI I-SID.
{slot/port[/sub-port] [-slot/port[/sub-port]][,...]}	Specifies the ports associated with the Switched UNI I-SID.

*Display C-VLAN and Switched UNI I-SID Information*

Use the following procedure to display C-VLAN and Switched UNI (S-UNI) I-SID information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.

2. Display the C-VLAN to I-SID associations:  

```
show vlan i-sid <1-4059>
```
3. Display I-SID information and Switched UNI to I-SID associations:  

```
show i-sid <1-16777215>
```
4. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:  

```
show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
```
5. Display all elan I-SID:
  - ```
show i-sid elan
```
6. Display I-SID configured on MLT:
 - ```
show mlt i-sid
```
7. Display I-SID configured on port:
  - ```
show interfaces gigabitethernet i-sid
```

Examples

```
Switch:1>show isis spbm i-sid all
```

```

| <i>spbm i-sid {all config discover}</i> | <ul style="list-style-type: none"> all: displays all I-SID entries config: displays configured I-SID entries discover: displays discovered I-SID entries |

Layer 2 VSN configuration using EDM

This section provides procedures to configure Layer 2 Virtual Services Networks (VSNs) using Enterprise Device Manager (EDM).

Configuring SPBM Layer 2 VSN

After you have configured the SPBM infrastructure, you can enable the SPBM Layer 2 Virtual Service Network (VSN) using the following procedure.

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Advanced** tab.
- To map a C-VLAN to a Service instance identifier (I-SID), in the **I-sid** field, specify the I-SID to associate with the specified VLAN.

- Click **Apply**.

Important

- When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.
- The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

Displaying the remote MAC table for a C-VLAN

Use the following procedure to view a the remote MAC table for a C-VLAN.

Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Remote MAC** tab.

Remote MAC field descriptions

Use the data in the following table to use the **Remote MAC** tab.

| Name | Description |
|-----------------------------|--|
| VlanId | Indicates the VLAN ID for this MAC address. |
| Addr | Indicates the customer MAC address for which the bridge has forwarding and/or filtering information |
| DestAddr | Indicates the provider MAC address for which the bridge has forwarding and/or filtering information. |
| PrimaryBVlanId | Indicates the primary B-VLAN ID for this MAC address. |
| PrimaryDestSysName | Indicates the primary system name of the node where the MAC address entry comes from. |
| PrimaryPort | Either displays the value 0, or indicates the primary port on which a frame came from. |
| SecondaryBVlanId | Indicates the secondary B-VLAN ID for this MAC address |
| SecondaryDestSysName | Indicates the secondary system name of the node where the MAC address entry comes from. |
| SecondaryPort | Either displays the value 0, or indicates the secondary port on which a frame came from. |

| Name | Description |
|-------------------|---|
| SmltRemote | Indicates the MAC address entry for the remote vIST peer. |
| Status | Indicates the status of this entry: <ul style="list-style-type: none"> • other • invalid • learned • self • mgmt |

Configure UNI

Use the following procedure to configure a Transparent Port UNI or Switched UNI by mapping an I-SID to a port or MLT and VLAN together.

Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

About This Task

You must first create a type of service instance identifier (I-SID) to create the different types of services available. After you create an I-SID you can add members (ports or MLTs) to the I-SID to create end-points for the service.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **ISID**.
3. Click the **Service** tab.
4. To create a Transparent Port UNI service:
 - a. Click **Insert**.
 - b. Select **elan Transparent** in the **Type** field.
 - c. Enter the I-SID in the **Id** field.
5. To create a Switched UNI service:

Note

Flex UNI must be enabled to create a Switched UNI service.

- a. Click **Insert**.
 - b. Select **elan** in the **Type** field.
 - c. Enter the I-SID in the **Id** field.
6. Click **Insert**.

Service Field Descriptions

Use the data in the following table to use the **Service** tab.

| Name | Description |
|---|--|
| ID | Specifies a unique value to identify the service associated with this entry. |
| Type | Specifies the type of service associated with this entry. |
| MacLimitEnable | Indicates whether the MAC limit is enabled (true) or disabled (false). |
| MaxMacLimit | Indicates the maximum learned value of the MAC address for each service I-SID. |
| Action | Specifies I-SID related actions. |
| OriginBitMap | Specifies the origin of the I-SID. |
| VnId | Identifies the VXLAN service associated with this I-SID. |
| Name

Note:
This field does not apply to all hardware platforms. | Specifies the name of the I-SID. |

Associate a Port and MLT with an ISID for Elan Transparent

Transparent Port UNI (T-UNI) maps a port or MLT to an I-SID. Transparent Port UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. Multiple ports on the same unit and on other Backbone Edge Bridges (BEBs) are switched on a common I-SID. No VLAN is involved in this process. The T-UNI port is not a member of any VLAN or STG.

Use the following procedure to associate a port and MLT with an ISID.

Before You Begin

- You must configure Transparent Port UNI. For more information, see [Configuring Transparent UNI](#).
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI ISID.

Caution

Ensure that a T-UNI LACP MLT is always associated with a VLAN (even if it is the default VLAN) before adding it to a T-UNI ISID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elanTransparent.
4. Select **ELAN**.
5. Select port members.
6. Select MLT Ids.
7. Select **Apply**.

Elan Transparent field descriptions

Use the data in the following table to use the Elan Transparent tab.

| Name | Description |
|-------------|--|
| PortMembers | The set of ports that are members of the elanTransparent service type. From the ports available, you can select single or multiple ports. |
| MltIds | The set of bits that represent the MLT Ids. From the MLTs available, you can select any, or all of the MLTs to be a part of elan transparent i-sid . |

Viewing the ISID forwarding database

View the I-SID forwarding database (FDB).

Note

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **ISID**.
3. Click the **FDB** tab.

Click **Filter** to filter rows based on specific filter criteria.

FDB field descriptions

Use the data in the following table to use the **FDB** tab.

| Name | Description |
|-----------------------------|--|
| IsidId | Specifies the service interface identifier (I-SID). |
| Address | Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID. |
| Status | Specifies the learning status of the associated MAC. |
| Port | Specifies the port on which the MAC is learned for the specific I-SID. |
| PortType | Specifies whether the MAC is a local or IST-peer or a remote MAC. |
| RemoteMacDestAddr | Specifies the virtual BMAC address or system-ID of the remote destination. |
| RemoteMacBVlanId | Specifies the BVLAN ID on which the remote destination was discovered. |
| RemoteMacDestSysName | Specifies the remote destination system name. |
| Cvid | Specifies the customer VLAN ID of the associated Switched UNI port. |

Associate a Port and MLT with an I-SID for Elan

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Use the following procedure to associate a port and MLT with an I-SID.

About This Task

You must configure Switched UNI.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elan.
4. Select **Switched Uni**.
5. Select **Insert**.
6. Enter the VLAN ID in the **Cvid** field.
7. Select **Port** or **Mlt** to update the interface index in the **IfIndex** field.
8. Select **Insert**.

Switched Uni field descriptions

Use the data in the following table to use the **Switched Uni** tab.

| Name | Description |
|---------------------|--|
| Isid | Displays the I-SID. |
| Cvid | Specifies the customer VLAN identifier. |
| IfIndex | Specifies the interface index of the Elan end point. |
| Bpdu | Enables or disables for an untagged end point. The default is disabled. |
| OriginBitmap | Specifies the origin information of the service associated with the I-SID Elan end point. |
| MacBased | Shows if the current entry is associated to a MAC-based Switched User Network Interface (S-UNI). |

Viewing the I-SID interface

View the I-SID interface.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **ISID**.
3. Click the **Interface** tab.
Click **Filter** to filter rows on specific filter criteria.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

| Name | Description |
|---------------------|--|
| IfIndex | Specifies the interface index. |
| Isid | Specifies the service interface identifier (I-SID). |
| Isid Name | Specifies the service interface identifier name. |
| Vlan | Specifies the platform VLAN. |
| Cvid | Specifies the customer VID. |
| Type | Specifies the type of service associated with the I-SID interface. |
| OriginBitMap | Specifies the origin of the service associated with the I-SID interface. |
| Bpdu | Specifies the BPDU forward option for the untagged traffic port. |
| MacBased | Specifies the Switched UNI MAC address. |

Modify Global I-SID Name

About This Task

Use this procedure to modify the assigned name for the Service Identifier (I-SID).

Note

Product Notice: For XA1400 Series, you can modify a service name for IPv4 static routes and IPv4 loopback CLIP interfaces only. For information about feature support, see [VOSS Feature Support Matrix](#).

Note

This procedure is not supported on VSP 8600 Series.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **ISID**.
3. Select **Global Name**.
4. View the name of the I-SID in the **ISID Name** field. To modify, double-click the name of the I-SID and type a new name.
5. Select **Apply**.

Global Name Field Descriptions

Use the data in the following table to use the **Global Name** tab.

| Name | Description |
|-------------------|---|
| ISID Id | Specifies the index number that uniquely identifies the I-SID. |
| ISID Name | Specifies the name of the I-SID, which can be up to 64 characters. This field is not supported on all hardware platforms. |
| UsedByType | Specifies the I-SIDs that are in use as services. An I-SID can have one base type or a combination of base types so that multiple services can use the same I-SID at the same time. |

Layer 2 VSN configuration examples

This section provides configuration examples to configure Layer 2 VSNs.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Layer 2 VSN Configuration Example

The following figure shows a sample Layer 2 VSN deployment.

Figure 96: Layer 2 VSN

The following sections show the steps required to configure the Layer 2 VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1105.

SwitchC

```
VLAN CONFIGURATION

Inter-VSN routing configuration fundamentals

This section provides fundamental concepts on Inter-VSN Routing.

Inter-VSN routing

Inter-VSN routing with SPBM allows routing between Layer 2 VLANs with different I-SIDs.

Figure 98: Inter-VSN routing

Inter-VSN routing provides a routing hub for Layer 2 Virtual Services Network edge devices, Layer 3 devices, routers, or hosts connected to the SPBM cloud using the SPBM Layer 2 VSN service. To go between a routed network, a Layer 2 VSN termination point provides the routing services to hop onto another Layer 2 VSN, using I-SID.

Note

The Layer 2 VLANs must be in the same VRF. You cannot route traffic between two different VRFs with Inter-VSN routing.

In this example, the C-VLANs are associated with I-SIDs on the BEBs using SPBM Layer 2 VSN. With Inter-VSN routing enabled, BCB C can route traffic between VLAN 11 (I-SID 2011) and VLAN 12 (I-SID 2012).

IP interfaces are where the routing instance exists. In this case, on Switch-20.

Note

The switch does not support IP multicast over Fabric Connect routing on inter-VSN routing interfaces.

Inter-VSN routing configuration using the CLI

This section provides a procedure to configure Inter-VSN routing using the CLI.

Configure SPBM Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. As a best practice, use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure IP interface where the routing instance exists.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Follow the procedures below on the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between.

- a. Create a customer VLAN (C-VLAN) by port:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

- b. Add ports in the C-VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

- c. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. On the Backbone Core Bridge (BCB), create a VRF and add a VLAN for each VSN:

- a. Create a VRF:

```
ip vrf WORD<1-16> vrfid <1-511>
```

- b. Create a VLAN to associate with each VSN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

- c. Enter VLAN Interface Configuration mode:

```
interface vlan <1-4059>
```

- d. Add a VLAN to the VRF you created in step a:

```
vrf WORD<1-16>
```

- e. Associate an I-SID with the VLAN:

```
vlan i-sid <1-4059> <0-16777215> [force]
```

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

- f. Configure an IP address for the VLAN:

```
ip address {A.B.C.D/X}
```

- g. Repeat steps b to f for every VLAN you want to route traffic between.

Variable Definitions

The following table defines parameters for the **vlan create** command.

| Variable | Value |
|--|--|
| <2-4059> | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>type port-mstprstp</i> <0-63>
<i>[color</i> <0-32>] | Creates a VLAN by port: <ul style="list-style-type: none"> • <0-63> is the STP instance ID. • <i>color</i> <0-32> is the color of the VLAN. |

The following table defines parameters for the **vlan members add** command.

| Variable | Value |
|--|--|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/ <i>sub-port</i>] [- <i>slot/port</i> [/ <i>sub-port</i>]]
[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **vlan i-sid** command.

| Variable | Value |
|--------------|--|
| <1-4059> | Specifies the primary VLAN ID.
Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0-16777215> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment.
This value is the same for the primary and secondary VLANs. |
| <i>force</i> | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists. |

The following table defines parameters for the **ip vrf** command.

| Variable | Value |
|----------------------|--|
| <i>WORD</i> <1-16> | Create the VRF and specify the name of the VRF instance. |
| <i>vrfid</i> <1-511> | Specifies the VRF instance by number. |

The following table defines parameters for the **vrf** command.

| Variable | Value |
|--------------------|---|
| <i>WORD</i> <1-16> | Specifies the VRF name. Associates a port to a VRF. |

The following table defines parameters for the **ip address** command.

| Variable | Value |
|-------------|--|
| {A.B.C.D/X} | Configures an IP address for the VLAN. |

Inter-VSN routing configuration using EDM

This section provides procedures to configure Inter-VSN routing using Enterprise Device Manager (EDM).

Configure BEBs for Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network

(VSN) for applications such as vMotion. Use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

About This Task

Follow the procedures below on the Backbone Edge Bridges (BEBs) that contain the VSNs you want to route traffic between.

Procedure

1. Create a customer VLAN (C-VLAN) by port and add ports in the C-VLAN. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. In the **Basic** tab, click **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **byPort**.
8. In the **PortMembers** box, click the **(...)** button.
9. Click on the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that appear dimmed cannot be selected as VLAN port members.

10. Click **OK**.
11. Click **Insert**.
12. Collapse the **VLANs** tab.
The VLAN is added to the Basic tab.
13. Map a C-VLAN to an I-SID. In the navigation pane, expand **Configuration > VLAN**.
14. Click **VLANs**.
15. Click the **Advanced** tab.
16. To map a C-VLAN to an I-SID, in the **Isid** field, specify the I-SID to associate with the specified VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

17. Click **Apply**.

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

18. Configure the Backbone Core Bridge (BCB) for Inter-VSN Routing. For more information, see [Configuring BCBs for Inter-VSN Routing](#) on page 1201.

Advanced Field Descriptions

Use the data in the following table to use the **Advanced** tab.

| Name | Description |
|--|--|
| Id | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| Name | Specifies the name of the VLAN. |
| IfIndex | Specifies the logical interface index assigned to the VLAN. |
| Type | Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private |
| Isid | Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 - 16777215. The default value is 0, which indicates that no I-SID is assigned. |
| Isid Name
Note:
This field does not apply to all hardware platforms. | Specifies the name of the I-SID. |
| ProtocolId | Specifies the network protocol for protocol-based VLANs.
If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field. |

| Name | Description |
|----------------------------------|---|
| AgingTime | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600. |
| MacAddress | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies. |
| Vlan Operation Action | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> • none • flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN. • flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN. • flushIpl: Configures action to flushIpl. This action removes the learned IP addresses from the forwarding table for the selected VLAN. • flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports. • all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions. <p>The default is none.</p> |
| Result | Specifies the result code after you perform an action. |
| NlbMode | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled. |
| SpbMulticast | Enables or disables Multicast over Fabric Connect. The default is disabled. |
| SpbPimGatewayMulticast | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled. |
| RmonEnable | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled. |
| Ipv6FhsSnoopDhcpEnable | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled. |
| Ipv6FhsNDInspectionEnable | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled. |

| Name | Description |
|-----------------------|---|
| DvrEnable | Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled.

Note:
You must enable DvR on every VLAN that is configured on a DvR Controller. |
| DvrGwIpv4Addr | Specifies the DvR gateway IPv4 address for a VLAN.

Important:
Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN. |
| DvrGwIpv4Onelp | Enables or disables the DvR One IP for a VLAN. The default is disabled (false). |

Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name | Description |
|-------------------------|--|
| Id | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| Name | Specifies the name of the VLAN. |
| IfIndex | Specifies the logical interface index assigned to the VLAN. |
| Color Identifier | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded. |
| Type | Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private |
| MstpInstance | Identifies the MSTP instance. |
| VrfId | Indicates the Virtual Router to which the VLAN belongs. |
| VrfName | Indicates the name of the Virtual Router to which the VLAN belongs. |

| Name | Description |
|-----------------------|--|
| PortMembers | Specifies the slot/port of each VLAN member. The sub-port only appears for channelized ports. |
| ActiveMembers | Specifies the slot/port of each VLAN member. The sub-port only appears for channelized ports. |
| StaticMembers | Specifies the slot/port of each static member of a policy-based VLAN. The sub-port only appears for channelized ports. |
| NotAllowToJoin | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The sub-port only appears for channelized ports. |
| ProtocolId | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| AgingTime | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600. |

Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the new name does not initially appear in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the old VLAN name appears in other tabs, click **Refresh** on those tabs as well.

Configuring BCBs for Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must configure the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between. For more information, see [Configure BEBs for Inter-VSN Routing](#) on page 1196.

About This Task

Follow the procedures below to configure the Backbone Core Bridge (BCB) for inter-VSN routing.

Procedure

1. On the Backbone Core Bridge (BCB), create a VRF. In the navigation pane, expand **Configuration > IP**.
2. Click **VRF**.
3. Click **Insert**.
4. Specify the VRF ID.
5. Name the VRF instance.
6. Configure the other parameters as required.
7. Click **Insert**.
8. Create a VLAN to associate with each VSN. In the navigation pane, expand **Configuration > VLAN**.
9. Click **VLANs**.
10. In the **Basic** tab, click **Insert**.
11. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
12. In the **Name** box, type the VLAN name, or use the name provided.
13. In the **Color Identifier** box, click the down arrow and choose a color from the list, or use the color provided.
14. In the **Type** box, select **byPort**.
15. In the **PortMembers** box, click the **(...)** button.
16. Click on the ports to add as member ports.

The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that appear dimmed cannot be selected as VLAN port members.
17. Click **OK**.
18. Click **Insert**.
19. Collapse the **VLANs** tab.

The VLAN is added to the **Basic** tab.
20. Associate the VLAN with an I-SID. In the navigation pane, expand **Configuration > VLAN**.
21. Click **VLANs**.
22. In the VLANs tab, click the **Advanced** tab.
23. In the **I-sid** box, specify the I-SID to associate with the VLAN.
24. Click **Apply**.
25. Configure a circuitless IP interface (CLIP). In the navigation pane, expand **Configuration > IP**.
26. Click **IP**.
27. Click the **Circuitless IP** tab.
28. Click **Insert**.
29. In the **Interface** field, assign a CLIP interface number.
30. Enter the IP address.
31. Enter the network mask.
32. Click **Insert**.

VRF field descriptions

Use the data in the following table to help you use the **VRF** tab.

| Name | Description |
|----------------------------|---|
| Id | Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter. |
| Name | Names the VRF instance. |
| ContextName | Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB module management. |
| TrapEnable | Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is true. |
| MaxRoutes | Configures the maximum number of routes allowed for the VRF. The maximum value varies per platform. See Release Notes for VOSS for platform-specific scaling information. The default value is 10000. |
| MaxRoutesTrapEnable | Enables the generation of the VRF Max Routes Exceeded traps. The default is true. |

Advanced field descriptions

Use the data in the following table to use the **Advanced** tab.

| Name | Description |
|----------------|--|
| Id | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| Name | Specifies the name of the VLAN. |
| IfIndex | Specifies the logical interface index assigned to the VLAN. |
| Type | Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private |
| Isid | Specifies the I-SID number assigned to a customer VLAN (C-VLAN). The range is 0 – 16777215. The default value is 0, which indicates that no I-SID is assigned. |

| Name | Description |
|--|---|
| Isid Name

Note:
This field does not apply to all hardware platforms. | Specifies the name of the I-SID. |
| ProtocolId | Specifies the network protocol for protocol-based VLANs.
If the VLAN type is not protocol-based, None is displayed in the Basic tab ProtocolId field. |
| AgingTime | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600. |
| MacAddress | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies. |
| Vlan Operation Action | Performs an operation on the VLAN. The values are: <ul style="list-style-type: none"> • none • flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN. • flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN. • flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN. • flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports. • all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions. The default is none. |
| Result | Specifies the result code after you perform an action. |
| NlbMode | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled. |
| SpbMulticast | Enables or disables Multicast over Fabric Connect. The default is disabled. |

| Name | Description |
|----------------------------------|---|
| SpbPimGatewayMulticast | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled. |
| RmonEnable | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled. |
| Ipv6FhsSnoopDhcpEnable | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled. |
| Ipv6FhsNDInspectionEnable | Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled. |
| DvrEnable | Enables or disables DvR on a VLAN that is configured on the DvR Controller. The default is disabled.

Note:
You must enable DvR on every VLAN that is configured on a DvR Controller. |
| DvrGwIpv4Addr | Specifies the DvR gateway IPv4 address for a VLAN.

Important:
Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN. |
| DvrGwIpv4Onelp | Enables or disables the DvR One IP for a VLAN. The default is disabled (false). |

Circuitless IP field descriptions

Use the data in the following table to use the **Circuitless IP** tab.

| Name | Description |
|-------------------|--|
| Interface | Specifies the number assigned to the interface, from 1 to 256. |
| Ip Address | Specifies the IP address of the CLIP. |
| Net Mask | Specifies the network mask. |

Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name | Description |
|-------------------------|--|
| Id | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| Name | Specifies the name of the VLAN. |
| IfIndex | Specifies the logical interface index assigned to the VLAN. |
| Color Identifier | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded. |
| Type | Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private |
| MstpInstance | Identifies the MSTP instance. |
| VrfId | Indicates the Virtual Router to which the VLAN belongs. |
| VrfName | Indicates the name of the Virtual Router to which the VLAN belongs. |
| PortMembers | Specifies the slot/port of each VLAN member. The sub-port only appears for channelized ports. |
| ActiveMembers | Specifies the slot/port of each VLAN member. The sub-port only appears for channelized ports. |
| StaticMembers | Specifies the slot/port of each static member of a policy-based VLAN. The sub-port only appears for channelized ports. |
| NotAllowToJoin | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The sub-port only appears for channelized ports. |

| Name | Description |
|-------------------|---|
| ProtocolId | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC).
If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |
| AgingTime | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs.
The default is 600. |

Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the new name does not initially appear in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Click **Refresh** in the VLAN **Basic** tab toolbar. If the old VLAN name appears in other tabs, click **Refresh** on those tabs as well.

Inter-VSN routing configuration example

This section provides a configuration example for Inter-VSN routing.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Inter-VSN Routing with SPBM Configuration Example

The following figure shows a sample Inter-VSN deployment.

Figure 99: Inter-VSN routing configuration

The following sections show the steps required to configure the Inter-VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: [SPBM configuration examples](#) on page 1105.

Note that the IP interfaces are configured where the routing instance exists, namely, on SwitchG.

SPBM Reference Architectures

Reference Architectures

SPBM has a straightforward architecture that simply forwards encapsulated C-MACs across the backbone. Because the B-MAC header stays the same across the network, there is no need to swap a label or perform a route lookup at each node. This architecture allows the frame to follow the most efficient forwarding path from end to end.

The following reference architectures illustrate SPBM with multiple switches in a network.

For information about solution-specific architectures like Video Surveillance or Data Center implementation using the VSP switch, see [Solution-Specific Reference Architectures](#) on page 1220.

The following figure shows the MAC-in-MAC SPBM domain with BEBs on the boundary and BCBs in the core.

The following figure illustrates an existing edge that connects to an SPBM core.

The boundary between the MAC-in-MAC SPBM domain and the 802.1Q domain is handled by the BEBs. At the BEBs, VLANs or VRFs are mapped into I-SIDs based on the local service provisioning. Services (whether Layer 2 or Layer 3 VSNs) only need to be configured at the edge of the SPBM backbone (on the BEBs). There is no provisioning needed on the core SPBM nodes.

Provisioning an SPBM core is as simple as enabling SPBM and IS-IS globally on all the nodes and on the core facing links. To migrate an existing edge configuration into an SPBM network is just as simple.

Figure 100: SPBM basic architecture

Figure 101: Access to the SPBM Core

All BEBs that have the same I-SID configured can participate in the same VSN. That completes the configuration part of the migration and all the traffic flows return to normal operation.

For Layer 3 virtualized routing (Layer 3 VSN), map IPv4-enabled VLANs to VRFs, create an IP VPN instance on the VRF, assign an I-SID to the VRF, and then configure the desired IP redistribution of IP routes into IS-IS.

For Layer 2 virtualized bridging (Layer 2 VSN), identify all the VLANs that you want to migrate into SPBM and assign them to an I-SID on the BEB.

Campus Architecture

For migration purposes, you can add SPBM to an existing network that has SMLT configured. In fact, if there are other protocols already running in the network, such as Open Shortest Path First (OSPF), you can leave them in place too. SPBM uses IS-IS, and operates independently from other protocols. However, as a best practice, eliminate SMLT in the core and eliminate other unnecessary protocols. This reduces the complexity of the network and makes it much simpler to maintain and troubleshoot.

Whether you configure SMLT in the core, the main point to remember is that SPBM separates services from the infrastructure. For example, in a large campus, a user may need access to other sites or data centers. With SPBM you can grant that access by associating the user to a specific I-SID. With this mechanism, the user can work without getting access to confidential information of another department.

The following figure depicts a topology where the BEBs in the edge and data center distribution nodes are configured in SMLT clusters. Prior to implementing SPBM, the core nodes would also have been configured as SMLT clusters. When migrating SPBM onto this network design, it is important to note that you can deploy SPBM over the existing SMLT topology without network interruption. After the SPBM infrastructure is in place, you can create VSN services over SPBM or migrate them from the previous end-to-end SMLT-based design.

Figure 102: SPBM campus without SMLT

After you migrate all services to SPBM, the customer VLANs (C-VLANs) will exist only on the BEB SMLT clusters at the edge of the SPBM network. The C-VLANs will be assigned to an I-SID instance and then associated with either a VLAN in an Layer 2 VSN or terminated into a VRF in an Layer 3 VSN. You can also terminate the C-VLAN into the default router, which uses IP shortcuts to IP route over the SPBM core.

In an SPBM network design, the only nodes where it makes sense to have an SMLT cluster configuration is on the BEB nodes where VSN services terminate. These are the SPBM nodes where C-VLANs exist and these C-VLANs need to be redundantly extended to non-SPBM devices such as Layer 2 edge stackable switches. On the BCB core nodes where no VSNs are terminated and no Layer 2 edge stackables are connected, there is no longer any use for the SMLT clustering functionality. Therefore, in the depicted SPBM design, the SMLT/vist configuration can be removed from the core nodes because they now act as pure BCBs that simply transport VSN traffic and the only control plane protocol they need to run is IS-IS.

Because SMLT BEB nodes exist in this design (the edge BEBs) and it is desirable to use equal cost paths to load balance VSN traffic across the SPBM core, all SPBM nodes in the network are configured with the same two B-VIDs.

Where the above figure shows the physical topology, the following two figures illustrate a logical rendition of the same topology. In both of the following figures, you can see that the core is almost identical. Because the SPBM core just serves as a transport mechanism that transmits traffic to the destination BEB, all the provisioning is performed at the edge.

In the data center, VLANs are attached to Inter-VSNs that transmit the traffic across the SPBM core between the data center on the left and the data center on the right. A common application of this service is VMotion moving VMs from one data center to another.

The following figure uses IP shortcuts that route VLANs. There is no I-SID configuration and no Layer 3 virtualization between the edge distribution and the core. This is normal IP forwarding to the BEB.

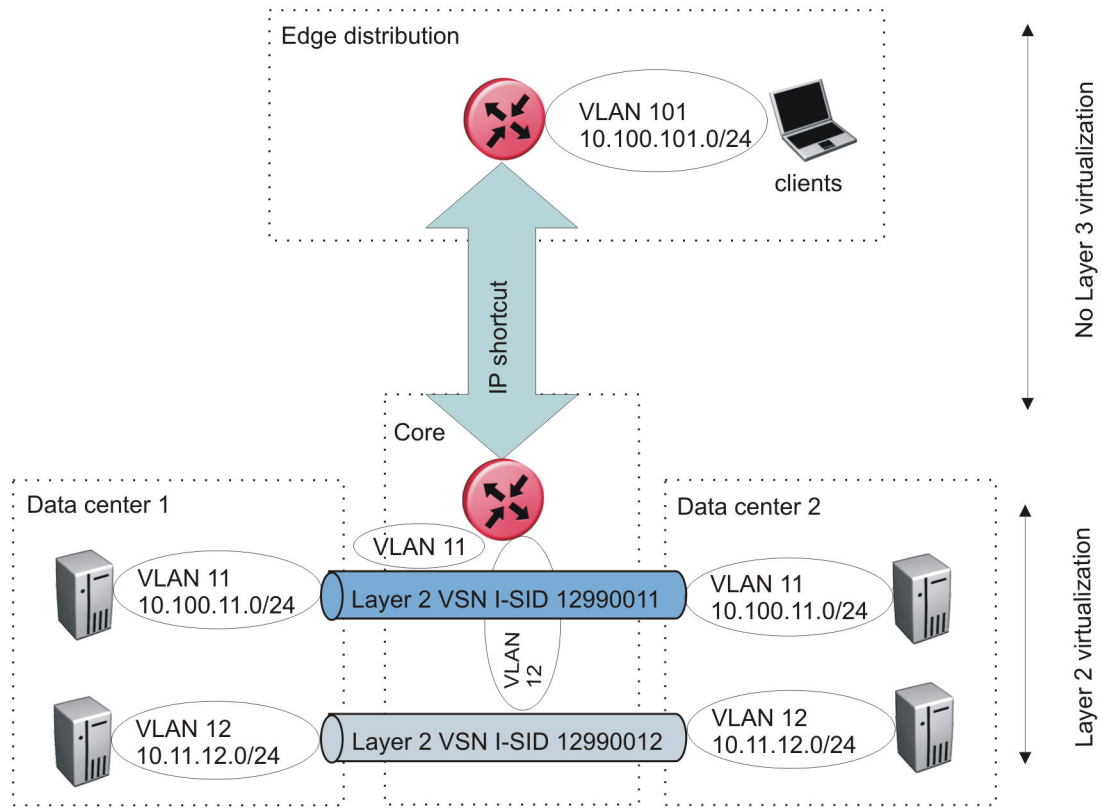

Figure 103: IP shortcut scenario to move traffic between data centers

The following figure uses Layer 3 VSNs to route VRFs between the edge distribution and the core. The VRFs are attached to I-SIDs and use Layer 3 virtualization.

Figure 104: VRF scenario to move traffic between data centers

Large data center architecture

SPBM supports data centers with IP shortcuts, Layer 2 VSNs, or Layer 3 VSNs. If you use vMotion, you must use Layer 2 between data centers (Layer 2 VSN). With Layer 2 VSNs, you can add IP addresses to the VLAN on both data centers and run Virtual Router Redundancy Protocol (VRRP) between them to allow the ESX server to route to the rest of the network.

The following figure shows an SPBM topology of a large data center. This figure represents a full-mesh data center fabric using SPBM for storage over Ethernet. This topology is optimized for storage transport because traffic never travels more than two hops.

Note

As a best practice, use a two-tier, full-mesh topology for large data centers.

Figure 105: SPBM data center—full mesh

Traditional data center routing of VMs

In a traditional data center configuration, the traffic flows into the network to a VM and out of the network in almost a direct path.

The following figure shows an example of a traditional data center with VRRP configured. Because end stations are often configured with a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks. VRRP eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost.

Figure 106: Traditional routing before moving VMs

A VM is a virtual server. When you move a VM, the virtual server is moved as is. This action means that the IP addresses of that server remain the same after the server is moved from one data center to the other. This in turn dictates that the same IP subnet (and hence VLAN) exist in both data centers.

In the following figure, the VM moved from the data center on the left to the data center on the right. To ensure a seamless transition that is transparent to the user, the VM retains its network connections through the default gateway. This method works, but it adds more hops to all traffic. As you can see in the figure, one VM move results in a complicated traffic path. Multiply this with many moves and soon the network look like a tangled mess that is very inefficient, difficult to maintain, and almost impossible to troubleshoot.

Figure 107: Traditional routing after moving VMs

Optimized data center routing of VMs

Two features make a data center optimized:

- VLAN routers in the Layer 2 domain (green icons)
- VRRP BackupMaster

The VLAN routers use lookup tables to determine the best path to route incoming traffic (red dots) to the destination VM.

VRRP BackupMaster solves the problem of traffic congestion on the vIST. Because there can be only one VRRP Master, all other interfaces are in backup mode. In this case, all traffic is forwarded over the vIST link towards the primary VRRP switch. All traffic that arrives at the VRRP backup interface is forwarded, so there is not enough bandwidth on the vIST link to carry all the aggregated riser traffic. VRRP BackupMaster overcomes this issue by ensuring that the vIST trunk is not used in such a case for primary data forwarding. The VRRP BackupMaster acts as an IP router for packets destined for the logical VRRP IP address. All traffic is directly routed to the destined subnetwork and not through Layer 2 switches to the VRRP Master. This avoids potential limitation in the available vIST bandwidth.

The following figure shows a solution that optimizes your network for bidirectional traffic flows. However, this solution turns two SPBM BCB nodes into BEBs where MAC and ARP learning will be enabled on the Inter-VSN routing interfaces. If you do not care about top-down traffic flows, you can omit the Inter-VSN routing interfaces on the SPBM BCB nodes. This makes the IP routed paths top-down less optimal, but the BCBs remain pure BCBs, thus simplifying core switch configurations.

Figure 108: Optimized routing before moving VMs

In the traditional data center, chaos resulted after many VMs were moved. In an optimized data center as shown in the following figure, the incoming traffic enters the Layer 2 domain where an edge switch uses Inter-VSN routing to attach an I-SID to a VLAN. The I-SID bridges traffic directly to the destination. With VRRP BackupMaster, the traffic no longer goes through the default gateway; it takes the most direct route in and out of the network.

Figure 109: Optimized routing after moving VMs

Solution-Specific Reference Architectures

The following sections describe solution-specific reference architectures, like for example for Video Surveillance or Data Center implementation, using the VSP 4450 Series.

Multi-tenant — fabric connect

This fabric connect-based solution leverages the fabric capabilities of the VSP platforms: a VSP 7000 core and a VSP 4450 Series edge. This solution provides the ability to run, by default, up to 24 VRFs for each wiring closet and is well suited for multi-tenant applications. The zero-touch core is enabled by the fabric connect endpoint provisioning capabilities.

Note

You can increase VRF scaling to run more than 24 VRFs. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [Release Notes for VOSS](#).

If this solution must support IPv6, then a central router-pair routes all IPv6 traffic. The IPv6 traffic is tunneled from each wiring closet to the IPv6 routers by extending Layer 2 VSNs to the q-tagged router interfaces.

Figure 110: Small core – multi-tenant

The following list outlines the benefits of the fabric connect-based solution:

- Endpoint provisioning
- Fast failover
- Simple to configure
- Layer 2 and Layer 3 virtualized

Hosted data center management solution – E-Tree

In some hosted data center solutions, the hosting center operating company takes responsibility for managing customer servers. For this shared management, shown in the following figure, servers that control the operating system level of the production servers, such as the patch level, are deployed. Because customer production servers do not communicate with each other, a distributed private VLAN solution based on fabric connect is deployed to manage all production servers. This solution builds a distributed set of E-Trees for each management domain.

The VSP switches as access, provide an elegant network-wide E-Tree solution. Spokes, or managed servers, cannot communicate to each other over this network, but the shared management servers on the hub ports can access all spokes. Because of the Layer 2 – E-Tree nature of this setup, the managed servers do not require any route entries, and only require one IP interface in this management private VLAN. This solution supports tagged and untagged physical and virtual (VM) servers.

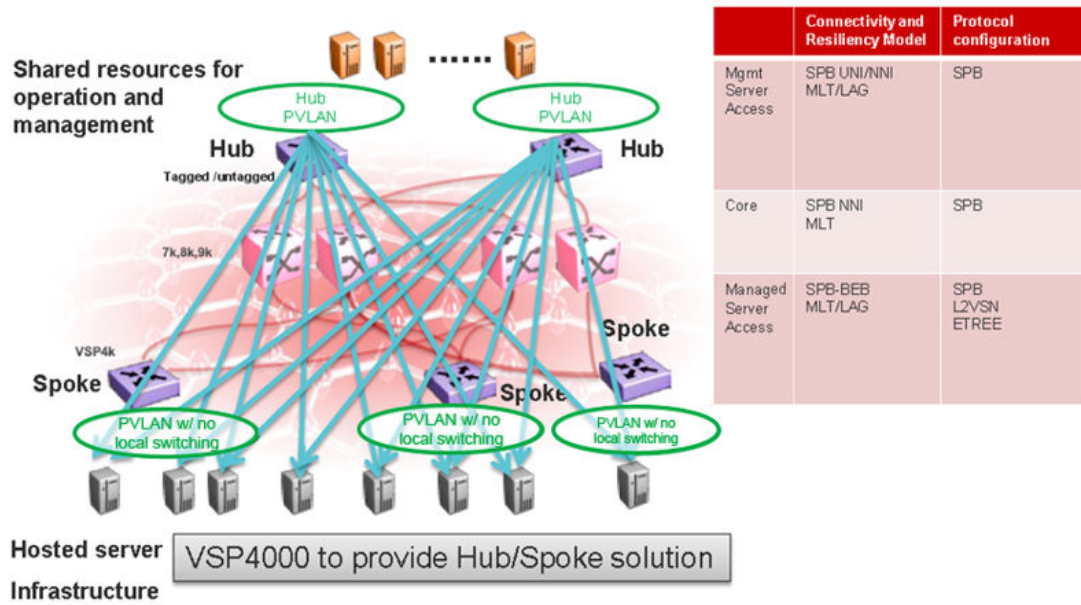

Figure 111: Data center hosting private VLAN

The following list outlines the benefits of the hosted data center management solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

Video surveillance – bridged

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying a fabric connect based IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone.

Figure 112: Deployment scenario — bridged video surveillance and IP camera deployment for transportation, airports, and government

The following list outlines the benefits of the bridged video surveillance solution:

- Easy end-point provisioning
- sub second resiliency and mc forwarding
- secure tenant separation
- quick camera switching

Video surveillance — routed

In a video surveillance solution, optimal traffic forwarding is a key requirement to ensure proper operation of the camera and recorder solutions. However, signaling is also important to ensure quick channel switching. This is achieved by deploying an IP multicast infrastructure that is optimized for multicast transport, so that the cameras can be selected quickly, and so that there is no unnecessary traffic sent across the backbone. In the topology shown in the following figure, each camera is attached to its own IP subnet. In a larger topology, this can reduce network overhead. To increase network scalability, you can attach a set of cameras to a Layer 2 switch that has IGMP, and then connect the cameras to the fabric edge (BEB) which has a routing instance.

In many customer scenarios, surveillance must be separated from the rest of the infrastructure. This can be achieved by deploying a Layer 3 VSN for the surveillance traffic to keep the surveillance traffic isolated from any other tenant.

Figure 113: Deployment scenario — Routed video surveillance and IP camera deployment for transportation, airports, and government

The following list outlines the benefits of the routed video surveillance solution:

- Easy endpoint provisioning
- Optimal resiliency and mc forwarding
- Secure tenant separation
- Rapid channel/camera switching

Metro-Ethernet Provider solution

VOSS switches provide an end-to-end Metro-Ethernet Provider solution. Leveraging fabric connect throughout the infrastructure enables a scalable and flexible wholesale provider infrastructure.

This use case extends the Transparent Port UNI functionality to transparently forward any customer VLAN across the services.

Figure 114: Metro ring access solution

The following list outlines the benefits of the Metro-Ethernet Provider solution:

- Easy endpoint provisioning
- Optimal resiliency
- Secure tenant separation

IP Shortcuts configuration fundamentals

This section provides fundamental concepts for IP Shortcuts.

Fabric Connect supports both IPv4 Shortcuts and IPv6 Shortcuts. Because IPv6 Shortcuts depend on IPv4 Shortcuts, you should understand how IPv4 Shortcuts work (see [SPBM IP shortcuts](#)) before jumping to the IPv6 section.

SPBM IP shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

Unlike Layer 2 VSN, with SPBM IP shortcuts, no I-SID configuration is required. Instead, SPBM nodes propagate Layer 3 reachability as “leaf” information in the IS-IS LSPs using Extended IP reachability TLVs (TLV 135), which contain routing information such as neighbors and locally configured subnets. SPBM nodes receiving the reachability information can use this information to populate the routes to the announcing nodes. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes.

The following figure shows a network running SPBM IP shortcuts.

Figure 115: SPBM IP Shortcuts

In this example, BEB A receives a packet with a destination IP address in the subnet of VLAN 14 and knows to forward the packet to BEB D based on the IP route propagation within IS-IS. After a route lookup, BEB A knows that BEB D is the destination for the subnet and constructs a new B-MAC header with destination B-MAC: D. BCBs B and C need only perform normal Ethernet switching to forward the packet to BEB D. A route lookup is only required once, at the source BEB, to identify BEB D as the node that is closest to the destination subnet.

In contrast to IP routing or Multiprotocol Label Switching (MPLS), SPBM IP shortcuts provide a simpler method of forwarding IP packets in an Ethernet network using the preestablished Ethernet FIBs on the BEBs. SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing SPT. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

In the above example, the SPBM nodes in the core that are not enabled with IP shortcuts can be involved in the forwarding of IP traffic. Since SPBM nodes only forward on the MAC addresses that comprise the B-MAC header, and since unknown TLVs in IS-IS are relayed to the next hop but ignored locally, SPBM nodes need not be aware of IP subnets to forward IP traffic.

With IP shortcuts, there is only one IP routing hop, as the SPBM backbone acts as a virtualized switching backplane.

The following figure shows a sample campus network implementing SPBM IP shortcuts.

Figure 116: SPBM IP shortcuts in a campus

To enable IP shortcuts on the BEBs, you must configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135.

In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct, static, OSPF, RIP, or BGP routes into IS-IS. To advertise IPv6 routes from the BEBs into the SPBM network, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.

SPBM IPv6 Shortcuts

Both IPv4 and IPv6 Shortcuts use IS-IS as the Interior Gateway Protocol (IGP) and the link state packet (LSP) for reachability information. However, IPv4 Shortcuts use TLV 135 and IPv6 Shortcuts use TLV 236. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes. IS-IS

transports the IPv6 reachability information to remote BEBs and uses the shortest path, calculated by SPBM, for data forwarding.

**Note**

You only configure the IPv6 address information on the edges. There is no IPv6 in the SPBM cloud.

IS-IS transports the IPv6 routes through TLV 236 in the LSP advertisements. These routes are installed in the Global Routing Table (GRT) with the node from which the LSPs carrying the IPv6 routes are received as the next hop.

IPv6 Shortcuts Dependency on IPv4 Shortcuts

IPv6 Shortcuts function in a very similar manner to IPv4 Shortcuts and depends on IPv4 Shortcuts for some functions. For example, IPv6 Shortcuts use the BMAC (local and remote) information created by IPv4 Shortcuts.

**Important**

IPv4 Shortcuts must be enabled before you enable IPv6 Shortcuts.

An error is displayed if you try to enable IPv6 Shortcuts but do not have IPv4 Shortcuts already enabled.

IPv6 Shortcuts alone can be disabled while leaving IPv4 Shortcuts enabled. When IPv4 Shortcuts is disabled without disabling IPv6 Shortcuts disabled first, a warning or error message is displayed indicating that IPv6 should be disabled first.

Circuitless IPv6 (CLIPv6)

To enable IPv6 Shortcuts on the BEBs and to advertise the local BEB to other IS-IS nodes, you must configure a circuitless IPv6 address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236.

IPv6 Shortcuts support Circuitless IPv6 (CLIPv6), which ensures uninterrupted connectivity to the switch as long as there is an actual path to reach it. This route always exists and the circuit is always up because there is no physical attachment.

Migrating the GRT to IPv6 Shortcuts

Use the following steps to migrate the Global Router Table (GRT) to use IPv6 Shortcuts over the SPBM core:

- Identify the nodes that should be enabled with IPv6 Shortcuts. Apply these steps to all of these nodes.
- Activate and validate basic IPv6 Shortcuts. For information, see [SPBM IPv6 Shortcuts](#) on page 1229.
- Configure IS-IS route preference to ensure that the IPv6 IGP protocol currently being used in the SPBM core is preferred over the IS-IS routes.
- Enable redistribution of direct and static IPv6 routes into IS-IS.
- Create route policies to permit only IPv6 IGP routes from the access side of the SPBM network.
- Configure redistribution of routes from the IPv6 route table from each of the IPv6 IGP protocols into IS-IS along with the appropriate route policy.

- Use the **show isis spbm ipv6-unicast-fib** command to check the IS-IS LSDB, IS-IS routes, and to verify that all the desired IPv6 routes are now in IS-IS.
- Configure redistribution of IS-IS routes from the IPv6 route table into each of the IPv6 IGP protocols in use. This redistribution does not require a route policy since IS-IS is only supported in the SPBM core.
- Change IS-IS route-preference to ensure that IS-IS routes are preferred over other IPv6 IGP routes.
- Disable/delete old IPv6 IGP in the SPBM core.

Important

Use only one IPv6 routing protocol in the SPBM core to prevent the possibility of routing loops.

IPv6 Shortcut Limitations and Considerations

The following features are not supported:

- Disabling and enabling alternate routes for IPv6 routes
- Redistribution of RIP into IS-IS
- 6-in-4 tunnels are not supported when the tunnel destination IP is reachable via IPv4 Shortcuts route.

Keep the following considerations in mind when configuring IPv6 Shortcuts:

- IPv4 Shortcuts must be enabled before enabling IPv6 Shortcuts.
- IPv6 Shortcuts support Circuitless IPv6 (CLIPv6) with the following limitations:
 - Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
 - IPv6 CLIP does not support link-local address configuration.
 - To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.

Note

This limitation does not apply to VSP 4450 Series switches.

- Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect when you configure a duplicate IPv6 address.
- Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
- You can configure a maximum of 64 IPv6 CLIP interfaces.
- IPv6 CLIP interface is enabled by default and it cannot be disabled.
- IPv6 with vIST provides the same support as IPv4 with vIST.
- To help with debugging, CFM provides full support for both IPv4 and IPv6 addresses for the **12ping** and **12traceroute** commands.

ECMP with IS-IS

The Equal Cost Multipath (ECMP) feature supports and complements the IS-IS protocol.

With ECMP, the switch can determine multiple equal-cost paths to the same destination prefix.

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

The number of multiple paths a switch can support differs by hardware platform. For more information about feature support, see [Release Notes for VOSS](#).

ECMP within IS-IS routes

Equal Cost Multipath (ECMP) allows the device to determine up to eight equal cost paths to the same destination prefix. The maximum number of equal cost paths you can configure depends on the hardware platform. For more information, see [Release Notes for VOSS](#).

If the device learns the same route from multiple sources, the information is ECMP only if the routes:

- are from the same VSN
- have the same SPBM cost
- have the same prefix cost
- have the same IP route preference

Multiple BEBs can announce the same route, either because the Layer 2 LAN connects to multiple BEBs for redundancy, or because segments of the LAN are Layer 2 bridged. In Layer 2, if the device has to tie-break between multiple sources, the tie-breaking is based on cost and hop count.

In Layer 3, hop count is not used for tie-breaking. Instead, the device uses the following precedence rules to tie-break. In the following order, the device prefers:

1. Routes that do not include nodes with the overload bit set.

When a router node runs out of system resources (memory or CPU), it alerts the other routers in the network by setting the overload bit in its link-state packets (LSPs). When this bit is set, the node is not used for transit traffic but only for traffic packets destined to the node's directly connected networks and IP prefixes.

2. Local routes over remote routes.

If a route is learned locally, for example, through inter-VRF route leaking, it is most preferred.

3. Routes with the lowest route preference.

By default, IS-IS routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. You can however, change the route preference using IS-IS accept policies.

4. Metric type internal (type 1) over metric type external (type 2).
5. Routes with the lowest SPBM cost.
6. Routes with the lowest prefix cost.

If the metric type is internal, then the tie-break is on SPB cost first, and then on the prefix cost. Otherwise the tie-break is only on the prefix cost.

You can either change this using a route-map on the remote advertising node with the **redistribute** command, or using a route-map on the local node with the IS-IS accept policy.

7. Routes within a VSN with a lower Layer 3 VSN I-SID.

The device considers the Global Routing Table (GRT) to have an I-SID equal to zero.

When you use multiple B-VLANs in the SPBM core, multiple paths exist to reach a particular SPBM node, one on each B-VLAN; therefore, any IP prefix or IPv6 prefix that the device receives from a BEB results in multiple ECMP paths. These paths may or may not be physically diverse. SPBM supports up to two B-VLANs; a primary B-VLAN and a secondary B-VLAN.

If more ECMP paths are available than the configured number of paths, then the device adds the routes using the following order: The device selects all routes from the primary B-VLAN and orders the routes learned through that B-VLAN from lowest system ID to the highest IS-IS system ID, then the device moves on to select all routes from the secondary B-VLAN, ordering those routes from lowest IS-IS system ID to the highest IS-IS system ID until you reach the number of equal paths configured.

For example, consider an SPB core configured with two B-VLANs (primary B-VLAN 1000 and secondary B-VLAN 2000), and the device learns routes from two BEBs called BEB-A (with a lower IS-IS system ID) and BEB-B (with a higher IS-IS system ID), then the order in which the next-hop is chosen for those routes are as follows.

If a route is learned only from BEB-A with the maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for that route is:

1. BEB-A B-VLAN 1000
2. BEB-A B-VLAN 2000

If routes are learned from both BEB-A and BEB-B with maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for those routes are:

1. BEB-A B-VLAN 1000
2. BEB-B B-VLAN 1000
3. BEB-A B-VLAN 2000
4. BEB-B B-VLAN 2000

If ECMP is disabled, the maximum number of allowed ECMP paths is 1 and the device adds the route from the lowest system ID with the primary B-VLAN. In this example, the device adds BEB-A B-VLAN 1000.

Note

- ECMP is supported for IPv6 Shortcut routes.
- To add IS-IS equal cost paths in the routing table, you must enable IPv6 ECMP feature globally.

ECMP Impact on IS-IS Route Selection for Inter-VRF Routes with vIST

This section illustrates the impact ECMP can have on a configuration that implements user-defined VRFs in a vIST cluster and how to avoid incorrect route selection.

Understanding the Configuration

Imagine the following configuration:

- A vIST cluster exists with multiple VRF contexts.
- On both nodes, VRF A redistributes routes into IS-IS as external. VRF B uses an IS-IS accept policy to accept these routes.
- Each node learns three paths to the route:
 - The nodes learn one path using local inter-VRF redistribution.
 - The nodes learn the other two paths from the IST peer.
- The routes are treated as ECMP paths because the preference, metric-type, and metric are equal.

IS-IS sorts paths for the same route by source-BEB B-MAC and B-VLAN ID. The primary B-VLAN ID is first installed for each B-MAC, followed by the secondary B-VLAN ID for each B-MAC, as long as the ECMP max-path value is not reached. On the node with the lowest B-MAC, the first path listed is its own local inter-vrf route, while on the other node, the MIM path across the vIST is listed first.

If you disable ECMP, all but the first path is removed. Because IS-IS orders the paths by B-MAC, each node in the vIST cluster selects the same B-MAC as the nexthop. This configuration leads one of the nodes to select itself, the local inter-vrf route, while the other node selects the MIM path across the vIST to get to the inter-vrf route. This situation results in an incorrect route selection.

Avoiding Incorrect Route Selection

To avoid this situation, create a policy to prevent IS-IS from determining that the MIM path across the vIST and the local inter-VRF route are ECMP paths. Configure the local inter-VRF path as the preferred path, and the vIST path as the backup. The following list identifies way that you can accomplish this:

- Redistribute the VRF route into IS-IS using the internal metric-type. IS-IS will always select the local inter-VRF route. For more information about the metric type for IS-IS routes, see [Fabric Basics and Layer 2 Services](#) on page 876.
- If an IS-IS internal metric-type is not an option, configure an IS-IS accept policy to change the preference of inter-VRF routes learned from the IST peer. The local inter-VRF route is preferred over the inter-VRF routes learned from the IST peer.

IS-IS IP Redistribution Policies

When you connect an SPBM core using IP shortcuts to existing networks running a routing protocol such as OSPF or RIP, a redundant configuration requires two switches:

- One router redistributes IP routes from Routing Information Protocol (RIP)/Open Shortest Path First (OSPF) into IS-IS (IP).
- The second router redistributes from IS-IS (IP) into RIP or OSPF.

The following figure illustrates this configuration.

Figure 117: Redundant OSPF or RIP Network

In this scenario it is necessary to take extra care when redistributing through both switches. By default the preference value for IP routes generated by SPBM-IP (IS-IS) is 7. This is a higher preference than OSPF (20 for intra-area, 25 for inter-area, 120 for ext type1, 125 for ext type2) or RIP (100).

Important

The lower numerical value determines the higher preference.

In the preceding diagram both nodes (SwitchG and SwitchD) have an OSPF or a RIP route to 192.168.10.0/24 with the next-hop to SwitchA.

As soon as the SwitchG node redistributes that IP route into IS-IS, the SwitchD node learns the same route through IS-IS from SwitchG. (The SwitchG node already has the route through OSPF or RIP). Because IS-IS has a higher preference, SwitchD replaces its 192.168.10.0 OSPF route with an IS-IS one that points at SwitchG as the next-hop. The following figure illustrates this scenario.

Figure 118: Redistributing Routes into IS-IS

Clearly this is undesirable and care needs to be taken to ensure that the two redistributing nodes (SwitchG and SwitchD) do not accept redistributed routes from each other. With IS-IS accept policies, you can associate an IS-IS accept policy on SwitchD to reject all redistributed IP routes received from SwitchG, and SwitchG to reject all redistribute IP routes from SwitchD.

An alternate way to solve the preceding problem with existing functionality is to reverse the problem by lowering the SPBM-IP (IS-IS) preference by configuring it to a value greater than RIP (100) or OSPF (20,25,120,125). For example, log on to Global Configuration mode and use the following command to configure a preference of 130:

```
ip route preference protocol spbm-level1 130
```

Note

For IPv6, the command is `ipv6 route preference protocol spbm-level1 130`

Now that the OSPF or RIP routes have a higher preference than SPBM-IP (IS-IS), the above problem is temporarily solved. However, the same issue resurfaces when the IS-IS IP routes are redistributed into OSPF or RIP in the reverse direction as shown in the following figure for OSPF:

Figure 119: Redistributing Routes into OSPF

In the preceding figure, both SwitchG and SwitchD have an IS-IS IP route for 172.16.0.0/16 with the next hop as SwitchC. As soon as SwitchG redistributes the IS-IS route into OSPF, the SwitchD node learns that same route through OSPF from SwitchG. (The SwitchG node already has the route through IS-IS).

Because OSPF has a higher preference, SwitchD replaces its 172.16.0.0/16 IS-IS route with an OSPF one. (Note that the 172.16.0.0/16 route will be redistributed into OSPF as an AS external route, hence with preference 120 or 125 depending on whether type1 or type2 was used). In this case, however, you can leverage OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. The following is a sample configuration:

```
enable
configure terminal
route-map

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "reject" 1
no permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable

OSPF ACCEPT CONFIGURATION - GlobalRouter

router ospf
accept adv-rtr {A.B.C.D}
```

```
accept adv-rtr {A.B.C.D} enable route-map "reject"  
exit
```

**Note**

Disable alternative routes by issuing the command **no ip alternative-route** to avoid routing loops on the SMLT Backbone Edge Bridges (BEBs).

In the preceding figure, if SwitchA advertises 25000 OSPF routes to SwitchG and SwitchD, then both SwitchG and SwitchD install the 25000 routes as OSPF routes. Since SwitchD and SwitchG have OSPF to IS-IS redistribution enabled, they also learn these 25000 routes as IS-IS routes. IS-IS route preference is configured with a higher numerical value (130) than the OSPF route preference (125), so SwitchD and SwitchG keep IS-IS learned routes as alternative routes.

If SwitchA withdraws its 25000 OSPF routes, SwitchG and SwitchD remove the OSPF routes. While the OSPF routes are removed the routing tables of SwitchG and SwitchD activate the alternative IS-IS routes for the same prefix. Since SwitchG and SwitchD have IS-IS to OSPF redistribution enabled, SwitchA learns these routes as OSPF and this causes a routing loop. Use the **no ip alternative-route** command to disable alternative routes on SwitchG and SwitchD to avoid routing loops.

In the preceding figure, you leveraged OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. In the case of a RIP access network, the preceding solution is not possible because RIP has no concept of external routes and no equivalent of accept policies. However, if you assume that a RIP network acts as an access network to an SPBM core, then it is sufficient to ensure that when IS-IS IP routes are redistributed into RIP they are aggregated into a single default route at the same time. The following figure and sample configuration example illustrates this scenario:

Figure 120: Redistributing Routes into RIP

SwitchG

```

IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 1/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

```

```
router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip rip apply redistribute isis
```

SwitchA

```
RIP PORT CONFIGURATION

interface gigabitethernet 1/2
ip rip default-listen enable
exit
interface gigabitethernet 1/3
ip rip default-listen enable
exit
```

SwitchD

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 2/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS
```

```
ip rip apply redistribute isis
```

You can control the propagation of the default route on the RIP network so that both SwitchG and SwitchD supply the default route on their relevant interfaces, and not accept it on the same interfaces. Likewise, SwitchA will accept the default route on its interfaces to both SwitchG and SwitchD but it will not supply the default route back to them. This will prevent the default route advertised by SwitchG from being installed by SwitchD, and vice-versa.

The preceding example where IS-IS IP routes are aggregated into a single default route when redistributed into the RIP network also applies when redistributing IS-IS IP routes into OSPF if that OSPF network is an access network to an SPBM core. In this case use the following redistribution policy configuration as an example for injecting IS-IS IP routes into OSPF:

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable
router ospf
as-boundary-router enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router ospf
redistribute isis
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip ospf apply redistribute isis
```

IS-IS Accept Policies

You can use Intermediate-System-to-Intermediate-System (IS-IS) accept policies (for IPv4 and IPv6) to filter incoming IS-IS routes over the SPBM cloud and apply route policies to the incoming IS-IS routes. IS-IS accept policies enable the device to determine whether to add an incoming route to the routing table.

IS-IS Accept Policies and DvR

Note

IPv6 IS-IS accept policies for DvR are not supported.

When you configure DvR in an SPB network, you can leverage IS-IS accept policies to control the DvR routes learned from the DvR backbone. The DvR backbone contains the master list of all the host routes learned from various DvR domains.

You can configure accept policies on a DvR Controller or a non-DvR BEB as a filter to determine which DvR host routes to accept into the routing table, from the DvR backbone. Accept policies apply to only those backbone (or inter-domain) host routes that are not part of the Controller's own DvR enabled subnets and do not have the same domain ID as that of the Controller.

For non-DvR BEBs, all the routes present in the backbone are learned, but you can still use the accept policies to filter specific routes.

For information on DvR, see [Distributed Virtual Routing](#) on page 660.

IS-IS Accept Policy Filters

You can filter traffic with IS-IS accept policies by:

- advertising BEB
- I-SID or I-SID list
- route-map
- backbone-route-map for IPv4 only
- a combination of route-map and backbone-route-map for IPv4 only

You can use IS-IS accept policies to apply at a global default level for all advertising Backbone Edge Bridges (BEBs) or for a specific advertising BEB.

IS-IS accept policies also allow you to use either a service instance identifier (I-SID) or an I-SID list to filter routes. The switch uses I-SIDs to define Virtual Services Networks (VSNs). I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. IS-IS accept policies can use I-SIDs or I-SID lists to filter the incoming virtualized traffic.

IS-IS accept policies can also apply route policies to determine what incoming traffic to accept into the routing table. With route policies the device can determine which routes to accept into the routing table based on the criteria you configure. You can match on the network or the route metric.

On DvR Controllers in a DvR domain, you can configure a backbone route policy to determine what host routes to accept from the DvR backbone, into the routing table. Also, just like on the route policy, you can configure match criteria, and set preferences on the backbone route policy.

To accept both IS-IS routes and host routes from the DvR backbone, you can configure both a route policy and a backbone route policy in the accept policy instance.

For more information on configuring route policies:

- For IPv4, see [IP routing operations fundamentals](#) on page 1742.
- For IPv6, see [IPv6 Routing Basics](#) on page 1806.

The following table describes IPv4 IS-IS accept policy filters.

| Filters into | Filter | Description |
|----------------------------|---|--|
| Global Routing Table (GRT) | <code>accept route-map WORD<1-64></code> | By default, the device accepts all routes into the GRT and VRF routing table. This is the default accept policy. |
| | <code>accept route-map WORD<1-64> backbone-route-map WORD<1-64></code> | This is the default accept policy with configuration to accept specific DvR host routes from the DvR backbone. |
| | <code>accept adv-rtr <x.xx.xx> route-map WORD<1-64> backbone-route-map WORD<1-64></code> | The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <code>accept i-sid <1-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64></code> | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <code>accept adv-rtr <x.xx.xx> i-sid <1-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64></code> | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <code>accept isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64></code> | The device filters based on the list of I-SIDs. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <code>accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64></code> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |

| Filters into | Filter | Description |
|--|--|--|
| Virtual Routing and Forwarding (VRF) routing table | <i>isis accept adv-rtr <x.xx.xx> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the specific advertising BEB defined by the SPBM nickname.
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <i>isis accept i-sid <0-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT).
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <i>isis accept adv-rtr <x.xx.xx> i-sid <0-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT).
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <i>isis accept isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT).
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <i>isis accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT).
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |
| | <i>isis accept route-map WORD<1-64> route-map WORD<1-64> backbone-route-map WORD<1-64></i> | The device filters based on the route policy.
The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter. |

The following table describes the IPv6 IS-IS accept policy filters:

| Filters into | Filter | Description |
|--|---|---|
| Global Routing Table (GRT) | <i>ipv6 accept route-map WORD<1-64></i> | By default, the device accepts all routes advertised. This is the default accept policy. |
| | <i>ipv6 accept adv-rtr <x.xx.xx> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB defined by the SPBM nickname. |
| | <i>ipv6 accept i-sid <1-16777215> route-map WORD<1-64></i> | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. |
| | <i>ipv6 accept adv-rtr <x.xx.xx> i-sid <1-16777215> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. |
| | <i>ipv6 accept isid-list WORD<1-32> route-map WORD<1-64></i> | The device filters based on the list of I-SIDs. |
| | <i>ipv6 accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). |
| Virtual Routing and Forwarding (VRF) routing table | <i>ipv6 isis accept route-map WORD<1-64> route-map WORD<1-64></i> | The device filters based on the route policy. |
| | <i>ipv6 isis accept adv-rtr <x.xx.xx> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB defined by the SPBM nickname. |
| | <i>ipv6 isis accept i-sid <0-16777215> route-map WORD<1-64></i> | The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). |
| | <i>ipv6 isis accept adv-rtr <x.xx.xx> i-sid <0-16777215> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). |
| | <i>ipv6 isis accept isid-list WORD<1-32> route-map WORD<1-64></i> | The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT). |
| | <i>ipv6 isis accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64></i> | The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). |

IS-IS Accept Policies for the GRT and VRFs

You can create an IS-IS accept policy for incoming routes for the Global Routing Table (GRT), which accepts routes into the routing table, or for a Virtual Routing and Forwarding (VRF) instance, which accepts incoming routes to the routing table of the VRF.

If you create an IS-IS accept policy on the switch for either the GRT or a VRF that operates at a global default level, the accept policy applies to all routes for all BEBs in the GRT or VRF.

If you create an IS-IS accept policy on the switch for a specific advertising BEB for either the GRT or a VRF, the IS-IS accept policy instance applies for that specific advertising BEB. If you use a more specific filter, the system gives preference to the specific filter over the global default level.

IS-IS Accept Policies for Inter-VRF Route Redistribution

You can also use the filter mechanism for IS-IS accept policies to redistribute routes between different VRFs, or between a VRF and the GRT. For inter-VRF route redistribution, you match the filter based on the I-SID, which represents the Layer 3 VSN context.

You can apply the filter at the global default level, where the IS-IS accept policy applies to all routes for that I-SID from all BEBs, or at a specific advertising BEB level, where the filter only applies to a specific advertising BEB. The device gives preference to a specific filter for a specific advertising BEB over the global default filter.

For inter-VRF route redistribution, an I-SID value of 0 represents the GRT. For inter-VRF route redistribution between VRFs, the I-SID is the source VRF (or remote VRF).

Note

If the primary B-VLAN is down either because you did not configure at least one NNI or all configured NNIs are down, the switch does not redistribute inter-VRF routes through IS-IS accept policies.

IS-IS Accept Policy Considerations

Consider the following when you configure IS-IS accept policies:

- If a VRF uses a different protocol to redistribute routes from another VRF, the IS-IS accept policy feature cannot be used. You can only use the IS-IS accept policy for inter-VSN route redistribution between VRFs.
- IPv4 and IPv6 IS-IS accept policies can exist on the same VRF and GRT; The I-SID list configuration is shared across both protocol versions.

Precedence rules in the same VSN

The following precedence rules apply for IS-IS accept policies used in the same VSN:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply either a default filter for all advertising BEBs or a filter for a specific advertising BEB.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device prefers the **accept adv-rtt** filter, which filters based on a specific advertising BEB, over the default filter for all advertising BEBs.

- The device accepts all routes within the same VSN by default. You can apply a route policy to filter or change the characteristics of the route by metric or preference.
- The **i-sid** or **isid-list** filters are not valid for routes within the same VSN.

Precedence rules for inter-VSN route redistribution

The following precedence rules apply for IS-IS accept policies used for inter-VSN route redistribution:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply filters at a global default level for all BEBs for a specific I-SID or I-SID list, or you can apply filters for a specific advertising BEB for a specific I-SID or I-SID list.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device requires a specific filter to redistribute routes between VSNs through the use of the **i-sid** or **isid-list** filters.
- The **i-sid** filter takes precedence over the **isid-list** filter.
- The **adv-rtr** filter for a specific advertising BEB takes precedence over a filter with the same **i-sid** filter without the **adv-rtr** filter.
- The **i-sid** or **isid-list** filters only apply to routes for inter-VSN route redistribution.
- If multiple **isid-list** filters have the same I-SID within the list, the first on the list alphabetically has the higher precedence.

Route Preference

The relative value of the route preference among different protocols determines which protocol the device prefers. If multiple protocols are in the routing table, the device prefers the route with the lower value. You can change the value at the protocol level, and you can also change the preference of incoming IS-IS routes using the route-map with the IS-IS Accept policy filter for IPv4 only.

Route Metric

Use route-map to change the metric of a route when you accept a remote IS-IS route with IS-IS accept policies.

You can use route-map to change the metric of a route when you redistribute the route from another protocol to IS-IS through the route redistribution mechanism.

You can also configure the route metric with the base **redistribute** command without the use of route-map.

Note

For both IPv4 and IPv6 IS-IS accept policies, if there is a mismatch in the route-map (inbound filtering) configured, all routes are accepted by default. Unlike the redistribute route-map (outbound filtering), where if there is a mismatch, all routes are denied by default. For more information, see [IP routing operations fundamentals](#) on page 1742.

For more information on the configuration of route-map:

- For IPv4, see [IP routing operations fundamentals](#) on page 1742.
- For IPv6, see [IPv6 Routing Basics](#) on page 1806.

IP Shortcuts configuration using the CLI

This section provides procedures to configure IP Shortcuts using the CLI.

Configuring SPBM IPv4 Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you must configure a circuitless IP (CLIP) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

Procedure

1. Enter Loopback Interface Configuration mode

```
enable

configure terminal

interface Loopback <1-256>
```
2. Configure a CLIP interface to use as the source address for SPBM IP shortcuts:

```
ip address [<1-256>] <A.B.C.D/X>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

```
exit
```
4. Log on to IS-IS Router Configuration mode:

```
router isis
```
5. Specify the CLIP interface as the source address for SPBM IP shortcuts:

```
ip-source-address <A.B.C.D>
```
6. Configure SPBM IP shortcuts:

```
spbm <1-100> ip enable
```
7. Display the status of SPBM IP shortcuts on the switch:

```
show isis spbm
```

8. Identify routes on the local switch to be announced into the SPBM network:

```
redistribute {bgp | direct | ospf | rip | static}
```
9. Enable routes to be announced into the SPBM network

```
redistribute {bgp | direct | ospf | rip | static} enable
```
10. If you want to delete the configuration, use the no option:

```
no redistribute {bgp | direct | ospf | rip | static}
```

```
no redistribute {bgp | direct | ospf | rip | static} enable
```
11. Exit to Global Configuration mode:

```
exit
```
12. Apply the configured redistribution:

```
isis apply redistribute {bgp | direct | ospf | rip | static | vrf  
WORD<1-16>}
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface loopback 1
Switch:1(config-if)# ip address 192.0.2.2/8
Switch:1(config-if)# exit
Switch:1(config)# router isis
Switch:1(config-isis)# ip-source-address 192.0.2.2
Switch:1(config-isis)# spbm 1 ip enable
Switch:1(config-isis)# show isis spbm
```

```
show isis spbm
```

```

Variable definitions

The following table defines parameters for the **ip address** command.

| Variable | Value |
|-------------|---|
| <1-256> | Specifies an interface ID value. This value is optional. |
| <A.B.C.D/X> | Specifies an IP address and subnet mask. Use the no option to delete the specified IP address. |
| <A.B.C.D> | Specifies an IP address. Use the no option to delete the specified IP address. |

The following table defines parameters for the **ip-source-address** command.

| Variable | Value |
|-----------|--|
| <A.B.C.D> | Specifies the CLIP interface to use as the source address for SPBM IP shortcuts. |

The following table defines parameters for the **spbm** command.

| Variable | Value |
|--------------------------|---|
| <1-100> <i>ip enable</i> | Enables or disables SPBM IP shortcut state.
The default is disabled. Use the no or default options to disable SPBM IP shortcuts. |

The following table defines parameters for the **redistribute** command.

| Variable | Value |
|--|---|
| <i>{bgp direct ospf rip static}</i> | Specifies the protocol. |
| <i>enable</i> | Enables the redistribution of the specified protocol into the SPBM network.
The default is disabled. Use the no option to disable the redistribution. |
| <i>metric</i> <0-65535> | Configures the metric (cost) to apply to redistributed routes. The default is 1. |
| <i>metric-type</i>
<i>{external internal}</i> | Configures the type of route to import into the protocol. The default is internal. |

| Variable | Value |
|---|---|
| <code>route-map WORD<0-64></code> | Configures the route policy to apply to redistributed routes. Type a name between 0 to 64 characters in length. |
| <code>subnets {allow suppress}</code> | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow. |

The following table defines parameters for the **isis apply redistribute** command.

| Variable | Value |
|---|-------------------------|
| <code>{bgp direct ospf rip static}</code> | Specifies the protocol. |

Configure SPBM IPv6 Shortcuts

Important

You must enable IPv4 Shortcuts before you enable IPv6 Shortcuts because IPv6 Shortcuts depend on IPv4 Shortcuts for some functions.

Configuring IPv6 Shortcuts is essentially the same as the IPv4 procedure except you use the following IPv6 commands instead of their IPv4 equivalents:

- Use **ipv6 interface address** to create a CLIPv6 interface with an IPv6 address.
- Use **ipv6 ipv6-source-address** to specify the CLIPv6 interface as the source address for IPv6 Shortcuts.
- Use **spbm ipv6 enable** to enable IPv6 Shortcuts.
- Use **ipv6 redistribute {bgp | direct | isis | rip | ospf | static} enable** to control the redistribution of GRT IPv6 routes into the SPBM IS-IS domain.
- Use **ipv6 route preference protocol spbm-level1** to change route preference values for IPv6 Shortcut routes learned through IS-IS.

To enable IPv6 Shortcuts on the BEBs, you must configure a circuitless IPv6 (CLIPv6) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address, and the CLIPv6 address prefix must be 128.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.

- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IPv6 addresses and network masks.

Procedure

1. Enter Loopback Interface Configuration mode

```
enable
```

```
configure terminal
```

```
interface Loopback <1-256>
```
2. Configure a CLIPv6 interface to use as the source address for SPBM IPv6 Shortcuts:

```
ipv6 interface address WORD<0-255>
```
3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

```
exit
```
4. Log on to IS-IS Router Configuration mode:

```
router isis
```
5. Specify the CLIPv6 interface as the source address for SPBM IPv6 Shortcuts:

```
ipv6-source-address WORD<0-46>
```
6. Enable SPBM IPv6 Shortcuts:

```
spbm <1-100> ipv6 enable
```
7. Display the status of SPBM IPv6 Shortcuts on the switch:

```
show isis spbm
```
8. Identify IPv6 routes on the local switch to be announced into the SPBM network.

```
ipv6 redistribute {bgp | direct | ospf | rip | static}
```
9. Enable the IPv6 routes to be announced into the SPBM network:

```
ipv6 redistribute {bgp | direct | ospf | rip | static} enable
```
10. Exit to Global Configuration mode:

```
exit
```
11. (Optional) Change route preference values for IPv6 Shortcut routes learned through IS-IS:

```
ipv6 route preference protocol spbm-level1 <0-255>
```
12. Apply the configured redistribution:

```
ipv6 isis apply redistribute {bgp | direct | ospf | rip | static |}  
[vrf WORD<1-16>]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 123
Switch:1(config-if)#ipv6 interface address 123::1/128
Switch:1(config-if)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#ipv6 ipv6-source-address <non-link-local ipv6-address>
Switch:1(config-isis)#spbm 1 ipv6 enable
Switch:1(config-isis)#show isis spbm

Variable Definitions

The following table defines parameters for the IPv6 Shortcuts commands.

| Variable | Value |
|--|---|
| <i>ipv6-source-address</i>
<i>WORD<0-46></i> | Specifies the source IPv6 address for locally generated IPv6 packets whose egress port is an SPBM NNI port. The <i>WORD<0-46></i> value must be a locally configured loopback IPv6 address (CLIPv6). Use the no option to delete the specified IPv6 address. |
| <i>spbm<1-100> ipv6 enable</i> | Enables or disables SPBM IPv6 Shortcuts. The default is disabled. Use the no or default options to disable SPBM IPv6 Shortcuts. |
| <i>ipv6 route preference</i>
<i>protocol spbm-level1 <0-255></i> | Sets the route preference value for IPv6 Shortcut routes learned through IS-IS. The default preference is 7. |
| <i>ipv6 redistribute {bgp</i>
<i> direct static </i>
<i>ospf rip} enable</i> | Specifies the GRT IPv6 route that you want to redistribute into the SPBM IS-IS domain. The default is disabled. Use the no option to disable the redistribution. |

Configuring inter-VRF IPv4 Accept Policies on VRFs

Configure IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IS-IS accept policies to redistribute routes between different VRFs, including the global routing table

(GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **accept** command for inter-VRF routes based on the remote I-SID, the device only accepts routes coming from remote BEBs. For instance, if a local Layer 3 VSN exists with the same I-SID, the device does not add the local routes. The assumption is that the device uses existent methods, either through use of another protocol or static configuration, to obtain those routes.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map to apply.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<0-16777215>][list WORD<1-1024>]
```

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Create an IS-IS accept policy instance to apply to routes from all Backbone Edge Bridges (BEBs):

```
isis accept [i-sid <0-16777215>][isid-list WORD<1-32>]
```

4. Create an IS-IS accept policy instance to apply to routes for a specific BEB:

```
isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list WORD<1-32>]
```

5. (Optional) Delete an IS-IS accept policy instance:

```
no isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>]
```
6. Specify an IS-IS route policy to apply to routes from all BEBs:

```
isis accept route-map WORD<1-64>
```
7. Specify an IS-IS route policy to apply for a specific BEB:

```
isis accept adv-rtr <x.xx.xx> route-map WORD<1-64>
```
8. (Optional) Delete an IS-IS route policy:

```
no isis accept [adv-rtr <x.xx.xx>] [route-map]
```
9. Enable a configured IS-IS accept policy instance:

```
isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>] [enable]
```
10. (Optional) Disable a configured IS-IS accept policy instance:

```
no isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list WORD<1-32>] [enable]
```
11. Exit VRF Router Configuration mode:

```
exit
```

You are in Global Configuration mode.
12. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
isis apply accept [vrf WORD<1-16>]
```

Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#isis accept i-sid 100
Switch:1(router-vrf)#isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept vrf green
```

Variable definitions

The following table defines parameters for the **ip isid-list** command.

| Variable | Value |
|--------------------------------|--|
| <i>WORD<1-32></i> | Creates a name for your I-SID list. |
| <i><0-16777215></i> | Specifies an I-SID value. |
| <i>list WORD<1-1024></i> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **isis accept** command.

| Variable | Value |
|--|--|
| <i>adv-rtr</i> <x.xx.xx> | Specifies a specific advertising BEB in which to apply the IS-IS accept policy to routes for a specific advertising BEB. x.xx.xx specifies an SPBM nickname.
The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.
The system requires an explicit filter to redistribute routes from a particular VSN. If the default global filter or the filter for a specific advertising BEB does not exist, the system does not redistribute the routes from the remote VSN. |
| <i>enable</i> | Enables the IS-IS accept policy. |
| <i>i-sid</i> <0-16777215> | Configures the I-SID to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |
| <i>isid-list</i>
<i>WORD</i> <1-32> | Configures a list of I-SIDs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |
| <i>route-map</i> <i>WORD</i>
<1-64> | Specifies a route policy.
You must configure a route policy earlier in a separate procedure. |

The following table defines parameters for the **isis apply accept** command.

| Variable | Value |
|-------------------------------|------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16> | Specifies a specific VRF instance. |

Configuring Inter-VRF IPv6 Accept Policies on VRFs

Configure IPv6 IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IPv6 IS-IS accept policies to redistribute routes between different VRFs, including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

Note

- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **ipv6 accept** command for inter-VRF routes based on the remote I-SID, the device accepts routes from other local VRFs to the current VRF, therefore if the accepted I-SID is configured on the local BEB, the device accepts its own IPv6 routes advertised under the accepted I-SID.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1251.
- You must configure IPv6 IPVPN.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<0-16777215> | list WORD<1-1024>}
```

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [route-map WORD<1-64>]
```

- b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

- c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

4. Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

5. Exit to Global Configuration mode:

```
exit
```

6. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD<1-16>]
```

Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ipv6 isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#ipv6 isis apply accept vrf red
```

Variable Definitions

The following table defines parameters for the **ip isid-list** command.

Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable | Value |
|---------------------------|--|
| <i>WORD</i> <1-32> | Creates a name for your I-SID list. |
| <0-16777215> | Specifies an I-SID value. |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable | Value |
|--------------------------------------|--|
| <i>adv-rtr</i>
< <i>x.xx.xx</i> > | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.

Note:
An IPv6 IS-IS accept policy that specifies the <i>adv-rtr</i> without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i> | Enables an IPv6 IS-IS accept policy. |
| <i>i-sid</i>
<0-16777215> | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies.
Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |

| Variable | Value |
|--|---|
| <i>isid-list</i>
<i>WORD</i> <1-32> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies.
Use the parameter to apply a default filter for all routes from specific I-SIDs, that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |
| <i>route-map</i> <i>WORD</i>
<1-64> | Specifies a route policy.
You must configure a route policy earlier in a separate procedure. |

The following table defines parameters for the **ipv6 isis apply accept** command.

| Variable | Value |
|-------------------------------|------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16> | Specifies a specific VRF instance. |

Configuring IS-IS Accept Policies

Use the following procedure to create and enable IS-IS accept policies to apply to routes from all Backbone Edge Bridges (BEBs) or to all routes from a specific BEB.

Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

If DvR is enabled on your switch, and the switch is either a DvR Controller or a non-DvR BEB within the domain, you can configure IS-IS accept policies to accept specific host routes from the DvR backbone. For information on DvR, see [Distributed Virtual Routing](#) on page 660.

IS-IS accept policies are disabled by default.

Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless the IS-IS accept policy was the last sequence in the configuration.
- The **isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IS-IS accept policy configuration, you must apply the **isis apply accept [vrf WORD<1-16>]** command at the end.
- The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the ISIS accept policy filters, which can be configured using the **ip isid-list [ISID#]**, **accept i-sid <value>**, or **accept adv-rtr <isis nn> i-sid <value>** commands.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an ip isid-list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IS-IS accept policy filters, which you implement with the **ip isid-list** or **accept policy** command. The I-SIDs used for Layer 3 VSNs can be reused in IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 3899. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [Release Notes for VOSS](#).

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.
- Ensure that DvR is enabled on the switch before you configure an IS-IS accept policy with a backbone route policy, to accept host routes from the DvR backbone.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
```

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

- (Optional) Delete an I-SID list:

```
no ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
```

Note

When deleting an I-SID list, ensure that the I-SID list is not associated with an IS-IS accept policy. Otherwise the deletion fails. An I-SID list associated with an accept policy cannot be deleted because it must contain at least one constituent I-SID.

- Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

Configure IS-IS accept policies with a route policy or a backbone route policy or a combination of both, to determine which routes the IS-IS accept policy applies to.

Configure one of the following types of IS-IS accept policies.

- **An IS-IS accept policy with only the route policy:**

The IS-IS routes are selectively accepted based on the route policy. Since the backbone route policy is not configured, all host routes from the DvR backbone are denied.

If you do not configure a route policy, by default, all IS-IS routes are accepted.

- **An IS-IS accept policy with only the backbone route policy:**

The DvR host routes from the DvR backbone are selectively accepted based on the backbone route policy. Since the route policy is not configured, all IS-IS host routes are accepted.

If you do not configure a backbone route policy, all host routes from the DvR backbone are denied.

- **An IS-IS accept policy with both route policy and backbone route policy:**

IS-IS routes are selectively accepted based on the route policy and host routes from the DvR backbone are selectively accepted based on the backbone route policy.

5. Configure an IS-IS accept policy instance with a route policy.

Use one of the following options:

- a. Create an IS-IS accept policy instance to apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>]
```
 - b. Create an IS-IS accept policy instance to apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> [i-sid <1-16777215>][isid-list WORD <1-32>]
```
 - c. (Optional) Delete an IS-IS accept policy instance:

```
no accept [adv-rtr <x.xx.xx>][i-sid <1-16777215>][isid-list WORD <1-32>]
```
 - d. Specify an IS-IS route policy to apply to routes from all BEBs:

```
accept route-map WORD<1-64>
```
 - e. Specify an IS-IS route policy to apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx>[route-map WORD<1-64>]
```
 - f. (Optional) Delete an IS-IS route policy:

```
no accept [adv-rtr <x.xx.xx>] [route-map]
```
 - g. Enable an IS-IS route accept instance:

```
accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]
```
 - h. (Optional) Disable an IS-IS route accept instance:

```
no accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]
```
6. Configure an IS-IS accept policy instance with a backbone route policy to accept host routes from the DvR backbone:

Note

IS-IS accept policies typically apply to all IS-IS routes. However, to accept DvR host routes from the DvR backbone, you must explicitly configure the IS-IS accept policy with a backbone route policy.

Use one of the following options:

- a. Create the default IS-IS accept policy instance to accept host routes from the DvR backbone:

```
accept backbone-route-map WORD <1-64>
```
- b. (Optional) Delete the default IS-IS accept policy instance with backbone route policy configuration:

```
no accept backbone-route-map
```
- c. Create an IS-IS accept policy instance to accept host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map WORD<1-64>
```
- d. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map
```

- e. Create an IS-IS accept policy instance to accept host routes from the DvR backbone and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> backbone-route-map WORD <1-64>
```
- f. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to a specific advertising BEB

```
no accept adv-rtr <x.xx.xx> backbone-route-map
```
7. Configure an IS-IS accept policy with both route policy and backbone route policy, to selectively accept IS-IS routes as well as host routes from the DvR backbone.
 - a. Create the default IS-IS accept policy instance with a route policy to accept IS-IS routes and a backbone route policy to accept host routes from the DvR backbone:

```
accept route-map WORD<1-32> backbone-route-map WORD <1-64>
```
 - b. (Optional) Delete the default IS-IS accept policy with route policy and backbone route policy configuration:

```
no accept route-map backbone-route-map
```
 - c. Create an accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map WORD<1-32> backbone-route-map WORD<1-64>
```
 - d. (Optional) Delete an accept policy instance with route policy and backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map backbone-route-map
```
 - e. Create an IS-IS accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> route-map WORD<1-32> backbone-route-map WORD <1-64>
```
 - f. (Optional) Delete an IS-IS accept policy instance with route policy and backbone route policy configuration, which applies to a specific advertising BEB:

```
no accept adv-rtr <x.xx.xx> route-map backbone-route-map
```
8. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
isis apply accept [vrf WORD <1-16>]
```
9. Exit IS-IS Router Configuration mode:

```
exit
```

You are in Global Configuration mode.

Example

Configure an I-SID based IS-IS accept policy with the route policy test:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map test 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit

Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 101
```

```
Switch:1(config-isis)#accept i-sid 101 route-map test
Switch:1(config-isis)#accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#isis apply accept
```

The following examples show the configuration of an IS-IS accept policy to accept host routes from the DvR backbone

Example 1:

To accept host routes from the DvR backbone, you must configure a backbone route policy and apply it to the IS-IS accept policy.

1. Configure a route policy for DvR:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#route-map dvrmap1 1
Switch:1(route-map)#enable
```

2. Configure an IS-IS accept policy for I-SID 10, and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap1
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
```

OR

Configure the default accept policy for IS-IS and DvR, and apply the route policy as a backbone route policy:

```
Switch:1(config)#route-map isismap1 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept route-map isismap1 backbone-route-map dvrmap1
```

3. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
Switch:1(config)#exit
```

4. Verify the configuration:

```
Switch:1#show ip isis accept

=====
                        Isis Accept - GlobalRouter
=====

ADV_RTR  I-SID    ISID-LIST          ENABLE POLICY          BACKBONE
-----  -
-         10        -                  TRUE                    dvrmap1
-         -         -                  isismap1                dvrmap1

2 out of 2 Total Num of Isis Accept Policies displayed
```

Example 2:

Configure an IS-IS accept policy for I-SID 10 that accepts DVR host routes in a subnet, for example, subnet 126.1.1.0/24.

1. Configure an IP prefix list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24
```

2. Create the route policy dvrmap2 to match the IP prefix list:

```
Switch:1(config)#route-map dvrmap2 1
Switch:1(route-map)#match network listPrefix
Switch:1(route-map)#enable
```

3. Create an IS-IS accept policy with I-SID 10 and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

The above command causes IS-IS to accept all routes with I-SID 10. To deny IS-IS routes and accept only DVR host routes, you can configure an additional IS-IS route policy as follows:

```
Switch:1(config)#route-map isismap2 1
Switch:1(route-map)#no permit
Switch:1(route-map)#enable

Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 route-map isismap2 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1#show ip isis accept

```

The following examples show the configuration of IS-IS accept policies for a specific VRF instance.

Example 1:

Configure IS-IS accept policies to accept host routes from the DvR backbone, for a specific VRF instance.

1. In the VRF green context, configure the route policy `dvrmap3` for DvR:

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap3 1
Switch:1(router-vrf-routemap)#enable
```

2. Use one of the following options to configure an IS-IS accept policy, and apply the route policy as a backbone route policy:

Configure an IS-IS accept policy for a specific advertising BEB with nickname `1.11.11`:

```
Switch:1(router-vrf-routemap)#isis accept adv-rtr 1.11.11 backbone-route-map dvrmap3
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#isis accept adv-rtr 1.11.11 enable
Switch:1(router-vrf)#show ip isis accept vrf green
```

```

Example 2:

Configure an accept policy for I-SID 10 that accepts DvR host routes in a subnet, for example, subnet 126.1.1.0/24.

1. Configure an IP prefix list:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24

```

2. For a specific VRF instance, create a route policy to match the IP prefix list:

```

Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap4 1
Switch:1(router-vrf-routemap)#match network listPrefix
Switch:1(router-vrf-routemap)#enable

```

```
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#
```

3. Create an IS-IS accept policy with I-SID 10, and apply the route policy as the backbone route policy:

```
Switch:1(router-vrf)#accept i-sid 10 backbone-route-map dvrmap4
Switch:1(router-vrf)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1(router-vrf)#show ip isis accept vrf green

Variable definitions

The following table defines parameters for the **ip isid-list** command.

| Variable | Value |
|---------------------------|--|
| <i>WORD</i> <1-32> | Creates a name for your I-SID list. |
| <1-16777215> | Specifies an I-SID number. |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **accept** command.

| Variable | Value |
|---------------------------------------|--|
| <i>adv-rtr</i> <x.xx.xx> | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. |
| <i>backbone-route-map WORD</i> <1-64> | Specifies the DvR backbone route map. |
| <i>enable</i> | Enables an IS-IS accept policy. |
| <i>i-sid</i>
<1-16777215> | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies.
Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |

| Variable | Value |
|---|---|
| <code>isis-list</code>
<code>WORD<1-32></code> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IS-IS accept policy applies.
Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |
| <code>route-map</code>
<code>WORD<1-64></code> | Specifies a route policy by name.
You must configure the route policy earlier in a separate procedure. |

The following table defines parameters for the **isis apply accept** command.

| Variable | Value |
|-----------------------------------|------------------------------------|
| <code>vrf WORD<1-16></code> | Specifies a specific VRF instance. |

Viewing IS-IS accept policy information

Use the following procedure to view IS-IS accept policy information on the switch.

Procedure

1. Display IS-IS accept policy information:

```
show ip isis accept [vrf WORD<1-16>][vrfids WORD<0-512>]
```

2. Display I-SID list information:

```
show ip isid-list [vrf WORD<1-16>][vrfids WORD<0-512>][WORD<1-32>]
```

3. Display route information:

```
show ip route [vrf WORD<1-16>]
```

The NH VRF/ISID column displays the I-SID for inter-Virtual Services Network (VSN) routes redistributed with IS-IS accept policies, only if the I-SID redistributed does not have an IP VSN associated with it. If an IP VSN exists for that I-SID, the VRF name displays. If the I-SID is 0, the column represents and displays as the GlobalRouter.

The existing IS-IS routes for Layer 3 VSNs continue to display as the VRF name of the IP VSN.

4. Display the SPBM IP unicast Forwarding Information Base (FIB):

```
show isis spbm ip-unicast-fib [all] [id <1-16777215>][spbm-nh-as-mac]
```

Example

View IS-IS accept policy information:

```
Switch:1#show ip route vrf test

Variable definitions

The following table defines parameters for the **show ip isis accept** command.

| Variable | Value |
|---------------------------------------|---|
| <code>vrf WORD<1-16></code> | Displays I-SID list information for a particular VRF by name. |
| <code>vrfids WORD<0-512></code> | Displays I-SID list information for a particular VRF ID. |

The following table defines parameters for the **show ip isid-list** command.

| Variable | Value |
|-----------------------------------|---|
| <i>vrf</i> <i>WORD</i> <1-16> | Displays I-SID list information for a particular VRF by name. |
| <i>vrfids</i> <i>WORD</i> <0-512> | Displays I-SID list information for a particular VRF ID. |
| <i>WORD</i> <1-32> | Displays I-SID list information for a particular I-SID list name. |

The following table defines parameters for the **show ip route** command.

| Variable | Value |
|-------------------------------|---|
| <i>vrf</i> <i>WORD</i> <1-16> | Displays I-SID list information for a particular VRF by name. |

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

| Variable | Value |
|------------------------|---|
| <i>all</i> | Displays all IS-IS SPBM IP unicast Forwarding Information Base (FIB) information. |
| <i>id</i> <1-16777215> | Displays IS-IS SPBM IP unicast FIB information by I-SID ID. |
| <i>spbm-nh-as-mac</i> | Displays the next hop B-MAC of the IP unicast FIB entry. |

Configuring IPv6 IS-IS Accept Policies

Perform the following procedure to create and enable IPv6 IS-IS accept policies based on a particular Backbone Edge Bridge (BEB), I-SID, or I-SID list. IPv6 IS-IS accept policies filter incoming IS-IS routes that the device receives over the SPBM cloud. IPv6 IS-IS accept policies apply to incoming traffic and determine whether to add the route to the routing table.

IPv6 IS-IS accept policies are disabled by default.

Note

- IPv6 IS-IS accept policies are not supported for DvR.
- The I-SID lists created can be associated with both IPv4 or IPv6 routes.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy associated with an accept policy changes, you must reapply the IPv6 IS-IS accept policy, unless the IPv6 IS-IS accept policy was the last sequence in the configuration.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IPv6 IS-IS accept policy configuration, you must apply the **ipv6 isis apply accept [vrf WORD<1-16>]** command at the end.

The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the IPv6 IS-IS accept policy filters.

The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an I-SID list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IPv6 IS-IS accept policy filters, which you implement with the **ip isid-list** or **ipv6 accept** command. The I-SIDs used for Layer 3 VSNs can be reused in IPv6 IS-IS accept policy filters without affecting the limit.

If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see [Configure the Maximum Number of VRFs](#) on page 3899. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [Release Notes for VOSS](#).

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Configure IPv6 Shortcuts. For more information, see [Configure SPBM IPv6 Shortcuts](#) on page 1251.
- You must configure a route-map.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

```
ip isid-list WORD<1-32> {<1-16777215> | list WORD<1-1024>}
```

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

- Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

- Configure an IPv6 IS-IS accept policy instance with a route policy.

Use one of the following options:

- Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

```
ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
[isid-list WORD<1-32>] [ [route-map WORD<1-64>]
```

- Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
```

- Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

```
ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-64>]
```

- Specify a particular route-map to use for all IS-IS routes from all BEBs unless a more specific filter exists for the advertising BEB. :

```
ipv6 isis accept route-map WORD<1-64>
```

- Enable the configured IPv6 IS-IS accept policies:

```
ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
WORD<1-32>] enable
```

- Exit to Global Configuration mode:

```
exit
```

- Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
ipv6 isis apply accept [vrf WORD <1-16>]
```

Example

Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfstest
```

```
Switch:1(config-isis)#ipv6 isis accept i-sid 101 route-map test
Switch:1(config-isis)#ipv6 isis accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#ipv6 isis apply accept
```

Variable Definitions

The following table defines parameters for the **ip isid-list** command.

Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

| Variable | Value |
|---------------------------|--|
| <i>WORD</i> <1-32> | Creates a name for your I-SID list. |
| <1-16777215> | Specifies an I-SID number. |
| <i>list WORD</i> <1-1024> | Specifies a list of I-SID values. For example, in the format 1,3,5,8-10. |

The following table defines parameters for the **ipv6 isis accept** command.

| Variable | Value |
|--|--|
| <i>adv-rtr</i>
< <i>x.xx.xx</i> > | Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.

Note:
An IPv6 IS-IS accept policy that specifies the <i>adv-rtr</i> without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB. |
| <i>enable</i> | Enables an IPv6 IS-IS accept policy. |
| <i>i-sid</i>
<0-16777215> | Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies.
Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |
| <i>isid-list</i>
<i>WORD</i> <1-32> | Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies.
Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |
| <i>route-map</i>
<i>WORD</i> <1-64> | Specifies a route policy by name.
You must configure the route policy earlier in a separate procedure. |

The following table defines parameters for the **ipv6 isis apply accept** command.

| Variable | Value |
|-----------------------------------|---------------------------|
| <code>vrf WORD<1-16></code> | Specifies a VRF instance. |

Displaying IPv6 IS-IS Accept Policy Information

Perform the following procedure to view IPv6 IS-IS accept policy information on the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display IPv6 IS-IS accept policy information:

```
show ipv6 isis accept [vrf WORD<1-16>] [vrfs WORD<0-512>]
```

Example

Display IPv6 IS-IS accept policy information for vrfRED:

```
Switch:1>enable
Switch:1#show ipv6 isis accept vrf vrfRED
=====
                        Isis Accept - VRF vrfRED
=====
ADV_RTR  I-SID    ISID-LIST                ENABLE POLICY
-----
1.11.11  1001        -                        TRUE
-----
1 out of 1 Total Num of Isis Accept Policies displayed
```

IP Shortcuts configuration using EDM

This section provides procedures to configure IP Shortcuts using Enterprise Device Manager (EDM).

Configure SPBM IP Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you must configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

After you have configured the SPBM infrastructure, you can enable SPBM IP shortcuts to advertise IP routes across the SPBM network using the following procedure.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.
- You must configure a circuitless IP (CLIP) interface:
 - To configure an IPv4 CLIP interface, see [Configure a Circuitless IPv4 Interface](#) on page 1799
 - To configure an IPv6 CLIP interface, see [Configure a Circuitless IPv6 Interface](#) on page 1872

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. From the **Globals** tab, in **IpSourceAddress**, specify the CLIP interface to use as the source address for SBPM IP Shortcuts.

Note

For IPv6 Shortcuts, select **ipv6** in **Ipv6SourceAddressType**, and then use **Ipv6SourceAddress** to specify the CLIPv6 interface to use as the source address for SBPM IPv6 Shortcuts.

4. Select **Apply**.
5. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
6. Select the **SPBM** tab.
7. In **IpShortcut**, select **enable**.

Note

For IPv6 Shortcuts, select **enable** in **Ipv6Shortcut**.

8. Select **Apply**.
9. In the navigation pane, expand **Configuration > IP**.
10. Select **Policy**.
11. Select the **Route Redistribution** tab.
12. Select **Insert** to identify routes on the local switch to be announced into the SPBM network.
13. Using the fields provided, specify the source protocols to redistribute into IS-IS. In **Protocol**, ensure you specify **isis** as the destination protocol.
14. Select **Insert**.

Configuring IPv4 IS-IS redistribution

Use this procedure to configure IS-IS redistribution. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IP VPN IP reachability information, the routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.

IS-IS Redistribute field descriptions

Use the data in the following table to configure the **IS-IS Redistribute** tab.

| Name | Description |
|--------------------|---|
| DstVrflid | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in the redistribution. |
| Protocol | Specifies the protocols that receive the redistributed routes. |
| SrcVrflid | Specifies the source VRF ID used in the redistribution. For IS-IS, the source VRF ID must be the same as the destination VRF ID. |
| RouteSource | Specifies the source protocol for the route redistribution entry. |
| Enable | Enables or disables a redistribution entry. The default is disable. |
| RoutePolicy | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain. |
| Metric | Specifies the metric for the redistributed route. The value can be a range between 0 to 65535. The default value is 0. Use a value that is consistent with the destination protocol. |
| MetricType | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2. |
| Subnets | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow. |

Configure IPv6 IS-IS Redistribution

Use this procedure to configure IS-IS redistribution for IPv6. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the IPv6 routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS:

v6direct, v6static, RIPng, OSPFv3, or BGPv6, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Note

RIPng is supported only on the Global Router.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IPv6 VPN reachability information, the IPv6 routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

Before You Begin

Change the VRF instance as required to configure IPv6 IS-IS redistribution on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.
7. Click **Apply**.

Redistribute Field Descriptions

Use the data in the following table to configure the **Redistribute** tab.

| Name | Description |
|--------------------|---|
| DstVrfId | Specifies the destination Virtual Routing and Forwarding (VRF) ID used in redistribution. |
| Protocol | Specifies the protocols that receive the redistributed routes. |
| SrcVrfId | Specifies the source Virtual Routing and Forwarding (VRF) ID used in redistribution. |
| RouteSource | Specifies the source protocol for the route redistribution entry. |
| Enable | Enables or disables a redistribution entry. The default is disabled. |
| RoutePolicy | Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain. |

| Name | Description |
|-------------------|---|
| Metric | Specifies the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol. |
| MetricType | Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2. |

Applying IPv4 IS-IS accept policies globally

Apply IS-IS accept policies globally. Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

After you apply the IS-IS accept filters, the device removes and re-adds all routes with updated filters.

IS-IS accept policies are disabled by default.

Note

- After you apply IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IP IS-IS filter exists.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.

Accept Global field descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name | Description |
|----------------------------------|--|
| DefaultPolicyName | Specifies the route policy name for the default filter. |
| DefaultBackbonePolicyName | Specifies the backbone host route policy name for the default filter. |
| Apply | Applies the default policy when you configure the field to apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IS-IS**.
3. Select the **Accept Nick Name** tab.
4. Select **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Select **Insert**.

Accept Nick Name field descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name | Description |
|---------------------------|--|
| AdvertisingRtr | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.
The value is 2.5 bytes in the format <x.xx.xx>. |
| Enable | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled. |
| PolicyName | Specifies a route policy.
You must configure a policy earlier in a separate procedure. |
| BackbonePolicyName | Specifies the route policy for the backbone routes.
You must configure a policy earlier in a separate procedure. |

Configure an IS-IS Accept Policy to Apply for a Specific I-SID

Configure an IS-IS accept policy for a specific I-SID number to represent a local or remote Layer 3 VSN, which allows the system to redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid field descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name | Description |
|---------------------------|---|
| Isid | Configures a specific I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies.
Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter.
An I-SID value of 0 represents the global routing table (GRT). |
| Enable | Enables or disables the I-SID entry. You must enable the value to filter. The default is disabled. |
| PolicyName | Specifies the route map name. You must configure a policy earlier in a separate procedure. |
| BackbonePolicyName | Specifies the backbone route map name. You must configure a policy earlier in a separate procedure. |

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name | Description |
|---------------------------|--|
| AdvertisingRtr | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.
The value is 2.5 bytes in the format <x.xx.xx>. |
| Isid | Specifies an I-SID used to filter. The value 0 is used for the Global Router. |
| Enable | Enables or disables the I-SID entry. The default is disabled. |
| PolicyName | Specifies the route policy name. You must configure a policy earlier in a separate procedure. |
| BackBonePolicyName | Specifies the backbone route policy name. You must configure a policy earlier in a separate procedure. |

Configuring an I-SID list for an IPv4 IS-IS accept policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IS-IS accept policy.

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.

Isid-List field descriptions

Use the data in the following table to configure the **Isid-List** tab.

| Name | Description |
|--------------------------|---|
| Name | Specifies the name of the I-SID list. |
| Isid or Isid-List | Specifies that you either want to add a particular I-SID or a list of I-SID numbers. |
| Isid | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |

Configure an IPv4 IS-IS Accept Policy for a Specific I-SID List

Configure an IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid-List field descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name | Description |
|---------------------------|---|
| Name | Specifies the name of I-SID list. |
| Enable | Enables or disables the I-SID list entry. The value must be enabled to filter. The default is disabled. |
| PolicyName | Specifies the route policy name. |
| BackBonePolicyName | Specifies the backbone route policy name. |

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID-list

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **enable** in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid-List field descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name | Description |
|---------------------------|--|
| AdvertisingRtr | Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. The value is 2.5 bytes in the format <x.xx.xx>. |
| Name | Specifies the name of the I-SID list used to filter. |
| Enable | Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled. |
| PolicyName | Specifies a route policy name. |
| BackBonePolicyName | Specifies a backbone route policy name. |

Applying IPv6 IS-IS Accept Policies Globally

Apply IPv6 IS-IS accept policies globally. Use IPv6 IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud.

After you apply the IPv6 IS-IS accept policy filters, the device removes and re-adds all IPv6 routes with updated filters.

IPv6 IS-IS accept policies are disabled by default.

Note

- After you apply IPv6 IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IPv6 IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IPv6 IS-IS routes, and adds the IPv6 IS-IS routes again. You should make all the relevant accept policy changes, and then apply IPv6 IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IPv6 IS-IS filter exists.
- Change the VRF instance as required to apply IPv6 IS-IS accept policies on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. (Optional) Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.
6. Click **Apply**.

Accept Global Field Descriptions

Use the data in the following table to configure the **Accept Global** tab.

| Name | Description |
|--------------------------|--|
| DefaultPolicyName | Specifies the route policy name for the default filter. |
| Apply | Applies the default policy when you select apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action. |
| NickNameTableSize | Shows the IPv6 IS-IS In Filter Nick Name table size. |

| Name | Description |
|----------------------------------|---|
| IsidTableSize | Shows the IPv6 IS-IS In Filter I-SID table size. |
| NickNameIsidTableSize | Shows the IPv6 IS-IS In Filter Nick Name I-SID table size. |
| IsidListTableSize | Shows the IPv6 IS-IS In Filter I-SID List table size. |
| NickNameIsidListTableSize | Shows the IPv6 IS-IS In Filter Nick Name I-SID List table size. |

Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IPv6 IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick Name** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Nick Name Field Descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

| Name | Description |
|-----------------------|--|
| AdvertisingRtr | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. |
| Enable | Enables the SPBM nickname advertising router entry. The default is disabled. |
| PolicyName | Specifies a route policy. |

Configuring an IPv6 IS-IS Accept Policy for a specific I-SID

Configure an IPv6 IS-IS accept policy for a specific I-SID to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the I-SID value.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid Field Descriptions

Use the data in the following table to configure the **Accept Isid** tab.

| Name | Description |
|-------------------|--|
| Isid | Specifies a particular I-SID number that represents local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |
| Enable | Enables or disables the I-SID entry. The default is disabled. |
| PolicyName | Specifies the route policy name. |

Configuring an IPv6 IS-IS accept policy for a specific advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

| Name | Description |
|-----------------------|--|
| AdvertisingRtr | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. |
| Isid | Specifies the I-SID value. The value 0 is used for the Global Router. |
| Enable | Enables or disables the I-SID entry. The default is disabled. |
| PolicyName | Specifies the route policy name. You must configure a policy earlier in a separate procedure. |

Configuring an I-SID List for an IPv6 IS-IS Accept Policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IPv6 IS-IS accept policy.

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Change the VRF instance as required to configure an I-SID list for an IPv6 IS-IS accept policy on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.
9. Click **Apply**.

Isid-List Field Descriptions

Use the data in the following table to configure the **Isid-List** tab.

| Name | Description |
|-------------|--|
| Name | Specifies the name of the I-SID list. |
| Isid | Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT). |

Configuring an IPv6 IS-IS Accept Policy for a specific I-SID List

Configure an IPv6 IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid-List Field Descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

| Name | Description |
|-------------------|--|
| Name | Specifies the name of I-SID list. |
| Enable | Enables or disables the I-SID list entry. The default is disabled. |
| PolicyName | Specifies the route policy name. |

Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB and I-SID List

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid-List Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

| Name | Description |
|-----------------------|---|
| AdvertisingRtr | Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. |
| Name | Specifies the I-SID list name. |
| Enable | Enables or disables the SPBM nickname advertising router entry. The default is disabled. |
| PolicyName | Specifies a route policy name. |

IP Shortcuts SPBM Configuration Example

The following figure shows a sample IP Shortcuts over SPBM deployment.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Figure 121: SPBM IP Shortcuts

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see [SPBM and IS-IS infrastructure configuration](#) on page 876.

Note the following:

- IP IS-IS redistribution needs to be configured to inject IP shortcuts routes into IS-IS. The one exception is the circuitless IP address configured as the IS-IS ip-source-address. This address is automatically advertised without the need for a redistribution rule.
- In the displayed configuration, only direct routes are injected (the same configuration is possible for static routes). To inject IPv6 routes, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.
- No IP address needs to be configured on SwitchG.

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example.

Layer 3 VSN Configuration Fundamentals

This section provides fundamental concepts on Layer 3 VSN.

For information about supported service types, see [Fabric Connect Service Types](#) on page 1144.

SPBM Layer 3 VSN

The SPBM Layer 3 VSN feature is a mechanism to provide IP connectivity over SPBM for VRFs. SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

Figure 122: SPBM Layer 3 VSN

In the preceding figure, the BEBs are connected over the SPBM cloud running IS-IS. VRF red and green are configured on the BEBs. VRF red on BEB A has to send and receive routes from VRF red on BEB D. Similar operations are required for VRF green on BEB A and BEB D.

IS-IS TLV 184 is used to advertise SPBM Layer 3 VSN route information across the SPBM cloud. To associate advertised routes with the appropriate VRF, each VRF is associated with an I-SID. All VRFs in the network that share the same I-SID participate in the same VSN.

Note

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN co-exist and share the same I-SID. You need to configure I-SID only once. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

In this example, I-SID 101 is associated with VRF green and I-SID 102 is associated with VRF red. The I-SID is used to tie the advertised routes to a particular VRF. This identifier has to be the same on all edge nodes for a particular VRF, and has to be unique across all the VRFs on the same node

When IS-IS receives an update from an edge node, it looks for the Layer 3 VSN TLV, and if one exists, it looks at the I-SID identifier. If that identifier is mapped to a local VRF, extracts the IPv4 or IPv6 routes and add them to the RTM of that VRF.

With SPBM Layer 3 VSN, the packet forwarding works in a similar fashion as the IP Shortcuts on the Global Router, with the difference that the encapsulation includes the I-SID to identify the VRF that the packet belongs to. The following figure shows the packet forwarding for VRF red.

Figure 123: Packet forwarding in SPBM Layer 3 VSN

When BEB A receives traffic from VRF red that must be forwarded to the far-end location, it performs a lookup and determines that VRF red is associated with I-SID 102 and that BEB D is the destination for I-SID 102. BEB A then encapsulates the IP data into a new B-MAC header, using destination B-MAC: D.

**Note**

With SPBM Layer 3 VSN, the C-MAC header is all null. This header does not have any significance in the backbone. It is included to maintain the same 802.1ah format for ease of implementation.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 102. After identifying the destination as VRF red, the node forwards the packet to the destination VRF.

**Note**

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN co-exist and share the same I-SID. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

IPv6 Layer 3 VSN limitations and considerations

Consider the following when you configure the IPv6 Layer 3 VSN :

- You can enable IPv6 Layer3 VSN only when **spbm boot** config flag is true.
- IPv4 Shortcuts and IPv6 Shortcuts must be enabled.

Enable/disable ICMP Response on VRFs/Layer 3 VSNs

This feature supports VRFs/Layer 3 VSNs to operate in stealth mode by disabling ICMP responses on specific VRFs/Layer 3 VSNs.

If the ICMP response is disabled, the switch does not respond to any ICMP requests received on the VRFs/Layer 3 VSNs.

If the ICMP response is enabled, the switch responds to ICMP requests received on the VRF/Layer 3 VSNs.

Layer 3 VSN configuration using the CLI

This section provides a procedure to configure Layer 3 VSNs using the command line interface (CLI).

Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 3891.
- You must create the Customer VLANs and add slots/ports.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create an IPv4 VPN instance on the VRF:

```
ipvpn
```

3. Configure SPBM Layer 3 VSN:

```
i-sid <0-16777215>
```

4. Enable IPv4 VPN on the VRF:

```
ipvpn enable
```

By default, a new IPv4 VPN instance is disabled.

5. Display all IPv4 VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

6. Identify routes on the local switch to be announced into the SPBM network:

```
isis redistribute {direct | bgp | ospf | rip | static}
```

7. Enable routes on the local switch to be announced into the SPBM network:

```
isis redistribute {direct | bgp | ospf | rip | static} enable
```

8. If you want to delete or disable the configuration, use the no option:

```
no isis redistribute {direct | bgp | ospf | rip | static}
```

```
no isis redistribute {direct | bgp | ospf | rip | static} enable
```

9. Identify other routing protocols to which to redistribute IS-IS routes:

```
ip {bgp | ospf | rip} redistribute isis
```

10. Enable IS-IS redistribution to other routing protocols:

```
ip {bgp | ospf | rip} redistribute isis enable
```

11. Exit Privileged EXEC mode:

```
exit
```

12. Apply the configured redistribution:

```
isis apply redistribute {direct | bgp | ospf | rip | static} vrf
WORD<1-16>
```

```
ip bgp apply redistribute isis vrf WORD<1-16>
```

```
ip ospf apply redistribute isis vrf WORD<1-16>
```

```
ip rip apply redistribute isis vrf WORD<1-16>
```

13. Display the redistribution configuration:

```
show ip isis redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Create the IPv4 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal

```

Variable Definitions

The following table defines parameters for the **show ip ipvpn** command.

| Variable | Value |
|---------------------------|-------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF ID. |

The following table defines parameters for the **i-sid** command.

| Variable | Value |
|--------------|---|
| <0-16777215> | Assigns an I-SID to the VRF being configured.
Use the no or default option to remove the I-SID to VRF allocation for this VRF. |

The following table defines parameters for the **isis redistribute** command.

| Variable | Value |
|---|---|
| <code>{direct bgp ospf rip static}</code> | Specifies the protocol. |
| <code>enable</code> | Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. Use the no or default options to disable the redistribution. |
| <code>metric <0-65535></code> | Configures the metric (cost) to apply to redistributed routes. The default is 1. |
| <code>metric-type {external internal}</code> | Configures the type of route to import into the protocol. The default is internal. |
| <code>route-map WORD<0-64></code> | Configures the route policy to apply to redistributed routes. Specifies a name. |
| <code>subnets {allow suppress}</code> | Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow . |

The following table defines parameters for the **isis apply redistribute** command.

| Variable | Value |
|---|--|
| <code>{direct bgp ospf rip static}</code> | Specifies the protocol. |
| <code>vrf WORD<1-16></code> | Applies IS-IS redistribute for a particular VRF. Specifies the VRF name. |

Configure SPBM IPv6 Layer 3 VSN using CLI

Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF instance on the switch. For more information, see [VRF Lite configuration using the CLI](#) on page 3891.

About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv6 routes across the SPBM network using the following procedure.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Create an IPv6 VPN instance on the VRF:

```
ipv6 ipvpn
```
3. Configure SPBM Layer 3 VSN:

```
i-sid <0-16777215>
```
4. Enable IPv6 VPN on the VRF:

```
ipv6 ipvpn enable
```
5. Display all IPv6 VPNs:

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```
6. Identify routes on the local switch to be announced into the SPBM network:

```
ipv6 isis redistribute {bgp | direct | ospf | static}
```
7. Enable routes on the local switch to be announced into the SPBM network:

```
ipv6 isis redistribute {direct | bgp | ospf | rip | static} enable
```
8. Identify the routing protocol to which to redistribute IS-IS routes:

```
ipv6 ospf redistribute isis
```
9. Enable IS-IS redistribution to OSPF:

```
ipv6 ospf redistribute isis enable
```
10. Return to Privileged EXEC mode:

```
end
```
11. Apply the configured redistribution to a specific VRF:

```
ipv6 isis apply redistribute {direct | bgp | ospf | rip | static} vrf
WORD<1-16>
```
12. Apply the OSPF configuration to a specific VRF:

```
ipv6 ospf apply redistribute isis vrf WORD<1-16>
```
13. Display the redistribution configuration:

```
show ipv6 isis redistribute [vrf WORD<1-16> | vrfids WORD<0-512>]
```
14. Verify IPv6 IS-IS routes:

```
show ipv6 route vrf WORD<1-16>
```

Examples

Create the IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====
```

```

=====

Variable Definitions

The following table defines parameters for the **ipv6 ipvpn** command.

| Variable | Value |
|---------------|--|
| <i>enable</i> | Enables IPv6 IPVPN. The default is disabled. |

The following table defines parameters for the **show ipv6 ipvpn** command.

| Variable | Value |
|---------------------------------|-------------------------|
| <i>vrf WORD<1-16></i> | Specifies the VRF name. |
| <i>vrfids WORD<0-512></i> | Specifies the VRF ID. |

The following table defines parameters for the **i-sid** command.

| Variable | Value |
|---------------------------|---|
| <i><0-16777215></i> | Assigns an I-SID to the VRF being configured. |

The following table defines parameters for the **isis redistribute** command.

| Variable | Value |
|---------------------------------------|---|
| <i>{bgp direct ospf static}</i> | Specifies the protocol. |
| <i>enable</i> | Enables the redistribution of the specified protocol into the SPBM network.
The default is disabled. |

Displaying SPBM IPv6 Unicast Forwarding Information Base

About This Task

Perform this procedure to display SPBM IPv6 unicast Forwarding Information Base (FIB).

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display SPBM IPv6 unicast FIB:
`show isis spbm ipv6-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-mac]`

Example

```
Switch:1>show isis spbm ipv6-unicast-fib all
=====
                        SPBM IPv6-UNICAST FIB ENTRY INFO
=====
VRF      VRF      Dest      OUTGOING  SPBM  PREFIX METRIC  IP ROUTE
VRF      ISID    ISID      Destination  NH BEB  VLAN  INTERFACE COST  COST  TYPE  PREFERENCE

vrf1    11      11        00:14:c7:e1:33:e0  ess   20  10/22   10   1   External  7
-----
Total number of SPBM IPv6-UNICAST FIB entries 4
=====
```

Variable Definitions

The following table defines parameters for the **show isis spbm ipv6-unicast-fib** command.

| Variable | Value |
|------------------------------|--|
| <i>all</i> | Displays all IS-IS SPBM IPv6 unicast Forwarding Information Base (FIB) information for all VRFs. |
| <i>id <1-16777215></i> | Displays IS-IS SPBM IPv6 unicast FIB information by I-SID ID. |
| <i>spbm-nh-as-mac</i> | Displays the next hop B-MAC of the IPv6 unicast FIB entry. |

Displaying IS-IS Link State Database Information

Perform the following procedure to display the IS-IS link state database related information on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS link state database information:
`show isis lsdb ipv6-unicast [i-sid <0-16777215>] [lspid
xxxx.xxxx.xxxx.xx-xx] [sysid xxxx.xxxx.xxxx]`

Example

```
Switch:1>show isis lsdb ipv6-unicast
```

```

Layer 3 VSN configuration using EDM

Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance on the switch. For more information about how to configure a VRF, see [VRF Lite configuration using Enterprise Device Manager](#) on page 3902.
- You must create the Customer VLANs and add slots/ports.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. To create an IP VPN instance, select **Insert**.
5. Select the ellipsis button (...), select a VRF to associate with the IP VPN, and click **Ok**.
6. Select **Insert**.
7. In the **Enable** column, select **enable** to enable the IP VPN on the VRF.
8. In the **IsidNumber** column, specify an I-SID to associate with the VPN.
9. Select **Apply**.
10. In the navigation pane, expand **Configuration > IP**.
11. Select **Policy**.
12. To identify routes on the local switch to be announced into the SPBM network, select the **Route Redistribution** tab.
13. Select **Insert**.
14. In the **DstVrflid** box, select the ellipsis (...), and then select the destination VRF ID and select **Ok**.
15. In the **Protocol** box, select **isis** as the route destination.

16. In the **SrcVrflid** box, select (...) button, select the source VRF ID and click **Ok**.
17. In the **RouteSource** box, select the source protocol.
18. In the **Enable** box, select **enable**.
19. In the **RoutePolicy** box, select the ellipsis (...), choose the route policy to apply to the redistributed routes and select **Ok**.
20. Configure the other parameters as required.
21. Select **Insert**.
22. To apply the redistribution configuration, select the **Applying Policy** tab.
23. Select **RedistributeApply**, and then select **Apply**.

Configuring SPBM IPv6 Layer 3 VSN using EDM

About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv6 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IPv6 VPN instance on the switch. For more information, see [VRF Lite configuration using Enterprise Device Manager](#) on page 3902.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6-VPN**.
3. Click the **VPN** tab.
4. Click **Insert**.
5. Click the ellipsis [...], and select a VRF.
6. Click **Ok**.
7. Click **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. Click **Apply**.
10. In the **Enable** column, select **true** or **false**.
11. Click **Apply**.
12. In the navigation pane, expand **Configuration > VRF Context View**.
13. Click **Set VRF Context View**.
14. Click the **VRF** tab.
15. Select a context to view.
16. Click **Launch VRF Context view**.

A new browser tab opens containing the selected VRF view

17. In the navigation pane, expand **Configuration > IPv6**.
18. Click **IS-IS**.
19. Click the **Redistribute** tab.
20. Click **Insert**.
21. Configure the parameters as required.
22. Click **Insert**.
23. Click **Apply**.

Layer 3 VSN configuration example

The following figure shows a sample Layer 3 VSN deployment.

Figure 124: Layer 3 VSN

The following sections show the steps required to configure the Layer 3 VSN parameters in this example.

Note that IP IS-IS redistribution needs to be configured to inject the VRF routes into IS-IS.

You must first configure basic SPBM and IS-IS infrastructure.

VRF green configuration

The following figure shows the green VRF in this Layer 3 VSN example.

Figure 125: Layer 3 VSN – VRF green

The following sections show the steps required to configure the green VRF parameters in this example.

Layer 3 Video Surveillance install script

Note

The Layer 3 Video Surveillance install script performs the same function as the **run vms endura** script. However, the switch continues to support the **run vms endura** script for backward compatibility.

The **run vms layer-3 switch** command runs the Layer 3 Video Surveillance install script that pre-configures basic and common configuration parameters to deploy a video surveillance network. Use this script to quickly and easily deploy a video surveillance network in accordance with best practices, using networking equipment.

Use this script to use a single command on a switch to configure the core switch where the video surveillance management and operation systems reside. Similarly, using the same command, you can configure each edge switch where the IP cameras connect.

The switch must be in a factory-default state, to ensure correct operation of the configuration.

The Layer 3 Video Surveillance install script performs the following tasks:

- Creates a Shortest Path Bridging (SPB) network core solution with IP Shortcuts to connect IP subnet zones between the core and edge IP subnets.
- Configures all network edge IP subnet areas containing IP cameras with an IP gateway address, that is redistributed over the SPB fabric. This enables the fabric core to act as a single IP routing entity for the solution.

- Relays DHCP services between each IP subnet area and the central server, for IP camera address allocation.
- Enables IP multicast over Fabric Connect virtualization, to support and allow efficient IP multicast communication over the fabric core from IP cameras to central Video Management System (VMS) servers, for viewing and recording video streams.

CLI Command Switch Value

You must specify a value for the switch in the install script command, and the value must be between 5 and 99. Use the value 5 for a core switch where the VMS core systems are connected.

Use the range 6–99 for switch values when you run the script on edge or access layer switches. Ensure that the switch value is unique for each additional switch that is part of the solution.

For example, the first edge or access switch with the IP Cameras connected would use a value of switch 6. For additional edge or access switches, use switch 7, switch 8, and so on, for each IP subnet and IP camera zone. You can connect up to 48 IP cameras to a switch within an IP subnet zone.

Switch Parameters Configured by the Script

The following list identifies the major parameters configured by the **run vms layer-3** command:

- SNMP-Server switch hostname
- SPB parameters such as System ID, Nickname, SPB Area ID, Backbone VLAN IDs (4051 and 4052), Multicast virtualization, and Connectivity Fault Management (CFM)
- IP loopback interface addresses
- IP redistribution over IS-IS (IP Shortcuts)
- All SFP ports as SPB NNI ports
- All copper RJ-45 ports as end device ports with Spanning Tree enabled
- Spanning Tree mstprstp mode
- VLAN port memberships
- VLAN IP address (Gateway IP for VLAN)
- DHCP Relay

Note

DHCP Relay parameters are configured only when you run the script on VSP4900-48P switches.

Configuration File

After successful completion of the Layer 3 Video Surveillance install script, the switch saves the configuration with a filename based on the switch value provided when you ran the script. The switch updates the primary boot configuration file flags with the new filename.

For example, running the command **run vms layer-3 switch 5** results in a switch configuration filename of `spb-switch-5.cfg`.

Hardware Considerations

The following list identifies which switches to configure as either a core or edge switch in a VMS solution:

- Core switch:
 - VSP 4450GSX-PWR+

Ports 13 to 50 are network-to-network interface (NNI) ports. All other ports are untagged access ports.
 - VSP4900-12MXU-12XE

Ports 1 to 12 and the Extreme Integrated Application Hosting (IAH) ports are untagged access ports. Ports 13 to 24, and optional Versatile Interface Module (VIM) ports, are NNI ports.
 - VSP4900-24S

Ports 1 to 12 are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.
 - VSP4900-24XE

Ports 1 to 12 and the IAH ports are untagged access ports. Ports 13 to 24, and optional VIM ports, are NNI ports.
- Edge switch:
 - VSP4900-48P

Note

To support this feature, VIM installation is mandatory in VSP4900-48P. The VIM ports are configured as NNI ports while all fixed ports are untagged access ports.

Modes

The **run vms layer-3** command can run in one of two modes:

- Non-verbose mode: This mode is a fully-automated configuration. The command runs the script with all of the variable defined values without user intervention. This mode is the default mode.
- Verbose mode: This mode prompts you to accept or change the default parameters.

Note

Product Notice: Verbose mode only applies to VSP 4900 Series.

Run the Layer 3 Video Surveillance install script

Use the following procedure to run the Layer 3 Video Surveillance install script.

Note

The **run vms layer-3 switch** command performs the same function as the **run vms endura switch** command. The switch supports the **run vms endura switch** command only for backward compatibility.

Before You Begin

The switch must be in a factory default state; the switch prompts you to confirm this.

About This Task

Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers connect. Use a switch value of 6 onwards (until and including 99) for all switches that connect IP Cameras at the network edge/access layer.

For each additional area and switch, increment the switch number by one. For example, use `switch 7` for the second edge switch. The configuration uses the number you specify to customize the IP subnet, loopback addresses, and SPB information.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Run the Layer 3 Video Surveillance install script:

```
run vms Layer-3 switch <5-99> [syntax | verbose]
```

Examples

The following example shows the configuration of a switch in the VMS core and shows the configuration file created by the script.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#run vms layer-3 switch 5
Do you want to execute the run vms script? Device needs to be in factory default state.
(y/n) ? y
CP1 [05/05/17 07:48:33.760:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
CP1 [05/05/17 07:48:37.951:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.

**Previous configurations stored in pre_vms_install.cfg**
**New VMS configurations stored in new primary config file spb-switch-5.cfg**

*** VMS script execution complete ***
Switch:1(config)#exit
Switch:1#
```

The following example shows the configuration of a switch at the edge, and shows the configuration file created by the script.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

switch:1(config)#run vms layer-3 switch 6
Do you want to execute the run vms script? Device needs to be in factory default state.
(y/n) ? y
CP1 [05/05/17 07:54:04.046:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
```

```

CP1 [05/05/17 07:54:05.760:IST] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.

**Previous configurations stored in pre_vms_install.cfg**
**New VMS configurations stored in new primary config file spb-switch-6.cfg**

*** VMS script execution complete ***
Switch:1(config)#exit
Switch:1#

```

Variable Definitions

The following table defines parameters for the **run vms Layer-3 switch** command.

| Variable | Value |
|----------------|--|
| <5-99> | <p>Specifies the numeric switch value used as a common element to configure switch parameters such as name, VLAN ID, SPB, and IP parameters.</p> <p>Note:
Use a switch value of 5 for a switch in the network core where the Video Management System (VMS) servers are connected. Use a value of 6 onwards (until and including 99) for all switches used for connecting IP Cameras at the network edge/access layer.</p> |
| <i>syntax</i> | <p>Species that the switch displays all the commands run by the script on the console. Use this parameter to see errors that the script encounters.</p> <p>Note:
The script does not stop if it encounters errors. To verify that the script runs without errors, use the <i>syntax</i> parameter to display errors or conflicting configurations on the switch.</p> |
| <i>verbose</i> | <p>Specifies that the switch prompts you to accept or change the default configuration values. If you do not use this optional parameter, the script runs without user intervention.</p> |

IP multicast fundamentals

IP multicast extends the benefits of Layer 2 multicasting on LANs to WANs. Use multicasting techniques on LANs to help clients and servers find each other. With IP multicast, a source can send information to multiple destinations in a WAN with a single transmission. IP multicast results in efficiency at the source and saves a significant amount of bandwidth.

Enabling multicast on the switch

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, use the boot flag called **spbm-config-mode**:

- The **spbm-config-mode** boot flag is enabled by default. This configuration enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.

- If you disable the boot flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you plan to disable the boot flag, remove all SPB configurations first.
- If you plan to use the default (enabled) setting, remove all PIM configurations first.

Simplified Virtual-IST

Simplified Virtual-IST (vIST) is for conventional network deployments that use SMLT and not SPB. The Simplified vIST feature provides a single CLI command to enable the virtual IST for SMLT deployments.

- Simplified vIST is available ONLY for conventional multicast deployments with PIM and IGMP when the boot flag (**spbm-config-mode**) is disabled.
- When the boot flag is enabled (default setting), Simplified vIST is not available. This means that you continue to configure SPB/IS-IS for vIST.
- Simplified vIST requires that the two vIST devices be directly connected.

**Note**

- PIM is supported with Simplified vIST only, not SPB vIST. However, you do not have to configure Simplified vIST to run PIM or IGMP Snooping in a **non-SMLT** topology.
- Do not configure LACP on SPB NNI MLT links or on the Simplified Virtual IST.
- Do not configure ECMP in PIM Simplified vIST scenarios. Running PIM in a Simplified vIST environment with ECMP enabled may lead to incorrect behavior since there are multiple options in terms of choosing the upstream node towards a host or source. For example, since the path chosen cannot be predicted (it is determined by the downstream PIM neighbor), we may end up not adding the Virtual IST MLT port in the PIM mroute's outgoing port list on the joined interface if the PIM Join Prune Message was received on an alternative path, different from the interface the local router considers to be the correct upstream to the source.

Traffic loss can occur in such an environment. Do not enable ECMP in PIM vIST scenarios.

After you disable the **spbm-config-mode** boot flag, you can configure PIM or IGMP Snooping on any VLAN including the vIST VLAN.

To configure the boot flag and Simplified vIST, see [Configuring IP multicast in SMLT topologies](#) on page 1390 or [Configuring multicast on the switch](#) on page 1409.

vIST VLAN IP addresses

Do not configure an RP or BSR on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the **ip pim enable** command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and RP
related configurations, as unicast packets to virtual IST vlan IP
```

address from outside of virtual IST vlan subnet will be dropped. Use Loopback or CLIP interface IP address for BSR and RP related configurations.

Overview of IP multicast

IP multicast transmits messages to multiple recipients at the same time. This one-to-many delivery mechanism is similar to broadcasting, except that multicasting transmits to specific groups and broadcasting transmits to all receivers on a network. Because IP multicast transmits only one stream of data to the network where it replicates to many receivers, multicasting saves a considerable amount of bandwidth.

IP multicast services benefit applications such as video conferencing, dissemination of datagram information, and dissemination of mail or news to a large number of recipients.

Multicast protocols use different techniques to discover delivery paths.

A distribution tree is a set of multicast routers and subnetworks that permit the members of a group to receive traffic from a source. The source of the tree depends on the algorithm used by the multicast protocol. The following diagram is an example of a simple distribution tree where S is the multicast source and the arrows indicate the multicast broadcast procedure.

Figure 127: Multicast distribution tree and broadcasting

Broadcast and prune methods use multicast traffic to build the distribution tree. Periodically, the source sends or broadcasts data to the extremities of the internetwork to search for active group members. If no local members of the group exist, the router sends a message to the host, removing itself from the distribution tree, and thus pruning the router.

The following diagram illustrates how the host prunes routers from the distribution tree. First, the router sends a message to the source, after which the pruned routers do not receive multicast data.

Figure 128: Pruning routers from a distribution tree

Reverse path multicast is based on the concept that a multicast distribution tree is built on the shortest path from the source to each subnetwork that contains active receivers. After a datagram arrives on an interface, the router determines the reverse path to the source of the datagram by examining the routing table of known network sources. If the datagram is not on the optimal delivery tree, the router discards it.

Multicast host groups and their group members enable the IP multicast router to transmit just to those groups interested in receiving the traffic. The switch uses the Internet Group Membership Protocol (IGMP) to learn the existence of host group members on their directly attached subnets. A router communicates with the hosts on a local network by sending IGMP queries. Hosts respond by issuing IGMP reports. For more information about host groups, see [Multicast host groups](#) and [Multicast addresses](#) on page 1324. For more information about IGMP, see [Internet Group Management Protocol](#).

Multicast traffic forwarding transmits frames to all interfaces or subnets for which it receives IGMP reports for the multicast group indicated in the destination IP address. Multicast packets forwarded within the same virtual LAN (VLAN) remain unchanged. The switch does not forward packets to networks that do not use members of the multicast group indicated in the destination IP address.

Multicast host groups

IP multicast is a method for addressing, routing, and delivering a datagram to a collection of receivers called a host group.

Host groups are permanent or transient, with the following characteristics:

- A permanent host group uses a well-known, administratively assigned IP multicast group address. This address is permanent and defines the group. A permanent host group can consist of zero or more members.

- A transient host group exists only as long as members need its services. IP addresses in the multicast range that are not reserved for permanent groups are available for dynamic assignment to transient host groups.

A host system on an IP network sends a message to a multicast group by using the IP multicast address for the group. To receive a message addressed to a multicast group, however, the host must be a member of the group and must reside on a network where that group is registered with a local multicast router.

An IP multicast host group can consist of zero or more members and places no restrictions on its membership. Host members can reside anywhere, they can join and leave the group at any time, and they can be members of more than one group at the same time.

In general, hosts that are members of the same group reside on different networks. However, a range of multicast addresses (224.0.0.x) is reserved for locally-scoped groups. All message traffic for these hosts typically remains on the local network. Hosts that belong to a group in this address range and that reside in different networks do not receive message traffic for each other.

Important

You can apply a special set of filters (global filters) to multicast packets. You can also create, deny, or accept filters to configure the sources that can receive and send data. For more information about how to configure filters, see [Traffic filtering fundamentals](#) on page 3386.

Multicast addresses

Each host group uses a unique multicast address. To reach all members of the group, a sender uses the multicast address as the destination address of the datagram.

An IP version 4 multicast address is a Class D address (the high-order bits are 1110) from 224.0.0.0 to 239.255.255.255. These addresses are assigned statically for use by permanent groups and dynamically for use by transient groups.

The block of addresses from 224.0.0.1 to 224.0.0.255 is reserved for routing protocols and other low-level protocols. Multicast routers do not forward datagrams with addresses in this range because the time-to-live (TTL) value for the packet is usually 1.

Multicast protocols

You can use the following protocols to enable multicast routing on a switch:

- Internet Group Management Protocol (IGMP)—learns the existence of host group members on directly attached subnets.
- Multicast Router Discovery (MRDISC) protocol—discovers multicast routers in a Layer 2 bridged domain configured for IGMP snoop.
- Protocol Independent Multicast (PIM)
 - Sparse Mode (PIM-SM) protocol—suitable for implementation on networks sparsely populated by receivers.
 - Source Specific Multicast (PIM-SSM) protocol—uses a one-to-many model where members can receive traffic from one or more specific sources. This protocol is suitable for television channels and other content-distribution applications.

Static source groups

Use static source groups to configure static source-group entries in the PIM-SM, or PIM-SSM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers for the group exist, the multicast stream for a static source-group entry stays active. PIM never prunes static forwarding entries. If you no longer need the entries, you must manually delete them.

To configure static source groups, you must first globally enable PIM. If you disable PIM, the switch saves all of the configured static source-group entries and deactivates them. After you re-enable PIM, the switch reactivates the static source groups.

Static source groups ensure that the multicast route (mroute) records remain in the distribution tree. After receivers join the group, they do not experience a delay in receiving multicast data because they do not need to graft onto the group, or start a join process in the case of PIM. This timing is essential for applications where the multicast data must send to a receiver as soon as the receiver joins the group, for example, when a switch delivers television channels to receivers. After the receiver turns the channel, which is equivalent to joining a group, the receiver can view the channel immediately.

Static entries result in continuous traffic if the source is active, even if no receivers exist. However, the system does not forward traffic with a static entry if no receivers exist, but forwards it continuously to the switch where the entry is programmed and crosses intermediate switches on the path.

You can configure static source-group entries for a specific source or subnet. If several sources on the same subnet send traffic to the same group, traffic for all these sources flows continuously when using the subnet configuration.

After you configure static source groups, keep the following points in mind:

- If you disable PIM, the switch deactivates all of the static source groups. After you re-enable PIM, the switch activates the static source groups.
- In PIM-SM configuration, the static source-group feature works for both specific source addresses and subnet addresses by using the SrcSubnetMask field.

When the network mask is 255.255.255.255, the full source address is used to match the (S,G) which is the specific source case. When the network mask field is a subnet mask for the source, only the source subnet is used to match (S,G)s.

- In PIM-SSM configurations, static source groups have the following limitations:
 - Subnets: SSM static source groups work only with specific IP addresses. Static source groups cannot work with source subnets, so the mask must use a full 32-bit mask, 255.255.255.255, and the source must use a host address.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. These extensions, combined with the use of IGMP snooping and querier functions at the edge of the SPBM cloud, efficiently transport IP multicast data by using sub-trees of the VSN shortest path tree per IP multicast group.

Internet Group Management Protocol

Table 143: Internet Group Management Protocol product support

| Feature | Product | Release introduced |
|---|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Internet Group Management Protocol (IGMP), including virtualization | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VSP 4000 4.0 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 4.2.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VSP 8200 4.0.1 |
| | VSP 8400 Series | VOSS 4.2 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | Not Supported |

A host uses IGMP to register group memberships with the local querier router to receive datagrams sent to this router targeted to a group with a specific IP multicast address.

A router uses IGMP to learn the existence of group members on networks to which it directly attaches. The router periodically sends a general query message to each of its local networks. A host that is a member of a multicasting group identifies itself by sending a response.

IGMP queries

When multiple IGMP routers operate on a network, one router is elected to send queries. This elected querier periodically sends host membership queries (also known as general queries) to the attached local subnets. The switch supports queries from all three versions of IGMP.

IGMP host reports

A host that receives a membership query from a local router can respond with a host membership report, one for each multicast group that joins. A host that receives a query delays its reply by a random interval and listens for a reply from other hosts in the same host group. For example, consider a network that includes two host members—host A and host B—of the same multicast group. The router sends out a host membership query on the local network. Both host A and host B receive the query and listen on the network for a host membership report. The delay timer for host B expires first, so it responds to the query with a membership report. Hearing the response, host A does not send a report of its own for the same group.

Each query from a router to a host includes a maximum response time field. IGMP inserts a value n into this field specifying the maximum time in tenths of a second within which the host must issue a reply. The host uses this value to calculate a random value between 0 and n tenths of a second for the period that it waits before sending a response. This calculation is true for IGMP versions 2 and 3. For IGMP version 1, this field is 0 but defaults to a value of 100, that is, 10 seconds.

If at least one host on the local network specifies that it is a member of a group, the router forwards to that network all datagrams that bear the multicast address for the group.

Upon initialization, the host can immediately issue a report for each of its supported multicast groups. The router accepts and processes these asynchronous reports the same as requested reports.

After hosts and routers are in a steady state, they communicate in a way that minimizes the exchange of queries and reports. The designated routers establish a path between the IP multicast stream source and the end stations and periodically query the end stations about whether to continue participation. As long as a client continues to participate, all clients, including nonparticipating end stations on the switch port, receive the IP multicast stream.

Host leave messages

If an IGMPv2 host leaves a group and it is the host that issues the most recent report, it also issues a leave group message. The multicast router on the network issues a group-specific query to determine whether other group members exist on the network. If no host responds to the query, the router assumes that no members belonging to that group exist on that interface.

Fast leave feature

The switch supports a fast leave feature that is useful for multicast-based television distribution applications. Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Fast leave alleviates the network from additional bandwidth demand after a customer changes television channels.

The switch provides several fast leave processes for IP multicast:

- immediate leave with one user for each interface
- immediate leave with several users for each interface
- standard IGMP leave based on a Last Member Query Interval (LMQI), which you can configure in tenths of seconds

Fast leave modifies the IGMP leave processing mechanism on an IGMP interface. After the system receives an IGMP leave message on a fast leave enabled interface, the switch does not send a group-specific query and immediately stops sending traffic to the leaving member (IGMP host) port. Without fast leave, traffic continues to forward until the group times out. This situation wastes bandwidth if no receiver that requires the group traffic exists.

Fast leave mode provides two options of the fast leave mechanism—single-user mode and multiple-users mode:

- **Single-user mode:** In this mode, the port stops receiving traffic immediately after a group member on that port sends a leave message. Use the single-user mode if each interface port connects to only one IGMP host.
- **Multiple-users mode:** Use this mode if the interface port connects to multiple IGMP hosts. In this case, the port stops receiving traffic after all members leave the IGMP group. The switch removes the leaving IGMP member and, if more group members exist on that port, the switch continues sending traffic to the port.

When operating in multiple-users mode, the switch must use the correct membership information. To support multiple-users mode, multicast receivers on the same interface cannot use IGMP report suppression. If you must use IGMP report suppression, do not use this mode. Instead, use the LMQI

(configurable in units of 1/10ths of seconds) to provide a faster leave process while still sending group-specific queries after the interface receives a leave message.

Fast leave mode applies to all fast-leave enabled IGMP interfaces.

IGMP snoop

The switch provides IP multicast capability and can support all three versions of IGMP to prune group membership for each port within a VLAN. This feature is IGMP snoop.

Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

Use the IGMP snoop feature to optimize the multicast data flow, for a group within a VLAN, to only those ports that are members of the group. The switch builds a database of group members by listening to IGMP reports from each port. The switch suppresses the reports heard by not forwarding them to ports other than the one receiving the report, thus forcing the members to continuously send their own reports. The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. Furthermore, the switch forwards multicast data only to the participating group members and to the multicast routers within the VLAN.

The multicast routing functionality can coexist with IGMP snoop on the same switch, but you can configure only one of IGMP snoop or an IP multicast routing protocol, excluding IGMP, on the same VLAN.

Multicast group trace for IGMP snoop

Use this feature to monitor the multicast group trace for an IGMP snoop-enabled switch. You can view the multicast group trace from CLI.

Multicast group trace tracks the data flow path of the multicast streams. Group trace tracks information such as the multicast group address, the source address, ingress VLAN and port, and egress VLAN and port.

IGMP proxy

If a switch receives multiple reports for the same multicast group, it does not transmit each report to the multicast upstream router. Instead, the switch consolidates the reports into a single report and forwards the one report. If you add another multicast group or the system receives a query since it last transmitted the report upstream, the system forwards the report onto the multicast router ports. This feature is IGMP proxy.

IGMP versions

The switch supports IGMPv1, IGMPv2, and IGMPv3. IGMPv1 and IGMPv2 are backward compatible and can exist together on a multicast network. The following list describes the purpose for each version:

- IGMPv1 provides the support for IP multicast routing. IGMPv1 specifies the mechanism to communicate IP multicast group membership requests from a host to its locally attached routers. For more information, see RFC1112.

- IGMPv2 extends the features in IGMPv1 by quickly reporting group membership termination to the routing protocol. This feature is important for multicast groups with highly volatile group membership. For more information, see RFC2236.
- IGMPv3 supports the PIM Source Specific Multicast (SSM) protocol, PIM-SM, and snooping. A host can selectively request or filter traffic from individual sources within a multicast group or from specific source addresses sent to a particular multicast group. Multicast routing protocols use this information to avoid delivering multicast packets from specific sources to networks where there are no interested receivers. For more information, see RFC3376.

For the switch implementation of PIM-SSM, each group can use multiple sources.

The following list identifies group records that a report message includes:

- current-state record
- source-list-change record
- filter-mode-change record

A current-state record is sent by a system in response to a query received on an interface. It reports the current reception state of that interface, with respect to a single multicast address.

The Record Type of a current-state record has one of the following two values:

- `MODE_IS_INCLUDE` — Indicates that the interface has a filter mode of include for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.
- `MODE_IS_EXCLUDE` — Indicates that the interface has a filter mode of exclude for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.

Source-List Change Record — The system sends a source-list-change record after a change of source list occurs that does not coincide with a filter-mode change on the interface for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a source-list-change record can be one of the following two values:

- `ALLOW_NEW_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the additional sources that the system wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were added to the list. If the change was to an exclude source list, these are the addresses that were deleted from the list.
- `BLOCK_OLD_SOURCES` — Indicates that the source address [i] fields in this group record contain a list of the sources that the system no longer wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were deleted from the list; if the change was to an exclude source list, these are the addresses that were added to the list.

If a change of source list results in both allowing new sources and blocking old sources, then two group records are sent for the same multicast address, one of type `ALLOW_NEW_SOURCES` and one of type `BLOCK_OLD_SOURCES`.

Filter Mode — The switch implements the filter-mode-change record. The system sends a filter-mode-change record whenever the filter mode changes (during a change from include to exclude, or from exclude to include) for a particular multicast address. The interface on which the change occurs sends a

report that includes the record. The record type of a filter-mode-change record can be one of the following two values:

- `CHANGE_TO_INCLUDE_MODE` — Indicates that the interface has changed to include filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.
- `CHANGE_TO_EXCLUDE_MODE` — Indicates that the interface has changed to exclude filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.

After you enable IGMPv3, the following actions occur:

- After you change the version on an interface to or from IGMPv3, the switch experiences a disruption to existing multicast traffic on that interface but traffic does recover. Do not make this change when the system passes multicast traffic.

IGMP states

Multicast routers implementing IGMPv3 keep one state for each group for every port in every attached network. This group state consists of a filter-mode, a list of sources, and various timers. For each attached network running IGMP, a multicast router records the desired reception state for that network. This state consists of a set of records of the following form:

- multicast address
- group timer
- filter mode (source records)

Each source record is of the form source address or source timer. If all sources within a given group are desired, an empty source record list is kept with filter-mode set to EXCLUDE. This means hosts on this network want all sources for this group to be forwarded. This is the IGMPv3 equivalent to a IGMPv1 or IGMPv2 group join.

Group timer

A group timer represents the time for the filter-mode to expire and switch to INCLUDE mode and is used only when a group is in EXCLUDE mode.

Group timers are updated according to the types of group records received. If a group timer is expiring when a router filter-mode for the group is EXCLUDE means, there are no listeners on the attached network in EXCLUDE mode. At this point, a router will transition to INCLUDE filter-mode.

Source timer

A source timer is maintained for every source record. Source timers are updated according to:

- the type and filter-mode of the group record received
- whenever the source is present in a received record for that group.

If a source timer expires with a router filter-mode for the group of INCLUDE, the router concludes that traffic from this particular source is no longer desired on the attached network, and deletes the associated source record.

If a source record has a running timer with a router filter-mode for the group of EXCLUDE, it means that at least one system desires the source. It should therefore be forwarded by a router on the network. If a source timer expires with a router filter-mode for the group of EXCLUDE, the router informs the routing

protocol that there is no receiver on the network interested in traffic from this source. The records are deleted when the group timer expires in the EXCLUDE router filter-mode.

Processing IGMP messages for groups in SSM range

IGMP messages are processed for groups in SSM range in the following scenarios:

1. IGMPv3 interface enabled; PIM-sparse or snooping enabled
 - IGMPv3 reports that contain group records with groups within SSM range are processed with no restrictions.
 - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type IS_EXCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
 - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type TO_INCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
2. IGMPv3 interface enabled; PIM-SSM or ssm-snooping enabled
 - IGMPv3 reports that contain group records with groups within SSM range received from members in the EXCLUDE mode are discarded (eg. IS_EXCLUDE and TO_EXCLUDE messages).
 - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type ALLOW{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.
 - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type BLOCK{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.

Note

In order to accept v2 messages, you must enable the compatibility mode on the IGMPv3 interface.

IGMPv3 source-specific forwarding rules

After a multicast router receives a datagram from a source destined to a particular group, the router must decide to forward the datagram to the attached network. The multicast routing protocol uses IGMPv3 information to forward datagrams to all required sources or groups on a subnetwork.

The following table describes the forwarding suggestions that IGMPv3 makes to the routing protocol. The table also identifies the action taken after the source timer expires, based on the filter mode of the group.

| Group filter-mode | Source-timer value | Action |
|-------------------|--------------------|--|
| INCLUDE | TIMER > 0 | Forward the traffic from the source. |
| INCLUDE | TIMER = 0 | Stop forwarding the traffic from the source, and remove the source record. If no more source records exist for the group, delete the group record. |

| Group filter-mode | Source-timer value | Action |
|-------------------|--------------------|---|
| INCLUDE | No source elements | Do not forward the source. |
| EXCLUDE | TIMER > 0 | Forward the traffic from the source. |
| EXCLUDE | TIMER = 0 | Do not forward the traffic from the source. If no more source records exist for the group, delete the group record. |
| EXCLUDE | No source elements | Forward the traffic from the source. |

IGMPv3 explicit host tracking

IGMPv3 explicit host tracking enables the IGMP to track all the source and group members. To track all the source and group members, the sources that are in the include mode hold a list of members who want to receive traffic from that source.

The members that are in the exclude mode are on hold on the reporter list under the port data. By default, IGMPv3 explicit host tracking is disabled.

Important

If explicit host tracking is enabled, you cannot downgrade the IGMPv3 interface to IGMPv1 or IGMPv2.

IGMPv3 fast leave

When a BLOCK message is received for a source, you must check if the member that sent this message is the last reporter for the source. If it is the last reporter, delete the source. Else, delete the member. No group and source specific queries are sent.

When a LEAVE message is received, you must check if the member that sent this message is the last reporter for the group. If it is the last reporter, switch to INCLUDE mode if sources are available (if no sources are available the port is deleted). Else, delete the member. No group and source specific queries or group specific queries are sent.

Important

To use the IGMPv3 fast leave feature, you must first enable the explicit host tracking feature.

Synchronization of IGMPv3 over SMLT

The implementation of IGMPv3 offers support for IGMPv3 over SMLT. The Virtual-IST (vIST) peers must be in sync with the IGMPv3 reports received over SMLT links to ensure effective performance. The vIST protocol ensures the infrastructure to send such information from one vIST peer to the other.

The synchronization of IGMPv3 members and their advertised sources is different from IGMPv1 and IGMPv2. Because of IGMPv3 compatibility mode, you must consider the IGMP member version. If you have version 1 or 2 members, you must synchronize the IGMP information as IGMPv1 or IGMPv2 reports, so the peer can build an accurate database. In particular, if members with version 1 or 2 exist, the group filter mode is exclude and the exclude source list is empty. Also no v1 or v2 member will be present on any source from include list.

Each member sends IGMP reports in the same manner for all IGMP versions. The sending mechanism depends on the SMLT state.

After a vIST peer receives an IGMPv3 report over an SMLT link, it must pass the message to its peer. If the SMLT state is up, the vIST peer sends the message encapsulated in an vIST IGMPv3 message. If the SMLT state is down, the vIST peer sends the message as a plain IGMPv3 report.

In both cases the IGMPv3 message is not altered and the receiving vIST peer processes it as expected in SMLT conditions (translating the receiving port to SMLT port if applicable).

**Note**

If you enable compatibility mode and the member sends an IGMPv1 or IGMPv2 report, the message is either a vIST IGMPv1 or v2 encapsulated Message or a plain IGMPv1 or IGMPv2 report.

After SMLT up or down events occur, the vIST peer must synchronize its IGMPv3 database to its peer, taking into account the new state of the SMLT link.

If you enable IGMP explicit host tracking, each include source stores information for each member that advertises that particular source in an include list. This information is synchronized with the vIST peer.

If you do not enable explicit host tracking, each source from include list contains only information related to the last member that sent an IGMPv3 report. Only this information is synchronized with the vIST peer.

Backward compatibility

IGMPv3 for PIM-SSM is backward compatible with IGMPv2. You can configure the switch to operate in v3-only mode or in v2-v3 compatibility mode. If you configure the switch to use v3-only mode, it ignores all v2 and v1 messages except the query message.

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv1, v2, and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message; if it is a v2 message, PIM-SM or IGMP snoop processes handle the message.

After the switch receives an IGMPv2 leave message and the group address in it is within SSM range, the switch sends the group-and-source specific query. If the group address is not within the SSM range, the switch sends the group specific query.

According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2 hears an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure if the switch dynamically downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

In v2-v3 compatibility mode, an IGMPv2 host can only join if you configure a static entry in SSM map and if the interface operates in PIM-SSM mode or IGMP SSM-Snoop mode.

You can use the compatibility mode with Split MultiLink Trunking (SMLT). One core switch sends an SMLT message to the other core switch after it receives an IGMPv3 message. This action synchronizes the IGMP host information.

Implementation of IGMP

You can enable and disable multicast routing on an interface basis. If you disable multicast routing on an interface, the interface does not generate IGMP queries. If the switch or interface is in IGMP router behavior mode, for example, PIM enabled, you cannot configure IGMP snoop. The switch still learns the group membership and snoops multicast receivers on the switch VLAN or ports.

IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

Overview

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

IGMP Snooping

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

- Generate the Layer 2 MAC forwarding tables used for further switching sessions
- Regulate the multicast traffic to prevent it from flooding the Layer 2 segment of the network

IGMP Layer 2 Querier and IGMP interaction

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

**Note**

Group Specific When Leave does not apply to IGMPv1.

IGMP Layer 2 Querier limitations

The following limitations apply to IGMP Layer 2 Querier.

- IGMP Layer 2 Querier is based on IGMP Snoop. If you disable IGMP Snoop, IGMP Layer 2 Querier does not work until you enable IGMP Snoop and IGMP Layer 2 Querier.
- After you enable IGMP Snoop and IGMP Layer 2 Querier on an interface, if the system receives no IGMP query messages, it becomes the querier.

IGMP Layer 2 Querier limitations and DvR

The following limitations apply when you configure IGMP Layer 2 Querier on DvR enabled nodes.

- You can configure IGMP Layer 2 Querier only on the DvR Controllers in a DvR domain. When you configure the following parameters on the Controllers, the configuration is automatically pushed to the DvR Leaf nodes within the domain.
 - IGMP version
 - IGMP query interval
 - IGMP query maximum response time
 - IGMP robustness value
 - IGMP last member query interval
 - IGMP compatibility mode
- You cannot configure IGMP snooping on DvR enabled Layer 2 VSNs.

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 661.

Multicast access control

Multicast access control is a set of features that operate with standard existing multicast protocols. You can configure multicast access control for an IP multicast-enabled port or VLAN with an access control policy that consists of several IP multicast groups.

You can use this feature to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams). For example, in a television distribution application, instead of applying a filter to each channel (multicast group), you can apply a multicast access policy to a range of channels (groups), thereby reducing the total number of filters and providing a more efficient and scalable configuration. Also, if you want to add or remove television channels from a package, you can modify the multicast access policy; you do not need to change filters for individual

VLANs or ports. Multicast access policies contain an ID and a name (for example, PremiumChannels), the list of IP multicast addresses, and the subnet mask.

Multicast access control is not a regular filtering configuration. Multicast access control is for multicast streams and relies on handling multicast control and initial data to prevent hosts from sending or receiving specified multicast streams; it does not use filters. Also, multicast access control provides a list of multicast groups in one configuration using the same routing policy prefix list configuration. For information about prefix lists, see [Configuring prefix lists](#) on page 2762. You can configure multicast access control and change it dynamically to support changes in the configuration without restarting the protocol. You can change the access capabilities of a user or service subscriber without loss of service.

The following paragraph describes a typical application.

The local cable television company offers three packages; each one includes 35 channels (35 multicast groups). The company configures each package in an access control policy. This policy applies to a set of VLANs or ports to prevent users from viewing the channels on those VLANs. Use the same policy to prevent users from sending traffic to those groups (also known as spoofing) by specifying the deny-tx option for that port. After you define the packages, you can use them for access policy configuration. You can easily change the package by changing the group range, without changing all the port configurations.

The multicast access control functionality applies to an IP multicast application where you must control user access. You can use it in financial-type applications and other enterprise applications, such as multicast-based video conferencing.

Six types of multicast access control policies exist:

- deny-tx
- deny-rx
- deny-both
- allow-only-tx
- allow-only rx
- allow-only-both

The tx policies control the sender and ingress interface for a group; the rx policies control the receivers and egress interface for a group.

deny-tx

Use the deny-tx access policy to prevent a matching source from sending multicast traffic to the matching group on the interface where you configure the deny-tx access policy. Configure this policy on the ingress interface to the multicast source. The deny-tx access policy performs the opposite function of the allow-only-tx access policy. Therefore, the deny-tx access policy and the allow-only-tx access policy cannot exist on the same interface at the same time.

For example, in [Figure 129](#), a VLAN 1, the ingress VLAN, uses a deny-tx access policy. This policy prevents multicast traffic sent by Sender from forwarding from VLAN 1 to a receiver, consequently preventing Receiver 1 and Receiver 2 from receiving data from the multicast group. You can create receive-only VLANs, such as VLAN 1, with the deny-tx policy.

Figure 129: Data flow using deny-tx policy

deny-rx

Use the deny-rx access policy to prevent a matching group from receiving IGMP reports from the matching receiver on the interface where you configure the deny-rx access policy. The deny-rx access policy performs the opposite function of the allow-only-rx access policy. Therefore, the deny-rx access policy and the allow-only-rx access policy cannot exist on the same interface at the same time.

For example, in [Figure 130](#), a VLAN 2 uses a deny-rx access policy, preventing IGMP reports sent by Receiver 1 from receiving on VLAN 2. You can deny a multicast group access to a specific VLAN or receiver using the deny-rx policy.

Figure 130: Data flow using deny-rx policy

deny-both

Use the deny-both access policy to prevent a matching IP address from both sending multicast traffic to, and receiving IGMP reports from, a matching receiver on an interface where you configure the deny-both policy. You can use this policy to eliminate all multicast activity for a receiver or source in a specific multicast group. The deny-both access policy performs the opposite function of the allow-only-both access policy. Therefore, the deny-both access policy and the allow-only-both access policy cannot exist on the same interface at the same time.

For example, in [Figure 131](#), a VLAN 2 uses a deny-both access policy, preventing VLAN 2 from receiving IGMP reports sent by Receiver 2, and preventing multicast traffic sent by Sender 2 from forwarding from VLAN 2. You can prevent certain VLANs from participating in an activity involving the specified multicast groups with the deny-both policy.

Figure 131: Data flow using deny-both policy

allow-only-tx

Use the *allow-only-tx* policy to allow only the matching source to send multicast traffic to the matching group on the interface where you configure the *allow-only-tx* policy. The interface discards all other multicast data it receives. The *allow-only-tx* access policy performs the opposite function of the *deny-tx* access policy. Therefore, the *allow-only-tx* access policy and the *deny-tx* access policy cannot exist on the same interface at the same time.

allow-only-rx

Use the *allow-only-rx* policy to allow only the matching group to receive IGMP reports from the matching receiver on the interface where you configure the *allow-only-rx* access policy. The interface discards all other multicast data it receives. The *allow-only-rx* access policy performs the opposite function of the *deny-rx* access policy. Therefore, the *allow-only-rx* access policy and the *deny-rx* access policy cannot exist on the same interface at the same time.

allow-only-both

Use the *allow-only-both* policy to allow only the matching IP address to both send multicast traffic to, and receive IGMP reports from, the matching receiver on the interface where you configure the *allow-only-both* access policy. The interface discards all other multicast data and IGMP reports. The *allow-only-both* access policy performs the opposite function of the *deny-both* access policy. Therefore, the *allow-only-both* access policy and the *deny-both* access policy cannot exist on the same interface at the same time.

Host addresses and masks

When you configure multicast access policies, you must specify the host (IP) address and host (subnet) mask of the host to filter (the host that sends multicast traffic).

You can use the host subnet mask to restrict access to a portion of the host network. For example, if you configure the host subnet mask as 255.255.255.255, you use the full host address. To restrict access to a portion of the network of a host, use a subnet mask such as 255.255.255.0. Access control applies to the specified subnet only.

Multicast stream limitation feature

You can configure the multicast stream limitation feature to limit the number of multicast groups that can join a VLAN. By limiting the number of concurrent multicast streams, a service provider can, for example, protect the bandwidth on a specific interface and control access to multicast streams.

Use multicast stream limitation in an environment where you want to limit users to a certain number of multicast streams simultaneously. For example, a television service provider can limit the number of television channels a user can watch at a time. (To a television service provider, a multicast stream is synonymous with a television channel.) If a user purchases a service contract for two single-tuner television receivers, they can use two channels flowing at the same time, but not a third. The service provider can control the bandwidth usage in addition to preventing users from watching more than the allowed number of channels at a point in time.

You can enable the multicast stream limitation feature on the switch by using one of the following methods:

- for each interface—This limitation controls the total number of streams for all clients on this router port.
- for each VLAN—This limitation controls the total number of streams for all clients on this VLAN. This method is equivalent to the interface stream limitation.
- for each VLAN port—This limitation controls the number of streams for all clients on this VLAN port. This method is equivalent to the interface port stream limitation.

You can configure the maximum number of streams for each limit independently. After the number of streams meets the limit, the interface drops additional join reports for new streams. The maximum number of streams for each limit is 65535 and the default is 4.

Multicast Router Discovery protocol

The Multicast Router Discovery (MRDISC) protocol can automatically discover multicast-capable routers. By listening to multicast router discovery messages, Layer 2 devices can determine where to send multicast source data and IGMP host membership reports. This feature is useful in a Layer 2 bridging domain that you configure for IGMP snoop.

IGMP multicast router discovery consists of three message types that discover multicast routers on the network:

- Multicast router advertisements: routers advertise that IP multicast forwarding is enabled on an interface.
- Multicast router solicitations: routers solicit a response of multicast router advertisements from all multicast routers on a subnet.
- Multicast router termination messages: a router terminates its multicast routing functions.

Multicast routers send multicast router advertisements periodically on all interfaces where you enable multicast forwarding. Multicast routers also send advertisements in response to multicast router solicitations.

Multicast router solicitations transmit to the IGMP-MRDISC all-routers multicast group that uses a multicast address of 224.0.0.2. Multicast router solicitations do not transmit if a router needs to discover multicast routers on a directly attached subnet.

Multicast router termination messages transmit after a router terminates its multicast routing functions. Other non-IP forwarding devices, such as Layer 2 switches, can send multicast router solicitations to solicit multicast router advertisements.

To function MRDISC on IGMP snoop interface, you must explicitly enable MRDISC. The Solicitation messages are sent only if IGMP snoop and MRDISC are enabled on the switch.

Multicast flow distribution over MLT

MultiLink Trunking (MLT) is a mechanism to distribute multicast streams over a multilink trunk and achieve an even distribution of the streams. The distribution is based on source-subnet and group addresses. In applications like television distribution, multicast traffic distribution is particularly important because the bandwidth requirements are substantial when you use a large number of television streams.

The switch enables this feature by default and you can not change the configuration.

Traffic distribution

Traffic distribution distributes the streams on the multilink trunk links if an MLT configuration change occurs. For example, you can add or delete ports.

This feature distributes active streams according to the distribution algorithm on the multilink trunk links. This distribution can cause minor traffic interruptions. To minimize the effect of distribution of multicast traffic on the multilink trunks, the implementation does not move the streams to the appropriate links at the same time. Instead, it distributes a few streams at every time tick of the system.

To that end, after a multilink trunk port becomes inactive, this feature distributes all the streams on the multilink trunk ports based on the assignment provided by the distribution algorithm.

By default, distribution is enabled and you can not change the configuration.

For more information about MLT, see [MultiLink Trunking](#) on page 2257 .

Multicast virtualization

Multicast provides simplified extension of internal video and data delivery to remote locations.

Virtualized multicast enables multiple VPN routing instances on devices and supports various unicast routing protocols so that you can provide the services of many virtual routers from one physical device.

You can configure multicast routing support with the Virtual Routing and Forwarding (VRF) Lite feature and you can use VRF Lite to emulate many virtual routers with one router.

Multicast virtualization support includes:

- IGMP snooping
- IGMP in Layer 2 virtual services networks (VSN)
- IGMP in Layer 3 VSNs

To implement multicast virtualization, you must perform the following tasks:

1. Create a VRF. For more information about how to create and configure a VRF, see [Create a VRF Instance](#) on page 3892.
2. Create a VLAN and associate it with the VRF.
3. Enable one of the following: IGMP snooping on the VLAN, Layer 2 VSN, or Layer 3 VSN.

If you use IGMP snooping on the VLAN, ensure the IGMP version on the multicast hosts or other network devices is either the same as the version on the VLAN, or enable compatibility mode.

Multicast virtualization does not support PIM. The switch supports IGMP with PIM only in the Global Router.

VRF Lite background

VRF Lite provides independent IPv4 forwarding instances and independent routing instances (contexts), which can reside on the same or different VLANs and ports.

While forwarding and routing instances are mapped to IP interfaces, incoming traffic is classified into a VLAN and IP interface and, depending on the IP interface, routed context traffic is forwarded.

Protocol Independent Multicast-Sparse Mode

Table 144: Protocol Independent Multicast - Sparse Mode product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Protocol Independent Multicast-Sparse Mode (PIM-SM) for IPv4 | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VOSS 4.1 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 4.2.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VOSS 4.0.1 |
| | VSP 8400 Series | VOSS 4.2 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | Not Supported |

PIM-SM, as defined in RFC2362, supports multicast groups spread out across large areas of a company or the Internet. PIM-SM sends multicast traffic only to routers that specifically join a multicast group. This technique reduces traffic flow over WAN links and overhead costs for processing unwanted multicast packets.

Dense-mode protocols use a flood-and-prune technique, which is efficient with densely-populated receivers. However, for sparsely populated networks, PIM-SM is more efficient because it sends multicast traffic only to those routers that belong to a specific multicast group and that choose to receive the traffic.

PIM-SM is independent of a specific unicast routing protocol, but it does require the presence of a unicast routing protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). PIM-SM uses the information from the unicast routing table to create and maintain multicast trees that enable PIM-enabled routers to communicate.

Typically, a PIM-SM network consists of several multipoint data streams, each targeted to a small number of LANs in the internetwork. For example, customers whose networks consist of multiple hosts

on different LANs can use PIM-SM to simultaneously access a video data stream, such as video conferencing, on a different subnet.

**Important**

In some cases, PIM stream initialization can take several seconds.

Hosts

A host is a source, a receiver, or both:

- A source, also known as a sender, sends multicast data to a multicast group.
- A receiver receives multicast data from one or several sources that sends data to a multicast group.

PIM-SM domain

PIM-SM operates in a domain of contiguous routers on which PIM-SM is enabled.

Each PIM-SM domain requires the following routers:

- designated router (DR)
- rendezvous point (RP) router
- bootstrap router (BSR)

Although a PIM-SM domain can use only one active RP router and one active BSR, you can configure additional routers as a candidate RP (C-RP) router and as a candidate BSR (C-BSR). Candidate routers provide backup protection in case the primary RP router or BSR fails.

As a redundancy option, you can configure several RPs for the same group in a PIM domain. As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

Designated router

The designated router (DR), the router with the highest IP address on a LAN, performs the following tasks:

- sends register messages to the RP router on behalf of directly connected sources
- sends join and prune messages to the RP router on behalf of directly connected receivers
- maintains information about the status of the active RP router for local sources in each multicast group

**Important**

The DR is not a required configuration. Switches act automatically as the DR for directly attached sources and receivers.

Rendezvous point router

PIM-SM builds a shared multicast distribution tree within each domain, and the RP router is at the root of this shared tree. Although you can physically locate the RP anywhere on the network, it must be as close to the source as possible. Only one active RP router exists for a multicast group.

At the RP router, receivers meet new sources. Sources use the RP to identify themselves to other routers on the network; receivers use the RP to learn about new sources.

The RP performs the following tasks:

- registers a source that wants to announce itself and send data to group members
- joins a receiver that wants to receive data for the group
- forwards data to group

Candidate rendezvous point router

You can configure a set of routers as C-RP routers that serve as backup to the RP router. If an RP fails, all the routers in the domain apply the same algorithm to elect a new RP from the group of C-RP routers. To make sure that the routers use a complete list of C-RP routers, the C-RP router periodically sends unicast advertisement messages to the BSR. The most common implementation is to configure a PIM-SM router as both a C-RP router and a C-BSR.

The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

Static rendezvous point router

You can configure a static entry for an RP router with static RP. This feature avoids the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. Static RP-enabled switches cannot learn about RPs through the BSR because the switch loses all dynamically learned BSR information and ignores BSR messages. After you configure static RP entries, the switch adds them to the RP set as if they were learned through the BSR.

Important

In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.

When you configure a PIM static RP in a switch, the next hop of the unicast route toward the PIM static RP must be a PIM neighbor. The PIM protocol fails to work, due to a route change, if the next hop toward an already configured static RP becomes a non-PIM neighbor. If a PIM neighbor cannot reach the configured RP, the RP does not activate and its state remains invalid.

A static RP-enabled switch can communicate with switches from other vendors that do not use the BSR mechanism. Some vendors use either early implementations of PIM-SM v1 that do not support the BSR or proprietary mechanisms like the Cisco Auto-RP. For a network to work properly with static RP, you must map all the switches in the network (including switches from other vendors) to the same RP or RPs, if several RPs exist in the network.

To avoid a single point of failure, you can also configure redundant static RPs.

Use the static RP feature when you do not need dynamic learning mode, typically in small networks, or for security reasons, where RPs are forced to devices in the network so that they do not learn other RPs.

Static RP configuration considerations

Before you can configure a static RP, you must enable PIM-SM and enable static RP.

After you meet these prerequisites, keep in mind the following configuration considerations:

- You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.
- All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.
- Static RPs do not age, that is, they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP.
- In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, you must ensure that all switches and routers use the same active RP because other vendors can use different algorithms to elect the active RP. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.

**Important**

To reduce convergence times, create only one static RP for each group. The more static RPs you configure for redundancy, the more time PIM requires to rebuild the mroute table and associate RPs.

- Static RP configured on the switch is active as long as the switch uses a unicast route to the static RP network. If the switch loses this route, the static RP is invalidated and the hash algorithm remaps all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm remaps the affected groups.

Bootstrap router

The BSR receives RP router advertisement messages from the candidate RPs. The BSR adds the RP router with its group prefix to the RP set. Only one BSR exists for each PIM-SM domain.

The BSR periodically sends bootstrap messages containing the complete RP set to all routers in the domain. The BSR ensures that all PIM-SM routers send join, prune, and register packets.

Within a PIM-SM domain, you can configure a small set of routers as C-BSRs. The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

**Important**

Configure C-BSRs on routers that are central to all candidate RPs.

Shared trees and shortest-path trees

A PIM-SM domain uses shared trees and shortest-path trees to deliver data packets to group members. This section describes both trees.

Shared trees

Group members in a PIM-SM domain receive the first packet of data from sources across a shared tree. A shared tree consists of a set of paths that connect all members of a multicast group to the RP. PIM creates a shared tree when sources and receivers send messages toward the RP.

Shortest-path trees

After receiving a certain number of packets from the RP, the DR changes from a shared tree to an SPT. Switching to an SPT creates a direct route between the receiver and the source. The switch changes to the SPT after it receives the first packet from the RP.

Figure 132 shows a shared tree and an SPT.

Figure 132: Shared tree and shortest-path tree

Receiver joining a group

The following steps describe how a receiver joins a multicast group:

1. A receiver multicasts an IGMP host membership message to the group that it wants to join.
2. After the last-hop router (the DR), normally the PIM router with the highest IP address for that VLAN, receives the IGMP message for a new group join, the router looks up the associated elected RP with responsibility for the group.
3. After it determines the RP router for the group, the last-hop router creates a (*,G) route entry in the multicast forwarding table and sends a (*,G) join message to the RP. After the last-hop router receives data packets from the RP, if the multicast packet arrival rate exceeds the DR threshold, the

last-hop router switches to the SPT by sending an (S,G) join message to the source. (S denotes the source unicast IP address, and G denotes the multicast group address.)

4. If the last-hop router switches to the SPT, the following actions occur:
 - All intermediate PIM routers along the path to the source create the (S,G) entry.
 - To trim the shared tree, the router sends an (S,G) prune message to the RP.

Receiver leaving a group

Before it leaves a multicast group, a receiver sends an IGMP leave message to the DR. If all directly connected members of a multicast group leave or time out, and no downstream members remain, the DR sends a prune message upstream and PIM-SM deletes the route entry after that entry times out.

When the system ages PIM mroutes, it does not clear the (S,G) entry for an inactive route immediately after the expiration period. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.

Source sending packets to a group

The following steps describe how a source sends multicast packets to a group:

1. A source directly attached to a VLAN bridges the multicast data to the DR. The DR for the VLAN (the router with the highest IP address) encapsulates each packet in a register message and sends a unicast message directly to the RP router to distribute to the multicast group.
2. If a downstream group member chooses to receive multicast traffic, the RP router sends a join or prune message toward the source DR and forwards the data down the RP tree after it obtains the data natively.
3. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.
4. If no downstream members want to receive multicast traffic, the RP router sends a register-stop message (for the source) to the DR.

The DR starts the register suppression timer after it receives the first register-stop message. During the register suppression timeout period (the default is 60 seconds), the following events occur:

- The DR for the source sends a probe packet to the RP router before the register suppression timer expires. The probe packet prompts the RP router to determine whether new downstream receivers joined the group.
- If no new receivers joined the group, the RP router sends another register-stop message to the DR for the source, and its register suppression timer restarts.
- After the RP router no longer responds with a register-stop message to the source DR probe message, the register suppression timer expires and the DR sends encapsulated multicast packets to the RP router. The RP router uses this method to tell the DR that new members joined the group.

The RP sends a register-stop message to the DR immediately after it receives the first multicast data packet.

Required elements for PIM-SM operation

For PIM-SM to operate, the following elements must exist in the PIM-SM domain:

- You must enable an underlying unicast routing protocol for the switch to provide routing table information to PIM-SM.
- You must configure an active BSR to send bootstrap messages to all PIM-v2 configured switches and routers to enable them to learn group-to-RP mapping. If you configure several BSRs in a network, an active BSR is elected based on priority and IP address (if priority is equal, the BSR with the higher IP address is elected).
- You must include an RP to perform the following tasks:
 - manage one or several IP multicast groups
 - become the root for the shared tree to these groups
 - accept join messages from receiver switches for groups that it manages
 - elect an active RP based on priority and IP address (if priority is equal, the RP with the higher IP address is elected)

PIM-SM simplified example

Figure 133 shows a simplified example of a PIM-SM configuration.

Figure 133: PIM-SM simplified example

In the sample configuration, the following events occur:

1. The BSR distributes RP information to all switches in the network.
2. R sends an IGMP membership report to S4.
3. Acting on this report, S4 sends a (*,G) join message to RP.
4. S sends data to G.

5. The DR (S1 in this example) encapsulates the data that it unicasts to RP (S2) in register messages.
6. S2 decapsulates the data, which it forwards to S4.
7. S4 forwards the data to R.
8. If the packet rate exceeds the DR threshold, S4 sends S1 an (S,G) join message.
9. S1 forwards data to S4. After S4 receives data from S1, it prunes the stream from the RP.

**Important**

[Figure 133](#) on page 1347 is a simplified example and is not the best design for a network if you locate the source and receiver as shown. In general, place RPs as close as possible to sources.

PIM-SM Static Source Groups

You can configure static source groups as static source-group entries in the PIM-SM multicast routing table. PIM-SM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1325.

Join and prune messages

The DR sends join and prune messages from a receiver toward an RP for the group to either join the shared tree or remove (prune) a branch from it. A single message contains both a join and a prune list. This list includes a set of source addresses that indicate the shortest-path trees or the shared trees that the host wants to join. The DR sends join and prune messages hop-by-hop to each PIM router on the path to the source or the RP.

Register and register-stop messages

The DR sends register messages to the RP for a directly connected source. The register message informs the RP of a new source, causing the RP to send join or prune messages back toward the DR of the source, which forwards the data down the RP tree after it obtains the data natively. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.

The DR stops sending encapsulated packets to the RP after it receives a register-stop message. This traffic stops without delay because the RP sends a register-stop message immediately after it receives the first multicast data packet, and joins the shortest-path tree.

PIM-SMLT

IP multicast routing support with Split MultiLink Trunking (SMLT) builds a virtual switch that represents the two switches of the split multilink trunk core.

When switches use PIM in the core, they need to exchange protocol-related updates as part of the interswitch trunking (IST) protocol. IST hides the fact that the edge switch attaches to two physical switches.

PIM-SMLT can work in triangular, square, and full mesh configurations with Layer 3 IP multicast. However, PIM-SSM in square or full mesh SMLT topologies is not supported.

The following rules apply:

- If a VLAN receives traffic from the IST link, it cannot forward on the split multilink trunk link or the edge for the same VLAN.
- If one side of the SMLT link toward the receiver is down, such that the traffic cannot be forwarded directly down the SMLT link from the router on which traffic is ingressing, the IST Peer **MUST** forward that traffic it receives over the IST link down its side of the SMLT toward the receiver. The decision of whether the IST Peer needs to forward traffic received over the IST to SMLT receivers is made in the datapath, which has full knowledge of the remote SMLT link state.
- Traffic can use the IST to route between VLANs if the forwarding decision for the multicast protocol requires that the other side of the core forwards the multicast traffic (follow the IP multicast routing and forwarding rules for routed traffic). Other VLANs that are not part of SMLT continue to behave in the same way.
- To create a temporary default route pointing to a peer IST, you must enable PIM on the IST VLAN.
- In a scaled multicast environment, if you must reconfigure the members of an MLT link, either SMLT or IST, by removing the ports from the MLT membership list, you must first shutdown the port by using the **shutdown** command at the port configuration level. Let the unicast and multicast traffic subside, and then remove the port from the MLT membership list. If you reconfigure the MLT without first shutting down the port, it can lead to excessive hardware updates to multicast forwarding records and can result in high utilization of the CPU.

Note

In a scaled PIM over Simplified vIST deployment, disabling all the PIM interfaces (**no ip routing**) causes the VLACP ports to bounce. With no user intervention, the packets start getting processed again in approximately 10 seconds. VLACP enables the ports and full functionality is restored.

SMLT provides for fast failover in all cases, but does not provide a functionality similar to Routed SMLT (RSMLT).

Important

You must enable square SMLT globally before you configure square or full-mesh configurations.

Traffic delay with PIM while restarting peer SMLT switches

If you restart peer SMLT switches, you can lose, or experience a delay in, PIM traffic. The local and remote SMLT links must be up to forward traffic. If a remote SMLT link is down, you can experience a traffic delay.

PIM uses a DR to forward data to receivers on a VLAN. If you restart the DR in an SMLT VLAN, you can lose data because of the following actions:

- If the DR is down, the non-DR switch assumes the role and starts forwarding data.
- After the DR comes back up, it takes priority (higher IP address) to forward data so the non-DR switch stops forwarding data.
- The DR is not ready to forward traffic due to protocol convergence and because it takes time to learn the RP set and create the forwarding path. This situation can result in a traffic delay of 2 to 3 minutes because the DR learns the RP set after Open Shortest Path First (OSPF) converges.

A workaround to this delay is to configure the static RP router on the peer SMLT switches. This feature avoids the process of selecting an active RP router from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. After the DR comes back up, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay to approximately 15 to 65 seconds.

Protocol Independent Multicast-Source Specific Multicast

Table 145: Protocol Independent Multicast-Source Specific Mode product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| PIM-Source Specific Mode (PIM-SSM) for IPv4 | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VOSS 4.1 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 4.2.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VOSS 4.0.1 |
| | VSP 8400 Series | VOSS 4.2 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | Not Supported |

Source Specific Multicast optimizes PIM-SM by simplifying the many-to-many model. Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM only builds source-based SPTs. Whereas PIM-SM always joins a shared tree first, and then switches to the source tree, SSM eliminates the need to start with a shared tree by immediately joining a source through the SPT. SSM avoids using an RP and RP-based shared trees, which can be a potential problem.

Until now only one channel for one group was allowed to exist in ssm map. From now on multiple channels for the members of the SSM group are allowed to be configured in this map.

This configuration is ideal for applications like television channel distribution and other content-distribution businesses. Banking and trade applications can also use SSM as it provides more control over the hosts receiving and sending data over their networks.

When a v2 report in SSM range is received it is translated to an igmpv3 report message with one group record with type ALLOW and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. When a v2 leave in SSM range is received it is translated to an igmpv3 report message with one group record with type BLOCK and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. This behaviour is displayed only when PIM-SSM mode is enabled.

SSM applications use IP addresses reserved by the Internet Assigned Numbers Authority (IANA) in the 232/8 range (232.0.0.0 to 232.255.255.255). SSM recognizes packets in this range and controls the behavior of multicast routing devices and hosts that use these addresses. When a source (S) transmits

IP datagrams to an SSM destination address (G), a receiver can receive these datagrams by subscribing to the (S,G) channel.

A channel is a source-group (S,G) pair where S is the source that sends to the multicast group and G is an SSM group address. SSM defines channels on an individual or multiple source basis, which enforces the one-to-many concept of SSM applications. In an SSM channel, each group is associated with multiple sources.

SSM features

PIM-SM requires a unicast protocol to forward multicast traffic within the network to perform the Reverse Path Forwarding (RPF) check. PIM-SM uses the information from the unicast routing table to create and maintain the shared and shortest multicast tree that PIM-enabled routers use to communicate. The unicast routing table must contain a route to every multicast source in the network as well as routes to PIM entities like the RPs and BSR.

SSM uses only a subset of the PIM-SM features such as the SPT, DR, and some messages (hello, join, prune, and assert). However, some features are unique to SSM. These features, described in the following sections, are extensions of the IGMP and PIM protocols.

PIM-SSM architecture

The following diagram illustrates how the PIM-SSM architecture requires routers to perform the following actions:

- support IGMPv3 source-specific host membership reports and queries at the edge routers
- initiate PIM-SSM (S,G) joins directly and immediately after receiving an IGMPv3 join report from the designated router
- restrict forwarding to SPTs within the SSM address range by all PIM-SSM routers

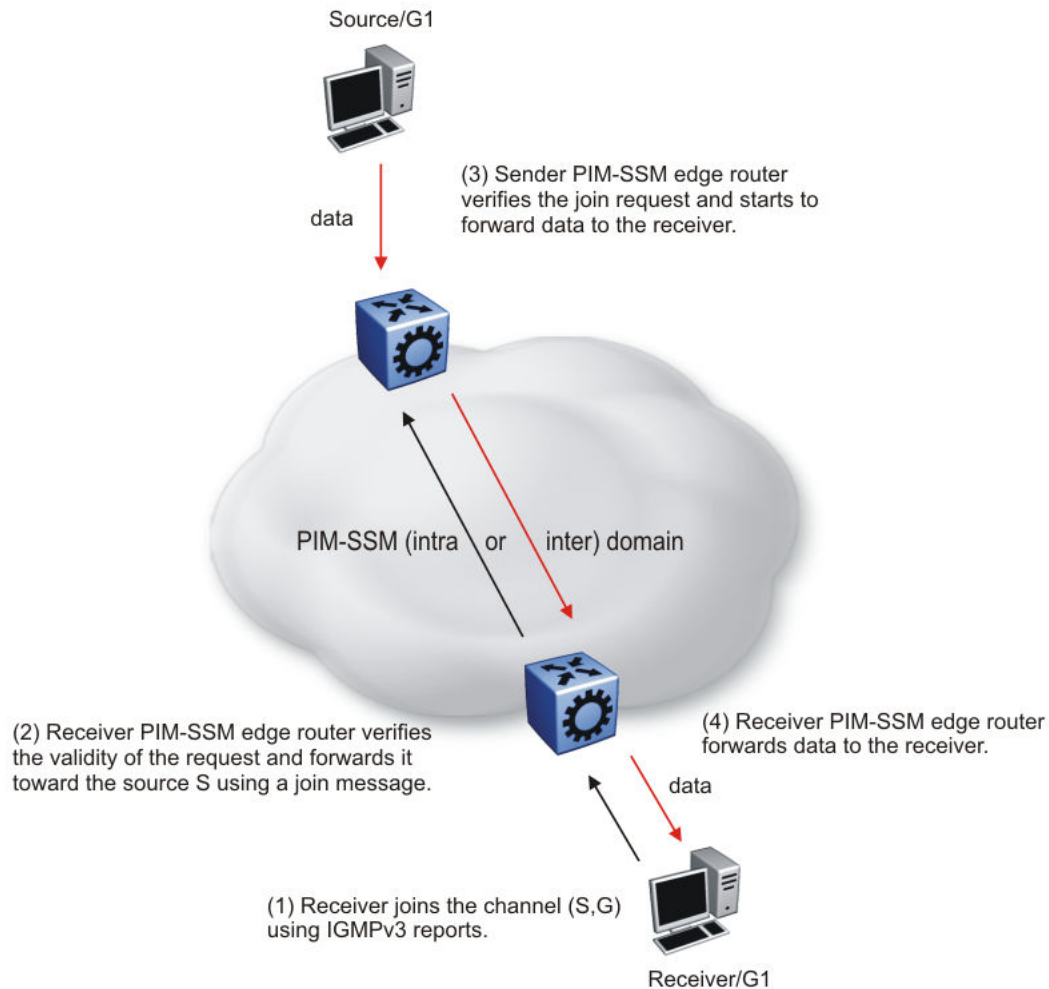

Figure 134: PIM-SSM architecture

The following rules apply to Layer 3 devices with SSM enabled:

- Receive IGMPv3 membership join reports in the SSM range and, if no entry (S,G) exists in the SSM channel table, create one.
- Receive IGMPv2 membership join reports, but only for groups that already use a static (S,G) entry in the SSM channel table.
- Send periodic join messages to maintain a steady SSM tree state.
- Use standard PIM-SM SPT procedures for unicast routing changes, but ignore rules associated with the SPT for the (S,G) route entry.
- Receive prune messages and use standard PIM-SM procedures to remove interfaces from the source tree.
- Forward data packets to interfaces from the downstream neighbors that sent an SSM join, or to interfaces with locally attached SSM group members.
- Drop data packets that do not use an exact-match lookup (S,G) in their forwarding database for S and G.

PIM-SSM Static Source Groups

You can configure static source group entries in the PIM-SSM multicast routing table with static source groups. PIM-SSM cannot prune these entries from the distribution tree. For more information about static source groups, see [Static source groups](#) on page 1325.

Implementation of SSM and IGMP

The following sections describe how the switch implements PIM-SSM and IGMP.

SSM range

The standard SSM range is 232/8, but you can extend the range to include an IP multicast address. Although you can configure the SSM range, you cannot configure it for all multicast groups (224/4 or 224.0.0.0/240.0.0.0 or 224.0.0.0/255.0.0.0).

You can extend the SSM range to configure existing applications without changing their group configurations.

SSM channel table

You can use the SSM channel to manually configure (S,G) entries that map existing groups to their sending source. These table entries apply to the whole switch, not for each interface, and both IGMPv2 and IGMPv3 hosts use the SSM channel table.

The following rule applies to an SSM channel table for an individual switch:

- You can map one source to multiple groups.
- You can allow multiple sources to the same group.

Important

Different switches can use different mappings for groups to sources, for example, different channels map differently even if they are on the same network.

SSM and IGMPv2

SSM-configured switches can accept reports from IGMPv2 hosts on IGMPv2 interfaces if the group uses an SSM channel table entry. However, the IGMPv2 host groups must exist in the SSM range defined on the switch, which is 232/8 by default.

- After the SSM switch receives an IGMPv2 report for a group that is in the SSM channel table, it joins the specified source immediately.
- After the SSM switch receives an IGMPv2 report for a group that uses an enabled static SSM channel table entry, it triggers PIM-SSM processing as if it received an equivalent IGMPv3 report.
- After the SSM switch receives an IGMPv2 report for a group out of the SSM range, it processes the report as if it is in PIM-SM mode.

Deleting or Disabling an ssm-map with IGMPv1 or IGMPv2

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate using IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

Consider the following configuration scenario:

- A device is PIM-enabled, running in SSM mode, with IGMPv1 or IGMPv2 configured on the interface.
- IGMPv1 and IGMPv2 hosts send IGMPv1 or IGMPv2 reports for groups in SSM range.

The following table identifies the expected behaviors in this scenario.

Table 146: Expected behaviors for ssm-map configuration

| Action | Expected behavior |
|---|--|
| You do not configure an ssm-map for the group in SSM range. | IGMPv1 and IGMPv2 reports are not processed. |
| You do configure an ssm-map for the group in SSM range. | IGMPv1 and IGMPv2 reports are processed and the group in SSM range is learned. |

SSM and IGMPv3

The switch supports IGMPv3 for SSM. With IGMPv3, a host can selectively request or filter traffic from sources within the multicast group. IGMPv3 is an interface-level configuration.

Important

IGMPv3 works without PIM-SSM or SSM-snoop enabled on the interface.

The following rules apply to IGMPv3-enabled interfaces:

- Send only IGMPv3 (source-specific) reports for addresses in the SSM range.
- Accept IGMPv3 reports.
- Drop IGMPv2 reports.

The IGMPv2 report mentioned in [SSM and IGMPv2](#) on page 1353 is processed because it is an IGMPv2 report received on an IGMPv2 interface. If an IGMPv2 interface receives an IGMPv3 report, it drops the report even if PIM-SSM is enabled and the entry is in the SSM channel table. The IGMP versions must match.

- Discard IGMP packets with a group address out of the SSM range.

The switch implements IGMPv3 in one of two modes: dynamic and static.

In dynamic mode, the switch learns about new (S,G) pairs from IGMPv3 reports and adds them to the SSM channel table. If you do not enable dynamic mode and an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report.

In static mode, you can statically configure (S,G) entries in the SSM channel table. If an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report. The interface also ignores the report if the group is in the table, but the source or mask does not match what is in the table.

Important

After you enable IGMPv3, changes to the query interval and robustness values on the querier switch propagate to other switches on the same VLAN through IGMP query.

Both IGMPv2 and IGMPv3 hosts use the SSM channel table:

- An IGMPv2 host (with an IGMPv2 VLAN) must use an existing SSM channel entry if the group is in the SSM range.
- If you enable dynamic learning for an IGMPv3 host, the SSM channel automatically learns the group. Otherwise, the SSM channel also needs a static entry.

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you disable IGMPv3 compatibility. In the following table, references to matching a static SSM channel entry assumes that the entry is enabled. If an entry is disabled, it is treated as though it is disallowed.

Table 147: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility disabled

| Host | VLAN | SSM range | Action |
|-------------|-------------|--------------------|--|
| IGMPv2 host | IGMPv3 VLAN | In or out of range | Drop report. |
| IGMPv3 host | IGMPv2 VLAN | In or out of range | Drop report. |
| IGMPv2 host | IGMPv2 VLAN | In range | If the report matches an existing static SSM channel entry, create (S,G).
If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 host | IGMPv2 VLAN | Out of range | Ignore the SSM channel table and process the report as if it is in PIM-SM mode. |
| IGMPv3 host | IGMPv3 VLAN | Out of range | Process the report. |
| IGMPv3 host | IGMPv3 VLAN | In range | Dynamic enabled. Create (S,G). |
| IGMPv3 host | IGMPv3 VLAN | In range | Dynamic disabled and matches an existing SSM channel entry. Create (S,G). |
| IGMPv3 host | IGMPv3 VLAN | In range | Dynamic disabled and does not match an existing SSM channel entry. Drop report. |

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you enable IGMPv3 compatibility.

Table 148: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility enabled

| Host | VLAN | SSM range | Action |
|-------------|-------------|--------------|--|
| IGMPv2 Host | IGMPv3 VLAN | In range | If the report matches an existing static SSM channel entry, create (S,G).
If the report does not match an existing static SSM channel entry, drop it. |
| IGMPv2 Host | IGMPv3 VLAN | Out of range | Process the report as in PIM-SM mode. |

If an IGMPv3 group report enters the VLAN port and the port must discard one or more of the groups in that packet after the application of IGMP access controls, the port drops the entire packet and does not forward it on to other ports of the VLAN.

If an IGMPv3 interface receives an IGMPv2 or v1 query, the interface backs down to IGMPv2 or v1. As a result, the interface flushes all senders and receivers on the interface.

Configuration limitations

Run PIM-SSM on either all switches in the domain or only on the edge routers. If you use a mix of PIM-SSM and PIM-SM switches in the domain, run PIM-SSM on all the edge routers and run PIM-SM on all the core routers.

Important

A PIM domain with edge routers running PIM-SM and core routers running PIM-SSM does not operate properly. If you prefer or require a mixed PIM-SM and PIM-SSM topology, run PIM-SSM on the edge switches and PIM-SM in the core. Ensure a valid RP configuration exists for groups that exist outside of the SSM range. If a valid RP configuration exists, the SSM switches process the joins in SM mode. If no RP exists, the SSM switches drop the reports.

Static source groups cannot conflict with SSM channels. If you configure a static source group or an SSM channel, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple groups to a single source for both static source group and an SSM channel.

PIM passive interfaces

You can configure the PIM interface as active or passive. The default is active. With an active interface, you can configure transmit and receive PIM control traffic. A passive interface drops all PIM control traffic, thereby reducing the load on the system. This feature is useful when you use a high number of PIM interfaces and these interfaces connect to end users, not to other switches.

A PIM passive interface does not transmit and drops messages of the following type:

- hello
- join
- prune
- register
- register-stop
- assert
- candidate-RP-advertisement
- bootstrap

If a PIM passive interface receives these types of messages, it drops them and the switch logs a message, detailing the type of protocol message and the IP address of the sending device. These log

messages help to identify the device that performs routing on the interface, which is useful if you must disable a device that does not operate correctly.

Important

A device can send register and register-stop messages to a PIM passive interface, but these messages cannot be sent out of that interface.

The PIM passive interface maintains information about hosts, through IGMP, that are related to senders and receivers, but the interface does not maintain information about PIM neighbors. You can configure a BSR or an RP on a PIM passive interface.

You can also use the PIM passive interface feature as a security measure to prevent routing devices from becoming attached and participating in the multicast routing of the network.

Important

Before you change the state (active or passive) of a PIM interface, disable PIM on that interface. This action prevents instability in the PIM operations, especially when neighbors exists or the interface receives streams. After you disable PIM, the switch loses traffic for approximately 80 seconds.

Multicast route statistics

Table 149: Mroute statistics product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|

| | VSP 8200 Series | VOSS 5.1 |
| | VSP 8400 Series | VOSS 5.1 |
| | VSP 8600 Series | Not Supported |
| | XA1400 Series | Not Supported |

The multicast route statistics feature provides statistics for multicast streams through the switch. Using the Command Line Interface (CLI), Simple Network Management Protocol (SNMP) or Enterprise Device Manager (EDM), you can track the number of senders sending multicast streams to a particular group address. You can also obtain a count of the packets or bytes being received for a particular multicast group address and the average size of the frames. Multicast route statistics are supported for both IPv4 and IPv6 group addresses.

Determining the route statistics is especially useful when debugging a multicast network and also when administering the network.

Multicast route statistics and DvR

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 661.

IP multicast network design

Use multicast routing protocols to efficiently distribute a single data source among multiple users in the network. This section provides information about how to design networks that support IP multicast routing.

For more design guidelines, conceptual, and configuration information about IP Multicast over Fabric Connect, see [IP Multicast over Fabric Connect](#) on page 1325.

Multicast scalability design rules

The following section lists the design rules to increase multicast route scaling.

Important

The switch does not support High Availability (HA).

The switch software supports the following:

- Protocol-Independent Multicast (PIM)
- Split MultiLink Trunking (SMLT) and Routed-SMLT (RSMLT)

Multicast scalability design rules

1. Whenever possible, use simple network designs that do not use VLANs that span several switches. Instead, use routed links to connect switches.
2. Whenever possible, group sources sending to the same group in the same subnet. The switch uses a single egress forwarding pointer for all sources in the same subnet sending to the same group. Be aware that these streams have separate hardware forwarding records on the ingress side.
3. Do not configure multicast routing on edge switch interfaces that do not contain multicast senders or receivers. By following this rule, you:
 - Provide secure control over multicast traffic that enters or exits the interface.
 - Reduce the load on the switch, as well as the number of routes. This improves overall performance and scalability.
4. Avoid initializing many (several hundred) multicast streams simultaneously. Initial stream setup is a resource-intensive task, and initializing a large number can increase the setup time. In some cases, this delay can result in stream loss.
5. Whenever possible, do not connect IP multicast sources and receivers by using VLANs that interconnect switches (see the following figure). In some cases, this can result in excessive hardware record use. By placing the source on the interconnected VLAN, traffic takes two paths to the destination, depending on the reverse path forwarding (RPF) checks and the shortest path to the source.

For example, if a receiver is on VLAN 1 on switch S1 and another receiver is on VLAN 2 on switch S1, traffic can be received from two different paths to the two receivers, which results in the use of two

forwarding records. If the source on switch S2 is on a different VLAN than VLAN 3, traffic takes a single path to switch S1 where the receivers are located.

Figure 135: IP multicast sources and receivers on interconnected VLANs

IP multicast address range restrictions

IP multicast routers use D class addresses, which range from 224.0.0.0 to 239.255.255.255. Although you can use subnet masks to configure IP multicast address ranges, the concept of subnets does not exist for multicast group addresses. Consequently, the usual unicast conventions—where you reserve the all 0s subnets, all 1s subnets, all 0s host addresses, and all 1s host addresses—do not apply.

Internet Assigned Numbers Authority (IANA) reserves addresses from 224.0.0.0 through 224.0.0.255 for link-local network applications. Multicast-capable routers do not forward packets with an address in this range. For example, Open Shortest Path First (OSPF) uses 224.0.0.5 and 224.0.0.6, and Virtual Router Redundancy Protocol (VRRP) uses 224.0.0.18 to communicate across local broadcast network segments.

IANA also reserves the range of 224.0.1.0 through 224.0.1.255 for well-known applications. IANA assigns these addresses to specific network applications. For example, the Network Time Protocol (NTP) uses 224.0.1.1, and Mtrace uses 224.0.1.32. RFC1700 contains a complete list of these reserved addresses.

Multicast addresses in the 232.0.0.0/8 (232.0.0.0 to 232.255.255.255) range are reserved only for source-specific multicast (SSM) applications, such as one-to-many applications. While this range is the publicly reserved range for SSM applications, private networks can use other address ranges for SSM.

Finally, addresses in the range 239.0.0.0/8 (239.0.0.0 to 239.255.255.255) are administratively scoped addresses; they are reserved for use in private domains. Do not advertise these addresses outside the private domain. This multicast range is analogous to the 10.0.0.0/8, 172.16.0.0/20, and 192.168.0.0/16 private address ranges in the unicast IP space.

In a private network, only assign multicast addresses from 224.0.2.0 through 238.255.255.255 to applications that are publicly accessible on the Internet. Assign addresses in the 239.0.0.0/8 range to multicast applications that are not publicly accessible.

Although you can use a multicast address you choose on your own private network, it is generally not good design practice to allocate public addresses to private network entities. Do not use public addresses for unicast host or multicast group addresses on private networks.

Multicast MAC address mapping considerations

Like IP, Ethernet has a range of multicast MAC addresses that natively support Layer 2 multicast capabilities. While IP has a total of 28 addressing bits available for multicast addresses, Ethernet has only 23 addressing bits assigned to IP multicast. The Ethernet multicast MAC address space is much larger than 23 bits, but only a subrange of that larger space is allocated to IP multicast. Because of this difference, 32 IP multicast addresses map to one Ethernet multicast MAC address.

IP multicast addresses map to Ethernet multicast MAC addresses by placing the low-order 23 bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01:00:5E:00:00:00. Thus, more than one multicast address maps to the same Ethernet address (see the following figure). For example, all 32 addresses 224.1.1.1, 224.129.1.1, 225.1.1.1, 225.129.1.1, 239.1.1.1, 239.129.1.1 map to the same 01:00:5E:01:01:01 multicast MAC address.

Figure 136: Multicast IP address to MAC address mapping

Most Ethernet switches handle Ethernet multicast by mapping a multicast MAC address to multiple switch ports in the MAC address table. Therefore, when you design the group addresses for multicast applications, take care to efficiently distribute streams only to hosts that are receivers.

The VSP 4450 Series devices switch IP multicast data based on the IP multicast address, not the MAC address, and thus, do not have this issue.

As an example, consider two active multicast streams using addresses 239.1.1.1 and 239.129.1.1. Suppose that two Ethernet hosts, receiver A and receiver B, connect to ports on the same switch and only want the stream addressed to 239.1.1.1. Suppose also that two other Ethernet hosts, receiver C and receiver D, also connect to the ports on the same switch as receiver A and B, and want to receive the stream addressed to 239.129.1.1. If the switch uses the Ethernet multicast MAC address to make forwarding decisions, then all four receivers receive both streams—even though each host only wants one stream. This transmission increases the load on both the hosts and the switch. To avoid this extra load, ensure that you manage the IP multicast group addresses used on the network.

The VSP 4450 Series switches do not forward IP multicast packets based on multicast MAC addresses—even when bridging VLANs at Layer 2. Thus, the platform does not encounter this problem. Instead, the platform internally maps IP multicast group addresses to the ports that contain group members.

When an IP multicast packet is received, the lookup is based on the IP group address, regardless of whether the VLAN is bridged or routed. While the problem described in the previous example does not affect the VSP 4450 Series switches, other switches in the network may be affected. This problem is particularly true of pure Layer 2 switches.

In a network that includes multiple hardware platforms, the easiest way to ensure that this issue does not arise is to use only a consecutive range of IP multicast addresses that correspond to the lower-order 23 bits of that range. For example, use an address range from 239.0.0.0 through 239.127.255.255. A group address range of this size can still easily accommodate the needs of even the largest private enterprise.

Dynamic multicast configuration changes

You must not perform dynamic multicast configuration changes when multicast streams flow in a network. For example, do not change the routing protocol that runs on an interface, or the IP address, or the subnet mask for an interface until multicast traffic ceases.

For such changes, ensure that you temporarily stop all multicast traffic. If the changes are necessary and you have no control over the applications that send multicast data, you can disable the multicast routing protocols before you perform the change. For example, consider disabling multicast routing before making interface address changes. In all cases, these changes result in traffic interruptions because they affect neighbor-state machines and stream-state machines.

In addition, when removing port members of an MLT group you must first disable the ports. Changing the group set without first shutting the ports down can result in high-CPU utilization and processing in a scaled multicast environment due to the necessary hardware reprogramming on the multicast records.

IGMPv3 backward compatibility

IGMPv3 for PIM is backward compatible with IGMPv1/v2. According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2, detects an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure the IGMP version of an interface to version 3 regardless of the PIM or snooping mode.

You can configure whether the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

Note

If you enable the explicit host tracking option on an IGMPv3 interface, you cannot downgrade to IGMPv1 or IGMPv2. You must disable explicit host tracking to downgrade the IGMP version.

TTL in IP multicast packets

The switch treats multicast data packets with a time-to-live (TTL) of 1 as expired packets and sends them to the CPU before dropping them. To avoid this issue, ensure that the originating application uses a hop count large enough to enable the multicast stream to traverse the network and reach all destinations without reaching a TTL of 1. Ensure that you use a TTL value of 33 or 34 to minimize the effect of looping in an unstable network.

Multicast MAC filtering

Certain network applications require multiple hosts to share a multicast MAC address. Instead of flooding all ports in the VLAN with this multicast traffic, you can use Multicast MAC filtering to forward traffic to a configured subset of the ports in the VLAN. This multicast MAC address is not an IP multicast MAC address.

At a minimum, map the multicast MAC address to a set of ports within the VLAN. In addition, if traffic is routed on the local host, you must configure an Address Resolution Protocol (ARP) entry to map the shared unicast IP address to the shared multicast MAC address. You must configure an ARP entry because the hosts can also share a virtual IP address, and packets addressed to the virtual IP address need to reach each host.

Ensure that you limit the number of such configured multicast MAC addresses to a maximum of 100. This number is related to the maximum number of possible VLANs you can configure, because for every multicast MAC filter that you configure the maximum number of configurable VLANs reduces by one. Similarly, configuring large numbers of VLANs reduces the maximum number of configurable multicast MAC filters downward from 100.

Although you can configure addresses starting with 01.00.5E, which are reserved for IP multicast address mapping, do not enable IP multicast with streams that match the configured addresses. This configuration can result in incorrect IP multicast forwarding and incorrect multicast MAC filtering.

Guidelines for multicast access policies

Use the following guidelines when you configure multicast access policies:

- Use masks to specify a range of hosts. For example, 10.177.10.8 with a mask of 255.255.255.248 matches hosts addresses 10.177.10.8 through 10.177.10.15. The host subnet address and the host mask must be equal to the host subnet address. An easy way to determine this is to ensure that the mask has an equal or fewer number of trailing zeros than the host subnet address. For example, 3.3.0.0/255.255.0.0 and 3.3.0.0/255.255.255.0 are valid. However, 3.3.0.0/255.0.0.0 is not.
- Apply receive-access policies to all eligible receivers on a segment. Otherwise, one host joining a group makes that multicast stream available to all.
- Receive access policies are initiated after the switch receives reports with addresses that match the filter criteria.
- Transmit access policies apply after the switch receives the first packet of a multicast stream.

Multicast access policies can apply to a routed PIM interface if Internet Group Management Protocol (IGMP) reports the reception of multicast traffic.

The following rules and limitations apply to IGMP access policy parameters when you use them with IGMP instead of PIM:

- The static member parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- The Static Not Allowed to Join parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- For multicast access control, the denyRx parameter applies to IGMP snooping and PIM. The DenyTx and DenyBoth parameters apply only to IGMP snooping.

Split-subnet and multicast

The split-subnet issue arises when you divide a subnet into two unconnected sections in a network. This division results in the production of erroneous routing information about how to reach the hosts on that subnet. The split-subnet problem applies to all types of traffic, but it has a larger impact on a PIM-SM network.

To avoid the split-subnet problem in PIM networks, ensure that the RP router is not in a subnet that can become a split subnet. Also, avoid having receivers on this subnet. Because the RP is an entity that must be reached by all PIM-enabled switches with receivers in a network, placing the RP on a split-subnet can impact the whole multicast traffic flow. Traffic can be affected even for receivers and senders that are not part of the split-subnet.

Protocol Independent Multicast-Sparse Mode guidelines

Protocol Independent Multicast-Sparse Mode (PIM-SM) uses an underlying unicast routing information base to perform multicast routing. PIM-SM builds unidirectional shared trees rooted at a RP router for each group and can also create shortest-path trees for each source.

PIM-SM and PIM-SSM Scalability

For more information on interface scaling, see the [Release Notes for VOSS](#).

The software does not support virtualized PIM. PIM is supported in the Global Routing Table only.

Interfaces that run PIM must also use a unicast routing protocol (PIM uses the unicast routing table), which puts stringent requirements on the system. With a high number of interfaces, take special care to reduce the load on the system.

Use few active IP routed interfaces. You can use IP forwarding without a routing protocol enabled on the interfaces, and enable only one or two with a routing protocol. You can configure proper routing by using IP routing policies to announce and accept routes on the switch. Use PIM passive interfaces on the majority of interfaces.

Important

For information on the maximum values for total PIM interfaces and active interfaces, see the [Release Notes for VOSS](#). If you configure the maximum number of active interfaces, all remaining interfaces must be passive.

When you use PIM-SM, the number of routes can scale up to the unicast route limit because PIM uses the unicast routing table to make forwarding decisions. For higher route scaling, use OSPF instead of Routing Information Protocol (RIP).

As a general rule, a well-designed network does not have many routes in the routing table. For PIM to work properly, ensure that all subnets configured with PIM are reachable and that PIM uses the information in the unicast routing table. For the RPF check, to correctly reach the source of any multicast traffic, PIM requires the unicast routing table.

PIM General Requirements

Design simple PIM networks where VLANs do not span several switches.

PIM relies on unicast routing protocols to perform its multicast forwarding. As a result, include in your PIM network design, a unicast design where the unicast routing table has a route to every source and receiver of multicast traffic, as well as a route to the RP router and Bootstrap router (BSR) in the network. Ensure that the path between a sender and receiver contains PIM-enabled interfaces. Receiver subnets are not always required in the routing table.

Use the following guidelines:

- Ensure that every PIM-SM domain is configured with an RP, either by static definition or via BSR.
- Ensure that every group address used in multicast applications has an RP in the network.
- As a redundancy option, you can configure several RPs for the same group in a PIM domain.
- As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups.
- In order to configure an RP to cover the entire multicast range, configure an RP to use the IP address of 224.0.0.0 and the mask of 240.0.0.0.
- Configure an RP to handle a range of multicast groups by using the mask parameter. For example, an entry for group value of 224.1.1.0 with a mask of 255.255.255.192 covers groups 224.1.1.0 to 224.1.1.63.
- In a PIM domain with both static and dynamic RP switches, you cannot configure one of the (local) interfaces for the static RP switches as the RP. For example, in the following scenario:

(static RP switch) Sw1 ----- Sw2 (BSR/Cand-RP1) -----Sw3

You cannot configure one of the interfaces on switch Sw1 as static RP because the BSR cannot learn this information and propagate it to Sw2 and Sw3. PIM requires that you consistently configure RP on all the routers of the PIM domain, so you can only add the remote interface Candidate-RP1 (Cand-RP) to the static RP table on Sw1.

- If a switch needs to learn an RP-set, and has a unicast route to reach the BSR through this switch, you cannot enable or configure static RP on a switch in a mixed mode of candidate RP and static RP switches. For examples, see the following two figures.

PIM and Shortest Path Tree Switchover

When an IGMP receiver joins a multicast group, PIM on the leaf router first joins the shared tree. After the first packet is received on the shared tree, the router uses the source address information in the packet to immediately switch over to the shortest path tree (SPT).

To guarantee a simple, yet high-performance implementation of PIM-SM, the switch does not support a threshold bit rate in relation to SPT switchover. Intermediate routers (that is, not directly connected IGMP hosts) do not switch over to the SPT until directed to do so by the leaf routers.

Other vendors can offer a configurable threshold, such as a certain bit rate at which the SPT switch-over occurs. Regardless of their implementation, no interoperability issues with the switch result. Switching to and from the shared and shortest path trees is independently controlled by each downstream router. Upstream routers relay joins and prunes upstream hop-by-hop, building the desired tree as they go.

Because a PIM-SM compatible router already supports shared and shortest path trees, no compatibility issues arise from the implementation of configurable switchover thresholds.

PIM Traffic Delay and SMLT Peer Reboot

PIM uses a designated router (DR) to forward data to receivers on the DR VLAN. The DR is the router with the highest IP address on a LAN. If this router is down, the router with the next highest IP address becomes the DR. However, if the VLAN is an SMLT VLAN, the DR is not a factor in determining which switch forwards the data down to the receiver. Either aggregate switch can forward data to the receiver, because the switches act as one. The switch that forwards depends on where the source is located (on another SMLT/vIST link or on a non-SMLT/non-vIST link) and whether either side of the receiver SMLT link is up or down. If the forwarder switch is rebooted, traffic loss occurs until protocol convergence is completed.

Consider the following cases:

- If the source is on an SMLT link that is not the receiver SMLT, the switch that directly received the data on its side of the source SMLT link forwards it down to the receiver on the receiver SMLT regardless of which switch is the DR for the receiver VLAN. The forwarding switch sends a copy of the data over the vIST link to the peer switch, which drops the data because it knows that the remote SMLT is up and therefore the remote peer has already forwarded the data. If the forwarding switch goes down, the other switch receives the data directly over its source SMLT link and takes over forwarding to the receivers. After the original switch comes back up, the original switch again receives the data directly over its source SMLT. The original switch may not be ready to forward the data because of the protocol reconvergence, so the original switch loses traffic until reconvergence is complete.
- If the source is not learned on another SMLT link or the vIST link on each aggregate switch; they have a route to the source which is not on an SMLT or across the vIST. The switches must choose which one forwards the data down the receiver SMLT link; which one is the designated forwarder, so that duplicate data does not occur. The highest IP address is the designated forwarder. If the designated forwarder becomes disabled, the other takes over. When it is reenabled, the other switch sees that it is no longer the highest IP address and it sees that the remote SMLT link comes up. The other switch then assumes that the vIST peer is capable of being the designated forwarder and it stops forwarding down to the receivers. If the original switch is not ready to forward the data due to reconvergence, traffic loss occurs.

In either case, configuring a static RP helps the situation. To avoid this traffic delay, a workaround is to configure a static RP on the peer SMLT switches. This configuration avoids the process of selecting an active RP router from the list of candidate RPs, and also of dynamically learning about RPs through the BSR mechanism. Then, when the DR comes back, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay.

Circuitless IP for PIM-SM

Use CLIP to configure a resilient RP and BSR for a PIM network. When you configure an RP or BSR on a regular interface, if it becomes nonoperational, the RP and BSR also become nonoperational. This status results in the election of other redundant RPs and BSRs, and can disrupt IP multicast traffic flow in the network. As a best practice for multicast networks design, always configure the RP and BSR on a CLIP interface to prevent a single interface failure from causing these entities to fail.

Also, configure redundant RPs and BSRs on different switches such that these entities are on CLIP interfaces. For the successful setup of multicast streams, ensure that a unicast route exists to all CLIP

interfaces from all locations in the network. A unicast route is mandatory because, for proper RP learning and stream setup on the shared RP tree, every switch in the network needs to reach the RP and BSR. You can use PIM-SM CLIP interfaces only for RP and BSR configurations, and are not intended for other purposes.

Do not configure non-SMLT IGMP leaf ports on a router to be one of the redundant RP CLIP devices. It is possible that these IGMP hosts can become isolated from the multicast data stream(s).

If you configure dual-redundant RPs (vIST peers with the same CLIP interface IP address used for the RP), the topology in the following figure does not work in link-failure scenarios. Use caution if you design a network with this topology where the vIST peers are PIM enabled, and the source and receiver edges are Layer 2.

Consider an example where one of the peers, vIST-A, is the PIM DR for the source VLAN, and the source data is hashed to vIST-A from the Layer 2 source edge. vIST-A forwards traffic to the receiver edge using the SMLT link from vIST-A to the receiver edge. If the SMLT link fails, vIST-A does not forward traffic over the vIST link to vIST-B, and the receiver edge does not receive the data.

In this topology, the receiver edge sends an IGMP membership report for a group, which is recorded on both vIST peers as an IGMP LEAF on the receiver SMLT port on the receiver VLAN.

Because both of the vIST peers are the RP for the group, they do not send a (*,g) PIM JOIN message toward the other RP. The (*,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (*,g) mroute records only a LEAF on the SMLT receiver port.

Because the source is local (Layer 2 edge), there is no PIM (s,g) JOIN message toward the source and the (s,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (s,g) mroute records only a LEAF on the SMLT receiver port.

If the source is hashed to vIST-A, the PIM DR for the incoming VLAN, traffic is forwarded to the receiver correctly. vIST-A does not forward traffic over the vIST to vIST-B, because no JOIN exists on the vIST port. If the receiver SMLT link from the vIST-A peer is down, the traffic is not forwarded to vIST-B, and is not received by the receiver edge. Traffic resumes after the link is restored. If the source data hashes to the non-DR peer, vIST-B, no problem occurs because the non-DR always forwards traffic to the DR.

A similar situation exists in this topology when vIST-A is both the RP and the DR for the Layer 2 receiver edge. The vIST port is not in the outgoing port list because there is no JOIN message from the peer toward the source (which is not PIM enabled). Therefore, if the SMLT link from vIST-A to the receiver edge is down, the system does not forward traffic to the peer vIST-B and down to the receiver.

You can avoid the preceding problems with this topology by performing one of the following actions:

- Enable PIM on the source edge.

The vIST peers send PIM joins toward the source and the JOIN is recorded on the vIST port for the (s,g). Data is forwarded to the peer.

- Do not configure dual redundant RPs.

One vIST peer is the RP for a group.

- Do not configure one vIST peer as both the DR for the source VLAN and the RP for the receiver group.

The system forwards the traffic to the RP or to the DR, depending on which peer receives the source, and, if the SMLT link to the receiver goes down there will be no data loss.

PIM-SM and Static RP

Use static RP to provide security, interoperability, and redundancy for PIM-SM multicast networks. Consider if the administrative ease derived from using dynamic RP assignment is worth the security risks involved. For example, if an unauthorized user connects a PIM-SM router that advertises itself as a candidate RP (C-RP), it can possibly take over new multicast streams that otherwise distribute through an authorized RP. If security is important, use static RP assignment.

You can use the static RP feature in a PIM environment with devices that run legacy PIM-SMv1 and Cisco Auto-RP. For faster convergence, you can also use static RP in a PIM-SMv2 environment. If you configure static RP with PIM-SMv2, the BSR is not active.

Static RP and Auto-RP

Some legacy PIM-SMv1 networks use the auto-RP protocol. Auto-RP is a Cisco proprietary protocol that provides equivalent functionality to the legacy platform supported PIM-SM RP and BSR. You can use the static RP feature to interoperate in this environment. For example, in a mixed-vendor network, you can use auto-RP among routers that support the protocol, while other routers use static RP. In such a network, ensure that the static RP configuration mimics the information that is dynamically distributed to guarantee that multicast traffic is delivered to all parts of the network.

In a mixed auto-RP and static RP network, ensure that the legacy platform does not serve as an RP because it does not support the auto-RP protocol. In this type of network, the RP must support the auto-RP protocol.

Static RP and RP Redundancy

You can provide RP redundancy through static RPs. To ensure consistency of RP selection, implement the same static RP configuration on all PIM-SM routers in the network. In a mixed vendor network, ensure that the same RP selection criteria is used among all routers. For example, to select the active RP for each group address, the switch uses a hash algorithm defined in the PIM-SMv2 standard. If a router from another vendor selects the active RP based on the lowest IP address, then the inconsistency prevents stream delivery to certain routers in the network.

If a group address-to-RP discrepancy occurs among PIM-SM routers, network outages occur. Routers that are unaware of the true RP cannot join the shared tree and cannot receive the multicast stream.

Failure detection of the active RP is determined by the unicast routing table. As long as the RP is considered reachable from a unicast routing perspective, the local router assumes that the RP is fully functional and attempts to join the shared tree of that RP.

The following figure shows a hierarchical OSPF network where a receiver is in a totally stubby area. If RP B fails, PIM-SM router A does not switch over to RP C because the injected default route in the unicast routing table indicates that RP B is still reachable.

Because failover is determined by unicast routing behavior, carefully consider the unicast routing design, as well as the IP address you select for the RP. Static RP failover performance depends on the convergence time of the unicast routing protocol. For quick convergence, ensure that you use a link state protocol, such as OSPF. For example, if you use RIP as the routing protocol, an RP failure can take minutes to detect. Depending on the application, this situation can be unacceptable.

Static RP failover time does not affect routers that have already switched over to the SPT; failover time only affects newly-joining routers.

Unsupported Static RP Configurations

If you use static RP, you disable dynamic RP learning. The following figure shows an unsupported configuration for static RP. In this example because of inter-operation between static RP and dynamic RP, no RP exists at switch 2. However, (S,G) creation and deletion occurs every 210 seconds at switch 16.

Switches 10, 15, and 16 use static RP, whereas switch 2 uses dynamic RP. The source is at switch 10, and the receivers are switches 15 and 16. The RP is at switch 15 locally. The receiver on switch 16 cannot receive packets because its SPT goes through switch 2.

Switch 2 is in a dynamic RP domain, so it cannot learn about the RP on switch 15. However, (S, G) records are created and deleted on switch 16 every 210 seconds.

Rendezvous Point Router Considerations

You can place an RP on a switch when VLANs extend over several switches. However, when you use PIM-SM, ensure that you do not span VLANs on more than two switches.

Use static group-range-to-RP mappings in an SMLT topology as opposed to RP set learning using the Bootstrap Router (BSR) mechanism. Static RP allows for faster convergence in box failure, reset and HA failover scenarios, whereas there are inherent delays in the BSR mechanism as follows:

- When a router comes back up after a failover or reset, to accept and propagate (*,g) join requests from surrounding routers (either PIM join messages or local IGMP membership reports) to the RP, a PIM router must determine the address of the RP for each group for which they desire (*,g) state. The PIM router must know the unicast route to the RP address. The route to the RP address is learned by using a unicast routing protocol such as OSPF, and the RP address is either statically configured or dynamically learned using the BSR mechanism.
- When a box comes up after a reset, if the RP is not statically configured, it must wait for the BSR to select the RP from candidate RP routers, and then propagate the RP set hop-by-hop to all PIM routers. This must be done before a join message can be processed. If the PIM router receives a join message before it learns the RP set, it drops the join message, and the router waits for another join or prune message to arrive before it creates the multicast route and propagates the join message to the RP. The default Join/Prune timer is 60 seconds, and because of this and the delays inherent in BSR RP-set learning, significant multicast traffic interruptions can occur. If the RP is statically configured, the only delay is in the unicast routing table convergence and the arrival of the Join/Prune messages from surrounding boxes.

Layer 3 Multicast Extended VLANS

Avoid using a Layer 3 multicast extended VLAN topology without SMLT.

Do not connect non-SMLT PIM routers in a linear fashion on the same VLAN. This topology is called an extended VLAN. Unlike a shared VLAN topology where all routers on the same VLAN are physically one hop away from each other, a VLAN router at one end of the extended VLAN has one or more routers in between it and the router at the far end of the extended VLAN. The following figure shows an extended VLAN.

In the preceding figure, all routers use PIM-SSM. The source connects to Router A on VLAN 10. All routers and receiver hosts connect on the same extended VLAN, VLAN 20. All routers have a receiver in VLAN 20. Router D is the PIM DR for VLAN 20 and the source host is not on VLAN 20. PIM-SSM does not require a Rendezvous Point (RP).

In this topology, each router receives an IGMP membership report from its local receiver host, and then sends a PIM SG join message towards the source on VLAN 20. VLAN flooding propagates the PIM SG join message through to Router A, the PIM DR for the source VLAN 10. Each router from Router D to Router A records a PIM join on the port on which the join message was received, and then sends out its own join message toward the source. Data then flows from the source to the receiver, as long as a join exists on those ports.

Because all routers are in the same VLAN 20, they receive joins from one another due to flooding in the VLAN. For example, Router D receives join messages from Router C on its port 'b', and Router C receives join messages from Router B on its port toward Router B. On VSP 9000 Series routers, PIM join suppression is always enabled. In accordance with the PIM protocol rules, suppression causes Router D to stop sending a join towards the source because it receives a join for the same group and same RP on the port (port b) of the upstream neighbor (the router towards the source). Router D does not need to send a redundant join on the same VLAN. Router D stops sending a join, and the join that is recorded on port c of Router C eventually times out and is removed from the egress list of the (s,g) multicast route entry on Router C. This removal causes Router C to stop forwarding multicast traffic to Router D, and to the receiver (R1).

The purpose of join suppression is to suppress joins on a shared VLAN, such that if all routers on the shared VLAN want to receive data from the same RP and group, then only one of them needs to send the join on the VLAN. One join is enough to pull the data from the source router to the shared VLAN for all routers to receive. The other routers can suppress sending their own joins when they see such a join on the port toward the upstream router. In this way, less protocol message congestion exists in the shared VLAN. In the following figure, Router D sends the initial join message, which is seen by Router B and Router C. Router B and Router C suppress their own join messages. Router A (the PIM DR for the source VLAN 10) sends the data to VLAN 20, which is received by Routers B, C, and D due to the shared (non-extended) VLAN topology, and traffic is forwarded to all receiver hosts.

The extended VLAN topology looks exactly like the non-extended shared VLAN topology to the router, which cannot distinguish between the two.

In the current release, you cannot disable join suppression on a router. This enhancement will be added in a future release. Until this enhancement is included, you can perform the following actions:

1. Avoid this type of extended VLAN topology, and instead use Layer 3 routing between the routers. Do not extend VLAN 20 throughout, but rather, create a different VLAN between each router.
2. Configure the PIM DR for VLAN 20 to be the router closer to the source (Router B) so that any join received on the VLAN 20 DR (Router B) will be recorded as an IGMP local leaf on VLAN 20 as opposed to a PIM join, which does not time out until the receiver host stops sending IGMP membership reports.

PIM-SM Design and the BSR Hash Algorithm

To optimize the flow of traffic down the shared trees in a network that uses a BSR to dynamically advertise candidate RPs, consider the hash function. The BSR uses the hash function to assign multicast group addresses to each C-RP.

The BSR distributes the hash mask used to compute the RP assignment. For example, if two RPs are candidates for the range 239.0.0.0 through 239.0.0.127, and the hash mask is 255.255.255.252, that range of addresses is divided into groups of four consecutive addresses and assigned to one or the other C-RP.

The following figure illustrates a suboptimal design where Router A sends traffic to a group address assigned to RP D. Router B sends traffic assigned to RP C. RP C and RP D serve as backups for each other for those group addresses. To distribute traffic, it is desirable that traffic from Router A use RP C and that traffic from Router B use RP D.

While still providing redundancy in the case of an RP failure, you can ensure that the optimal shared tree is used by using the following methods.

1. Use the hash algorithm to proactively plan the group-address-to-RP assignment.

Use this information to select the multicast group address for each multicast sender on the network and to ensure optimal traffic flows. This method is helpful for modeling more complex redundancy and failure scenarios, where each group address has three or more C-RPs.

2. Allow the hash algorithm to assign the blocks of addresses on the network, and then view the results using the command **show ip pim active-rp**.

Use the command output to assign multicast group addresses to senders that are located near the indicated RP. The limitation to this approach is that while you can easily determine the current RP for a group address, the backup RP is not shown. If more than one backup for a group address exists, the secondary RP is not obvious. In this case, use the hash algorithm to reveal which of the remaining C-RPs take over for a particular group address in the event of primary RP failure.

The hash algorithm works as follows:

1. For each C-RP router with matching group address ranges, a hash value is calculated according to the formula:

$$\text{Hash value [G, M, C(i)]} = \{1\ 103\ 515\ 245 * [(1\ 103\ 515\ 245 * (G\&M) + 12\ 345) \text{ XOR } C(i)] + 12\ 345\} \text{ mod } 2^{31}$$

The hash value is a function of the group address (G), the hash mask (M), and the IP address of the C-RP C(i). The expression (G&M) guarantees that blocks of group addresses hash to the same value for each C-RP, and that the size of the block is determined by the hash mask.

For example, if the hash mask is 255.255.255.248, the group addresses 239.0.0.0 through 239.0.0.7 yield the same hash value for a given C-RP. Thus, the block of eight addresses are assigned to the same RP.

2. The C-RP with the highest resulting hash value is chosen as the RP for the group. In the event of a tie, the C-RP with the highest IP address is chosen.

This algorithm runs independently on all PIM-SM routers so that every router has a consistent view of the group-to-RP mappings.

Candidate RP Considerations

The C-RP priority parameter determines an active RP for a group. The hash values for different RPs are only compared for RPs with the highest priority. Among the RPs with the highest priority value and the same hash value, the C-RP with the highest RP IP address is chosen as the active RP.

You cannot configure the C-RP priority. Each RP has a default C-RP priority value of 0, and the algorithm uses the RP if the group address maps to the grp-prefix that you configure for that RP. If a different router in the network has a C-RP priority value greater than 0, the switch uses this part of the algorithm in the RP election process.

Currently, you cannot configure the hash mask used in the hash algorithm. Unless you configure a different PIM BSR in the network with a nondefault hash mask value, the default hash mask of 255.255.255.252 is used. Static RP configurations do not use the BSR hash mask; they use the default hash mask.

For example:

RP1 = 128.10.0.54 and RP2 = 128.10.0.56. The group prefix for both RPs is 238.0.0.0/255.0.0.0. Hash mask = 255.255.255.252.

The hash function assigns the groups to RPs in the following manner:

The group range 238.1.1.40 to 238.1.1.51 (12 consecutive groups) maps to 128.10.0.56. The group range 238.1.1.52 to 238.1.1.55 (4 consecutive groups) maps to 128.10.0.54. The group range 238.1.1.56 to 238.1.1.63 (8 consecutive groups) maps to 128.10.0.56.

PIM-SM RP Selection Algorithm Inconsistency between Platforms

In topologies where VOSS platforms are interoperating with ERS or VSP 9000 Series platforms, the selection of the RP from multiple candidate RPs may produce different results on VOSS than it does on ERS or VSP 9000 Series. VOSS platforms conform to PIM RFC 4601, while ERS and VSP 9000 Series platforms conform to RFC 2362. RFC 4601 is not backward compatible with RFC 2362 regarding how it defines the selection algorithm for an RP, specifically when there are several candidate RPs for the same group, but with different prefix lengths. Both RFCs have the RP selection mechanism based on a specific hash function, common to all routers in PIM domain, however there are differences in determining the pool of candidate RPs to which the hash function will be applied. In RFC 4601, only the RP of the group range with the longest prefix match for the group range will be chosen to apply the hash function and thus participate in the actual election. In RFC 2362, longest prefix match is not part of the selection criteria, and therefore ERS/VSP 9000 Series could potentially choose a different RP, since they will apply the hash function on a different pool of candidate RPs. This would cause inconsistencies in the PIM-SM network.

In order to work around this issue, please define RP group ranges with the same prefix length, such that the next RFC-defined match rule will be applied equally across all platforms in the network.

PIM-SM Receivers and VLANs

Some designs cause unnecessary traffic flow on links in a PIM-SM domain. In these cases, traffic is not duplicated to the receivers, but wastes bandwidth.

The following figure shows such a situation. Switch B is the DR between switches A and B. Switch C is the RP. A receiver R is on the VLAN (V1) that connects switches A and B. A source sends multicast data to the receiver.

IGMP reports that the messages that the receiver sends are forwarded to the DR, and both A and B create (*,G) records. Switch A receives duplicate data through the path from C to A, and through the second path from C to B to A. Switch A discards the data on the second path (assuming the upstream source is A to C).

To avoid this waste of resources, do not place receivers on V1. This configuration guarantees that no traffic flows between B and A for receivers attached to A. In this case, the existence of the receivers is only learned through PIM join messages to the RP [for (*,G)] and of the source through SPT joins.

PIM Network with Non-PIM Interfaces

For proper multicast traffic flow in a PIM-SM domain, as a general rule, enable PIM-SM on all interfaces in the network (even if paths exist between all PIM interfaces). Enable PIM on all interfaces because PIM-SM relies on the unicast routing table to determine the path to the RP, BSR, and multicast sources. Ensure that all routers on these paths have PIM-SM enabled interfaces.

The following figure provides an example of this situation. If A is the RP, then initially the receiver receives data from the shared tree path (that is, through switch A).

If the shortest path from C to the source is through switch B, and the interface between C and B does not have PIM-SM enabled, then C cannot switch to the SPT. C discards data that comes through the

shared path tree (that is, through A). The simple workaround is to enable PIM on VLAN1 between C and B.

Source Filtering

The system can report interest in receiving packets from only a specific source address (INCLUDE), from all but specific source addresses (EXCLUDE), or sent to specific multicast addresses. IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

Protocol Independent Multicast-Source Specific Multicast guidelines

PIM-Source Specific Multicast (SSM) is a one-to-many model that uses a subset of the PIM-SM features. In this model, members of an SSM group can only receive multicast traffic from a specific source or sources, which is more efficient and puts less load on multicast routing devices.

IGMPv3 supports PIM-SSM by enabling a host to selectively request traffic from individual sources within a multicast group. The system can report interest in receiving packets from only specific source addresses (INCLUDE). IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

IGMPv2 SSM extensions

VSP 4450 Series processes messages according to the following rules:

- After IGMPv3 receives an IGMPv2 report in the SSM range, the system translates the report to an IGMPv3 report message.
- After an IGMPv2 router sends queries on an IGMPv3 interface, the switch downgrades this interface to IGMPv2 (backward compatibility).

This can cause traffic interruption, but the switch recovers quickly.

PIM-SSM design considerations

Use the following information when you design an SSM network:

- If you configure SSM, it affects SSM groups only. The switch handles other groups in sparse mode (SM) if a valid RP exists on the network.
- You can configure PIM-SSM only on switches at the edge of the network. Core switches use PIM-SM if they do not have receivers for SSM groups.
- For networks where group addresses are already in use, you can change the SSM range to match the groups.
- One switch has a single SSM range.
- You can have different SSM ranges on different switches.

Configure the core switches that relay multicast traffic so that they cover all of these groups in their SSM range, or use PIM-SM.

- One group in the SSM range can have multiple sources for a given SSM group.

Multicast for Multimedia

The switch provides a flexible and scalable multicast implementation for multimedia applications. Several features are dedicated to multimedia applications and in particular to television distribution.

Join and leave performance

For TV applications, you can attach several TVs directly to the switch, or through an IGMP-capable Ethernet switch. Base this implementation on IGMP; the set-top boxes use IGMP reports to join a TV channel and IGMP leaves to exit the channel. After a viewer changes channels, the switch issues an IGMPv2 leave for the old channel (multicast group), and sends a membership report for the new channel. If viewers change channels continuously, the number of joins and leaves can become large, particularly if many viewers attach to the switch.

The switch supports more than a thousand joins and leaves per second, which is well adapted to TV applications.

Important

For IGMPv3, ensure a join rate of 1000 per second or less. This ensures the timely processing of join requests.

If you use the IGMP proxy functionality at the receiver edge, you reduce the number of IGMP reports received by switch. This provides better overall performance and scalability.

Fast Leave

IGMP Fast Leave supports two modes of operation: single-user mode and multiple-user mode.

In single-user mode, if more than one member of a group is on the port and one of the group members leaves the group, everyone stops receiving traffic for this group. Single-user mode does not send a group-specific query before the effective leave takes place.

Multiple-user mode allows several users on the same port or VLAN. If one user leaves the group and other receivers exist for the same stream, the stream continues. The switch tracks the number of receivers that join a given group. For multiple-user mode to operate properly, do not suppress reports. This ensures that the switch properly tracks the correct number of receivers on an interface.

The Fast Leave feature is particularly useful in IGMP-based TV distribution where only one receiver of a TV channel connects to a port. If a viewer changes channels quickly, you create considerable bandwidth savings if you use Fast Leave.

You can implement Fast Leave on a VLAN and port combination; a port that belongs to two different VLANs can have Fast Leave enabled on one VLAN (but not on the other). Thus, with the Fast Leave feature enabled, you can connect several devices on different VLANs to the same port. This strategy does not affect traffic after one device leaves a group to which another device subscribes. For example, you can use this feature when two TVs connect to a port through two set-top boxes, even if you use the single-user mode.

To use Fast Leave, you must first enable explicit host tracking. IGMP uses explicit host tracking to track all source and group members. Explicit host tracking is disabled by default. For configuration information, see [Configuring Fast Leave Mode](#) on page 1493.

Last member query interval tuning

If an IGMPv2 host leaves a group, it notifies the router by using a leave message. Because of the IGMPv2 report suppression mechanism, the router cannot access information of other hosts that require the stream. Thus, the router broadcasts a group-specific query message with a maximum response time equal to the last member query interval (LMQI).

Because this timer affects the latency between the time that the last member leaves and the time the stream actually stops, you must properly tune this parameter. This timer can especially affect TV delivery or other large-scale, high-bandwidth multimedia applications. For instance, if you assign a value that is too low, this can lead to a storm of membership reports if a large number of hosts are subscribed. Similarly, assigning a value that is too high can cause unwanted high-bandwidth stream propagation across the network if users change channels rapidly. Leave latency also depends on the robustness value, so a value of 2 equates to a leave latency of twice the LMQI.

Determine the proper LMQI value for your particular network through testing. If a very large number of users connect to a port, assigning a value of 3 can lead to a storm of report messages after a group-specific query is sent. Conversely, if streams frequently start and stop in short intervals, as in a TV delivery network, assigning a value of 10 can lead to frequent congestion in the core network.

Another performance-affecting factor that you need to be aware of is the error rate of the physical medium. For links that have high packet loss, you can find it necessary to adjust the robustness variable to a higher value to compensate for the possible loss of IGMP queries and reports.

In such cases, leave latency is adversely affected as numerous group-specific queries are unanswered before the stream is pruned. The number of unanswered queries is equal to the robustness variable (default 2). The assignment of a lower LMQL can counterbalance this effect. However, if you configure the LMQL too low, it can actually exacerbate the problem by inducing storms of reports on the network. LMQL values of 3 and 10, with a robustness value of 2, translate to leave latencies of 6/10 of a second and 2 seconds, respectively.

When you choose an LMQL, consider all of these factors to determine the best configuration for the given application and network. Test that value to ensure that it provides the best performance.

**Important**

In networks that have only one user connected to each port, use the Fast Leave feature instead of LMQL, because no wait is required before the stream stops. Similarly, the robustness variable does not affect the Fast Leave feature, which is an additional benefit for links with high loss.

Layer 3 switch clustering and multicast SMLT

Switch clustering is the logical aggregation of two nodes to form one logical entity known as the switch cluster. The two peer nodes in a switch cluster connect using a virtual interswitch trunk (vIST). The vIST exchanges forwarding and routing information between the two peer nodes in the cluster. This section provides guidelines for switch clusters that use multicast and Split Multilink Trunking (SMLT).

General guidelines

The following list identifies general guidelines to follow if you use multicast and switch clustering:

- Enable Protocol Independent Multicast - Sparse Mode (PIM-SM) on the vIST VLAN for fast recovery of multicast. A unicast routing protocol is not required.
- Enable Internet Group Management Protocol (IGMP) snooping and proxy on the edge switches.

The following figure shows multicast behavior in an SMLT environment. The configuration in the following figure provides fast failover if the switch or rendezvous point (RP) fails.

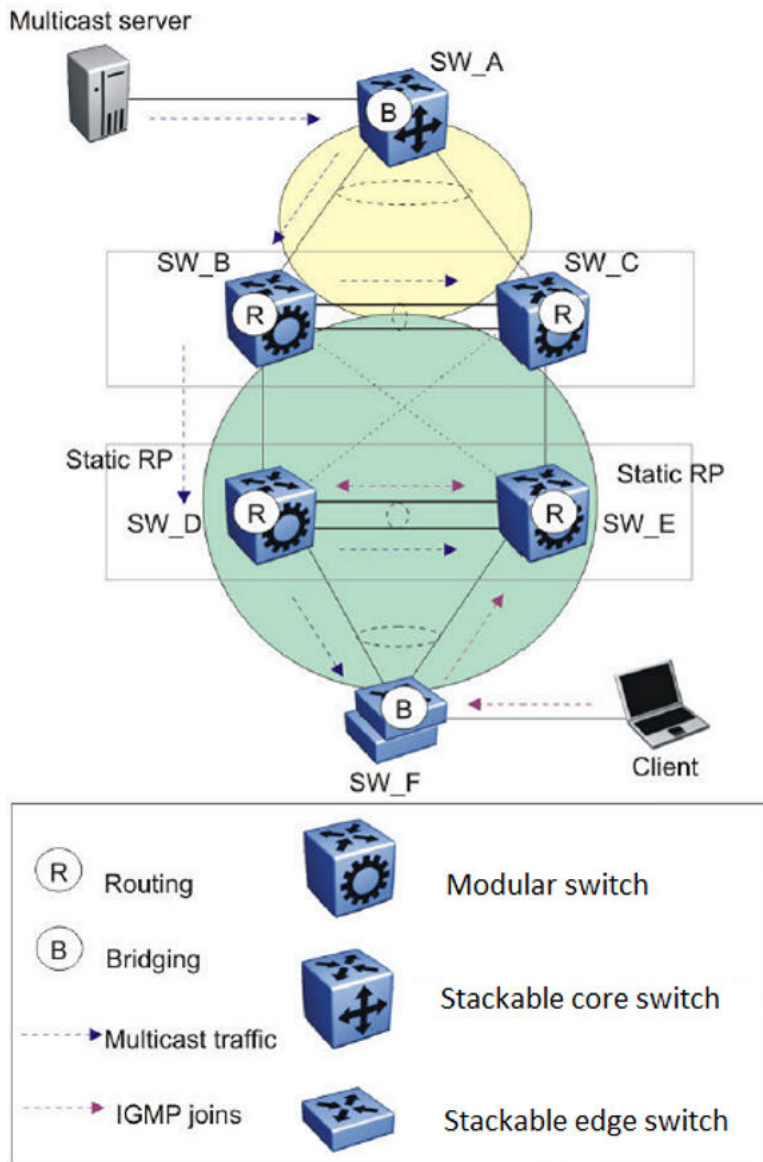

Figure 137: Multicast behavior in SMLT environment

In Multicast behavior in SMLT environment the following actions occur:

1. The multicast server sends multicast data towards the source designated router (DR).
2. The source DR sends register messages with encapsulated multicast data towards the RP.
3. After the client sends IGMP membership reports towards the multicast router, the router creates a (*,G) entry.
4. The RP sends join messages towards the source DR on the reverse path.
5. After the source DR receives the join messages, it sends native multicast traffic.
6. After SW_B or SW_D receives multicast traffic from upstream, it forwards the traffic on the vIST as well as on the SMLT link. Other aggregation switches drop multicast traffic received over the vIST at

gress. This action provides fast failover for multicast traffic. Both SW_D and SW_E (Aggregation switches) have similar (S,G) records.

- In case of SW_D or RP failure, SW_B changes only the next-hop interface towards SW_E. Because the circuitless IP (CLIP) RP address is the same, SW_B does not flush (S,G) entries and achieves fast failover.

Multicast triangle topology

A triangle design is an SMLT configuration that connects edge switches or SMLT clients to two aggregation switches. Connect the aggregation switches together with a vIST that carries all the SMLT trunks configured on the switches.

The switch supports the following triangle configurations:

- a configuration with Layer 3 PIM-SM routing on both the edge and aggregation switches
- a configuration with Layer 2 snooping on the client switches and Layer 3 routing with PIM-SM on the aggregation switches

To avoid using an external query device to provide correct handling and routing of multicast traffic to the rest of the network, use the triangle design with IGMP Snoop at the client switches. Use multicast routing at the aggregation switches as shown in the following figure.

Figure 138: Multicast routing using PIM-SM

Client switches run IGMP Snoop or PIM-SM, and the aggregation switches run PIM-SM. This design is simple and, for the rest of the network, PIM-SM performs IP multicast routing. The aggregation switches are the query devices for IGMP, so an external query device is not required to activate IGMP membership. These switches also act as redundant switches for IP multicast.

Multicast data flows through the vIST link when receivers are learned on the client switch and senders are located on the aggregation switches, or when sourced data comes through the aggregation switches. This data is destined for potential receivers attached to the other side of the vIST. The data

does not reach the client switches through the two aggregation switches because only the originating switch forwards the data to the client switch receivers.

Note

Always place multicast receivers and senders on the core switches on VLANs different from those that span the vIST.

The following figure shows a switch clustering configuration with a single switch cluster core and dual-connected edge devices. This topology represents different VLANs spanning from each edge device and those VLANs routed at the switch cluster core. You can configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster core.

Figure 139: Multicast SMLT triangle

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either Virtual Router Redundancy Protocol (VRRP) BackupMaster or Routed SMLT (RSMLT) Layer 2 Edge on the switch cluster core.

Square and full-mesh topology multicast guidelines

A square design connects a pair of aggregation switches to another pair of aggregation switches. A square design becomes a full-mesh design if the aggregation switches are connected in a full-mesh. The switch supports Layer 3 IP multicast (PIM-SM only) over a full-mesh SMLT or RSMLT configuration.

In a square design, configure all switches with PIM-SM. Place the bootstrap router (BSR) and RP in one of the four core switches; and place the RP closest to the source. If using PIM-SM over a square or full-mesh configuration, enable the **multicast smlt-square** flag.

The following three figures show switch clustering configurations with two-switch cluster cores and dual-connected edge devices.

Figure 140: Multicast SMLT square 1

In the preceding figure, only one of the switch cluster cores performs Layer 3 multicast routing while the other is strictly Layer 2. Configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster cores.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster core.

Figure 141: Multicast SMLT square 2

In the preceding figure, both of the switch cluster cores performs Layer 3 multicast routing, while the edge devices are Layer 2 IGMP.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

Figure 142: Multicast SMLT square 3

In the preceding figure, both of the switch cluster cores and the edge devices perform Layer 3 multicast routing.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

SMLT and multicast traffic issues

If PIM-SM or other multicast protocols are used in an SMLT environment, enable the protocol on the vST. Routing protocols in general are not run over an vST but multicast routing protocols are an exception. When using PIM-SM and a unicast routing protocol, ensure the unicast route to the BSR and RP has PIM-SM active and enabled. If multiple OSPF paths exist and PIM-SM is not active on each pair, the BSR is learned on a path that does not have PIM-SM active. The following figure demonstrates this issue.

Figure 143: Unicast route example

The network configuration in the preceding figure is as follows:

- 5510A is on VLAN 101.
- 5510B is on VLAN 102.
- Switch B is the BSR.
- Switch A and Switch B have OSPF enabled.
- PIM is enabled and active on VLAN 101.
- PIM is either disabled or passive on VLAN 102.

In this example, the unicast route table on Switch A learns the BSR on Switch B through VLAN 102 using OSPF. The BSR is either not learned or does not provide the RP to Switch A.

Protocol Independent Multicast over IPv6

Table 150: PIM over IPv6 product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| PIM over IPv6 | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VOSS 5.1 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 5.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VOSS 5.1 |
| | VSP 8400 Series | VOSS 5.1 |
| | VSP 8600 Series | Not Supported |
| | XA1400 Series | Not Supported |

Several multicast protocols are used to enable IP multicast.

Hosts use the Internet Group Management Protocol (IGMP) for IPv4 and Multicast Listener Discovery (MLD v1/v2) for IPv6 to report multicast group memberships of directly attached multicast listeners to neighboring multicast routers. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4.

Routers use Protocol Independent Multicast-Sparse Mode (PIM-SM) and PIM source Specific Mode (SSM) to exchange multicast routing information. The PIM-SM protocol is the multicast routing protocol that uses the underlying unicast routing information base to build unidirectional shared trees to group members rooted at the RP per group, and creates shortest-path trees (SPT) per source. The router forwards multicast packets along these trees. PIM-SSM does not require RP and only supports SPT.

PIM over IPv6 uses the IPv6 unicast routing table for reverse path information about source and RP.

Note

IPv4 and IPv6 multicast streams cannot interact. To configure an end-to-end PIM IPv6 network, all nodes from sender to receiver must support PIM IPv6.

PIM-SM over IPv6 features

The following are features of PIM-SM over IPv6:

- Compliant with RFC 4601
- Multicast networks built by PIM IPv4 and PIM IPv6 do not overlap
- IPv4 receiver hosts cannot receive data from IPv6 source hosts and vice versa
- IPv4 and IPv6 multicast protocols can be enabled at the same time on the same VLAN
- PIM IPv4 and PIM IPv6 can be configured on the same VLAN
- PIM IPv4 and PIM IPv6 must be configured separately
- Supports sparse and ssm modes

Operational note for PIM-SM over IPv6

The following are operational considerations when deploying PIM-SM over IPv6:

- You can only configure PIM-SM if you configure the `spbm_config_mode` boot flag to false
- The following HELLO messages options are not supported:
 - GENid
 - DR priority
 - LAN-PRUNE delay
 - T-bit
- IPv6 multicast is not supported over SPBM
- IPv6 multicast routing is not virtualized, it is supported only on GRT
- IPv6 multicast configuration on SMLT VLAN is not supported. vIST peers cannot form PIM-SM over IPv6 neighbor adjacencies. Senders and receivers on the vIST peers (SMLT and non-SMLT) cannot communicate. MLT and LACP is supported.
- The switch does not support the following features:
 - Static entries
 - Bootstrap message (BSR)
 - Anycast RP
 - Virtual PIM neighbors
 - Fast join prune
 - Software forwarding
 - Passive PIM interfaces
 - IP mroute stream limit
 - Bidirectional PIM
 - Multicast Border Router (PMBR)
 - VRF support for PIM (GRT only)
 - IGMP and PIM mtrace capability
 - High Availability (HA)

IPv6 interface multiple addresses

IPv6 interfaces can have multiple addresses associated with them. A router running PIM for IPv6 has a network unique domain-wide reachable IPv6 VLAN address used for multiple hop messages. A link local address is associated with the VLAN. The link local address is a non-routable unicast IPv6 address used as source address (primary interface address) for transmitting different types of PIM messages.

IP multicast configuration and DvR

Configuration of IPv4 multicast is supported only on the Controller nodes of a DvR domain. You cannot configure IP multicast on the DvR Leaf nodes. The following sections detail IP multicast configuration support on DvR enabled nodes (Controllers or Leaf nodes).

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 661.

Multicast configuration that is pushed from DvR Controllers to DvR Leaf nodes

When you perform the following multicast configuration on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- IP multicast over Fabric Connect
- IGMP Layer 2 Querier parameters, such as the IGMP Layer 2 Querier version, query interval, query maximum response time, robustness value, last member query interval and compatibility mode
- Enabling and clearing of multicast route statistics

Multicast configuration that is not supported on DvR enabled Layer 2 VSNs

- IGMP Snooping on DvR enabled Layer 2 VSNs
- SPB-PIM Gateway

For more information on SPB-PIM Gateway, see [SPB-PIM Gateway configuration](#) on page 3045.

IP multicast basic configuration using CLI

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts subscribe to multicast services using a host membership protocol. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

Configuring IP multicast in SMLT topologies

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

Before You Begin

SPBM must not be enabled on the vIST peers or any router that participates in the PIM network.

About This Task

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable the boot flag:

```
no boot config flags spbm-config-mode
```

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-mode
is changed to disable, removes SPBM configurations from the
configuration file.
```

3. Save the configuration and, then reboot the switch.

Important

Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.

4. Create the vIST VLAN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

```
interface vlan <1-4059>
```

```
ip address <A.B.C.D/X>
```

5. Configure the vIST peer address and VLAN:

```
virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
```

6. Configure the SMLT MLT:

```
mlt <1-512> enable
```

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

```
interface mlt <1-512>
```

```
smlt
```

7. Configure the vIST MLT:

```
mlt <1-512> enable

mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}

mlt <1-512> encapsulation dot1q

interface mlt <1-512>

virtual-ist enable
```

Note

The **virtual-ist enable** command enables Simplified vIST and is only available when the **spbm-config-mode** boot flag is disabled.

8. Create a customer VLAN and assign the SMLT MLT ID:

```
vlan create <2-4059>

vlan mlt <1-4059> <1-512>

interface vlan <1-4059>

ip address <A.B.C.D/X>
```

9. Configure PIM or IGMP Snooping on the SMLT VLAN:

```
interface vlan <1-4059>

ip pim enable or ip igmp snooping
```

10. Configure PIM on the vIST VLAN:

```
interface vlan <1-4059>

ip pim enable
```

11. Enable PIM globally:

```
ip pim enable
```

Note

You can also configure other global PIM attributes such as **ip pim join-prune-interval**.

Example

```
enable
configure terminal
no boot config flags spbm-config-mode
```

Save the configuration and reboot the switch.

```
virtual-ist peer-ip 198.51.100.0 vlan 50

mlt 3 enable
mlt 3 member 1/35,1/36
interface mlt 3
smlt
```

```
exit
mlt 5 enable
mlt 5 member 2/15,2/17
mlt 5 encapsulation dot1q
interface mlt 5
virtual-ist enable
exit
vlan create 50 type port-mstprstp 0
interface vlan 50
ip address 198.51.100.0 255.255.255.0 1
exit
vlan create 100
vlan mlt 100 3
interface vlan 100
ip address 192.0.2.0 255.255.255.0 2
exit
interface vlan 100
ip pim enable (or ip igmp snooping)
exit
interface vlan 50
ip pim enable
exit
ip pim enable
```

Configuring PIM-SM globally

Configure PIM-SM to enable or disable PIM-SM globally on the switch and change default global parameters.

About This Task

PIM-SM is the default mode so you do not need to configure the PIM mode.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable PIM-SM:
`ip pim enable`
3. Configure the time between bootstrap messages:
`ip pim bootstrap-period <5-32757>`
4. Configure the timeout to discard data:
`ip pim disc-data-timeout <5-65535>`
5. Enable the fast join prune interval:
`ip pim fast-joinprune`
6. Configure the forward cache timeout:
`ip pim fwd-cache-timeout <10-86400>`
7. Configure the interval for join and prune messages:
`ip pim join-prune-interval <1-18724>`
8. Specify how long to suppress register messages:
`ip pim register-suppression-timeout <6-65535>`

- Specify how often the candidate-redirect point (C-RP) sends advertisements:

```
ip pim rp-c-adv-timeout <5-26214>
```

- Configure the polling interval for the routing table manager (RTM):

```
ip pim unicast-route-change-timeout <2-65535>
```

- Verify the configuration changes:

```
show ip pim
```

Example

Verify the configuration changes:

```
Switch:1(config)#show ip pim
```

```

Enabling or disabling IPv6 PIM-SM globally

About This Task

Use this procedure to enable or disable IPv6 PIM-SM globally. By default, IPv6 PIM-SM is disabled.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Enable IPv6 PIM-SM:

```
ipv6 pim enable
```
- Disable IPv6 PIM-SM:

```
no ipv6 pim enable
```
- Set IPv6 PIM-SM status to default:

```
default ipv6 pim enable
```

Configuring global IPv6 PIM-SM properties

About This Task

Use this procedure to configure the global IPv6 PIM-SM parameters on the switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the timeout to discard data:

```
ipv6 pim disc-data-timeout <5-65535>
```
3. Configure the forward cache timeout:

```
ipv6 pim fwd-cache-timeout <10-86400>
```
4. Configure the interval for join and prune messages:

```
ipv6 pim join-prune-interval <1-18724>
```
5. Specify how long to suppress register messages:

```
ipv6 pim register-suppression-timeout <10-65535>
```
6. Configure the polling interval for the routing table manager (RTM):

```
ipv6 pim unicast-route-change-timeout <2-65535>
```
7. Configure the PIM mode:

```
ipv6 pim mode <sparse> <ssm>
```
8. Verify the configuration changes:

```
show ipv6 pim
```

Example

Verify the configuration changes:

```
Switch:1(config)#show ipv6 pim
```

```
=====
                          Pim General Group - GlobalRouter
=====
PimStat           : disabled
Mode              : sparse
StaticRP          : disabled
FwdCacheTimeout  : 210
DiscDataTimeout  : 60
RegSupprTimeout  : 60
UniRouteChangeTimeout : 5
JoinPruneInt     : 60
```

Variable definitions

The following table describes the variables for the `ipv6 pim` command.

| Variable | Description |
|--------------------------------|--|
| disc-data-timeout
<5-65535> | Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard |

| Variable | Description |
|--|--|
| | record is created after a register packet is sent, until the timer expires or the switch receives a join message.

The default value is 60. |
| enable | Enables PIM globally on the switch.

The default is disabled. |
| fwd-cache-timeout
<10-86400> | Specifies the forward cache timeout value.

The default value is 120. |
| join-prune-interval
<1-18724> | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.

The default value is 60. |
| mode <sparse> <ssm> | Configures PIM mode on the switch.

The default value is sparse. |
| register-suppression-timeout
<10-65535> | Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP.

The default value is 60. |
| static-rp | Add new static-rp entries and enable static-rp. |
| unicast-route-change-timeout
<2-65535> | Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM.

The default value is 5. |

Configuring PIM on a VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you configure PIM on a VLAN.
- The interface uses a valid IP address.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Create a PIM interface on a VLAN:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

5. Verify the configuration:

```
show ip pim interface vlan [<1-4059>]
```

Example

Configure the interval for join and prune messages, the time between hello messages, and then verify the configuration.

```
Switch:1(config-if)#ip pim join-prune-interval 60
Switch:1(config-if)#ip pim hello-interval 30
Switch:1(config-if)#show ip pim interface vlan 10
```

```
=====
                        Vlan Ip Pim
=====
VLAN-ID   PIM-ENABLE MODE   HELLOINT  JPINT   CBSRPREF   INTF TYPE
-----
10        enable   sparse   30      60      -1 (disabled) active
```

Configuring PIM on a port

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you configure it on an interface.
- The interface uses a valid IP address.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

Example

Configure the interval for join and prune messages and the time between hello messages:

```
Switch(config-if)#ip pim join-prune-interval 60
Switch(config-if)#ip pim hello-interval 30
```

Configuring IPv6 PIM on a port or VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- Enable IPv6 interface.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port or VLAN:

```
ipv6 pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ipv6 pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ipv6 pim hello-interval <0-18724>
```

Example

```
Switch:1(config-if)#ipv6 pim join-prune-interval 60
Switch:1(config-if)#ipv6 pim hello-interval 30
```

Variable definitions

The following table describes the variables for the `ipv6 pim` command.

| Variable | Description |
|----------------------------------|---|
| hello-interval
<0-18724> | Specifies the duration in seconds before the PIM router sends out the next hello message to neighboring switches.

The default value is 30 seconds. |
| join-prune-interval
<1-18724> | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.

The default value is 60 seconds. |

Configuring SSM globally

Configure SSM to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Before You Begin

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using CLI](#) on page 2661. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2362.
- Enable PIM globally.

About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure PIM-SSM:

```
ip pim mode ssm
```

Configuring IPv6 SSM globally

Configure IPv6 SSM to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 2671. For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2401.

- Enable IPv6 PIM globally.

About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model which requires only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure IPv6 PIM-SSM:

```
ipv6 pim mode ssm
```

Configuring IGMP on a VLAN

Configure IGMP for each interface to change default multicasting operations.

Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

For more information on DvR, see .

Before You Begin

- For PIM interfaces, you must enable PIM globally and on the VLAN. For snooping interfaces, do not enable PIM.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable  
  
configure terminal  
  
interface vlan <1-4059>
```
2. Enable IGMP v2-v3 compatibility mode:

```
ip igmp compatibility-mode
```
3. Configure the system to downgrade the version of IGMP:

```
ip igmp dynamic-downgrade-version
```
4. Configure message intervals and response times:

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]  
[query-max-response <0-255>]
```
5. Configure expected packet loss and IGMP version:

```
ip igmp robust-value <2-255> [version <1-3>]
```
6. Add multicast router ports:

```
ip igmp mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
7. Enable proxy-snoop:

```
ip igmp proxy
```
8. Enable router alert:

```
ip igmp router-alert
```
9. Enable snooping:

```
ip igmp snooping
```
10. Enable SSM-snooping:

```
ip igmp ssm-snoop
```

Example

Enter VLAN Interface Configuration Mode for VLAN 10:

```
Switch:1(config)# interface vlan 10
```

Configure the last member query interval to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp last-member-query-interval 15
```

Configure the query interval to 100 seconds.

```
Switch:1(config-if)# ip igmp query-interval 100
```

Configure the query maximum response time to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp query-max-response 15
```

Configure the robustness value to 4 seconds.

```
Switch:1(config-if)# ip igmp robust-value 4
```

Enable proxy snoop for the VLAN.

```
Switch:1(config-if)# ip igmp proxy
```

Enable snoop for the VLAN.

```
Switch:1(config-if)# ip igmp snooping
```

Enable support for SSM on the snoop interface.

```
Switch:1(config-if)# ip igmp ssm-snoop
```

Enable IGMPv3.

```
Switch:1(config-if)# ip igmp version 3
```

Variable Definitions

Use the definitions in the following table to use the **ip igmp** command.

| Variable | Value |
|---|--|
| <i>access-list WORD<1-64>
{A.B.C.D/X} <eny-tx deny-rx
deny-both allow-only-tx
allow-only-rx allow-only-
both></i> | Specifies the name of the access list from 1-64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic |
| <i>compatibility-mode</i> | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
default ip igmp compatibility-mode
, or use the no option to disable compatibility mode:
no ip igmp compatibility-mode |
| <i>dynamic-downgrade-version</i> | Configures the version of IGMP to handle older query messages if the system downgrades. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
default ip igmp dynamic-downgrade-version
or use the no option to disable downgrade:
no ip igmp dynamic-downgrade-version |
| <i>igmpv3-explicit-host-tracking</i> | Enables explicit host tracking on IGMPv3. The default state is disabled. |
| <i>immediate-leave</i> | Enables fast leave on a VLAN. |

| Variable | Value |
|--|---|
| <code>immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>last-member-query-interval <0-255></code> | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3-10 (equal to 0.3 - 1.0 seconds). |
| <code>mrdisc [maxadvertinterval <2-180>] [maxinitadvertinterval <2-180>] [maxinitadvertisements <2-15>] [minadvertinterval <3-180>] [neighdeadinterval <2-180>]</code> | Configures the multicast router discovery options to enable the automatic discovery of multicast capable routers. The default parameter values are: <ul style="list-style-type: none"> • maxadvertinterval: 20 seconds • maxinitadvertinterval: 2 seconds • maxinitadvertisements: 3 • minadvertinterval: 15 seconds • neighdeadinterval: 60 seconds |
| <code>mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Adds multicast router ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>proxy</code> | Activates the proxy-snoop option globally for the VLAN. |
| <code>query-interval <1-65535></code> | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds. |
| <code>query-max-response <0-255></code> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). <p>Important:
You must configure this value lower than the query-interval.</p> |
| <code>robust-value <2-255></code> | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss. |

| Variable | Value |
|--|--|
| <code>router-alert</code> | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.

Important:
To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |
| <code>snoop-querier</code> | Enables the IGMP Layer 2 Querier feature on the VLAN. The default is disabled. |
| <code>snoop-querier-addr {A.B.C.D}</code> | Specifies the IGMP Layer 2 Querier source IP address. |
| <code>snooping</code> | Activates the snoop option for the VLAN. |
| <code>ssm-snoop</code> | Activates support for PIM-SSM on the snoop interface. |
| <code>static-group {A.B.C.D} {A.B.C.D} {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static blocked]</code> | Configures IGMP static members to add members to a snoop group.
<code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry.
<code>[static blocked]</code> configures the route to static or blocked. |
| <code>stream-limit stream-limit-max-streams <0-65535></code> | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4. |
| <code>stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams <0-65535></code> | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4. |
| <code>version <1-3></code> | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2). |

Configuring IGMP ports

Configure IGMP for each interface to change default multicasting operations.

Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

For more information on DvR, see .

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IGMP v2-v3 compatibility mode:

```
ip igmp compatibility-mode
```

3. Configure the system to downgrade the version of IGMP:

```
ip igmp dynamic-downgrade-version
```

4. Configure message intervals and response times:

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]
[query-max-response <0-255>]
```

5. Configure expected packet loss and IGMP version:

```
ip igmp robust-value <2-255> [version <1-3>]
```

6. Configure IGMP for a specific port:

```
ip igmp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. Enable router alert:

```
ip igmp router-alert
```

Example

Configure message intervals and response times:

```
Switch(config-if)#ip igmp last-member-query-interval 30 query-interval 60 query-max-response 90
```

Configure expected packet loss and IGMP version:

```
Switch(config-if)#ip igmp robust-value 2 version 3
```

Configure IGMP for a specific port:

```
Switch(config-if)#ip igmp port 1/4
```

Enable router alert:

```
Switch(config-if)#ip igmp router-alert
```

Variable definitions

Use the definitions in the following table to use the **ip igmp** command.

| Variable | Value |
|--|--|
| <i>access-list WORD<1-64>
{A.B.C.D/X} <eny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both></i> | Specifies the name of the access list from 1–64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic |
| <i>compatibility-mode</i> | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
default ip igmp compatibility-mode
, or use the no option to disable compatibility mode:
no ip igmp compatibility-mode |
| <i>dynamic-downgrade-version</i> | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
default ip igmp dynamic-downgrade-version
or use the no option to disable downgrade:
no ip igmp dynamic-downgrade-version |
| <i>igmpv3-explicit-host-tracking</i> | Enables explicit host tracking on IGMPv3. The default state is disabled. |
| <i>immediate-leave</i> | Enables fast leave on a port. |

| Variable | Value |
|---|--|
| <code>last-member-query-interval</code>
<0-255> | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.
Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3-10 (equal to 0.3 - 1.0 seconds). |
| <code>port {slot/port[/sub-port]</code>
<code>[-slot/port[/sub-port]]</code>
<code>[,...]}</code> | Configures IGMP for a specific port.
Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>query-interval</code> <1-65535> | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds. |
| <code>query-max-response</code> <0-255> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).

Important:
You must configure this value lower than the query-interval. |
| <code>robust-value</code> <2-255> | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss. |
| <code>router-alert</code> | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.

Important:
To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |
| <code>stream-limit stream-limit-max-streams</code> <0-65535> | Configures multicast stream limitation on a port to limit the number of concurrent multicast streams on the port. The default is 4. |
| <code>version</code> <1-3> | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2). |

Configuring IGMP on a VRF

You configure IGMP on a VRF instance the same way you configure IGMP for the Global Router, except that you must use VRF Router Configuration mode.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Enable SSM dynamic learning:

```
ip igmp ssm dynamic-learning
```

3. Configure the range group:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The following message appears..

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter y to continue.

4. Enable the SSM map table for all static entries:

```
ip igmp ssm-map all
```

5. Create a static entry for a specific group:

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

6. Enable the generation of IGMP traps:

```
ip igmp generate-trap
```

7. Enable the generation of IGMP log messages:

```
ip igmp generate-log
```

8. Configure the fast leave mode:

```
ip igmp immediate-leave-mode {multiple-user|one-user}
```

Example

For the VRF Red context, configure a new IP multicast group address and create an SSM map table entry for the multicast group and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ip igmp ssm group-range 232.1.1.10/32
```

```
WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(router-vrf)#ip igmp ssm-map 232.1.1.10 192.32.99.151
Switch:1(router-vrf)#ip igmp ssm-map all
```

Variable definitions

Use the definitions in the following table to use the `ip igmp` command on a VRF.

| Variable | Value |
|--|---|
| <code>generate-log</code> | Enables the generation of IGMP log messages. The default is disabled. |
| <code>generate-trap</code> | Enables the generation of IGMP traps. The default is disabled. |
| <code>immediate-leave-mode {multiple-user one-user}</code> | <ul style="list-style-type: none"> multiple-user: Removes (from the group) the IGMP member who sent the leave message. The default is multiple-user. one-user: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. |
| <code>ssm dynamic-learning</code> | Enables dynamic learning from IGMPv3 reports. The default is enabled. |
| <code>ssm group-range {A.B.C.D/X}</code> | Changes the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |
| <code>ssm-map <all {A.B.C.D} {A.B.C.D} enable</code> | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group. Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

IP multicast basic configuration using EDM

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts use a host membership protocol to subscribe to multicast services. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast-Sparse Mode (PIM-SM) and Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

Configuring multicast on the switch

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

Before You Begin

SPBM must not be enabled on the *vIST* peers or any router participating in the PIM network.

Procedure

1. In the navigation pane, expand the **Configuration > Edit > Chassis** folders.
2. Click the **Boot Config** tab.
3. Clear the **EnableSpbmConfigMode** to disable the boot flag.

The system responds with these messages:

Warning: Please save the configuration and reboot the switch for this to take effect.

Warning: Please carefully save your configuration file before rebooting the switch. Saving configuration file when `spbm-config-mode` is changed to `disable`, removes SPBM configurations from the configuration file.

4. Click **Apply**.
5. Save the configuration, and then reboot the switch.

Important

Any change to the **EnableSpbmConfigMode** boot flag requires a reboot for the change to take effect.

6. Configure the *SMLT* MLT:
 - a. Expand the following folders: **Configuration > VLAN > MLT/LACP**.
 - b. Click the **MultiLink/LACP Trunks** tab.
 - c. Click **Insert**.
 - d. In the **Id** box, type the ID number of the MLT.
 - e. In the **PortMembers** box, click the (...) button.
 - f. In the **Port Editor: PortMembers** dialog box, select the desired ports.
 - g. Click **Ok**
 - h. Click **Insert**.

The switch adds the *SMLT* MLT to the MultiLink/LACP Trunks tab in the `MLT_LACP` box.

7. Configure the *vIST* MLT:
 - a. Repeat steps 6a to 6g to configure the MLT.
 - b. Click **MltVistEnable** to enable Simplified *vIST*.

Note

The **MltVistEnable** field enables Simplified *vIST* and is only available when the **EnableSpbmConfigMode** boot flag is disabled.

- c. Click **Insert**.
8. Create the *vIST* VLAN:
 - a. Expand the following folders: **Configuration > VLAN > VLANs**
 - b. In the **Basic** tab, click **Insert**.

- c. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
 - d. In the **MstpInstance** box, click the down arrow, and then choose an MSTI instance from the list.
 - e. In the **Type** box, select **byPort**.
 - f. Click **OK**.
 - g. Click **Insert**.
 - h. Select the vIST VLAN from the list of VLANs, and then click **IP**.
 - i. Click **Insert**.
 - j. Configure the IP address for the vIST VLAN.
9. Repeat Step 8 to create an *SMLT* VLAN and assign the SMLT MLT ID to it. Do not use the vIST MLT ID.
 10. Configure PIM or IGMP Snooping on the *SMLT* VLAN:
 - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
 - b. To enable IGMP Snooping, select the SMLT VLAN from the list of VLANs and click **IP > IGMP**. Select **SnoopEnable** and click **Apply**.
 11. Configure PIM on the *SMLT* VLAN:
 - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
 12. Click **IP > PIM > Globals** to enable PIM globally.
 13. Select the **Enable** check box, and then click **Apply**.

Enabling PIM-SM globally

Enable PIM-SM to offer multicasting services. After you enable PIM-SM globally and on a particular interface, the IGMP parameters take effect.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Click **sm** (sparse mode).
5. Select the **Enable** check box.
6. Click **Apply**.

Globals field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name | Description |
|--------------------------|--|
| Mode | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast). |
| Enable | Enables or disables PIM. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1-18724 and the default is 60 seconds. |

| Name | Description |
|---------------------------|--|
| RegisterSuppTimer | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 6–65535 and the default is 60 seconds. |
| UniRouteChgTimeOut | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds.

Important:
If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| DiscardDataTimeOut | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds. |
| CRPADVTimeOut | Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR). The range is from 5–26214 and the default is 60 seconds. |
| BootStrapPeriod | Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages. The range is from 5–32757 and the default is 60 seconds. |
| StaticRP | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism. |
| FwdCacheTimeOut | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes. |
| FastJoinPrune | Enables or disables the PIM fast join prune feature. |

Enabling IPv6 PIM-SM globally

Enable IPv6 PIM-SM to offer multicasting services. After you enable IPv6 PIM-SM globally and on a particular interface, the MLD parameters take effect.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select the **Enable** check box.
5. Click **sm** (sparse mode).
6. Click **Apply**.

Globals field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name | Description |
|---------------------------|--|
| Enable | Enables or disables PIM. |
| Mode | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast). |
| RegisterSuppTimer | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 10–65535 and the default is 60 seconds. |
| UniRouteChgTimeOut | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds.

Important:
If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| DiscardDataTimeOut | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds. |
| StaticRP | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism. |
| FwdCacheTimeOut | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1–18724 and the default is 60 seconds. |

Enabling PIM on a port

Enable PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you enable it on an interface.
- The interface uses a valid IP address.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.

3. Click **IP**.
4. Click the **PIM** tab.
5. Select the **Enable** check box.
6. Click **Apply**.

PIM field descriptions

Use the data in the following table to use the **PIM** tab.

| Name | Description |
|--------------------------|--|
| Enable | Enables (true) or disables (false) PIM for the specified port. |
| Mode | Displays the mode currently running on the routing switch. |
| IntfType | Indicates the interface type as active or passive. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds. |
| CBSRPreference | Configures the preference for this local interface to become a candidate BSR (C-BSR). The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

Enabling IPv6 PIM on a port

Enable IPv6 PIM for each interface to enable the interface to perform multicasting operations.

About This Task

You can also right-click the port and use the **Edit IPv6** shortcut menu to reach this same tab.

Before You Begin

- You must enable IPv6 interface before you enable PIM on a port.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IPv6**.
4. Click the **PIM** tab.
5. Select **Enable**.
6. Click **Apply**.

PIM field descriptions

Use the data in the following table to use the **PIM** tab.

| Name | Description |
|--------------------------|--|
| Address | Specifies the IPv6 address of the PIM interface. |
| NetMask | Specifies the network mask for the IPv6 address of the PIM interface. |
| Enable | Enables (true) or disables (false) PIM for the specified port. |
| Mode | Displays the mode currently running on the routing switch. |
| DR | Specifies the designated router on this PIM interface. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds. |
| OperState | Specifies the current operational state of this PIM interface. |
| Type | Specifies the type of interface. |

Enabling SSM globally

Enable Source Specific Multicast (SSM) to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

Before You Begin

- Configure a unicast protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using EDM](#) on page 2676. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2424.
- Enable PIM globally.

Important

After you enable PIM in SSM mode, the IGMP parameters take effect. To take full advantage of SSM, enable IGMPv3 if hosts that attach to the switch run IGMPv3 or configure the SSM table.

About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Click **ssm** (source specific multicast).
5. Select the **Enable** check box.
6. Click **Apply**.

The following message appears:

```
Are you sure you want to change the PIM mode? The traffic will not be
stopped immediately. All Static Source Group entries in the SSM range
will be deleted. Do you wish to continue?
```

7. Click **Yes**.

Enabling IPv6 SSM globally

Enable Source Specific Multicast (SSM) to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the IPv6 PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using EDM](#) on page 2686. For more information about OSPFv3, [OSPFv3 Configuration using EDM](#) on page 2453.

- Enable PIM globally.

Important

After you enable IPv6 PIM in SSM mode, the MLD parameters take effect. To take full advantage of SSM, enable MLDv2 if hosts that attach to the switch run MLDv2.

About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select the **Enable** check box.
5. Click **ssm** (source specific multicast).

- Click **Apply**.

The following message appears:

```
Warning: RP entries in the SSM range will be deleted
```

```
Do you wish to continue? (y/n)?
```

- Click **Yes**.

Enabling PIM on a VLAN interface

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you enable it on an interface.

Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Basic** tab.
- Select the VLAN ID that you want to configure with PIM.
- Click **IP**.
- Click the **PIM** tab.
- Select the **Enable** check box.
- Click **Apply**.

PIM field descriptions

Use the descriptions in the following table to use the **PIM** tab.

| Name | Description |
|--------------------------|--|
| Enable | Enables (true) or disables (false) PIM. |
| Mode | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field. |
| IntfType | Specifies the type of interface: active or passive. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724. |
| CBSRPreference | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

Enabling IPv6 PIM on a VLAN interface

Configure IPv6 PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable IPv6 PIM globally before you enable it on an interface.

Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Basic** tab.
- Select the VLAN ID that you want to configure with PIM.
- Click **IPv6**.
- Click the **PIM** tab.
- Select the **Enable** check box.
- Click **Apply**.

PIM field descriptions

Use the descriptions in the following table to use the **PIM** tab.

| Name | Description |
|--------------------------|--|
| IfIndex | Specifies the interface index for PIM. |
| Address | Specifies the IPv6 address of the PIM interface. |
| Netmask | Specifies the network mask for the IPv6 address of the PIM interface. |
| Enable | Enables (true) or disables (false) PIM. |
| Mode | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field. |
| DR | Specifies the designated router on this PIM interface. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724. |
| OperState | Specifies the current operational state of this PIM interface. |
| Type | Specifies the type of interface. |

Configuring IGMP parameters on a port

Configure IGMP for each interface to enable the interface to perform multicasting operations.

Procedure

- On the Device Physical View tab, select a port.
- In the navigation pane, expand the following folders: **Configuration > Edit > Port**.

3. Click **IP**.
4. Click the **IGMP** tab.
5. Edit the appropriate values.

**Note**

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

For information on DvR, see .

**Note**

To use the fast leave feature on IGMP, enable explicit-host-tracking.

6. Click **Apply**.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name | Description |
|-----------------------------|---|
| QueryInterval | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The range is from 1-65535 and the default is 125. |
| QueryMaxResponseTime | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0-255 and the default is 100 tenths of a second (equal to 10 seconds).

Important:
You must configure this value lower than the QueryInterval. |
| Robustness | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2-255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |

| Name | Description |
|---------------------------------|--|
| LastMembQueryIntvl | Configures the maximum response time (in 1/10 seconds) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, Use values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| SnoopEnable | Enables snoop on the interface. The default is disabled. |
| SsmSnoopEnable | Enables SSM snoop. The default is disabled. |
| ProxySnoopEnable | Enables proxy snoop on the interface. The default is disabled. |
| Version | Configures the version of IGMP (1, 2 or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. |
| FastLeaveEnable | Enables fast leave on the interface. |
| StreamLimitEnable | Enables or disables stream limitation on this port. |
| Maximum Number Of Stream | Configures the maximum number of streams this port permits. The range is from 0–65535 and the default is 4. |
| Current Number Of Stream | Displays the current number of streams. This variable is a read-only value. |
| FastLeavePortMembers | Lists ports that are enabled for fast leave. |
| SnoopMRouterPorts | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.

Important:
Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| RouterAlertEnable | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.
To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |

| Name | Description |
|-----------------------------------|--|
| DynamicDowngradeEnable | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network. |
| CompatibilityModeEnable | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2. |
| ExplicitHostTrackingEnable | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3. |

Configuring IGMP parameters on a VLAN

Configure IGMP for each interface to enable the interface to perform multicasting operations.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Select **IGMP**.
7. Configure the relevant variables.

Note

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

Configuration of IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

8. Click **Apply**.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name | Description |
|---------------------------------|--|
| QueryInterval | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1–65535 and the default is 125. |
| QueryMaxResponseTime | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1.
Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds.)

Important:
You must configure this value lower than the QueryInterval. |
| Robustness | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |
| LastMembQueryIntvl | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.
Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |
| SnoopEnable | Enables snoop on the interface. The default is disabled. |
| SsmSnoopEnable | Enables SSM snoop. The default is disabled. |
| ProxySnoopEnable | Enables proxy snoop on the interface. The default is disabled. |
| Version | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. |
| FastLeaveEnable | Enables or disables fast leave on the interface. |
| StreamLimitEnable | Enables or disables stream limitation on this VLAN. |
| Maximum Number Of Stream | Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4. |
| Current Number Of Stream | Displays the current number of streams. This value is a read-only value. |
| FastLeavePortMembers | Lists ports that are enabled for fast leave. |

| Name | Description |
|-----------------------------------|--|
| SnoopMRouterPorts | <p>Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.</p> <p>Important:
Configure this field only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.</p> |
| RouterAlertEnable | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p>To maximize network performance, configure this parameter according to the version of IGMP currently in use:</p> <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |

If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.</p> |
| CompatibilityModeEnable | <p>Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.</p> |
| ExplicitHostTrackingEnable | <p>Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.</p> |
| SnoopQuerierEnable | <p>Enables snoop querier. The default is disabled.</p> <p>When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.</p> <p>Enable Layer 2 Querier on only one node in the VLAN.</p> |
| SnoopQuerierAddr | <p>Specifies the pseudo IP address of the IGMP snoop querier. The default IP address is 0.0.0.0.</p> |

Multicast Listener Discovery

Table 151: Multicast Listener Discovery product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Multicast Listener Discovery (MLD) | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VOSS 5.1 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 5.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VOSS 5.1 |
| | VSP 8400 Series | VOSS 5.1 |
| | VSP 8600 Series | Not Supported |
| | XA1400 Series | Not Supported |

MLD Fundamentals

MLD is an asymmetric protocol. It specifies separate behaviors for multicast address listeners (that is, hosts or routers that listen to multicast packets) and multicast routers. Each multicast router learns, for each directly attached link, which multicast addresses and which sources have listeners on that link. The information that MLD gathers is provided to the multicast routing protocols that the router uses. This information ensures that multicast packets arrive at all links where listeners require such packets.

A multicast router can itself be a listener of one or more multicast addresses; that is, the router performs both the multicast router role and the multicast address listener part of the protocol. The router collects the multicast listener information needed by the multicast routing protocol and informs itself and other neighboring multicast routers of the listening state.

IPv6 routers use MLD to discover:

- The presence of multicast listeners on directly attached links
- Multicast addresses required by neighboring nodes

MLD versions

The purpose of the MLD protocol in the IPv6 multicast architecture is to allow an IPv6 router to discover the presence of multicast listeners on directly-attached links and to discover which multicast addresses are of interest to neighboring nodes. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4. The MLD implementation described in this document is based on the MLDv2 standard, which is a backward-compatible update to the MLDv1 standard.

There are three versions of IGMP, and two versions of MLD. IGMPv2 is equivalent in function to MLDv1 and IGMPv3 is equivalent to MLDv2.

MLD Querier

MLD Querier is similar to IGMP querier. A multicast query router communicates with hosts on a local network by sending MLD queries. This router periodically sends a general query message to each local network of the router. This is standard multicast behavior.

Note

Queries are sent only if PIM is enabled globally and on the interface. PIM and snooping cannot be enabled at the same time.

Each VLAN using MLD multicast must have a router performing multicast queries. Networks with no stand-alone devices currently have no capability for implementing the pruning of multicast traffic. A dedicated querier must be available on the network.

There are several behavioral differences between a traditional query router and a switch or stack using the MLD Querier functionality. The following are the differences:

- There is no election process. When a switch or stack restarts, queries are sent as part of MLD startup. This process stops other devices from sending queries while they detect the new device starting up. The last active device sending queries on the network is the active one. This is not the case with Layer 3 MLD behavior.
- If the current active device stops sending queries, a timeout period must elapse before another device takes over. This can result in an ageout of groups, and subsequent flooding, before a new query is sent and the pruning process restarts. This occurs only during the transition between active query devices. Once the new device is established, queries are sent as configured in the Query Interval and Robust Values fields.
- Multiple active query devices are not supported. Enabling multiple devices establishes one active device and other devices listening to take over should the active device fail.

The querier version is determined by the received query version and establishes the interface operational version. By default, the interface operational version is MLDv1. If the interface operational version is downgraded from MLDv2 to MLDv1 (when operational version is MLDv2 and a MLDv1 query is received), then all MLDv2 listeners (registered by MLDv2 reports) are removed and all incoming MLDv2 reports are dropped.

MLD snooping

MLD snooping is an IPv6 multicast constraining mechanism running on Layer 2 devices. When MLD snooping is enabled on a VLAN, the switch examines the MLD messages between hosts and multicast routers and learns which hosts are interested in receiving traffic for a multicast group. Based on the learning, the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

The following figure shows an example of this scenario. On the left side of the figure, IPv6 multicast packets are transmitted when MLD snooping is not enabled. All the hosts that are interested and not interested receive the IP Multicast traffic consuming bandwidth. Whereas, on the right side of the figure, when MLD snooping is enabled and IPv6 multicast packets are transmitted, only the interested hosts receive the IP multicast packets.

Figure 144: IPv6 multicast packet transmission when MLD snooping is enabled and not enabled

The following figure shows IPv6 multicast packets transmitted when MLD v2 snooping is enabled and not enabled.

Figure 145: IPv6 multicast packet transmission when MLD v2 snooping is enabled and not enabled

MLD snooping configuration guidelines and restrictions

You can perform the following configurations to manage and control IPv6 multicast groups using the MLD snooping feature:

- Enable or disable MLD snooping on each VLAN. MLD snooping can be enabled on a maximum of 512 VLANs.
- Enable IGMP snooping and MLD snooping on the same VLAN.

Limitations

Following are the limitations for MLD snooping configuration:

- The maximum (S,G,V) entries supported in the IPv6 multicast routing table (L3_ENTRY_IPV6_MULTICAST) is 512.

MLD snooping shares the (S,G,V) entries with IGMP snooping, where the (S,G,V) entries number = (G,V) MLD_V1 type entries number + (S,G,V) MLD_V2 type entries number + (*,G,V) MLD_V2 type entries number + number of groups without (*,G,V) registered listeners.

- IPv6 MLD proxy functionality is not supported.

- Multicast Flood Control (MFC) is not supported.
- Static mrouter ports cannot be configured.
- IPv6 MLD send query functionality is not supported.
- Configure static router ports is not supported.

MLD configuration using the CLI

This chapter describes the procedures you can use to configure and display Multicast Listener Discovery (MLD) parameters using the CLI.

Configuring MLD trap generation

About This Task

Use this procedure to enable MLD traps.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable MLD trap generation:
`ipv6 mld generate-trap`
3. Disable MLD trap generation:
`no ipv6 mld generate-trap`
4. Set MLD trap enable status to default:
`default ipv6 mld generate-trap`

Configuring MLD log status

About This Task

Use this procedure to enable MLD traps.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable MLD log status:
`ipv6 mld generate-log`
3. Disable MLD log status:
`no ipv6 mld generate-log`
4. Set MLD log enable status to default:
`default ipv6 mld generate-log`

*Configuring MLD version***About This Task**

Use this procedure to configure MLD version.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MLD version:

```
ipv6 mld version <1-2>
```

**Note**

For MLD to function correctly, the MLD version must be the same on all routers in the network.

3. Set MLD version to default:

```
default ipv6 mld version
```

Variable definitions

The following table describes the variables for the `ipv6 mld version` command.

| Variable | Description |
|----------|---|
| <1-2> | Indicates the version of MLD that runs on this interface. |

*Configuring the MLD last listener query interval***About This Task**

Use this procedure to configure the last listener query interval in seconds for the MLD interface.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the last listener query interval:

```
ipv6 mld last-listener-query-interval <0-60>
```

3. Set the last listener query interval to its default value:

```
default ipv6 mld last-listener-query-interval
```

Variable definitions

The following table describes the variables for the `ipv6 mld last-listener-query-interval` command.

| Variable | Description |
|----------|--|
| <0-60> | Indicates the last listener query interval in seconds. |

*Configuring the MLD query interval***About This Task**

Use this procedure to configure the query interval for the MLD interface.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query interval for the MLD interface:

```
ipv6 mld query-interval <1-65535>
```

3. Set the query interval to its default value:

```
default ipv6 mld query-interval
```

Variable definitions

The following table describes the variables for the `ipv6 mld query-interval` command.

| Variable | Description |
|-----------|---|
| <1-65535> | Indicates the frequency at which MLD host query packets transmit on this interface. |

Configuring the MLD query maximum response time

About This Task

Use this procedure to configure the query maximum response time for mld interface.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[, ...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the query maximum response time for mld interface:

```
ipv6 mld query-max-response-time <0-60>
```
3. Set the query maximum response time to its default value:

```
default ipv6 mld query-max-response-time
```

Variable definitions

The following table describes the variables for the `ipv6 mld query-max-response-time` command.

| Variable | Description |
|----------|--|
| <0-60> | Indicates the query maximum response interval time in seconds. |

Configuring the MLD robustness

About This Task

The robustness value allows the tuning for the expected packet loss on a link. If a link expects packet loss, increase the robustness variable value.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the MLD robustness:

```
ipv6 mld robust-value <2-255>
```

3. Set the MLD robustness to its default value:

```
default ipv6 mld robust-value
```

Variable definitions

The following table describes the variables for the `ipv6 mld robust-value` command.

| Variable | Description |
|----------|--|
| <2-255> | Specifies a numerical value for MLD snooping robustness. |

*Enabling MLD snooping on a VLAN***About This Task**

Use this procedure to enable MLD snooping on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable MLD snooping:

```
ipv6 mld snooping
```

3. Set the MLD snooping to its default value:

```
default ipv6 mld snooping
```

*Enabling MLD ssm-snooping on a VLAN***About This Task**

Use this procedure to enable IPv6 MLD ssm-snooping on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable MLD snooping:

```
ipv6 mld ssm-snoop
```
3. Set the MLD snooping to its default value:

```
default ipv6 mld ssm-snoop
```

Displaying MLD snooping configuration status

About This Task

Use this procedure to display information about the MLD snooping configuration for the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display the switch MLD snooping configuration status:

```
show ipv6 mld snooping
```

Example

```
Switch:1#show ipv6 mld snooping
=====
Mld Snooping - GlobalRouter
=====
IFINDEX SNOOP      SSM      ACTIVE      MROUTER
         ENABLE    SNOOP    MROUTER    EXPIRATION
         ENABLE    ENABLE   PORTS      TIME
-----
V666      False   False   NONE      0
1 out of 1 entries displayed
```

Job Aid

The following table describes the column headings in the command output for `show ipv6 mld snooping`.

| Variable | Description |
|------------------|---|
| IFINDEX | Identifies the index of the physical interface. |
| SNOOP ENABLE | Identifies whether snoop is enabled (true) or disabled (false). |
| SSM SNOOP ENABLE | Identifies whether SSM snoop is enabled (true) or disabled (false). |

| Variable | Description |
|-------------------------|--|
| ACTIVE MROUTER PORTS | Displays all dynamic (querier port) and static mrouter ports that are active on the interface. |
| MROUTER EXPIRATION TIME | Specifies the time remaining before the multicast router is aged out on this interface. If the switch does not receive queries before this time expires, it flushes out all group memberships known to the VLAN. The Query Max Response Interval (obtained from the queries received) is used as the timer resolution. |

Displaying MLD snooping tracing information

About This Task

Use this procedure to display MLD snooping tracing information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the MLD snooping tracing information:
show ipv6 mld snoop-trace

Example

```
Switch:1#show ipv6 mld snoop-trace
=====
Mld Snoop Trace - GlobalRouter
=====

5051:0:0:0:0:1:84:51
```

Job Aid

The following table describes the column headings in the command output for `show ipv6 mld snoop-trace`.

| Variable | Description |
|----------------|---|
| GROUP ADDRESS | Specifies the IP multicast address of the group traversing the router |
| SOURCE ADDRESS | Specifies the IP source address of the multicast group address. |
| IN VLAN | Specifies the ingress VLAN ID for the multicast source. |
| IN PORT | Specifies the ingress port for the multicast group. |

| Variable | Description |
|----------|---|
| OUT VLAN | Specifies the egress VLAN ID for the multicast group. |
| OUT PORT | Specifies the egress port of the multicast group. |
| TYPE | Specifies the port type on which the snoop entry is learnt. |

Displaying MLD interface information

About This Task

Use this procedure to display MLD snooping interface parameters.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display MLD interface information:
show ipv6 mld interface [gigabitethernet {slot/port[/sub-port]}] [vlan <1-4059>]

Example

```
Switch:1#show ipv6 mld interface
=====
Mld Interface - GlobalRouter

1 out of 1 entries displayed
```

Variable definitions

The following table describes the variables for the `show ipv6 mld interface` command.

| Variable | Description |
|---|---|
| <code>vlan <1-4059></code> | Displays MLD snooping information for the configured VLANs. |
| <code>gigabitEthernet {slot/port[/sub-port]}</code> | Displays MLD snooping information on a specific interface. |

Job Aid

The following table describes the column headings in the command output for `show ipv6 mld interface`.

| Variable | Description |
|--------------------------|--|
| VLAN ID | Indicates the VLAN ID of the physical interface. |
| PORT NUM | Indicates the port number of the physical interface. |
| QUERY INTVL | Indicates the query interval, the frequency at which IPv6 MLD snooping host-query packets are transmitted on this interface. |
| QUERY MAX RESP | Indicates the maximum query response time advertised in IPv6 MLD snooping queries on this interface. |
| ROBUST | Indicates the robustness value. |
| VERSION | Indicates the version. |
| LAST LIST QUERY | Indicates the last listener query interval. The last listener query interval is the maximum response delay inserted into group-specific queries sent in response to leave group messages, and it is also the amount of time between group-specific query messages. |
| SNOOP ENABLE | Indicates if snooping is enabled. |
| SSM SNOOP ENABLE | Indicates if ssm-snooping is enabled. |
| DYNAMIC DOWNGRADE ENABLE | Enables dynamic downgrade of the MLD version when older version query message is received. |

Displaying MLD system parameters

About This Task

Use this procedure to display information about the MLD traps and logs.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the system parameters:
show ipv6 mld sys

Example

```
Switch:1#show ipv6 mld sys
=====
Mld System Parameters - GlobalRouter
=====
generate-trap : disable
generate-log : disable
```

*Displaying MLD cache information***About This Task**

Use this procedure to display the learned multicast groups in the cache.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the learned multicast groups in the cache:
show ipv6 mld cache

Example

```
Switch:1#show ipv6 mld cache
=====
MLD Cache Information
=====
GRPADDRESS/LASTREPORTER          INTERFACE  EXPIRATION

Job Aid

The following table describes the column headings in the command output for `show ipv6 mld cache`.

| Variable | Description |
|--------------|--|
| GRPADDR | Indicates the IPv6 address of the multicast address of interest. |
| LASTREPORTER | Indicates the IPv6 address of the last reporter. |
| INTERFACE | Indicates the ingress interface for MLDv2. |

*Displaying the MLD group information***About This Task**

Use this procedure to display the MLD group information to show the learned multicast groups and the attached ports.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the MLD group information:
show ipv6 mld group [count] [group] [member-subnet]

Example

```
Switch:1#show ipv6 mld group
=====
Mld Group - GlobalRouter
=====
GRPADDR/MEMBER                               INPORT           EXPIRATION

```

Job Aid

The following table describes the column headings in the command output for `show ipv6 mld group`.

| Variable | Description |
|----------|---|
| GRPADDR | Specifies the multicast group address that others want to join to. A group address can be the same for many incoming ports. |

| Variable | Description |
|------------|--|
| MEMBER | Specifies the IP address of a source that has sent group report wishing to join this group. |
| INPORT | Identifies a physical interface or a logical interface which has received group reports from various sources. |
| EXPIRATION | Specifies the time left before group report expires on this port. This is updated upon receiving a group report. |

View IPv6 MLD Host Cache

View the learned multicast group addresses in the host cache.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv6 MLD host cache:

```
show ipv6 mld-host-cache
```
3. View IPv6 MLD host cache for a management interface:

```
show ipv6 mld-host-cache mgmtEthernet [mgmt]
```

Note

This step only applies to VSP 8600 Series.

Example

```
Switch:1#show ipv6 mld-host-cache
=====
                        MLD Cache Information
=====
PORT/VID  GRADDRESS                SELF
-----
mgmt      ff02::1:ff00:3           enabled
mgmt      ff02::1:ff4c:9400       enabled
mgmt      ff02::1                   enabled
```

Job aid

The following table describes the fields in the output for the **show ipv6 mld-host-cache** command.

| Parameter | Description |
|------------------|---|
| <i>GRADDRESS</i> | Shows the IP address of the multicast group. When combined with the group mask, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <i>SELF</i> | Indicates whether or not the group is locally registered into MLD Host Cache. <ul style="list-style-type: none"> • enabled — group is locally registered into MLD Host Cache • disabled — group is not locally registered into MLD Host Cache |
| <i>PORT/VID</i> | Shows the port or VLAN that learns the multicast group. |

MLD configuration using EDM

This chapter describes the procedures you can use to configure and display Multicast Listener Discovery (MLD) snooping parameters using Enterprise Device Manager (EDM).

Configuring MLD globally

About This Task

Use the following procedure to configure MLD parameters for the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Globals** tab.
4. Configure the MLD global parameters as required.
5. On the toolbar, click **Apply** to save the changes.
6. On the toolbar, click **Refresh** to update the changes.

Globals field description

Use the data in the following table to use the **Globals** tab.

| Field | Description |
|--------------|--------------------------------|
| GenerateTrap | Enables MLD to generate traps. |
| GenerateLog | Enables MLD to generate logs. |

Viewing the MLD SSM global information

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Ssm Globals** tab.

Ssm Globals field description

Use the data in the following table to use the **Ssm Globals** tab.

| Field | Description |
|------------|-------------------------------|
| RangeGroup | Specifies the ssm range. |
| RangeMask | Specifies the ssm range mask. |

MLD interface configuration

Configure the interfaces so that the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

Configuring an MLD interface

Perform this procedure to change the configuration of existing MLD interfaces.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Interfaces** tab.
4. On the toolbar, click **Insert**.
5. Configure the MLD interface parameters.
6. Click **Insert**.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

MLD interfaces field description

Use the data in the following table to use the **Interfaces** tab.

| Field | Description |
|-----------------------|---|
| IfIndex | Specifies the internetwork layer interface value of the interface for which MLD is enabled. |
| QueryInterval | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version | Indicates the MLD version. |
| Querier | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached. |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60. |
| Joins | Specifies the number of times a group membership has been added on this interface. |
| Groups | Specifies the current number of entries for this interface in the cache table. |
| Robustness | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255. |
| LastListenQueryIntvl | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60.
This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable | Indicates if snooping is enabled. |

| Field | Description |
|------------------------|--|
| FlushAction | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> flushGrpMember flushMrouter flushSender |
| SsmEnable | Indicates if ssm is enabled. |
| NewQuerier | Specifies the IPv6 address of the new MLD querier. |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received. |
| OperVersion | Specifies the operational version of the MLD running on this interface. |
| McastMode | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> snoop pim snoopSpb routerSpb dvmrp none |

Configuring MLD on a port

Configure the MLD on a port.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IPv6**.
4. Click the **MLD** tab.
5. Configure the MLD interface parameters.
6. On the toolbar, click **Apply** to save the changes.
7. On the toolbar, click **Refresh** to update the changes.

MLD field description

Use the data in the following table to use the **MLD** tab.

| Field | Description |
|---------------|--|
| QueryInterval | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version | Indicates the MLD version. |
| Querier | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached. |

| Field | Description |
|------------------------|---|
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60. |
| Joins | Specifies the number of times a group membership has been added on this interface. |
| Groups | Specifies the current number of entries for this interface in the cache table. |
| Robustness | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255. |
| LastListenQueryIntvl | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60.
This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable | Indicates if snooping is enabled. |
| FlushAction | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> flushGrpMember flushMrouter flushSender |
| SsmEnable | Indicates if ssm is enabled. |
| NewQuerier | Specifies the IPv6 address of the new MLD querier. |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received. |
| OperVersion | Specifies the operational version of the MLD running on this interface. |
| McastMode | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> snoop pim snoopSpb routerSpb dvmrp none |

Configuring MLD on a VLAN

About This Task

Configure MLD on a VLAN.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Select a VLAN from the list.
4. Click the **IPv6** tab.
5. Click the **MLD** tab.
6. Configure the MLD interface parameters.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

MLD field description

Use the data in the following table to use the **MLD** tab.

| Field | Description |
|-----------------------|---|
| QueryInterval | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version | Indicates the MLD version. |
| Querier | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached. |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60. |
| Joins | Specifies the number of times a group membership has been added on this interface. |
| Groups | Specifies the current number of entries for this interface in the cache table. |
| Robustness | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255. |
| LastListenQueryIntvl | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60.
This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable | Indicates if snooping is enabled. |

| Field | Description |
|------------------------|--|
| FlushAction | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> flushGrpMember flushMrouter flushSender |
| SsmEnable | Indicates if ssm is enabled. |
| NewQuerier | Specifies the IPv6 address of the new MLD querier. |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received. |
| OperVersion | Specifies the operational version of the MLD running on this interface. |
| McastMode | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> snoop pim snoopSpb routerSpb dvmrp none |

Configuring MLD snooping

About This Task

Use the following procedure to enable MLD snooping on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click **Snooping** tab.
4. Select a value, double-click the cell in **SnoopEnable** column, select **True** or **False**.
5. Select a value, double-click the cell in **SsmEnable** column, select **True** or **False**.
6. Click **Apply**.

Snooping field description

Use the data in the following table to use the **Snooping** tab.

| Field | Description |
|-------------|---|
| IfIndex | Specifies the interface on which you enabled MLD snooping. It specifies the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN. |
| SnoopEnable | Indicates the status of MLD snooping on the specified interface: <ul style="list-style-type: none"> • True – MLD snooping is enabled • False – MLD snooping is disabled |
| SsmEnable | Indicates the status of SSM on the specified interface: <ul style="list-style-type: none"> • True – SSM is enabled • False – SSM is disabled |

Viewing the MLD snoop trace information

About This Task

Use this procedure to display information about the multicast groups traversing the snoop enabled router.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Snoop Trace** tab.

Snoop Trace field description

Use the data in the following table to use the **Snoop Trace** tab.

| Field | Description |
|---------|--|
| GrpAddr | Specifies the IP multicast address of the group traversing the router. |
| SrcAddr | Specifies the IP source address of the multicast group address. |
| OutVlan | Specifies the egress VLAN ID for the multicast group. |
| OutPort | Specifies the egress port of the multicast group. |
| InVlan | Specifies the ingress VLAN ID for the multicast source. |
| InPort | Specifies the ingress port for the multicast group. |
| Type | Specifies the port type on which the snoop entry is learnt. |

*Viewing the MLD cache information***About This Task**

Use this procedure to display information about the learned multicast groups in the cache.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Cache** tab.

MLD cache field description

Use the data in the following table to use the **Cache** tab.

| Field | Description |
|--------------|---|
| Address | The IPv6 multicast group address for which this entry contains information. |
| IfIndex | Indicates the internetwork-layer interface for which this entry contains information for an IPv6 multicast group address. |
| LastReporter | Indicates the source IPv6 address of the last membership report received for this IPv6 Multicast group address on this interface. If membership report is not received, the value is 0::0 |
| ExpiryTime | Indicates the minimum amount of time remaining before the entry ages out. |

*Viewing the MLD V2 cache information***About This Task**

Use this procedure to display information about the MLDv2 corresponding to each interface, port and multicast group paired on a router.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **V2 Cache** tab.

V2 Cache field description

Use the data in the following table to use the **V2 Cache** tab.

| Field | Description |
|-------------------|--|
| GroupAddress | Specifies the multicast group address that others want to join. A group address can be the same for many incoming ports. |
| Ifindex | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources. |
| InPort | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources. |
| Version1HostTimer | Specifies the time remaining until the local router assumes that there are no more MLDv1 members on the IP subnet attached to the interface. This is applicable only for MLDv1 hosts. Upon receiving an MLDv1 report, this value is reset to the group membership timer. |
| SourceFilterMode | Specifies the current group state applicable on MLDv2 compatible nodes. |

Viewing IPv6 MLD host cache

View the learned multicast group addresses in the host cache.

Note

Not all hardware platforms include a dedicated, physical management interface. For more information about supported interfaces, see your hardware documentation.

Procedure

1. In the navigation tree, expand the **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Host Cache** tab.

MLD host cache field descriptions

Use the data in the following table to use the **Host Cache** tab.

| Name | Description |
|-----------------------------|---|
| IfIndex | Shows the index value that uniquely identifies the interface to which this entry applies. |
| GrpAddress | Shows the IP address for the multicast group. |
| GrpLocallyRegistered | Shows the Group Locally Registered for an IPv6 MLD host-cache entry. |
| GrpLastReporter | Shows the Group Last Reporter address for an IPv6 MLD host-cache entry. |

| Name | Description |
|----------------------|---|
| GrpUpTime | Shows the Group Uptime for an IPv6 MLD host-cache entry. |
| GrpExpiryTime | Shows the Group Expiry Time for an IPv6 MLD host-cache entry. |
| GrpFilterMode | Shows the Group Filter Mode for an IPv6 MLD host-cache entry. |

Viewing the MLD source information

About This Task

Use this procedure to display information about the MLD source.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Source** tab.

Source field description

Use the data in the following table to use the **Source** tab.

| Field | Description |
|---------------|--|
| GroupAddress | Specifies the IPv6 multicast group address for which this entry contains information. |
| Ifindex | Specifies the interface for which this entry contains information for an IP multicast group address. |
| InPort | Identifies a physical interface or logical interface (VLAN), which has received group reports for this source. |
| HostAddress | Specifies the host address to which this entry corresponds. |
| MemberAddress | Specifies the IPv6 address of a member that has sent source specific report wishing to join this source. |
| Expire | Specifies the state of this entry. |
| Mode | Specifies the current member state. This is applicable to MLDv2 compatible nodes. |
| MemberExpire | Specifies the time until the member for this source expires. |

Viewing the MLD sender information

About This Task

Use this procedure to display information about the multicast senders.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Sender** tab.

Source field description

Use the data in the following table to use the **Sender** tab.

| Field | Description |
|------------|--|
| GrpAddr | Specifies the IPv6 multicast group address. |
| Ifindex | Specifies the interface index of the sender. |
| MemberAddr | Specifies the IPv6 host address. |
| Action | Specifies the MLD action as one of the following: <ul style="list-style-type: none"> • none • flushEntry • flushGrp |
| Port | Specifies the MLD sender port. |

Viewing the MLD group information

About This Task

Use this procedure to display information about the groups configured in this device.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Group** tab.

Group field description

Use the data in the following table to use the **Group** tab.

| Field | Description |
|-------------|---|
| IPv6Address | Specifies the multicast group address that others want to join to. A group address can be the same for many incoming ports. |
| Members | Specifies the IP address of a source that has sent group report wishing to join this group. |
| InPort | Identifies a physical interface or a logical interface which has received group reports from various sources. |

| Field | Description |
|------------|--|
| Expiration | Specifies the time left before group report expires on this port. This is updated upon receiving a group report. |
| IfIndex | Identifies a physical interface or a logical interface which has received group reports from various sources. |

PIM Configuration Using the CLI

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Before You Begin

For an IPv4 PIM configuration using the CLI:

- Configure an IPv4 interface.

For more information, see [IP routing configuration using the CLI](#) on page 1753.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using CLI](#) on page 2661. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2362.

- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- You must first configure and enable PIM on an IP interface, which can be circuitless, before you can utilize that interface as a candidate rendezvous point (RP). To configure PIM-SM RP for an IP interface, see [Configuring a candidate rendezvous point](#) on page 1456.
- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using the CLI:

- Configure an IPv6 interface.

For more information, see [Configure an IPv6 Interface](#) on page 1831.

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 2671. For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2401.

- Enable IPv6 PIM-SM globally
- Enable IPv6 PIM-SM on individual interfaces.

Changing the interface status to passive

Change the PIM interface status to passive to deny PIM control traffic on the interface.

Before You Begin

- The PIM interface is disabled.

About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a passive interface and enable it simultaneously:

```
ip pim passive
```

3. Create a passive interface in the disabled state:

```
ip pim interface-type passive
```

You must manually enable the interface.

4. Enable a disabled interface:

```
ip pim enable
```

Variable definitions

Use the data in the following table to use the **ip pim** command.

| Variable | Value |
|----------------|--|
| <i>active</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the default operator with the command. |
| <i>passive</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the default operator with the command. |

Changing the interface status to active

Change the PIM interface status to active to allow PIM control traffic on the interface.

Before You Begin

- The PIM interface is disabled.

About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an active interface in the disabled state:

```
ip pim interface-type active
```

You must manually enable the interface.

3. Create an active interface and enable it simultaneously:

```
ip pim active
```

OR

```
ip pim enable
```

The second command enables an active interface only if this is the first PIM interface you create on the port or VLAN or you created an active interface in the disabled state. If you already created a passive interface in the disabled state, the second command enables that passive interface.

Variable definitions

Use the data in the following table to use the **ip pim** command.

| Variable | Value |
|----------------|--|
| <i>active</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the default operator with the command. |
| <i>passive</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the default operator with the command. |

Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the PIM virtual neighbor:

```
ip pim virtual-neighbor <A.B.C.D> <A.B.C.D>
```

Example

Configure the PIM virtual neighbor:

```
Switch:1(config)#ip pim virtual-neighbor 192.0.2.0 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the `ip pim virtual-neighbor` command.

| Variable | Value |
|----------------------------------|--|
| <code>{A.B.C.D} {A.B.C.D}</code> | The first IP address indicates the IP address of the selected interface. The second IP address indicates the IP address of the neighbor. |

Configuring a candidate rendezvous point

Configure a candidate rendezvous point (C-RP) to serve as backup to the RP router.

About This Task

You can configure only one interface on the switch for multiple groups. You cannot configure multiple interfaces for multiple groups.

With the mask value, you can configure a C-RP router for several groups in one configuration.

For example, if you use a C-RP configuration with a group address of 224.0.0.0 and a group mask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Add a candidate rendezvous point:

```
ip pim rp-candidate group <A.B.C.D> <A.B.C.D> rp <A.B.C.D>
```
3. Remove a candidate rendezvous point:

```
no ip pim rp-candidate group <A.B.C.D> <A.B.C.D>
```
4. Display information about the candidate rendezvous points for the PIM-SM domain:

```
show ip pim rp-candidate
```

Example

Add a candidate rendezvous point:

```
Switch:1(config)#ip pim rp-candidate group 224.1.1.0 255.255.255.0 rp 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the `ip pim rp-candidate` command.

| Variable | Value |
|--|---|
| <code>group {A.B.C.D}</code>
<code>{A.B.C.D}</code> | Specifies the IP address and the address mask of the multicast group. After the IP address and group mask are combined, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <code>rp {A.B.C.D}</code> | Specifies the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces. |

Job aid

The following table shows the field descriptions for the `show ip pim rp-candidate` command.

Table 152: show ip pim rp-candidate field descriptions

| Field | Description |
|---------|---|
| GRPADDR | Displays the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| GRPMASK | Displays the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| RPADDR | Displays the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces. |

Configuring static RP

Configure a static RP to ignore the bootstrap router (BSR) mechanism and use the statically configured RPs.

Before You Begin

- Enable PIM-SM globally.

About This Task

Static RP-enabled switches use this feature to communicate with switches from other vendors that do not use the BSR.

Important

You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.

All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable static RP:

```
ip pim static-rp
```

The following message appears:

```
WARNING: RP information learnt dynamically through BSR functionality will be lost.
Do you wish to enable Static RP? (y/n) ?
```

3. Enter `y`.

4. Configure a static RP entry:

```
ip pim static-rp {A.B.C.D/X} {A.B.C.D}
```

5. Configure all the switches in the network (including switches from other vendors) to map to the same RP.

6. Display information about the candidate rendezvous points for the PIM-SM domain:

```
show ip pim static-rp
```

Example

Configure a static RP:

```
Switch:1(config)# ip pim static-rp 239.255.0.0/255.255.0.0 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the `ip pim static-rp` command.

| Variable | Value |
|--------------------------|---|
| <code>{A.B.C.D/X}</code> | Specifies the IP address and address mask of the multicast group. When combined, the IP address and address mask identify the range of the multicast addresses that the RP handles. |
| <code>{A.B.C.D}</code> | Specifies the IP address of the static RP. |

Configuring IPv6 PIM static RP

On IPv6 PIM BSR mechanism is not supported so static RP must be configured.

Before You Begin

Enable IPv6 PIM-SM globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable static RP:

```
ipv6 pim static-rp
```
3. Configure an IPv6 static RP entry:

```
ipv6 pim static-rp WORD<0-255> WORD<0-255>
```
4. Configure all the switches in the network (including switches from other vendors) to map to the same RP.
5. Display information about the candidate rendezvous points for the PIM-SM domain:

```
show ipv6 pim static-rp
```

Variable definitions

The following table describes the variables for the `ipv6 pim static-rp` command.

| Variable | Description |
|-------------|---|
| WORD<0-255> | Specifies the IPv6 address and address mask of the multicast group. When combined, the IPv6 address and address mask identify the range of the multicast addresses that the RP handles. |
| WORD<0-255> | Specifies the IPv6 address of the static RP. |

Configuring a candidate BSR on a port

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

Before You Begin

- Static RP is disabled.

About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a candidate BSR:

```
ip pim bsr-candidate preference <0-255>
```

Example

Configure a candidate BSR:

```
Switch:1(config-if)#ip pim bsr-candidate preference 2
```

Variable definitions

Use the definitions in the following table to use the **ip pim bsr-candidate** command.

| Variable | Value |
|---------------------------------------|--|
| <code>preference <0-255></code> | Activates the C-BSR on this interface and configures its preference value, from 0-255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. To set this option to the default value, use the default operator with the command. |

Configuring a candidate BSR on a VLAN

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

Before You Begin

- Static RP is disabled.

About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure a candidate BSR on a VLAN:

```
ip pim bsr-candidate preference <0-255>
```

Example

Configure a candidate BSR on a VLAN:

```
Switch:1(config-if)#ip pim bsr-candidate preference 5
```

Variable definitions

Use the definitions in the following table to use the **ip pim bsr-candidate** command.

| Variable | Value |
|---------------------------------------|--|
| <code>preference <0-255></code> | Activates the C-BSR on this interface and configures its preference value, from 0-255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. To configure this option to the default value, use the default operator with the command. |

Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

About This Task

Important

The following command also activates full-mesh configurations.

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable square-SMLT:

```
multicast smlt-square
```

PIM Configuration Using EDM

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

Before You Begin

For an IPv4 PIM configuration using EDM:

- Configure an IP interface.

For more information, see [IP routing configuration using Enterprise Device Manager](#) on page 1780.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using EDM](#) on page 2676. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2424.

- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- Configure one or more rendezvous points (RP) for the groups that multicast applications use in the network.

Important

If you configure the rendezvous point (RP) to be the address of a circuitless IP (CLIP) interface, then you must first configure and enable PIM on the CLIP interface before you can utilize that interface as a candidate RP. To configure a PIM-SM RP for a circuitless IP interface, see [Configuring a candidate RP](#) on page 1472.

- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using EDM:

- Configure an IPv6 interface. For more information, see [Configure an IPv6 Interface](#) on page 1858.
- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM. For more information about RIPng, see [RIPng Configuration using EDM](#) on page 2686. For more information about OSPFv3, see [OSPFv3 Configuration using EDM](#) on page 2453.
- Enable IPv6 PIM-SM globally.
- Enable IPv6 PIM-SM on individual interfaces.

Enabling static RP

Enable static RP to avoid the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.

The following message appears:

```
RP information learnt dynamically through BSR functionality will be
lost. Do you wish to enable Static RP?
```

8. Click **Yes**.

Enabling IPv6 static RP

Use this procedure to enable IPv6 static RP.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.
8. Click **Yes**.

Configuring a static RP

Configure a static RP to ignore the BSR mechanism and use the statically configured RPs only. A static RP-enabled switch uses this feature to communicate with switches from other vendors that do not use the BSR mechanism.

Before You Begin

- Before you can configure a static RP, you must enable the following:
 - PIM-SM
 - static RP

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.

2. Click **PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

Static RP field descriptions

Use the descriptions in the following table to use the **Static RP** tab.

| Name | Description |
|---------------------|---|
| GroupAddress | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles. |
| GroupMask | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| Address | Configures the IP address of the static RP. |
| Status | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP and is invalid otherwise. |

Job aid

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

Configuring an IPv6 static RP entry

Configure an IPv6 static RP to use the statically configured RPs. A static RP-enabled switch uses this feature to elect the active RP only from the statistically configured switches, without any relation to the RP information of other switches.

Before You Begin

- Before you can configure a static RP, you must enable the following:
 - IPv6 PIM-SM
 - IPv6 static RP

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

Static RP field descriptions

Use the descriptions in the following table to use the **Static RP** tab.

| Name | Description |
|---------------------|---|
| GroupAddress | Configures the IPv6 address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles. |
| GroupMask | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| Address | Configures the global IPv6 address of the static RP. |
| Status | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP. |

Job aid

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

Viewing the active RP

Perform this procedure to show information about the active RP for all the running multicast groups on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Active RP** tab.

Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

| Name | Description |
|---------------------|---|
| GroupAddress | Shows the IP address of the multicast group. |
| Address | Shows the IP address of the RP router. This address must be one of the local PIM-SM enabled interfaces. |
| Priority | Shows the priority of the RP. |

Viewing the IPv6 active RP

Perform this procedure to show information about the IPv6 active RP for all the running multicast groups on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Active RP** tab.

Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

| Name | Description |
|---------------------|---|
| GroupAddress | Shows the IPv6 address of the multicast group. |
| Address | Shows the IPv6 address of the RP router. This address can be one of the local PIM-SM enabled interfaces or any reachable global IPv6 address configured using the static-rp CLI command.

Note:
IPv6 link local address is always used as the PIM interface address. |
| Priority | Shows the priority of the RP. |

Configuring a candidate bootstrap router

Configure routers as candidate bootstrap routers (C-BSR) to provide backup protection in case the primary BSR fails. PIM-SM cannot operate without a BSR. A PIM-SM domain can use only one active BSR.

About This Task

The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Click **Enable**.
6. In the **CBSRPreference** box, type the preference.

The C-BSR with the highest BSR-preference and address becomes the active BSR. The default is -1, which indicates that the current interface is not a C-BSR.

7. Click **Apply**.

Viewing current BSR information

View the current BSR information to review the configuration.

Before You Begin

- You must disable static RP.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Current BSR** tab.

Current BSR field descriptions

Use the descriptions in the following table to use the **Current BSR** tab.

| Name | Description |
|--------------------|--|
| Address | Shows the IP address of the current BSR for the local PIM domain. |
| FragmentTag | Shows a randomly generated number that distinguishes fragments that belong to different bootstrap messages. Fragments that belong to the same bootstrap message carry the same fragment tag. |
| HashMask | Shows the mask used in the hash function to map a group to one of the C-RPs from the RP set. The hashmask allows a small number of consecutive groups to always hash to the same RP. |

| Name | Description |
|-----------------------|---|
| Priority | Shows the priority of the current BSR. The C-BSR with the highest BSR priority and address (referred to as the preferred BSR) is elected as the BSR for the domain. |
| BootStrapTimer | Shows the bootstrap timer. After the bootstrap timer expires, the BSR sends out bootstrap messages. |

Changing VLAN interface type

Change the state (active or passive) of PIM on a VLAN interface.

Before You Begin

- Before you change the state of PIM on a VLAN interface, you must first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Clear the **Enable** check box.
8. Click **Apply**.
9. Select **active** or **passive**.
10. Reenable PIM on the VLAN interface.
11. Click **Apply**.

Editing PIM interface parameters

Edit PIM parameters for an interface to customize the PIM configuration.

Before You Begin

- Before you change the state (active or passive) of a PIM interface, first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name | Description |
|--------------------------|---|
| IfIndex | Shows the interface Index. This variable is a read-only field. |
| Address | Shows the IP address of the PIM interface. This variable is a read-only field. |
| NetMask | Shows the network mask for the IP address of the PIM interface. This variable is a read-only field. |
| Mode | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field. |
| InterfaceType | Specifies if the interface is active or passive. |
| DR | Shows the router with the highest IP address on a LAN designated to perform these tasks. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. |
| CBSRPreference | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. |
| OperState | Indicates the status of PIM on this interface: Up or Down. |

Editing IPv6 PIM interface parameters

Edit the IPv6 PIM parameters for an interface to customize the IPv6 PIM configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name | Description |
|----------------|--|
| IfIndex | Shows the interface Index. This variable is a read-only field. |
| Address | Shows the IPv6 address of the PIM interface. This variable is a read-only field. |

| Name | Description |
|--------------------------|--|
| NetMask | Shows the network mask for the IPv6 address of the PIM interface. This variable is a read-only field. |
| Enable | Shows the configured mode of this PIM interface. sparseDense mode is valid only for PIMv1. |
| Mode | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field. |
| DR | Shows the router with the highest IPv6 address on a LAN designated to perform these tasks. |
| HelloInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds. |
| JoinPruneInterval | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. |
| OperState | Indicates the status of PIM on this interface: Up or Down. |
| Type | Specifies the interface type. |

Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Virtual Neighbors** tab.
4. Click **Insert**.
5. Specify the IP address of the virtual neighbor.
6. Specify the interface index for the PIM interface.
7. Click **Insert**.

Virtual Neighbors field descriptions

Use the descriptions in the following table to use the **Virtual Neighbors** tab.

| Name | Description |
|----------------|--|
| Address | Specifies the IP address of the neighbor. |
| IfIndex | Specifies the IP address of the PIM interface. |

Viewing PIM-SM neighbor parameters

View PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the descriptions in the following table to use the **Neighbors** tab.

| Name | Description |
|-------------------|---|
| Address | Shows the IP address of the PIM neighbor. |
| IfIndex | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| UpTime | Shows the time since this neighbor became a neighbor of the local router. |
| ExpiryTime | Shows the time remaining before the neighbor expires. |

Viewing IPv6 PIM-SM neighbor parameters

View IPv6 PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the descriptions in the following table to use the **Neighbors** tab.

| Name | Description |
|-------------------|---|
| Address | Shows the IPv6 address of the PIM neighbor. |
| IfIndex | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| UpTime | Shows the time since this neighbor became a neighbor of the local router. |
| ExpiryTime | Shows the time remaining before the neighbor expires. |

Viewing IPv6 Neighbor Secondary Address

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbor Secondary Address** tab.

Neighbor Secondary Address field descriptions

Use the descriptions in the following table to use the **Neighbor Secondary Address** tab.

| Name | Description |
|-------------------|---|
| IfIndex | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| Type | Shows the address type of this PIM neighbor. |
| Primary | The primary IPv6 address of this PIM neighbor. |
| SecAddress | The secondary IPv6 address of this PIM neighbor. |

Viewing RP set parameters

View the RP set to see a list of rendezvous point addresses. The BSR constructs this list from C-RP advertisements, and then distributes it to all PIM routers in the PIM domain for the BSR. View the parameters for troubleshooting purposes.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **RP Set** tab.

RP Set field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name | Description |
|---------------------|--|
| GroupAddress | Shows the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| GroupMask | Shows the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| Address | Shows the IP address of the C-RP router. |
| HoldTime | Shows the time specified in a C-RP advertisement that the BSR uses to time out the RP. After the BSR receives an advertisement for the RP, it restarts the timer. If no advertisement arrives before the timer expires, the BSR removes that RP from the RP set. |
| ExpiryTime | Shows the time remaining before this C-RP router times out. |

Configuring a candidate RP

Configure a C-RP router to add it to the RP Set.

About This Task

You can configure only one interface on a switch for multiple groups; that is, you cannot configure multiple interfaces for multiple groups.

Using the GroupMask value, you can configure a candidate RP for several groups in one configuration. For example, if you use a C-RP configuration with a GroupAddress value of 224.0.0.0 and a GroupMask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Candidate RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

Candidate RP field descriptions

Use the descriptions in the following table to use the **Candidate RP** tab.

| Name | Description |
|-------------------------|---|
| GroupAddress | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| GroupMask | Configures the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| InterfaceAddress | Configures the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces. |

Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

About This Task

Important

The following configuration also activates full-mesh configurations.

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**

2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select **MulticastSquareSmltEnable**.
Clear this check box if you want to disable square-SMLT globally.
5. Click **Apply**.

Viewing IPv6 RP set parameters

View the IPv6 RP set to see a list of rendezvous point addresses. View the parameters for troubleshooting purposes.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **RP Set** tab.

RP Set field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name | Description |
|---------------------|---|
| GroupAddress | Specifies the IPv6 address of the multicast group. When combined with the group mask, this value identifies a group prefix for which the address is a static RP. |
| GroupMask | Specifies the address mask of the multicast group. When combined with the group address, this value identifies a group prefix for which the address is a static RP. |
| Address | Specifies the IPv6 address of the static RP. |
| HoldTime | Specifies the hold time of the static RP. The value is 0. |
| ExpiryTime | Specifies the minimum time remaining before the static RP is down. The value is 0. |

Viewing IPv6 Mroute interface information

Use the following procedure to view IPv6 Mroute information for an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Interfaces** tab.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name | Description |
|-----------------|---|
| IfIndex | Displays the slot and port number or VLAN ID for this entry. |
| Ttl | Displays the datagram time-to-live (TTL) threshold for the interface. IPv6 multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> other(1): none of the following local(2): manually configured netmgmt(3): configured by a network management protocol pimSparseMode(8): PIM-SMv2 igmpOnly(10) pimSsmMode(11) spb |

Viewing IPv6 Mroute next hop information

Use the following procedure to view IPv6 Mroute next hop information.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Next Hop** tab.

Next Hop field descriptions

Use the data in the following table to use the **Next Hop** tab.

| Name | Description |
|-------------------|--|
| Group | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface. |
| Source | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| SourceMask | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| IfIndex | Displays the slot and port number or VLAN ID for this entry. |
| Address | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface. |

| Name | Description |
|--------------------------|---|
| State | Displays whether the outgoing interface and next hop represented by this entry currently forward IPv6 datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used. |
| ExpiryTime | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| ClosestMemberHops | Displays the minimum number of hops between this router and members of the IPv6 multicast group reached through the next hop on this outgoing interface. IPv6 multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb |

Configuring resource usage counter for IPv6 Mroute

Configure the resource usage counters to query the number of ingress and egress IPv6 multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

Resource Usage field descriptions

Use the data in the following table to use the **Resource Usage** tab.

| Name | Description |
|-------------------------------|--|
| Ingress Records In-Use | Displays the number of ingress records (source or group) traversing the switch. |
| Egress Records In-Use | Displays the number of egress records traversing the switch. |
| Ingress Threshold | Configures the ingress threshold level (0–32767). |
| Egress Threshold | Configures the egress threshold level (0–32767). |
| SendTrapAndLog | Sends both trap and log notification messages after the number of streams exceeds a threshold level. |
| SendTrapOnly | Sends only trap notification messages after the number of streams exceeds a threshold level. You can configure only one notification type. |
| LogMsgOnly | Sends only log notification messages after the number of streams exceeds a threshold level. |

Viewing IPv6 multicast route information

Use the following procedure to view IPv6 Mroute route information.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Route** tab.

IPv6 Multicast Route field descriptions

Use the data in the following table to use the **Route** tab.

| Name | Description |
|-------------------------|---|
| Group | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface. |
| Source | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| SourceMask | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| UpStreamNeighbor | Shows the address of the upstream neighbor from which the IPv6 datagrams from these sources are received. |
| IfIndex | Displays the slot and port number or VLAN ID for this entry. |

| Name | Description |
|-------------------|---|
| ExpiryTime | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb |

IGMP Configuration Using the CLI

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Before You Begin

- Complete one of the following tasks:
 - Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
 - Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Configuring IGMP on a VRF](#) on page 1408.

Configuring multicast stream limitation on an Ethernet port

Configure multicast stream limitation on an Ethernet port to limit the number of concurrent multicast streams on the port. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the port drops joins to new streams. A service provider uses this feature to control the

overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

3. If stream-limit is already enabled on the interface, change the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

4. Display multicast stream limitation information for the ports on a specific interface:

```
show ip igmp stream-limit interface
```

Example

Enable multicast stream limitation on the Ethernet port and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

Variable definitions

Use the data in the following table to use the **ip igmp stream-limit-max-streams** command.

| Variable | Value |
|-----------|--|
| <0-65535> | Configures the maximum number of allowed streams on this port. The range is from 0-65535 and the default is 4. |

Job aid

The following tables show the field descriptions for the **show ip igmp stream-limit interface** command.

Table 153: show ip igmp stream-limit interface field descriptions

| Field | Description |
|-------------|--|
| INTERFACE | Indicates the interface IP address. |
| MAX STREAMS | Indicates the maximum number of streams. |
| NUM STREAMS | Indicates the current number of streams. |

Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops joins to new streams. A service provider uses this feature to control the overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable multicast stream limitation and configure the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```
3. If stream-limit is already enabled on the VLAN, change the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```
4. Display multicast stream limitation information for the ports on a specific interface:

```
show ip igmp stream-limit port
```

Example

Enable multicast stream limitation and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

Variable definitions

Use the data in the following table to use the **ip igmp stream-limit** command.

| Variable | Value |
|-----------|--|
| <0-65535> | Configures the maximum number of allowed streams on this VLAN. The range is from 0-65535 and the default is 4. |

Job aid

The following tables show the field descriptions for the **show ip igmp stream-limit port** command.

Table 154: show ip igmp stream-limit port field descriptions

| Field | Description |
|-------------|--|
| INTERFACE | Indicates the interface IP address. |
| PORT | Indicates the port for the VLAN. |
| MAX STREAMS | Indicates the maximum number of streams. |
| NUM STREAMS | Indicates the current number of streams. |

Configuring VLAN multicast stream limitation members

Configure multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN.

Procedure

- Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
- Configure multicast stream limitation members on a VLAN:

```
ip igmp stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] } enable max-streams <0-65535>
```

Example

Enable multicast stream limitation on ports 2/3 to 2/8 and configure the maximum allowed number of streams to 6 for this interface.

```
Switch:1(config-if)# ip igmp stream-limit-group 2/3-2/8 max-streams 6
```

Variable definitions

Use the data in the following table to use the `ip igmp stream-limit-group` command.

| Variable | Value |
|---|---|
| <0-65535> | Configures the maximum number of allowed streams for the specified ports on this VLAN. The range is from 0-65535 and the default is 4. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Configuring multicast router discovery options

Configure the multicast router discovery options to enable the automatic discovery of multicast-capable routers.

About This Task

Important

The switch does not support the Multicast Router Discovery (MRDISC) protocol on brouter ports.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable multicast router discovery:

```
ip igmp mrdisc
```
3. Configure the maximum advertisement intervals between successive advertisements:

```
ip igmp mrdisc maxadvertinterval <2-180> maxinitadvertinterval <2-180>
```
4. Configure the maximum advertisements after initialization:

```
ip igmp mrdisc maxinitadvertisements <2-15>
```
5. Configure the minimum advertisement interval between successive advertisements:

```
ip igmp mrdisc minadvertinterval <3-180>
```
6. Configure the time allowed before a neighbor is declared dead:

```
ip igmp mrdisc neighdeadinterval <2-180>
```

Example

Configure the maximum advertisement intervals between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc maxadvertinterval 30 maxinitadvertinterval 5
```

Configure the maximum advertisements after initialization:

```
Switch:1(config-if)#ip igmp mrdisc maxinitadvertisements 8
```

Configure the minimum advertisement interval between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc minadvertinterval 30
```

Configure the time allowed before a neighbor is declared dead:

```
Switch:1(config-if)#ip igmp mrdisc neighdeadinterval 60
```

Variable definitions

Use the data in the following table to use the **ip igmp mrdisc** command.

| Variable | Value |
|--------------------------------------|--|
| <i>maxadvertinterval</i> <2-180> | Configures the maximum number (in seconds) between successive advertisements.
For this change to take effect, you must save the configuration, and then reset the switch.
To configure this option to the default value, use the default operator with the command. The default is 20. |
| <i>maxinitadvertinterval</i> <2-180> | Configures the maximum number (in seconds) between successive initial advertisements.
For this change to take effect, you must save the configuration, and then reset the switch.
To configure this option to the default value, use the default operator with the command. The default is 2. |
| <i>maxinitadvertisements</i> <2-15> | Configures the maximum number of initial multicast advertisements after initialization.
For this change to take effect, you must save the configuration, and then reset the switch.
To configure this option to the default value, use the default operator with the command. The default is 3. |
| <i>minadvertinterval</i> <3-180> | Configures the minimum number (in seconds) between successive advertisements.
For this change to take effect, you must save the configuration, and then reset the switch.
To configure this option to the default value, use the default operator with the command. The default is 15. |
| <i>neighdeadinterval</i> <2-180> | Configures the multicast router discovery dead interval—the number of seconds the multicast route neighbors for the switch must wait before assuming that the multicast router is down.
To configure this option to the default value, use the default operator with the command. The default is 60. |

Configuring explicit host tracking

Configure explicit host tracking to track all the source and group members.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure explicit host tracking:

```
ip igmp igmpv3-explicit-host-tracking
```

3. Display all the tracked members for a specific group:

```
show ip igmp group group <A.B.C.D> tracked-members [member-subnet
<A.B.C.D/X>] [source-subnet <A.B.C.D/X>] [port {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}] [vlan <1-4059>]
```

4. Display the IGMPv3 specific data:

```
show ip igmp group group <A.B.C.D> detail port {{slot/port[/sub-port]
[-slot/port[/sub-port]] [,...]} vlan <1-4059>
```

Example

Configure explicit host tracking:

```
Switch:1(config-if)#ip igmp igmpv3-explicit-host-tracking
```

Display all the tracked members:

```
Switch:1(config-if)#show ip igmp group
```

```
=====
                                Igmpp Group - GlobalRouter
=====
```

Interface Group Include Source List:
      Source Address  Expires
      133.133.133.200 114
```

Variable definitions

Use the data in the following table to use the **ip igmp igmpv3-explicit-host-tracking** command.

| Variable | Value |
|-------------------------------|---|
| <i>explicit-host-tracking</i> | Enables explicit host tracking on IGMPv3. The default state is disable. |
| <A.B.C.D> | Specifies the IP address of the group of the tracked member. |

Configuring IGMP static members

Configure IGMP static members to add members to a snoop group. You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams are always forwarded to the multicast router within the VLAN, in addition to the ports in this static entry.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure interface static members:

```
ip igmp static-group {A.B.C.D} {A.B.C.D} {port {slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]} [static|blocked]
```

Example

Configure interface static members:

```
Switch:1(config-if)#ip igmp static-group 239.1.1.1 239.1.2.1 port 2/1 static
```

Variable definitions

Use the data in the following table to use the `ip igmp static-group` command.

| Variable | Value |
|--|---|
| <code>{A.B.C.D} {A.B.C.D}</code> | Indicates the IP address range of the selected multicast group. |
| <code>port</code> | Adds ports to a static group entry |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Creates a static group entry. Specifies the port or list of ports that is a member of the VLAN interface being configured to which you want to redirect the multicast stream for this multicast group.
Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code><static blocked></code> | Configures the route to static or blocked. |

Configuring SSM dynamic learning and range group

Configure SSM dynamic learning and a range group to enable the IGMPv3 dynamic learning feature and to extend the default SSM range of 232/8 to include an IP multicast address. As new SSM channels are learned, they appear in the SSM channel table.

Before You Begin

- To define the range group, you must first disable PIM.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Enable SSM dynamic learning:

```
ip igmp ssm dynamic-learning
```

- Configure the range group:

```
ip igmp ssm group-range <A.B.C.D/X>
```

The following message appears:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter y to continue.

Example

Define the SSM range group address (234.0.0.0) and mask (255.0.0.0). Enable dynamic learning from IGMPv3 reports.

```
Switch:1(config)#ip igmp ssm group-range 234.0.0.0/255.0.0.0

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(config)#ip igmp ssm dynamic-learning
```

Variable definitions

Use the data in the following table to use the **ip igmp ssm** command.

| Variable | Value |
|-------------|--|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

Changing the SSM range group

Change the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address.

Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

About This Task

Important

This procedure reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), it also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable PIM:

```
no ip pim enable
```

If you forget to disable PIM, the following error message appears:

```
Error: PIM is enabled in SSM mode, disable PIM
```

3. Delete each entry in the SSM channel table:

```
no ip igmp ssm-map [all] [{A.B.C.D} enable]
```

If you forget to delete the SSM channels, the following error message appears:

```
Error: SSM source group table not empty
```

4. Configure the new IP multicast group address:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The following message appears:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter **y** to continue.

5. Enable PIM:

```
ip pim enable
```

Example

Configure the new IP multicast group address:

```
Switch:1(config)#ip igmp ssm group-range 232.0.0.0/16
```

```
WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
```

Variable definitions

Use the data in the following table to use the `ip igmp ssm group-range` and `ip igmp ssm` commands.

| Variable | Value |
|-------------|--|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple sources to the same group for both static source group and an SSM map.

About This Task

The consistency check applies to all SSM map entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenable it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable the SSM map table for all static entries:

```
ip igmp ssm-map all
```
3. Create a static entry for a specific group:

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

Example

Create an SSM map table entry for the multicast group 234.0.1.0 and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1(config)#ip igmp ssm-map 234.0.1.0 192.32.99.151
Switch:1(config)#ip igmp ssm-map all
```

Variable definitions

Use the data in the following table to use the `ip igmp ssm-map` command.

| Variable | Value |
|----------------------------------|--|
| <code>{A.B.C.D} {A.B.C.D}</code> | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group. |
| <code>{A.B.C.D} enable</code> | Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

Configuring multicast access control for an IGMP Ethernet port

Configure multicast access control for an IGMP Ethernet port to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> {A.B.C.D/X} <deny-tx|deny-rx|deny-both|  
allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64>> {A.B.C.D/X} mode <deny-tx|deny-rx|  
deny-both|allow-only-tx|allow-only-rx|allow-only-both>
```

Variable definitions

Use the data in the following table to use the **ip igmp access-list** command

| Variable | Value |
|--|--|
| <i>{A.B.C.D/X}</i> | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| <i>deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both</i> | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic |
| <i>mode</i> | Changes the access control group configuration. |
| <i>WORD<1-64></i> | Specifies the name of the access list from 1-64 characters. |

Configuring multicast access control for a VLAN

Configure multicast access control for an IGMP VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] <deny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] mode <deny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both>
```

Variable definitions

Use the data in the following table to use the **ip igmp access-list** command.

| Variable | Value |
|--|--|
| <i>{A.B.C.D/X}</i> | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| <i>deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both</i> | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic |

| Variable | Value |
|-------------------------|---|
| <i>mode</i> | Changes the access control group configuration. |
| <i>WORD<1–64></i> | Specifies the name of the access list from 1–64 characters. |

Configuring Fast Leave Mode

Configure fast (immediate) leave mode to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces. Normal IGMP behavior is skipped. Fast leave mode provides one command that controls all IGMP fast leave enabled interfaces.

Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode for IGMPv3. For more information on enabling explicit-host-tracking, see [Configuring explicit host tracking](#) on page 1483.

About This Task

If a single user connects to an interface, you do not need to track if other users exist on the interface to perform the fast leave. In cases like this, you must change the mode to one-user.

Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- View the current fast leave mode:

```
show ip igmp sys
```

Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

- Configure fast leave mode:

```
ip igmp immediate-leave-mode <multiple-user|one-user>
```

Example

Change the mode to one-user.

```
Switch:1(config)#ip igmp immediate-leave-mode one-user
```

Variable definitions

Use the data in the following table to use the `ip igmp immediate-leave-mode` command.

| Variable | Value |
|-------------------------------------|--|
| <code>multiple-user one-user</code> | <code>multiple-user</code> removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This configuration is the default.
<code>one-user</code> removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process. |

Enabling fast leave mode on a port

Enable fast (immediate) leave mode to specify if a port receives a leave message from a member of a group. If you enable fast leave mode on a port, it uses the global fast leave mode configuration.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable fast leave:

```
ip igmp immediate-leave
```

Configuring IGMP fast leave members on a VLAN

Configure IGMP fast leave members on a VLAN to specify fast leave capable ports.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable fast leave on the VLAN:

```
ip igmp immediate-leave
```

- Configure fast leave members on a VLAN:

```
ip igmp immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

Variable definitions

Use the data in the following table to use the **ip igmp immediate-leave-members** command.

| Variable | Value |
|--|---|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Enable IGMP Layer 2 Querier

When no multicast router exists in your network, you can use IGMP Layer 2 Querier to allow the Layer 2 switch to act as a multicast router so that the system can participate in multicast environments where multicast routing is not required.

Before You Begin

- You must enable IGMP snooping.

About This Task

When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.

By default, IGMP Layer 2 Querier is disabled.

Enable Layer 2 Querier on only one node in the VLAN.

On Shortest Path Bridging (SPB) Customer VLANs (CVLAN), IGMP Querier is enabled automatically when you enable snooping on the VLAN.

Procedure

- Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Enable IGMP Layer 2 Querier:

```
ip igmp snoop-querier
```

What to Do Next

You must enable the IGMP Layer 2 Querier address. See [EnablingIGMPLayer2QuerierAddress](#)

Enabling IGMP Layer 2 Querier address

To use the IGMP Layer 2 Querier feature you must designate the IGMP Layer 2 Querier source IP address, the address the system uses in the query message.

Before You Begin

- Enable IGMP Layer 2 Querier.

About This Task

You must configure the IGMP Layer 2 Querier address to an IP address in the IP subnet that IGMP hosts, and to which IGMP snoopers in the VLAN belong.

The default IP address is 0.0.0.0 when the IGMP Layer 2 Querier is disabled.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```
3. Verify the configuration:

```
show ip igmp snooping [vrf WORD<0-16>] [vrfids WORD<0-512>
```

Example

Enable the IGMP Layer 2 Querier feature for VLAN 4, and configure the querier address. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 4
Switch:1(config-if)#ip igmp snoop-querier
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1(config-if)#show ip igmp snooping
```

```

IGMP configuration using EDM

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

Important

The **EnableSpmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

Before You Begin

- Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
- Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM), or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Select and Launch a VRF Context View](#) on page 3909.

Enabling IGMP snoop on a VLAN

Enable IGMP snooping on a VLAN to optimize the multicast data flow for a group within a VLAN to only those that are members of the group that uses IGMP snoop.

About This Task

The switch listens to group reports from each port and builds a database of multicast group members for each port. The switch suppresses the reports heard by not forwarding them to other hosts, forcing the members to continuously send their own reports.

The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. The switch multicasts data only to the participating group members and to the multicast routers within the VLAN.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. Select the **ProxySnoopEnable** check box.
9. For SteamLimtEnable, select **enable**.
10. Click **Apply**.

Configuring IGMP interface static members

Configure IGMP interface static members to add members to a snoop group.

About This Task

You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams always forward to the multicast router within the VLAN, in addition to the ports in this static entry.

Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Static** tab.
4. Click **Insert**.
5. Type the appropriate information.
6. Click **Insert**.

Static field descriptions

Use the data in the following table to use the **Static** tab.

| Name | Description |
|----------------|--|
| IfIndex | Shows the interface where the IGMP entry is enabled. |
| GrpAddr | Indicates the start of the IP multicast address range of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message. |

| Name | Description |
|-------------------------|---|
| ToGrpAddr | Indicates the end of the IP multicast address range of the multicast stream. If an address is not entered, the IP address in the GrpAddr field is the single address. |
| MemberPorts | Specifies the ports to which you want to redirect the multicast stream for this multicast group. The ports must be member ports of the VLAN. |
| NotAllowedToJoin | Specifies the ports that do not receive the multicast stream for this multicast group. |

Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) or multiple groups to different sources for both static source group and an SSM channel.

Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

About This Task

The consistency check applies to all SSM channel entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenabling it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Map** tab.
4. Select **Insert**.
5. Type the IP address for the multicast group and source.
6. Select **Insert**.

You can change the default status of an SSM map from enable to disable in the **AdminState** field.

Ssm Map field descriptions

Use the data in the following table to use the **Ssm Map** tab.

| Name | Description |
|-----------------------|---|
| IpMulticastGrp | Specifies an IP multicast address that is within the SSM range. |
| IpSource | Specifies the IP address of the source that sends traffic to the group. |
| LearningMode | Displays whether the entry is statically configured (Static) or dynamically-learned from IGMPv3 (Dynamic). This variable a read-only field. |
| Activity | Displays the current activity of the selected (S,G) entry. True indicates that traffic is flowing to the switch, otherwise, it appears false. This variable a read-only field. |
| AdminState | Configures the administrative state for the selected static entry. This state determines whether the switch uses the static entries. Configure this field to enable (default) to use the entry or disable to save for future use. |

Configure SSM Range and Global Parameters

Configure the SSM range parameter to extend the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without changing their group configurations.

Before You Begin

- To change the RangeGroup configuration, you must first disable PIM.
- To change the RangeGroup configuration, you must delete all entries in the SSM channel table before you configure the new IP multicast group address.

About This Task

The other global parameters enable the IGMPv3 dynamic learning feature and configure the administrative state for all the entries in the SSM channel table.

Important

If you change the RangeGroup configuration, the switch reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), this procedure also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Global** tab.
4. Configure the appropriate fields.

5. Select **Apply**.

Ssm Global field descriptions

Use the data in the following table to use the **SsmGlobal** tab.

| Name | Description |
|--------------------------|--|
| DynamicLearning | Activates the dynamic learning of SSM channel (S,G) pairs from IGMPv3 reports. As new SSM channels are learned, they appear in the SSM channel table. |
| RangeGroup | Configures the IP multicast group address. The lowest group address is 224.0.0.0 and the highest is 239.255.255.255. The default is 232.0.0.0. |
| RangeMask | Configures the address mask of the multicast group. The default is 255.0.0.0. |
| SsmMapAdminAction | Configures the administrative state, which determines whether the switch uses the table entries: <ul style="list-style-type: none"> • enableAll—Globally activates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries. • disableAll—Globally inactivates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries. |

Configuring multicast stream limitation on an interface

Configure multicast stream limitation to limit the number of concurrent multicast streams on the interface. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the interface drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit** tab.
4. To change the status of an interface, double-click on the **StreamLimitEnable** field for the interface, and then select **enable** or **disable** from the menu. If the interface is enabled, you can edit the **Maximum Number of Stream** field.
5. Click **Apply**.

StreamLimit field descriptions

Use the data in the following tab to use the **StreamLimit** tab.

| Name | Description |
|---------------------------------|--|
| Interface | Displays the slot and port number or VLAN ID for this interface. |
| StreamLimitEnable | Enables or disables stream limitation on this interface. |
| Maximum Number Of Stream | Configures the maximum number of streams allowed on this interface. The range is from 0–65535, and the default is 4. |
| Current Number Of Stream | Displays the current number of streams received on this interface. This value is a read-only value. |

Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific VLAN and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. For StreamLimitEnable, select **enable**.
8. Configure the maximum number of streams.
9. Click **Apply**.

Configuring multicast stream limitation on a port

Configure multicast stream limitation to limit the number of concurrent multicast streams on the port. Limit the number of streams to protect the bandwidth on a specific port and control access to multicast streams.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.

4. Click the **IGMP** tab.
5. In the StreamLimitEnable field, select the **Enable** option button.
6. Configure the maximum number of streams.
7. Click **Apply**.

Configuring multicast stream limitation members

Configure multicast stream limitation members on ports of the specified interface to configure the maximum number of streams on the interface.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click **Insert**.
5. Type the number of the VLAN to which you want to add a member or click **Vlan** to select an ID from the list.
6. Type the number of the slot and port that you want to add as a member or click **Port**, and then select one from the graphic display. If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Important

You must select one of the ports in the VLAN that you selected in step 4.

7. Type a maximum number of streams or accept the default of 4.
8. Click **Insert**.

StreamLimit Members field descriptions

Use the data in the following table to use the **StreamLimit Members** tab.

| Name | Description |
|----------------|---|
| IfIndex | Displays the ID of the VLAN. |
| Port | Lists each slot and port number for this interface with stream limitation enabled.
Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

| Name | Description |
|-------------------|--|
| MaxStreams | Configures the maximum number of allowed streams for this specific port. The number of allowed streams cannot exceed the maximum number for the interface. The range is from 0-65535 and the default is 4. |
| NumStreams | Displays the current number of streams received on this interface. This value is a read-only value. |

Deleting multicast stream limitation member

Delete a multicast stream limitation member from an interface to remove it from the configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click on the row that lists the member you want to delete.
5. Click **Delete**.

Configuring the IGMP interface

Configure the IGMP interface to change global IGMP values for the interface. Use the Interface tab to view or edit the IGMP interface table.

About This Task

If an interface does not use an IP address, it does not appear in the IGMP table. If an interface uses an IP address, but PIM-SM is not enabled, the interface appears as notInService in the Status field.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Interface** tab.
4. Edit the appropriate information.
5. Click **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name | Description |
|-----------------------------|---|
| IfIndex | Shows the interface where IGMP is enabled. |
| QueryInterval | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125. |
| Status | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService. |
| Version | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. |
| OperVersion | Shows the version of IGMP that currently runs on this interface. |
| Querier | Shows the address of the IGMP querier on the IP subnet to which this interface attaches. |
| QueryMaxResponseTime | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).

Important:
You must configure this value lower than the QueryInterval. |
| WrongVersionQueries | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch. |
| Joins | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time. |
| Robustness | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |

| Name | Description |
|------------------------------------|---|
| LastMembQueryIntvl | <p>Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.</p> <p>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)</p> |
| OtherQuerierPresent Timeout | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0. |
| FlushAction | <p>Configures the flush action to one of the following:</p> <ul style="list-style-type: none"> • none • flushGrpMem • flushMrouter • flushSender |
| RouterAlertEnable | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p>Important:
To maximize network performance, configure this parameter according to the version of IGMP currently in use.</p> <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |
| SsmSnoopEnable | Enables SSM snoop. |
| SnoopQuerierEnable | Enables IGMP Layer 2 Querier. |
| SnoopQuerierAddr | Specifies the pseudo address of the IGMP snoop querier. |
| ExplicitHostTrackingEnable | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3. |
| McastMode | <p>Indicates the protocol configured on the VLAN.</p> <ul style="list-style-type: none"> • snoop — Indicates IGMP snooping is enabled on a VLAN. • snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). • pim — Indicates PIM is enabled. • routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts. |

| Name | Description |
|----------------------------------|--|
| ExtnUpnpFilterEnable | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled. |
| ExtnUpnpFilterAddress | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32. |
| ExtnUpnpFilterAddressMask | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached. |

Configuring IGMP sender entries

Configure IGMP sender entries to identify a source that sends multicast data to a multicast group.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Sender** tab.
4. Change the appropriate options.
5. Click **Apply**.

Sender field descriptions

Use the data in the following table to use the **Sender** tab.

| Name | Description |
|-------------------|--|
| IfIndex | Specifies the interface where you enabled the IGMP entry. |
| GrpAddr | Specifies the multicast group address of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message. |
| MemberAddr | Specifies the IP address of a host. |
| Action | Flushes an entry or a group. |
| TPort | Identifies the T port. |
| State | Indicates whether a sender exists because of an IGMP access filter. The options are filtered and not filtered. |
| L2Isid | Specifies the Layer 2 I-SID of the C-VLAN. |

Configuring Fast Leave Mode

Configure fast leave mode to control all IGMP fast leave enabled interfaces.

Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode. To enable explicit-host-tracking, see [Configuring IGMP parameters on a port](#) on page 1418 and [Configuring IGMP parameters on a VLAN](#) on page 1421.

About This Task

Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Use this global parameter to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces.

Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

- In the navigation pane, expand the following folders: **Configuration > IP**.
- Click **IGMP**.
- Click the **Global** tab.
- Select the mode.
- Click **Apply**.

Global field descriptions

Use the data in the following table to use the **Global** tab.

| Name | Description |
|----------------------|--|
| FastLeaveMode | Configures the mode to one of the following values: <ul style="list-style-type: none"> multipleUser: Removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This value is the default. oneUser: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process. |
| GenerateTrap | Generates a trap. The default is disable. |
| GenerateLog | Generates a log message. The default is disable. |

Configuring multicast access control for an interface

Configure multicast access control for a selected IGMP interface or VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Access Control** tab.
4. Click **Insert**.
5. Type the number of the slot and port or VLAN ID that you want to add as a member or click the appropriate button, and then select one from the graphic display.
6. Click the ellipsis button (...) next to **PrefixListId**.
7. Select a prefix list ID.
8. Click **OK**.
9. Type the host address and host mask.
10. Select the action mode that you want for the specified host.
11. Click **Insert**.

Access Control field descriptions

Use the data in the following table to use the **Access Control** tab.

| Name | Description |
|-----------------------|--|
| IfIndex | Specifies the interface where the IGMP entry is enabled. |
| PrefixListId | Specifies a numeric string that identifies the prefix list. |
| HostAddr | Specifies the IP address of the host. |
| HostMask | Specifies the subnet mask that determines the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| PrefixListName | Specifies the name of the prefix list. |
| ActionMode | Specifies the action for the host identified by HostAddr. The options include the following: <ul style="list-style-type: none"> • denied IP multicast transmitted traffic (deny-tx). • denied IP multicast received traffic (deny-rx). • denied both IP multicast transmitted and received traffic (deny-both). • allowed IP multicast transmitted traffic (allow-only-tx). • allowed IP multicast received traffic (allow-only-rx). • allowed both IP multicast transmitted and received traffic (allow-only-both). |

Viewing IGMP cache information

View IGMP cache information to view the group for which members exist on a specific interface.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Cache** tab.

Cache field descriptions

Use the data in the following table to use the **Cache** tab.

| Name | Description |
|--------------------------|--|
| Address | Shows the IP multicast group address for this entry that contains this information. |
| IfIndex | Shows the interface from which the corresponding multicast group address is heard. |
| LastReporter | Shows the IP address of the source of the last membership report received for this IP multicast group address on this interface. If no membership report is received, the object uses the value 0.0.0.0. |
| ExpiryTime | Shows the amount of time (in seconds) that remain before this entry ages out. |
| Version1HostTimer | Shows the time that remains until the local router assumes that no IGMPv1 members exist on the IP subnet attached to the interface. Upon hearing IGMPv1 membership report, this value resets to the group membership timer. When the time that remains is nonzero, the local router ignores IGMPv2 leave messages for this group that it receives on this interface. |
| Type | Shows the type of IGMP entry. |
| StaticPorts | Shows the static ports associated with the entry. |

Viewing IGMPv3 cache

View the IGMPv3 specific data corresponding to each interface, port, and multicast group pair on a router.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.

- Click the **IGMPv3 Cache** tab to view the IGMPv3 cache information.

IGMPv3 Cache field descriptions

Use the data in the following table to use the **IGMPv3 Cache** tab.

| Name | Description |
|--------------------------|---|
| GroupAddress | Specifies the Multicast group Address (Class D) that others want to join. A group address can be the same for many incoming ports. |
| IfIndex | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources. |
| InPort | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources. |
| ModeExpiryTimer | Represents the time remaining before the interface EXCLUDE state expires and the interface state transitions to INCLUDE mode. This value is applicable only to IGMPv3-compatible nodes. |
| Version1HostTimer | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 1 members on the IP subnet attached to this interface. This entry only applies to IGMPv1 hosts. Upon hearing any IGMPv1 report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 Leave messages for this group that it receives on this interface. |
| Version2HostTimer | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 membership report, this value is reset to the group membership timer. Assuming no IGMPv1 hosts have been detected, the local router does not ignore any IGMPv2 Leave messages for this group that it receives on this interface. |
| SourceFilterMode | Specifies the current group state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE. |

Viewing and editing multicast router discovery information

View multicast router discovery information to view the current configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

- In the navigation pane, expand the following folders: **Configuration > IP**.
- Click **IGMP**.

3. Click the **Multicast Router Discovery** tab.
4. To edit the current configuration, double-click the value, make the change, and then click **Apply**.

Multicast Router Discovery field descriptions

Use the data in the following table to use the **Multicast Router Discovery** tab.

| Name | Description |
|------------------------------------|--|
| Interface | Shows the interface where IGMP is enabled. |
| MrdiscEnable | Enables (true) or disables (false) the router interface to listen for multicast router discovery messages to determine where to send multicast source data and IGMPv2 reports. If you enable snoop, you automatically enable multicast router discovery. |
| DiscoveredRouterPorts | Lists ports that the Multicast Router Discovery (MRDISC) protocol discovers.

Important:
The switch does not support the MRDISC protocol on brouter ports. |
| MaxAdvertiseInterval | Shows the maximum time allowed between sending router advertisements from the interface, in seconds. The range is from 2-180 seconds. The default is 20 seconds. |
| MinAdvertiseInterval | Shows the minimum time allowed between sending unsolicited router advertisements from the interface, in seconds. This value must be more than 3 seconds but no greater than the value assigned to the MaxAdvertiseInterval value. |
| MaxInitialAdvertiseInterval | Configures the maximum number (in seconds) of multicast advertisement intervals that you can configure on the switch. |
| MaxInitialAdvertisements | Configures the maximum number of initial multicast advertisements that you can configure on the switch. |
| NeighborDeadInterval | Shows the time interval (in seconds) before the router interface drops traffic after a user leaves the multicast group. |

Viewing the IGMP router source list

View the source list entries corresponding to each interface and multicast group pair on a router.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Igmp Router Source List** tab to view the IGMPv3 cache information.

Igmp router source list field descriptions

Use the data in the following table to use the **Igmp Router Source List** tab.

| Name | Description |
|----------------------|---|
| GroupAddress | Specifies the IP multicast group address for which this entry contains information. |
| IfIndex | Specifies the interface for which this entry contains information for an IP multicast group address. |
| InPort | Specifies a unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports for this source. |
| HostAddress | Specifies the host address to which this entry corresponds. |
| MemberAddress | Specifies the IP Address of a member that has sent source specific report wishing to join this source. |
| Expire | This value indicates the relevance of the source list entry, where a non-zero value indicates this is an INCLUDE state value, and a zero value indicates this to be an EXCLUDE state value. |
| Mode | Specifies the current member state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE. |
| MemberExpire | This value indicates the time until the member for this source expires. |

Viewing IGMP snoop information

View information about IGMP snoop to see the current configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop** tab.

Snoop field descriptions

Use the data in the following table to use the **Snoop** tab.

| Name | Description |
|--------------------|---|
| Interface | Shows the VLAN ID for the VLAN. |
| SnoopEnable | Shows the status of IGMP snoop. IGMP snoop works only if a multicast router exists in the VLAN. |

| Name | Description |
|--------------------------------|---|
| SsmSnoopEnable | Shows the status of SSM snoop. |
| ProxySnoopEnable | Indicates whether the IGMP report proxy feature is enabled. If you enable this feature, the switch forwards reports from hosts to the multicast router once for each group for each query interval, or after new group information is available. If you disable this feature, the switch forwards all reports from different hosts to multicast routers, and can forward more than one group report for the same multicast group for each query interval. The default is enabled. |
| FastLeaveEnable | Shows the status of fast leave for this port. |
| FastLeavePortMembers | Lists ports that are enabled for fast leave. |
| SnoopMRouterPorts | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.

Important:
Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| SnoopActiveMRouterPorts | Shows the active multicast router ports. Active multicast router ports are ports that directly attach to a multicast router. These ports include the querier port and all ports in the forwarding state that you configure as well as those that were dynamically learned through receiving queries. |
| SnoopMRouterExpiration | Indicates the time that remains before the multicast router ages out. If the switch does not receive queries before this time expires, it flushes out all group memberships known to the VLAN. The query maximum response interval (obtained from the queries received) is used as the timer resolution. |

View IGMP Snoop Trace Information

View the multicast group trace to track the data flow path of multicast streams.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop Trace** tab.

Snoop Trace Field Descriptions

Use the data in the following table to use the **Snoop Trace** tab.

| Name | Description |
|----------------|---|
| GrpAddr | Displays the IP multicast address of the group traversing the router. |
| SrcAddr | Displays the IP source address of the multicast group. |

| Name | Description |
|----------------|---|
| OutVlan | Displays the egress VLAN ID for the multicast group. |
| InPort | Displays the ingress port for the multicast group. |
| InVlan | Displays the ingress VLAN ID for the multicast group. |
| OutPort | Displays the egress port of the multicast group. |
| Type | Displays the port type on which the snoop entry is learned. |

View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

About This Task

Note

The following procedure displays the dynamically learned IGMP groups. **IP > IGMP > Static** displays statically configured IGMP groups. This is in contrast to the CLI command **show ip igmp group**, which displays both dynamically learned and statically configured IGMP groups, and the CLI command **show ip igmp static**, which displays only the statically configured groups.

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Groups** tab.

Groups Field Descriptions

Use the data in the following table to use the **Groups** tab.

| Name | Description |
|-------------------|--|
| IpAddress | Shows the multicast group address (Class D). A group address can be the same for many incoming ports. |
| Members | Shows the IP address of the host that issues the membership report to this group. |
| InPort | Shows the port that receives the group membership report. |
| IfIndex | Shows a unique value that identifies a physical interface or a logical interface (VLAN) that receives the membership report. |
| Expiration | Shows the time left before the group report expires on this port. This variable is updated after the port receives a group report. |

Route management using the CLI

With multicast route commands, you can configure and view IP multicast routing parameters on the switch.

Configuring multicast stream limits

Limit the number of multicast streams to protect the CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

About This Task

You can enable or disable the mroute stream limit for the entire device or for individual ports when the switch is operating. If you enable the mroute stream limit for the device and for an individual port, only the periodic check is performed for that port.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable stream limitation globally:
`ip mroute stream-limit`
3. Enter GigabitEthernet Interface Configuration mode.
`interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}`
4. Enable stream limits:
`ip mroute stream-limit`
5. For Gigabit Ethernet interfaces, configure the maximum number of streams and the interval at which to sample:
`ip mroute max-allowed-streams <1-32768> max-allowed-streams-timer-check <1-3600>`
6. Show the mroute stream limit configuration:
`show ip mroute interface gigabitethernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

Example

```
Switch:1(config)#ip mroute stream-limit
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#ip mroute stream-limit
Switch:1(config-if)#ip mroute max-allowed streams 1000 max-allowed-streams-timer-check 20
```

Variable definitions

Use the data in the following table to use the **interface** command.

| Variable | Value |
|---|--|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **ip mroute** command.

| Variable | Value |
|---|--|
| <i>max-allowed-streams</i> <1-32768> | Configures the maximum number of streams on the specified port. The port is shut down if the number of streams exceeds this limit. The value is a number between 1-32768. The default value is 1984 streams. To configure this option to the default value, use the default operator with the command. |
| <i>max-allowed-streams-timer-check</i> <1-3600> | Configures the sampling interval, which checks if the number of ingress multicast streams to the CPU is under a configured limit or if the port needs to shut down. The range is between 1-3600. The default value is 10 seconds. To configure this option to the default value, use the default operator with the command. |

Job aid

The following message appears if the system shuts down the port due to excessive multicast streams:

```
Shutdown port <port> due to excessive multicast streams <# of streams
ingressed>; Configured limit max streams <configured limit> in
<configured sampling interval> sec. Please disable and re-enable the
port.
```

The following table shows the field descriptions for the **show ip mroute interface** command.

Table 155: show ip mroute interface field descriptions

| Field | Description |
|------------------------|---|
| PORT | Indicates the slot and port number. |
| MROUTE STR LIMIT | Indicates the maximum number of multicast streams that can enter the CPU through this port. |
| MROUTE STR LIMIT TIMER | Indicates the sampling period (in seconds) to check the number of multicast streams that enter the CPU through this port. |
| ENABLE | Indicates the status of the mroute stream limit on the port. |

Configuring multicast static source groups

Configure static source group entries in the Protocol Independent Multicast (PIM) multicast routing table. The PIM cannot prune these entries from the distribution tree.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
 - PIM-Sparse Mode (SM)
 - PIM-Source Specific Multicast (SSM)

About This Task

Even if no receivers exist in the group, the multicast stream for a static source group entry remains active.

The maximum number of static source groups must not exceed 1024.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a static source group entry:

```
ip mroute static-source-group <A.B.C.D> <A.B.C.D/X>
```

Example

Create a static source group for two multicast groups: 224.32.2.1 and 226.50.2.2. The static source group for group 224.32.2.1 is for a source subnet 10.10.10.0/24. The static source group for group 226.50.2.2 is for the host 20.20.20.100/32.

```
Switch:1(config)# ip mroute static-source-group 224.32.2.1 10.10.10.0/24
Switch:1(config)# ip mroute static-source-group 226.50.2.2 20.20.20.100/32
```

Variable definitions

Use the definitions in the following table to use the `ip mroute static-source-group` command.

| Variable | Value |
|--------------------------|--|
| <i>A . B . C . D</i> | Specifies the IP address of the multicast group. Use the no operator to later remove this configuration. |
| <i>A . B . C . D / X</i> | Specifies the multicast source IP address and subnet mask for the static source group entry. You cannot create duplicate groups. How you configure the source address depends on the protocol and mode you use. Use the no operator to later remove this configuration. |

Configuring IP multicast software forwarding

When you use the IP multicast software forwarding feature you can avoid initial data loss experienced by multicast applications; this is suitable for low bandwidth conditions.

When you configure the IP multicast software forwarding feature the system forwards the initial packets of an IP multicast data stream it receives and creates a corresponding hardware record for subsequent packets.

By default, multicast software forwarding is disabled.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware continues to forward IP multicast traffic. The software only forwards initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only.

If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding and packet suppression by the hardware is disabled.

If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

Important

To avoid overloading the CPU, ensure that you do not use the IP multicast software forwarding feature for video multicast applications.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable software forwarding:
`multicast software-forwarding`
3. Show the software forwarding configuration:
`show multicast software-forwarding`

Example

```
Switch:1#show multicast software-forwarding
```

```
=====
                        Mcast Software Forwarding - GlobalRouter
=====
McastSoftwareForwarding      :enabled
```

Configuring the resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

After you configure the counter thresholds for ingress and egress records, if the record usage exceeds the threshold, you receive notification by a trap on the console, a logged message, or both.

If you do not configure the thresholds, the system displays only the ingress and egress records currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the thresholds:
`ip mroute resource-usage egress-threshold <0-32767> ingress-threshold <0-32767>`

3. Configure one of the following notification methods:

- Configure a log-only notification method:

```
ip mroute resource-usage log-msg
```

- Configure a trap-only notification method:

```
ip mroute resource-usage trap-msg
```

- Configure both notification methods:

```
ip mroute resource-usage log-msg trap-msg
```

Example

Configure the egress threshold to 200.

```
Switch:1(config)# ip mroute resource-usage egress-threshold 200
```

Configure the ingress threshold to 100.

```
Switch:1(config)# ip mroute resource-usage ingress-threshold 100
```

Enable the log message notification method.

```
Switch:1(config)# ip mroute resource-usage log-msg
```

Variable definitions

Use the data in the following table to use the **ip mroute resource-usage** command.

| Variable | Value |
|------------------------------------|---|
| <i>egress-threshold</i> <0-32767> | Configures the egress record threshold (S,G). The system sends a notification message after the number of streams exceeds a threshold level. To configure this option to the default value, use the default operator with the command. The default is 0. |
| <i>ingress-threshold</i> <0-32767> | Configures the ingress record threshold. The system sends a notification message after the number of streams exceeds a threshold level. To configure this option to the default value, use the default operator with the command. The default is 0. |

Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

About This Task

Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a prefix list:

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [le <0-32>]
```

3. (Optional) Rename an existing prefix list:

```
ip prefix-list WORD<1-64> name WORD<1-64>
```

4. Display the prefix list:

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<0-16>] [vrfids  
WORD<0-512>] [WORD <1-64>]
```

Example

Configure a prefix-list. Display the prefix list.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list LIST1 47.17.121.50/255.255.255.0
Switch:1(config)#show ip prefix-list LIST1
=====
                          Prefix List - GlobalRouter
=====
      PREFIX                MASKLEN FROM TO
-----
List 1    LIST1:
          47.17.121.50      24      24  24
1 Total Prefix List entries configured
=====
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range
```

Variable definitions

Use the data in the following table to use the **ip prefix-list** command.

| Variable | Value |
|------------------------------|--|
| <i>{A.B.C.D/X}</i> | Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> a.b.c.d/x a.b.c.d/x.x.x.x default |
| <i>ge <0-32></i> | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |
| <i>le <0-32></i> | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |
| <i>name WORD<1-64></i> | Renames the specified prefix list. The name length is 1-64 characters. |
| <i>WORD<1-64></i> | Specifies the name for a new prefix list. |

Use the data in the following table to use the **show ip prefix-list** command.

| Variable | Value |
|---------------------------------|--|
| <i>{A.B.C.D}</i> | Specifies the prefix to include in the command output. |
| <i>vrf WORD<0-16></i> | Specifies the name of the VRF. |
| <i>vrfids WORD<0-512></i> | Specifies the ID of the VRF and is an integer in the range of 0-512. |
| <i>WORD<1-64></i> | Specifies a prefix list, by name, to use for the command output. |

Use the following table to use the **show ip prefix-list** command output.

| Variable | Value |
|----------|---|
| PREFIX | Indicates the member of a specific prefix list. |
| MASKLEN | Indicates the prefix mask length in bits. |
| FROM | Indicates the prefix mask starting point in bits. |
| TO | Indicates the prefix mask endpoint in bits. |

Route management using EDM

View or edit interface configuration information for Layer 3 IP multicast protocols on the switch.

View Multicast Route Information

View multicast route information for troubleshooting purposes.

This tab shows multicast routing information for IP datagrams from a particular source and addressed to a particular IP multicast group address.

About This Task

Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Select the **Routes** tab.

Routes field descriptions

Use the data in the following table to use the **Routes** tab.

| Name | Description |
|-------------------------|--|
| Group | Displays the IP multicast group address for this entry that contains multicast routing information. |
| Source | Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information. |
| SourceMask | Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source. |
| UpstreamNeighbor | Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local. |
| Interface | Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received. |
| ExpiryTime | Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb (12) • spbpimgw(13) |

View Multicast Next-Hop Information

View all multicast next-hop information.

This tab shows information about the next hops used by outgoing interfaces to route IP multicast datagrams. Each entry is one in a list of next hops on outgoing interfaces for particular sources that send to a particular multicast group address.

About This Task

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Next Hops** tab.

Next Hops field descriptions

Use the data in the following table to use the **Next Hops** tab.

| Name | Description |
|--------------------------|--|
| Group | Displays the IP multicast group for this entry that specifies a next hop on an outgoing interface. |
| Source | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| SourceMask | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| ReceiverPort | Displays the receiver port for this next hop. |
| OutInterface | Displays the interface slot and portnumber or VLAN ID for the outgoing interface for this next hop. |
| Address | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface. |
| State | Displays whether the outgoing interface and next hop represented by this entry currently forward IP datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used. |
| UpTime | Displays the up time for this entry. |
| ExpiryTime | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| ClosestMemberHops | Displays the minimum number of hops between this router and members of the IP multicast group reached through the next hop on this outgoing interface. IP multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop. |

| Name | Description |
|-----------------|---|
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb |
| Pkts | Displays the number of next hop packets. |

View Multicast Interface Information

View multicast interface information to verify the multicast configuration.

This tab shows multicast routing information specific to interfaces.

About This Task

You can view multicast interface information for a Layer 3 VSN the same way you view the Global Router except that you must first launch the appropriate VRF context.

Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Interfaces** tab.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name | Description |
|------------------|---|
| Interface | Displays the slot and port number or VLAN ID for this entry. |
| Ttl | Displays the datagram time-to-live (TTL) threshold for the interface. IP multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb |

Adding new static source groups

Add a new static source group to create an entry that the switch cannot prune from the distribution tree. An attempt to add a duplicate of an existing source-group entry results in an error message.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
 - PIM-SM
 - PIM-SSM

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Click **Insert**.
5. Complete the information in the dialog box.
6. Click **Insert**.

Editing static source groups

Configure static source-group entries in the PIM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers exist in the group, the multicast stream for a static source-group entry stays active.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
 - PIM-Sparse Mode (SM)
 - PIM-Source Specific Multicast (SSM)

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The maximum number of static source groups must not exceed 1024.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Edit the required information.
5. Click **Apply**.

Static Source Group field descriptions

Use the data in the following table to use the **Static Source Group** tab.

| Name | Description |
|----------------------|--|
| GroupAddress | Configures the multicast group IP address for this static source-group entry. |
| SourceSubnet | Configures the multicast source address for this static source-group entry. How you configure the source address depends on the protocol and mode you use. |
| SrcSubnetMask | Configures the subnet mask of the source for this static source-group entry. |

Configuring IP multicast software forwarding

Configure IP multicast software forwarding to enable the system to initially forward IP multicast data until a hardware record is created. The system forwards the initial packets of a stream it receives and creates a corresponding hardware record for subsequent packets. The advantage of this feature is that it avoids initial data loss experienced by multicast applications and is most suited for low bandwidth.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware still forwards IP multicast traffic. The software forwards only initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only. If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding. If you enable software forwarding, packet suppression by the hardware is disabled. If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

By default, the feature is disabled.

Important

To avoid overloading the CPU, do not use the IP multicast software forwarding feature for video multicast applications.

If you configure multicast software forwarding from within a VRF context, the configuration applies to the Global Router and all VRF contexts. You cannot change the multicast software forwarding configuration for individual VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select the **SWForwardingEnable** check box.
5. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

| Name | Description |
|---------------------------|--|
| SWForwardingEnable | Enables the system to initially forward IP multicast data until a hardware record is created. The default is disabled. |
| StatsEnabled | Enables or disables multicast route statistics. The default is disabled. |
| StatsClear | Clears multicast route statistics. |

Configuring mroute stream limit

Limit the number of multicast streams to protect a CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Select the **Mroute Stream Limit** tab.
5. Select the **StreamLimitEnable** box.
6. Edit other fields as required.
7. Click **Apply**.

Mroute Stream Limit field descriptions

Use the data in the following table to use the **Mroute Stream Limit** tab.

| Name | Description |
|--------------------------|---|
| StreamLimitEnable | Enables or disables mroute stream limit on the port. |
| StreamLimit | Specifies the maximum number of multicast streams allowed to enter the CPU through this port. |
| StreamTimerCheck | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through this port. |

Configuring Mroute Stream Limit on an Extreme Integrated Application Hosting Port

About This Task

Perform this procedure to limit the number of multicast streams to protect a Central Processing Unit (CPU) from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization, or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Insight Port**.
2. Select the Extreme Integrated Application Hosting (IAH) port you want to configure.
3. Select the **Mroute Stream Limit** tab.
4. Select **StreamLimitEnable**.
5. Configure other fields as required.
6. Select **Apply**.

Mroute Stream Limit Field Descriptions

Use data in the following table to configure the **Mroute Stream Limit** tab.

| Name | Description |
|--------------------------|---|
| StreamLimitEnable | Enables or disables mroute stream limit on the Extreme Integrated Application Hosting (IAH) port. The default is disabled. |
| StreamLimit | Specifies the maximum number of multicast streams allowed to enter the CPU through the IAH port. The default value is 1984. |
| StreamTimerCheck | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through the IAH port. The default is 10 seconds. |

Configuring resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

About This Task**Note**

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

**Important**

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Select the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

Resource Usage field descriptions

Use the data in the following table to use the **Resource Usage** tab.

| Name | Description |
|-------------------------------|--|
| Egress Records In-Use | Displays the number of egress records traversing the switch. |
| Ingress Records In-Use | Displays the number of ingress records (source or group) traversing the switch. |
| Egress Threshold | Configures the egress threshold level (0–32767). |
| Ingress Threshold | Configures the ingress threshold level (0–32767). |
| SendTrapOnly | Sends only trap notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. You can configure only one notification type. |
| SendTrapAndLog | Sends both trap and log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. |
| LogMsgOnly | Sends only log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. |

Multicast route statistics configuration using the CLI

The following sections provide procedural information you can use to configure multicast route statistics using the Command Line Interface (CLI).

Enabling IP multicast route statistics

Enable the collection and display of IP multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

Note

When you enable IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the collection of IP multicast route statistics.

```
ip mroute stats enable
```
3. (Optional) Set the IP multicast route statistics to default.

```
default ip mroute stats enable
```

- (Optional) Disable the collection of IP multicast route statistics.

```
no ip mroute stats enable
```

- View the IP multicast route statistics.

```
show ip mroute stats [WORD<3-160> {A.B.C.D[,E.F.G.H] [,...]}]
```

Note

The maximum number of multicast group IP addresses is 10.

Example

Enable the collection of IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip mroute stats enable
```

View the IP multicast route statistics:

```
Switch:1#show ip mroute stats

=====
                          Multicast Stats
=====
-----
                          Statistics : Enabled
-----
```

View the statistics for the multicast group IP address 225.0.0.1:

```
Switch:1#show ip mroute stats 225.0.0.1

=====
                          Multicast Stats - GlobalRouter
=====
-----
GroupAddress      SourceCounter      IngressPackets      IngressBytes      AverageSize
-----
225.0.0.1         1                  30452198             3897881344        128
```

View the statistics for multiple (up to a maximum of 10) group IP addresses.

```
Switch:1#show ip mroute stats
225.0.0.1,225.0.0.2,225.0.0.3,225.0.0.4,225.0.0.5,225.0.0.6,225.0.0.7,225.0.0.8,225.0.0.9,
225.0.0.10

=====
                          Multicast Stats - GlobalRouter

Variable definitions

Use the data in the following table to use the **show ip mroute stats** command.

| Variable | Definition |
|--|---|
| WORD<3-160>
{A.B.C.D[,E.F.G.H][,...]} | Specifies the multicast group IP address for which to display statistics.
The group IP address is in one of the following formats: a single IP address or a series of IP addresses.
You can specify a maximum of 10 groups. |

Job aid

The following table shows the field descriptions for viewing multicast route statistics.

| Field | Description |
|----------------|--|
| GroupAddress | Specifies the multicast group IP address for which to show statistics. |
| SourceCounter | Specifies the number of sources associated with the multicast route record. |
| IngressPackets | Specifies the number of packets received for the associated IP address. |
| IngressBytes | Specifies the number of bytes received for the associated IP address. |
| AverageSize | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the formula: ingress packet/ingress byte. |

Clearing IP multicast route statistics

Use this procedure to clear the IP multicast route statistics. This resets the IP multicast statistics counters.

Note

When you clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Clear the IP multicast route statistics:
`clear ip mroute stats`

Example:

Clear the IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ip mroute stats
```

Monitoring IP multicast route statistics

Use this procedure to monitor the IP multicast route statistics at regular intervals.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Monitor the IP multicast route statistics:
monitor ip mroute stats WORD<7-160> {A.B.C.D[,E.F.G.H][,...]}

Note

You can monitor a maximum of 10 group IP addresses.

Example:

Monitor the IP multicast route statistics for the group IP address 225.0.0.1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>en
Switch:1#monitor ip mroute stats 225.0.0.1
```

Variable definitions

Use the data in the following table to use the **monitor ip mroute stats** command.

| Variable | Definition |
|--|---|
| WORD<7-160>
{A.B.C.D[,E.F.G.H][,...]} | Specifies the multicast group IP address for which to monitor statistics.
The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
configure terminal
```
2. Enable the collection of IPv6 multicast route statistics.

```
ipv6 mroute stats enable
```
3. (Optional) Set the IPv6 multicast route statistics to default:

```
default ipv6 mroute stats
```
4. (Optional) Disable the collection of IPv6 multicast route statistics.

```
no ipv6 mroute stats
```
5. View the IPv6 multicast route statistics.

```
show ipv6 mroute stats [WORD<7-400> {Ipv6address[,Ipv6address][,...]}]
```

Note

The maximum number of multicast group IP addresses is 10.

Example:

Enable collection of IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ipv6 mroute stats enable
```

View the IPv6 multicast route statistics:

```
Switch:1#show ipv6 mroute stats

=====
                          Multicast Stats
=====
-----
                          Statistics : Enabled
```

View the statistics for the multicast group IP address FF05::1:

```
Switch#show ipv6 mroute stats FF05::1

=====
                          Multicast Stats - GlobalRouter

```

Variable definitions

Use the data in the following table to use the **show ipv6 mroute stats** command

| Variable | Definition |
|---|---|
| WORD<7-400>
{Ipv6address [, Ipv6address]
[, ...]} | Specifies the multicast group IP address for which to display statistics.
The group IP address is in one of the following formats: a single IP address or a series of IP addresses.
You can specify a maximum of 10 groups. |

Job aid

The following table shows the field descriptions for viewing multicast route statistics.

| Field | Description |
|----------------|--|
| GroupAddress | Specifies the multicast group IP address for which to show statistics. |
| SourceCounter | Specifies the number of sources associated with the multicast route record. |
| IngressPackets | Specifies the number of packets received for the associated IP address. |
| IngressBytes | Specifies the number of bytes received for the associated IP address. |
| AverageSize | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the formula: ingress packet/ingress byte. |

Clearing IPv6 multicast route statistics

Use this procedure to clear the IPv6 multicast route statistics. This resets the IP multicast statistics counters.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Clear the IPv6 multicast route statistics:
`clear ipv6 mroute stats`

Example:

Clear the IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ipv6 mroute stats
```

Monitoring IPv6 multicast route statistics

Use this procedure to monitor IPv6 multicast route statistics at regular intervals.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Monitor IPv6 multicast route statistics:
monitor ipv6 mroute stats WORD<7-400> {Ipv6address[,Ipv6address]
[,...]}

Note

You can monitor a maximum of 10 group IP addresses.

Example:

Monitor the IPv6 multicast route statistics for the group IPv6 address FF05::1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>enable
Switch:1#monitor IPv6 mroute stats FF05::1

Variable definitions

Use the data in the following table to use the **monitor ipv6 mroute stats** command:

| Variable | Definition |
|---|---|
| WORD<7-400>
{ <i>Ipv6address</i> [, <i>Ipv6address</i>]
[, ...]} | Specifies the multicast group IP address for which to monitor statistics.
The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

Multicast route statistics configuration using EDM

The following sections provide procedural information you can use to configure multicast route statistics using the Enterprise Device Manager (EDM).

Enabling IP multicast route statistics

Use this procedure to enable IP multicast route statistics.

Note

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **Multicast**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

Globals Field Definitions

Use the data in the following table to use the **Globals** tab.

| Field | Description |
|--------------|---|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear | Clears the multicast route statistics. |

Viewing IP multicast route statistics

Use this procedure to view IP multicast route statistics.

Before You Begin

- You must enable the collection of multicast statistics.

Procedure

- In the navigation pane, expand the following folders: **Configuration > IP**.
- Click **Multicast**.
- Click the **Stats** tab to view the statistics.

Stats Field Definitions

Use the data in the following table to use the **Stats** tab.

| Field | Description |
|-------------------|--|
| GroupAddress | Specifies the multicast group IP address for which to show statistics. |
| SourceCounter | Specifies the number of sources associated with the multicast route record. |
| Pkts | Specifies the number of packets received for the associated IP address. |
| Bytes | Specifies the number of bytes received for the associated IP address. |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

Procedure

- In the navigation pane, expand the following folders: **Configuration > IPv6**.
- Click **IPv6 Mroute**.
- Click the **Globals** tab.
- In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.

5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

Globals Field Definitions

Use the data in the following table to use the **Globals** tab.

| Field | Description |
|--------------|---|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear | Clears the multicast route statistics. |

Viewing IPv6 multicast route statistics

Use this procedure to view IPv6 multicast route statistics.

Before You Begin

- You must enable the collection of multicast statistics.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Stats** tab to view the statistics.

Stats Field Definitions

Use the data in the following table to use the **Stats** tab.

| Field | Description |
|-------------------|--|
| GroupAddress | Specifies the multicast group IP address for which to show statistics. |
| SourceCounter | Specifies the number of sources associated with the multicast route record. |
| Pkts | Specifies the number of packets received for the associated IP address. |
| Bytes | Specifies the number of bytes received for the associated IP address. |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

CLI show command reference

This reference information provides show commands to view the operational status of multicast routing on the switch.

Note

If you do not specify a VRF name or range of VRF IDs in the show command, the results display information for the Global Router.

If you do specify a VRF name or range of VRF IDs, the results display information only for the VRFs you specify.

General show commands

This section explains the show commands for general multicast routing operations.

Multicast route information

Use the **show ip mroute route** command to display information about the multicast routes on the switch. The syntax for this command is as follows.

```
show ip mroute route [vrf WORD <0-32>] [vrfids <0-255>]
```

Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The following section shows a sample output for the **show ip mroute route** command.

In this table, every stream uses one (*,G) entry and x (S,G) entries, depending on how many servers forward traffic to the same group.

The 0.0.0.0 mask is always tied to a (*,G) entry.

Every time a new stream comes in, Protocol Independent Multicast (PIM) creates two entries in the table; one is a (*,G) entry that points toward the rendezvous point (RP) router, and the other is an (S,G) entry that points toward the source.

```
Switch:1#show ip mroute route
```

| Mroute Route - GlobalRouter | | | | | | |
|-----------------------------|---------------|---------------|--------------|----|-------|------------|
| GROUP | SOURCE | SRCMASK | UPSTREAM_NBR | IF | EXPIR | PROT |
| 233.252.0.1 | 0.0.0.0 | 0.0.0.0 | 0.0.0.0 | V3 | 30 | pimsm |
| 233.252.0.1 | 198.51.100.99 | 255.255.255.0 | 0.0.0.0 | - | 0 | pimsm |
| 233.252.0.2 | 0.0.0.0 | 0.0.0.0 | 0.0.0.0 | V2 | 30 | pimsm |
| 225.1.1.1 | 198.51.100.99 | 255.255.255.0 | 0.0.0.0 | V3 | 173 | spb-pim-gw |
| Total 4 | | | | | | |

The following table shows the field descriptions for this command.

Table 156: show ip mroute route command

| Field | Description |
|--------------|--|
| GROUP | Indicates the IP multicast group for this multicast route. |
| SOURCE | Indicates the network address that, when combined with the corresponding value of SRCMASK, identifies the sources for this multicast route. |
| SRCMASK | Indicates the network mask that, when combined with the corresponding value of SOURCE, identifies the sources for this multicast route. |
| UPSTREAM_NBR | Indicates the address of the upstream neighbor from which IP datagrams from these sources to this multicast address are received, or 0.0.0.0 if the (S,G) source is local or if the RP for this the (*,G) group is an address on this router. |
| IF | Indicates the value of ifIndex for the interface that receives IP datagrams sent by these sources to this multicast address. A value of 0 in a (*,G) route indicates that datagrams are not subject to an incoming interface check, but datagrams can be received on any interface. |
| EXPIR | Indicates the minimum amount of time remaining before this entry ages out. The value 0 indicates that the entry is not subject to aging.

Note:
The value you configure for fwd-cache-timeout applies only to the locally learned sender; it does not apply to SMLT synchronized sender records. |
| PROT | Indicates the multicast protocol through which the switch learned this route. |

Multicast route next hop

Use the **show ip mroute next-hop** command to show information about the next hop for the multicast routes on the switch. The syntax for this command is as follows.

```
show ip mroute next-hop [vrf WORD <0-16>] [vrfids <0-512>]
```

The following table shows the field descriptions for this command.

Table 157: show ip mroute next-hop command

| Field | Description |
|-----------|---|
| INTERFACE | Indicates the interface identity. |
| GROUP | Indicates the IP multicast group for which this entry specifies a next-hop PIM neighbor toward receivers for a specific outgoing interface. |
| SOURCE | Indicates the network address, which when combined with the corresponding value of SRCMASK, identifies the sources for which this entry specifies a next-hop PIM neighbor toward receivers for a specific outgoing interface. |
| SRCMASK | Indicates the network mask, which when combined with the corresponding value of SOURCE, identifies the sources for which this entry specifies a next-hop PIM neighbor toward receivers for a specific outgoing interface. |

Table 157: show ip mroute next-hop command (continued)

| Field | Description |
|----------|--|
| ADDRESS | Indicates the address of the next hop specific to this entry. The next hop must be the address of a PIM neighbor. This table does not represent local receivers. |
| STATE | Indicates whether the outgoing interface and next hop represented by this entry currently forward IP datagrams. The value forwarding indicates the information is currently used; the value pruned indicates it is not used. |
| EXPTIME | Indicates the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| CLOSEHOP | Indicates the minimum number of hops between this router and members of this IP multicast group reached through this next hop on this outgoing interface. IP multicast datagrams for the group that use a time-to-live less than this number of hops are forwarded to the next hop |
| PROTOCOL | Indicates the routing mechanism through which the switch learned this next hop. |
| L2ISID | Indicates the I-SID associated with the Layer 2 interface. |

Multicast routes on an interface

Use the **show ip mroute interface** command to display information about the multicast routes on the switch for a specific interface. The syntax for this command is as follows.

```
show ip mroute interface gigabitethernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ... ]}]
```

```
show ip mroute interface [vrf WORD <1-16>] [vrfids WORD <0-512>]
```

**Note**

This command is not supported on a node configured as the DVR Leaf within a DvR domain.

The following table shows the field descriptions for this command if you do not use optional command parameters.

Table 158: show ip mroute interface command without parameters

| Field | Description |
|-----------|---|
| INTERFACE | Indicates the interface. |
| TTL | Indicates the datagram TTL threshold for the interface. IP multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means all multicast packets are forwarded out of the interface. |
| PROTOCOL | Indicates the routing protocol running on this interface. |

The following table shows the field descriptions for this command if you use optional command parameters.

Table 159: show ip mroute interface command with parameters

| Field | Description |
|----------------------|---|
| PORT | Shows the slot and port location. |
| MROUTE STR LIMIT | Indicates the maximum number of multicast streams that can enter the CPU through this port. |
| MROUTE STR LIMIT TMR | Indicates the sampling period (in seconds) to check number of multicast streams that enter the CPU through this port. |
| ENABLE | Indicates the status of the mroute stream limit on the port. |

Multicast hardware resource usage

Use the **show ip mroute hw-resource-usage** command to display information about the hardware resource use of an IP multicast route.

Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The syntax for this command is as follows:

show ip mroute hw-resource-usage [vrf WORD <0-32>] [vrfids WORD <0-255>]

| Field | Description |
|--------------------|--|
| EGRESS REC IN-USE | Displays the number of egress records traversing the switch. |
| INGRESS REC IN-USE | Displays the number of ingress records (source or group) traversing the switch. |
| EGRESS THRESHOLD | Displays the configured egress threshold level (0-32767).
A notification message is sent if this value is exceeded.
The default is 0. |
| INGRESS THRESHOLD | Displays the configured ingress threshold level (0-32767).
A notification message is sent if this value is exceeded.
The default is 0. |
| LOG MSG ONLY | Displays whether only log notification messages are sent after the threshold level is exceeded.
The default is false (disabled). |
| SEND TRAP ONLY | Displays whether only trap notification messages are sent after the threshold level is exceeded.
The default is false (disabled). |
| SENT TRAP AND LOG | Displays whether both trap and log notification messages are sent after the threshold level is exceeded.
The default is false (disabled). |

Static source groups

Use the **show ip mroute static-source-group** command to display information about the static source groups. You can see all the valid entries that were created. If an entry is created with a x bit mask, it shows as a x bit in the output. The syntax for this command is as follows.

```
show ip mroute static-source-group [<A.B.C.D>] [vrf WORD <0-32>] [vrfids WORD <0-255>]
```

Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The following table shows the field descriptions for this command.

Table 160: show ip mroute static-source-group command

| Field | Description |
|----------------|---|
| Group Address | Indicates the IP multicast group address. |
| Source Address | Indicates the network address. |
| Subnet Mask | Indicates the network mask. |

VLAN port data

Use the **show vlan members** command to display VLAN port data. The syntax for this command is as follows.

```
show vlan members <1-4059> [port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]
```

The following table shows the field descriptions for this command.

Table 161: show vlan members command

| Field | Description |
|------------------|---|
| VLAN ID | Indicates the VLAN ID. |
| PORT MEMBER | Indicates the set of ports that are members (static or dynamic) of this VLAN. |
| ACTIVE MEMBER | Indicates the set of ports that are currently active in this VLAN. Active ports include all static and dynamic ports that meet the VLAN policy. |
| STATIC MEMBER | Indicates the set of ports that are static members of this VLAN. A static member of a VLAN is always active and never ages. |
| NOT_ALLOW MEMBER | Indicates the set of ports that cannot become members of this VLAN. |
| VLAN PORT NUM | Indicates the VLAN port number for the passive OSPF interface. |

IGMP show commands

This section explains the show commands for the Internet Group Management Protocol (IGMP).

IGMP access

Use the **show ip igmp access** command to display information about the IGMP multicast access control groups. The syntax for this command is as follows.

```
show ip igmp access [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

**Note**

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The following table shows the field descriptions for this command.

Table 162: show ip igmp access field descriptions

| Field | Description |
|------------|---|
| INTERFACE | Identifies the interface where multicast access control is configured. |
| GRP PREFIX | Shows an alphanumeric string that identifies the name of the access policy. |
| HOSTADDR | Shows the IP address of the host. |
| HOSTMASK | Shows the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the host network. |
| ACCESSMODE | Specifies the action of the access policy. The actions are: <ul style="list-style-type: none"> deny-tx—deny IP multicast transmitted traffic. deny-rx—deny IP multicast received traffic. deny-both—deny both IP multicast transmitted and received traffic. allow-only-rx—allow IP multicast transmitted traffic. allow-only-rx—allow IP multicast received traffic. allow-only-both—allow both IP multicast transmitted and received traffic. |

IGMP cache

Use the **show ip igmp cache** command to display information about the IGMP cache. The syntax for this command is as follows.

```
show ip igmp cache [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

The following table shows the field descriptions for this command.

Table 163: show ip igmp cache command

| Field | Description |
|-----------|---|
| GRPADDR | Indicates the multicast group address (Class D) that others want to join. Many incoming ports can use the same group address. |
| INTERFACE | Indicates the physical interface or a logical interface (VLAN), which received group reports from various sources. |

Table 163: show ip igmp cache command (continued)

| Field | Description |
|--------------|---|
| LASTREPORTER | Indicates the IP address of the source of the last membership report received for this IP multicast group address on this interface. If the interface does not receive a membership report, this object uses the value 0.0.0.0. |
| EXPIRATION | Indicates the minimum amount of time that remains before this entry ages out. |
| VIHOSTTIMER | Indicates the time that remains until the local router assumes that no IGMPv1 members exist on the IP subnet attached to this interface. |
| TYPE | Indicates whether the entry is learned dynamically or is added statically. |
| STATICPORTS | Indicates the list of statically-defined ports. |
| L2ISID | Indicates the I-SID associated with the Layer 2 interface. |

IGMP group

Use the **show ip igmp group** command to display information about the IGMP group. The syntax for this command is as follows.

```
show ip igmp group [count] [member-subnet {default|A.B.C.D/X}] [group {A.B.C.D} <detail|tracked-members>] [vrf WORD <0-16>] [vrfids <0-512>]
```

**Note**

The CLI command **show ip igmp group** displays both static and dynamically learned IGMP groups, and the CLI command **show ip igmp static** command displays only the statically configured IGMP groups. In contrast, the EDM display command under **IP > IGMP > Groups** displays the dynamically learned groups, and the EDM command under **IP > IGMP > Static** displays the statically configured IGMP groups.

The following table shows the field descriptions for this command.

Table 164: show ip igmp group command

| Field | Description |
|------------|--|
| GRPADDR | Indicates the multicast group address (Class D) that others want to join. Many incoming ports can use the same group address. |
| INPORT | Indicates the physical interface or a logical interface (VLAN), which received group reports from various sources. |
| MEMBER | Indicates the IP address of a source that sent a group report to join this group. |
| EXPIRATION | Indicates the time left before the group report expires on this port. The port updates this variable after it receives a group report. |
| TYPE | Indicates the group type. |
| L2ISID | Indicates the I-SID associated with the Layer 2 interface. |

```
Switch:1(config)#show ip igmp group
```

```
Switch:1#show ip igmp group

=====
                        Igmp Group - GlobalRouter

IGMP interface

Use the **show ip igmp interface** command to display information about the interfaces where IGMP is enabled. This syntax for this command is as follows.

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]}|vlan <1-4059>] [vrf WORD <1-16>] [vrfs WORD
<0-512>]
```

The following table shows the field descriptions for this command if you do not use optional parameters.

show ip igmp interface command without parameters

| Field | Description |
|---------------|--|
| IF | Indicates the interface where IGMP is configured. |
| QUERY INTVL | Indicates the frequency at which IGMP host query packets transmit on this interface. |
| STATUS | Indicates the activation of a row, which activates IGMP on the interface. The destruction of a row disables IGMP on the interface. |
| VERS. | Indicates the version of IGMP that runs on this interface. This object configures a router capable of running either version. For IGMP to function correctly, you must configure all routers on a LAN to run the same version of IGMP. |
| OPER VERS | Indicates the operational version of IGMP. |
| QUERIER | Indicates the address of the IGMP querier on the IP subnet to which this interface attaches. |
| QUERY MAXRSPT | Indicates the maximum query response time (in tenths of a second) advertised in IGMPv2 queries on this interface. |
| WRONG QUERY | Indicates the number of queries received where the IGMP version does not match the interface version. You must configure all routers on a LAN to run the same version of IGMP. If queries are received with the wrong version, a configuration error occurs. |

| Field | Description |
|---------------|--|
| JOINS | Indicates the number of times this interface added a group membership. |
| ROBUST | Indicates the robustness variable, which you can configure for the expected packet loss on a subnet. If you expect packet loss on a subnet, increase the robustness variable. |
| LASTMEM QUERY | Indicates the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages, and is also the amount of time between group-specific query messages. Use this value to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. This variable does not apply to IGMPv1. |
| MODE | Indicates the protocol configured on the VLAN added. <ul style="list-style-type: none"> snoop—Indicates IGMP snooping is enabled on a VLAN. snoop-spb—Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). pim—Indicates PIM is enabled. routed-spb—Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts. pim-gw-spb—Indicates the SPB-PIM Gateway is enabled on the interface. |
| L2ISID | Indicates the I-SID associated with the Layer 2 interface. |

The following table shows the field descriptions for this command if you use the interface parameters.

Table 165: show ip igmp interface command with interface parameters

| Field | Description |
|---------------------|---|
| VLAN ID or PORT NUM | Identifies the VLAN or port where IGMP is configured. |
| QUERY INTVL | Indicates the frequency at which IGMP host query packets transmit on this interface. |
| QUERY MAX RESP | Indicates the maximum query response time (in tenths of a second) advertised in IGMPv2 queries on this interface. |
| ROBUST | Indicates the robustness variable, which you can configure for the expected packet loss on a subnet. If you expect packet loss on a subnet, increase the robustness variable. |
| VERSION | Indicates the version of IGMP that runs on this interface. This object configures a router capable of running either version. For IGMP to function correctly, you must configure all routers on a LAN to run the same version of IGMP. |
| LAST MEMB QUERY | Indicates the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages, and is also the amount of time between group-specific query messages. Use this value to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. This variable does not apply to IGMPv1. |
| PROXY SNOOP ENABLE | Indicates if proxy snoop is enabled on the interface. |

Table 165: show ip igmp interface command with interface parameters (continued)

| Field | Description |
|---|--|
| SNOOP ENABLE | Indicates if snoop is enabled on the interface. |
| SSM SNOOP ENABLE | Indicates if SSM snoop is enabled on the interface. |
| UPnP FILTER ENABLE | Indicates if Universal Plug and Play (uPnP) Filtering is enabled to filter multicast packets destined for a specific range. The default is disabled. |
| FAST LEAVE ENABLE | Indicates if fast leave mode is enabled on the interface. |
| FAST LEAVE PORTS (VLAN parameter only) | Indicates the set of ports that are enabled for fast leave |
| SNOOP QUERIER ENABLE (VLAN parameter only) | Indicates if the IGMP Layer 2 Querier feature is enabled. |
| SNOOP QUERIER ADDRESS (VLAN parameter only) | Indicates the IP address of the IGMP Layer 2 querier. |
| DYNAMIC DOWNGRADE VERSION | Indicates if the dynamic downgrade feature is enabled. |
| COMPATIBILITY MODE | Indicates if compatibility mode is enabled. |
| EXPLICIT HOST TRACKING | Indicates if explicit host tracking is enabled to track all the source and group members. |
| UPnP FILTER ADDRESS | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32. |

IGMP multicast router discovery

Use the **show ip igmp mrdisc** command to display information about the IGMP multicast discovery routes. The syntax for this command is as follows.

show ip igmp mrdisc [vrf WORD <0-16>] [vrfids WORD <0-512>]

Note

This command is not supported on a node configured as the DVR Leaf within a DvR domain.

The following table shows the field descriptions for this command.

Table 166: show ip igmp mrdisc command

| Field | Description |
|-----------------------|--|
| VLAN ID | Indicates the VLAN ID. |
| MRDISC | Indicates the status of multicast router discovery. |
| MAX ADV INTERVAL | Indicates the maximum number (in seconds) between successive advertisements. |
| MIN ADV INTERVAL | Indicates the minimum number (in seconds) between successive advertisements. |
| MAX INIT ADV INTERVAL | Indicates the maximum number (in seconds) between successive initial advertisements. |
| MAX INIT ADV | Indicates the maximum number of initial multicast advertisements after initialization. |
| NBR DEAD INTERVAL | Indicates the multicast router discovery dead interval — the number of seconds the multicast route neighbors for the switch must wait before assuming that the multicast router is down. |
| DISCOVERED RTR PORTS | Indicates the ports discovered. |

IGMP multicast router discovery neighbors

Use the **show ip igmp mrdisc neighbors** command to display information about the IGMP multicast router discovery neighbors. The syntax for this command is as follows.

```
show ip igmp mrdisc neighbors [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

The following table shows the field descriptions for this command.

Table 167: show ip igmp mrdisc-neighbors command

| Field | Description |
|------------|---|
| VLAN ID | Indicates the VLAN ID. |
| SRC_PORT | Indicates the source port. |
| IP Addr | Indicates the IP address. |
| Advert-int | Indicates the advertisement interval in seconds. |
| QUERY-int | Indicates the query interval in seconds. |
| Robust-val | Indicates the tuning for the expected packet loss on a subnet. If you expect packet loss on a subnet, increase the robustness variable. |

IGMP router-alert

Use the **show ip igmp router-alert** command to display the status of IGMP router alert. The syntax for this command is as follows.

```
show ip igmp router-alert [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

**Note**

This command is not supported on a node configured as the DvR Leaf within the DvR domain.

The following table shows the field descriptions for this command.

Table 168: show ip igmp router-alert command

| Field | Description |
|---------------------|---|
| IFINDEX | Indicates the interface index number. |
| ROUTER ALERT ENABLE | Indicates the status of the router alert check. |

IGMP sender

Use the **show ip igmp sender** command to display information about the IGMP senders. The syntax for this command is as follows.

```
show ip igmp sender [count] [member-subnet {default|A.B.C.D/X}] [group {A.B.C.D}] [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

The following table shows the field descriptions for this command.

Table 169: show ip igmp sender command

| Field | Description |
|----------|--|
| GRPADDR | Indicates the IP multicast address. |
| IFINDEX | Indicates the interface index number. |
| MEMBER | Indicates the IP address of the host. |
| PORT/MLT | Indicates the IGMP sender ports. |
| STATE | Indicates if a sender exists because of an IGMP access filter. Options include filtered and nonfiltered. |
| L2ISID | Indicates the I-SID associated with the Layer 2 interface. |

Display information about IGMP senders:

```
Switch:1#show ip igmp sender
```

```

```

IGMP snoop

Use the **show ip igmp snooping** command to display the status of IGMP snoop. The syntax of this command is as follows.

```
show ip igmp snooping [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

Note

This command is not supported on a node configured as the DvR Leaf within the DvR domain.

The following table shows the field descriptions for this command.

Table 170: show ip igmp snooping command

| Field | Description |
|--------------------|---|
| IFINDEX | Indicates the interface index number. |
| SNOOP ENABLE | Indicates the status of IGMP snoop. |
| PROXY SNOOP ENABLE | Indicates the status of IGMP proxy snoop. |
| SSM SNOOP ENABLE | Indicates the status of IGMP Source Specific Multicast (SSM) snoop. |

Table 170: show ip igmp snooping command (continued)

| Field | Description |
|---------------------------|--|
| STATIC MROUTER PORTS | Indicates the set of ports in this VLAN that provide connectivity to an IP multicast router. |
| ACTIVE MROUTER PORTS | Indicates the active ports. |
| MROUTER EXPIRATION TIME | Indicates the multicast querier router aging timeout in seconds. |
| SNOOP QUERIER ENABLE | Indicates if the IGMP Layer 2 Querier feature is enabled. |
| SNOOP QUERIER ADDRESS | Indicates the IP address of the IGMP Layer 2 querier. |
| DYNAMIC DOWNGRADE VERSION | Indicates if the switch downgrades the version of IGMP to handle older query messages. |
| COMPATIBILITY MODE | Indicates if IGMPv3 is compatible with IGMPv2 |

IGMP static and blocked ports

Use the **show ip igmp static** command to display information about the static and blocked ports for the IGMP-enabled interfaces. The syntax for this command is as follows.

```
show ip igmp static [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

**Note**

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The following table shows the field descriptions for this command.

Table 171: show ip igmp static command

| Field | Description |
|--------------|---|
| GRPADDR | Indicates the IP multicast address. The group address holds the starting range for the address range. |
| TO-GRPADDR | Indicates the end of the range for the group address. |
| INTERFACE | Indicates the interface IP address. |
| STATICPORTS | Indicates the egressing ports. |
| BLOCKEDPORTS | Indicates the ports not allowed to join. |

Multicast group trace for IGMP snoop

Use the **show ip igmp snoop-trace** command to view multicast group trace information for IGMP snoop. Multicast group trace tracks the data flow path of the multicast streams. This command provides information such as the multicast group address, the source address, ingress VLAN and port, and egress VLAN and port. The syntax for the command is as follows.

```
show ip igmp snoop-trace [source {A.B.C.D}] [group {A.B.C.D}] [vrf WORD
<0-16>] [vrfids WORD <0-512>]
```

**Note**

This command is not supported on a node configured as the DvR Leaf within the DvR domain.

The following table provides the field descriptions for this command.

Table 172: show ip igmp snoop-trace command

| Field | Description |
|----------------|--|
| GROUP ADDRESS | Indicates the IP multicast group address for which this entry contains information. |
| SOURCE ADDRESS | Indicates the source of the multicast traffic. |
| IN VLAN | Indicates the incoming VLAN ID. |
| IN PORT | Indicates the incoming port number. |
| OUT VLAN | Indicates the outgoing VLAN ID. |
| OUT PORT | Indicates the outgoing port number. |
| TYPE | Indicates where the stream is learned. ACCESS indicates the stream is learned locally. |

```
Switch:1# show ip igmp snoop-trace

=====
                        Snoop Trace - GlobalRouter
=====
GROUP          SOURCE          IN    IN    OUT   OUT   TYPE

```

SSM map information

Use the **show ip igmp ssm-map** command to display the list of SSM maps. The syntax for this command is as follows.

```
show ip igmp ssm-map [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

The following table shows the field descriptions for this command.

Table 173: show ip igmp ssm-map command

| Field | Description |
|--------|--|
| GROUP | Indicates the IP multicast group address that uses the default range of 232/8. |
| SOURCE | Indicates the IP address of the source that sends traffic to the group source. |
| MODE | Indicates that the entry is a statically configured entry (static) or a dynamically learned entry from IGMPv3 (dynamic). |

Table 173: show ip igmp ssm-map command (continued)

| Field | Description |
|--------|---|
| ACTIVE | Indicates the activity on the corresponding source and group. If the source is active and traffic is flowing to the switch, this status is active; otherwise, it is nonactive. |
| STATUS | Indicates the administrative state and whether to use the entry. If the status is enabled (default), the entry is used. If the status is disabled, the entry is not used but is saved for future use. |

```
Switch:1(config)#show ip igmp ssm-map

```

SSM group range and dynamic learning status

Use the **show ip igmp ssm** command to display the SSM group range and the status of dynamic learning. The syntax for this command is as follows.

```
show ip igmp ssm [vrf WORD <0-16>] [vrfids WORD <0-512>]
```

Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

The following table shows the field descriptions for this command.

Table 174: show ip igmp ssm command

| Field | Description |
|------------------|--|
| DYNAMIC LEARNING | Indicates whether dynamic learning is enabled at a global level. |
| SSM GROUP RANGE | Indicates the IP address range for the SSM group. |

PIM show commands

This section explains the show commands for Protocol Independent Multicast (PIM).

PIM active RP

Use the **show ip pim active-rp** command to display information about the active rendezvous point (RP) for all groups or a specific group. If you do not specify an IP address, you receive information about the active RP for all the running multicast groups on the switch. The syntax for this command is as follows.

show ip pim active-rp [group {A.B.C.D}]

The following table shows the field descriptions for this command.

Table 175: show ip pim active-rp command

| Field | Description |
|-------------|---|
| GRPADDR | Shows the IP address of the multicast group. |
| RP-ADDR | Shows the IP address of the RP router. This address must be one of the local PIM-SM enabled interfaces. |
| RP-PRIORITY | Shows the priority of the RP. |

Display information about the active rendezvous points:

```
Switch#show ip pim active-rp
```

```

=====
                          Pim Grp->RP Active RP Table - GlobalRouter
=====
GRPADDR          RP-ADDR          RP-PRIORITY
-----
239.0.0.1        20.0.0.90        0
239.0.0.2        20.0.0.90        0
239.0.0.3        20.0.0.90        0
239.0.0.4        20.0.0.90        0
239.0.0.5        20.0.0.90        0
239.255.255.250 20.0.0.90        0

```

PIM bootstrap router

Use the **show ip pim bsr** command to display information about the bootstrap router (BSR) for this PIM-SM domain. The syntax for this command is as follows.

show ip pim bsr

The following table shows the field descriptions for this command.

Table 176: show ip pim bsr command

| Field | Description |
|----------------------|---|
| Current BSR address | Shows the IP address of the current BSR for the local PIM domain. |
| Current BSR priority | Shows the priority of the current BSR. The C-BSR with the highest BSR priority and address (referred to as the preferred BSR) is elected as the BSR for the domain. |

Table 176: show ip pim bsr command (continued)

| Field | Description |
|----------------------|--|
| Current BSR HaskMask | Shows the mask used in the hash function to map a group to one of the C-RPs from the RP set. The hash-mask allows a small number of consecutive groups (for example, 4) to always hash to the same RP. |
| Current BSR Fragment | Shows a randomly generated number that distinguishes fragments that belong to different bootstrap messages. Fragments that belong to the same bootstrap message carry the same fragment tag. |
| Pim Bootstrap Timer | Shows the bootstrap timer. After the bootstrap timer expires, the BSR sends out bootstrap messages. |

PIM candidate rendezvous points

Use the **show ip pim rp-candidate** command to display information about the candidate rendezvous points for the PIM-SM domain. The syntax for this command is as follows.

show ip pim rp-candidate

The following table shows the field descriptions for this command.

Table 177: show ip pim rp-candidate command

| Field | Description |
|---------|---|
| GRPADDR | Displays the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| GRPMASK | Displays the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| RPADDR | Displays the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces. |

PIM interface

Use the **show ip pim interface** command to display information about the PIM-SM interface configuration on the switch. The syntax of this command is as follows.

```
show ip pim interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]] [,...] | vlan <1-4059>]
```

The following table shows the field descriptions for this command if you do not use optional parameters.

Table 178: show ip pim interface command without parameters

| Field | Description |
|-----------|---|
| IF | Indicates the slot and port number or VLAN ID of the interface where PIM is enabled. |
| ADDR | Shows the IP address of the PIM interface. |
| MASK | Shows the network mask for the IP address of the PIM interface. |
| MODE | Indicates the configured mode of this interface. The valid modes are SSM and Sparse. |
| DR | Shows the designated router (DR) for this interface. |
| HLINT | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default hello interval is 30 seconds. |
| JPINT | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default join and prune interval is 60 seconds. |
| CBSR | Specifies the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. |
| OPSTAT | Indicates the status of PIM on this interface: up or down. |
| INTF TYPE | Indicates whether the PIM interface is active or passive. |

The following table shows the field descriptions for this command if you use optional parameters.

Table 179: show ip pim interface command with parameters

| Field | Description |
|---------------------|---|
| VLAN-ID or PORT-NUM | Indicates the slot and port number or VLAN ID of the interface where PIM is enabled. |
| PIM ENABLE | Indicates the administrative status of PIM. |
| MODE | Indicates the configured mode of this interface. The valid modes are SSM and Sparse. |
| HELLOINT | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default hello interval is 30 seconds. |
| JPINT | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default join and prune interval is 60 seconds. |
| CBSRPREF | Specifies the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. |
| INTF TYPE | Indicates whether the PIM interface is active or passive. |

Switch:1(config)#show ip pim interface

```

PIM mode

Use the **show ip pim mode** command to show the PIM mode (SM or SSM). The syntax for this command is as follows.

show ip pim mode

The following table shows the field description for this command.

Table 180: show ip pim mode command

| Field | Description |
|-------|--------------------------------------|
| Mode | Indicates the PIM mode as SM or SSM. |

PIM neighbor

Use the **show ip pim neighbor** command to display information about the neighboring routers configured with PIM-SM. The syntax for this command is as follows.

show ip pim neighbor

The following table shows the field descriptions for this command.

Table 181: show ip pim neighbor command

| Field | Description |
|-----------|--|
| INTERFACE | Indicates the interface number. |
| ADDRESS | Indicates the IP address of the PIM neighbor. |
| UPTIME | Indicates the elapsed time since this PIM neighbor last became a neighbor of the local router. |
| EXPIRE | Indicates the time that remains before this PIM neighbor times out. |

PIM route

Use the **show ip pim mroute** command to display information from the route table. The syntax for this command is as follows.

show ip pim mroute [group <A.B.C.D>] [source <A.B.C.D>] [terse]

Note

In a PIM-SM or PIM-SSM Layer 3 MLT/SMLT multicast environment, when an SMLT link down or SMLT link up event occurs, or when an individual port in an (S)MLT goes down or comes back up, traffic can be re-hashed (switched over) either to another port in the (S)MLT or to any of the IST's MLT ports. This is valid, as the nature of the (S)MLT environment is that traffic can ingress on any one of these ports and be successfully forwarded to receivers. However, the Incoming Port record in the following table may not accurately reflect which port the data is arriving on at any given time. This does not cause traffic loss. Checking traffic statistics on the ports of the (S)MLT/ IST can be used to determine the ingress port.

The following table shows the field descriptions for this command.

Table 182: show ip pim mroute command

| Field | Description |
|----------|--|
| Src | Displays the IP address of the source that sends the multicast stream. A nonzero value indicates that a source sends multicast traffic. 0.0.0.0 indicates that this entry is created in response to a receiver that wants to receive this traffic. |
| Grp | Displays the IP multicast group address. |
| RP | Displays the IP address of the RP router. |
| Upstream | Displays the IP address of the next hop that a multicast packet takes when received on the correct port as listed on the incoming interface. |
| Flags | Displays the flags configured based on the condition of the receivers, the RP, and the senders. Use the legend at the bottom of the output to explain the flag values. |

Table 182: show ip pim mroute command (continued)

| Field | Description |
|---------------------|---|
| Incoming Port | Lists the port through which a multicast packet can ingress. If the port is a member of a Multi-Link Trunk (MLT), the packets can ingress on any port of the MLT. |
| Outgoing Ports | Lists all ports through which traffic that enters on incoming ports exit. |
| Joined Ports | Lists all ports that received PIM join messages. |
| Pruned Ports | List all ports that received PIM prune messages. |
| Leaf Ports | Lists multicast receivers that directly connect to the router. |
| Asserted Ports | Lists all ports that received assert messages. The router uses assert messages to help determine the best path to the source. |
| Prune Pending Ports | Lists all ports currently in the prune-pending state. |
| Assert Winner Ifs | Lists interfaces elected the assert winner. The winner continues to forward multicast traffic to the LAN. |
| Assert Loser Ifs | Lists interfaces not elected as the assert winner. The loser interface is pruned. |
| Timers | Displays the up time and expiration time for the entry in the routing table. |
| AssertVifTimer | Displays the time after which the assert winner state refreshes. |

```
Switch:1(config)#show ip pim mroute
```

```

PIM virtual neighbor

Use the **show ip pim virtual-neighbor** command to display the virtual neighbor. The syntax for this command is as follows.

```
show ip pim virtual-neighbor
```

The following table shows the field descriptions for this command.

Table 183: show ip virtual-neighbor command

| Field | Description |
|-----------|---|
| INTERFACE | Indicates the interface. |
| ADDRESS | Indicates the IP address of the virtual neighbor. |

Rendezvous points (for groups)

Use the **show ip pim rp-hash** command to display information about the RPs selected for a multicast group. The syntax for this command is as follows.

```
show ip pim rp-hash
```

The following table shows the field descriptions for this command.

Table 184: show ip pim rp-hash command

| Field | Description |
|------------|--|
| GRPADDRESS | Shows the IP address of the multicast group. When combined with the group mask, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| GRPMASK | Shows the address mask of the multicast group. When combined with the group address, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| ADDRESS | Shows the IP address of the C-RP router. |

Table 184: show ip pim rp-hash command (continued)

| Field | Description |
|----------|--|
| HOLDTIME | Shows the time specified in a C-RP advertisement that the BSR uses to time out the RP. After the BSR receives an advertisement for the RP, it restarts the timer. If no advertisement arrives before the timer expires, the BSR removes that RP from the RP set. |
| EXPTIME | Shows the time that remains before this C-RP router times out. |

Static RP table

Use the **show ip pim static-rp** command to display the static RP table. The syntax for this command is as follows.

show ip pim static-rp

The following table shows the field descriptions for this command.

Table 185: show ip pim static-rp command

| Field | Description |
|---------|--|
| GRPADDR | Indicates the IP address of the multicast group. When combined with the group mask, it identifies the prefix that the local router uses to advertise itself as a static RP. |
| GRPMASK | Indicates the address mask of the multicast group. When combined with the group address, it identifies the prefix that the local router uses to advertise itself as a static RP. |
| RPADDR | Indicates the IP address of the static RP. This address must be one of the local PIM-SM enabled interfaces. |
| STATUS | Indicates the status of static RP. |

Display the static RP table:

```
Switch#show ip pim static-rp
```

```

IPv6 PIM show commands

This section explains the show commands for IPv6 Protocol Independent Multicast (PIM).

IPv6 PIM mode

Use the **show ipv6 pim mode** command to show the IPv6 PIM mode (SM or SSM). The syntax for this command is as follows.

show ipv6 pim mode

```
Switch:1(config)#show ipv6 pim mode
=====
                          Pim Global Mode - GlobalRouter
=====
Mode      : sparse
```

The following table shows the field description for this command.

Table 186: show ipv6 pim mode command

| Field | Description |
|-------|--------------------------------------|
| Mode | Indicates the PIM mode as SM or SSM. |

IPv6 PIM neighbor

Use the **show ipv6 pim neighbor** command to display information about the neighboring routers configured with IPv6 PIM-SM. The syntax for this command is as follows.

show ipv6 pim neighbor

```
Switch:1(config)#show ipv6 pim neighbor
=====
                          Pim Neighbor - GlobalRouter
=====
INTERFACE ADDRESS                                UPTIME                                EXPIRE
-----
Vlan2      fe80:0:0:0:12cd:aeff:fe69:f900  0 day(s), 00:08:33  0 day(s), 00:01:43
Vlan7      fe80:0:0:0:b647:5eff:fe3a:8582  0 day(s), 00:08:30  0 day(s), 00:01:18

Total PIM Neighbors Displayed:  2/2
-----
```

The following table shows the field descriptions for this command.

Table 187: show ipv6 pim neighbor command

| Field | Description |
|-----------|--|
| INTERFACE | Indicates the interface number. |
| ADDRESS | Indicates the IPv6 address of the PIM neighbor. |
| UPTIME | Indicates the elapsed time since this PIM neighbor last became a neighbor of the local router. |
| EXPIRE | Indicates the time that remains before this PIM neighbor times out. |

IPv6 PIM interface

Use the **show ipv6 pim interface** command to display information about the IPv6 PIM-SM interface configuration on the switch. The syntax of this command is as follows.

```
show ipv6 pim interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]}|vlan <1-4059>]
```

```
Switch:1(config)#show ipv6 pim interface
=====
                          Pim Interface - GlobalRouter
=====

  ADDR/MASK :   fe80:0:0:0:12cd:aeff:fe6a:1901/64
  DR          :   fe80:0:0:0:12cd:aeff:fe6a:1901

Total PIM Interface Entries:  4/0
=====
```

The following table shows the field descriptions for this command if you do not use optional parameters.

Table 188: show ipv6 pim interface command without parameters

| Field | Description |
|-----------|--|
| IF | Indicates the slot and port number or VLAN ID of the interface where PIM is enabled. |
| MODE | Indicates the configured mode of this interface. The valid modes are SSM and Sparse. |
| HLINT | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default hello interval is 30 seconds. |
| JPINT | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default join and prune interval is 60 seconds. |
| OPSTAT | Indicates the status of PIM on this interface: up or down. |
| INTF TYPE | Indicates the PIM interface type. The PIM interface type is active. |

The following table shows the field descriptions for this command if you use optional parameters.

Table 189: show ip pim interface command with parameters

| Field | Description |
|---------------------|--|
| VLAN-ID or PORT-NUM | Indicates the slot and port number or VLAN ID of the interface where PIM is enabled. |
| PIM ENABLE | Indicates the administrative status of PIM. |
| MODE | Indicates the configured mode of this interface. The valid modes are SSM and Sparse. |
| HELLOINT | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default hello interval is 30 seconds. |
| JPINT | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default join and prune interval is 60 seconds. |
| INTF TYPE | Indicates the PIM interface type. The PIM interface type is active. |

Show IPv6 PIM route

Use the **show ipv6 pim mroute** command to display information from the route table. The syntax for this command is as follows.

show ipv6 pim mroute [group WORD<0-255>] [source WORD<0-255>] [terse]

```
Switch:1(config)#show ipv6 pim mroute
=====

The following table shows the field descriptions for this command.

Table 190: show ipv6 pim mroute command

| Field | Description |
|----------------|--|
| Src | Displays the IPv6 address of the source that sends the multicast stream. A nonzero value indicates that a source sends multicast traffic. 0:0:0:0:0:0:0:0 indicates that this entry is created in response to a receiver that wants to receive this traffic. |
| Grp | Displays the IPv6 multicast group address. |
| RP | Displays the IPv6 address of the RP router. |
| Upstream | Displays the IPv6 address of the nexthop router towards the source of the multicast traffic or RP. |
| Flags | Displays the flags configured based on the condition of the receivers, the RP, and the senders. Use the legend at the bottom of the output to explain the flag values. |
| Incoming Port | Lists the port through which a multicast packet can ingress. If the port is a member of a Multi-Link Trunk (MLT), the packets can ingress on any port of the MLT. |
| Outgoing Ports | Lists all ports through which traffic that enters on incoming ports exit. |
| Joined Ports | Lists all ports that received PIM join messages. |
| Pruned Ports | Lists all ports that received PIM prune messages. |
| Leaf Ports | Lists multicast receivers that directly connect to the router. |

Table 190: show ipv6 pim mroute command (continued)

| Field | Description |
|---------------------|---|
| Asserted Ports | Lists all ports that received assert messages. The router uses assert messages to help determine the best path to the source. |
| Prune Pending Ports | Lists all ports currently in the prune-pending state. |
| Assert Winner Ifs | Lists interfaces elected the assert winner. The winner continues to forward multicast traffic to the LAN. |
| Assert Loser Ifs | Lists interfaces not elected as the assert winner. The loser interface is pruned. |
| Timers | Displays the up time and expiration time for the entry in the routing table. |
| AssertVifTimer | Displays the time after which the assert winner state refreshes. |

IPv6 PIM active RP

Use the **show ipv6 pim active-rp** command to display information about the active rendezvous point (RP) for all groups or a specific group. If you do not specify an IPv6 address, you receive information about the active RP for all the running multicast groups on the switch. The syntax for this command is as follows.

show ipv6 pim active-rp [group WORD<0-255>]

```
Switch:1(config)#show ipv6 pim active-rp
=====
                Pim Grp->RP Active RP Table - GlobalRouter
=====
GRPADDR/
RP-ADDR                               RP-PRIORITY
-----
ff30:0:0:0:0:0:1
5040:0:0:0:0:1:84:1
```

The following table shows the field descriptions for this command.

Table 191: show ipv6 pim active-rp command

| Field | Description |
|-------------|---|
| GRPADDR | Shows the IPv6 address of the multicast group. |
| RP-ADDR | Shows the IPv6 address of the RP router. This address can be one of the local PIM-SM enabled interfaces or a global IPv6 address of the chosen RP based on hash function. |
| RP-PRIORITY | Shows the priority of the RP. |

IPv6 Rendezvous points (for groups)

Use the **show ipv6 pim rp-hash** command to display information about the RPs selected for a multicast group. The syntax for this command is as follows.

show ipv6 pim rp-hash

```
Switch:1(config)#show ipv6 pim rp-hash
=====
                          Pim RPSet - GlobalRouter

Table 194: show ipv6 mroute next-hop

| Field | Description |
|---------------------|---|
| Group | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface. |
| Source | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| Source Mask | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| State | Displays whether the outgoing interface and next hop represented by this entry is currently being used to forward IPv6 datagrams as one of the following: <ul style="list-style-type: none"> forwarding: Indicates that it is currently being used pruned: Indicates that it is not being used |
| Expire Time | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging. |
| Protocol | Displays the protocol as one of the following: <ul style="list-style-type: none"> other(1): none of the following local(2): manually configured netmgmt(3): configured by a network management protocol pimSparseMode(8): PIM-SMv2 igmpOnly(10) pimSsmMode(11) spb |
| Closest Member Hops | Displays the minimum number of hops between this router and any member of this IPv6 multicast group reached via this next hop on this outgoing interface. Any IPv6 multicast datagrams for the group which have a TTL less than this number of hops is not forwarded to this next hop. |

IPv6 mroute route

Use the **show ipv6 mroute route** command to display the IPv6 mroute route information. The syntax for this command is as follows.

show ipv6 mroute route

```
Switch:1(config)#show ipv6 mroute route

=====
Mroute Route - GlobalRouter

IP Multicast over Fabric Connect Fundamentals

IP Multicast over Fabric Connect

Extreme Networks is leading the industry with a new approach to transporting IP multicast using IP Multicast over Fabric Connect. IP Multicast over Fabric Connect greatly simplifies multicast deployment, with no need for any multicast routing protocols such as Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM). A BEB can forward a multicast stream anywhere in an SPBM network where IS-IS advertises the stream to the rest of the fabric.

The advantage of this solution over traditional approaches is the simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

You can compare the quick convergence times for IP Multicast over Fabric Connect to Interior Gateway Protocols like Open Shortest Path First (OSPF) combined with PIM-SM or PIM-SSM. OSPF combined with PIM-SM or PIM-SSM can have recovery times that are sub optimal with convergence times that take tens of seconds. PIM experiences longer convergence times, in part, because unicast IP routing protocols must converge before PIM can converge. PIM also maintains the network state for every multicast group and uses a mechanism based on each hop to update the network about state changes, which affects scalability.

IP Multicast over Fabric Connect is extremely scalable because you only apply the multicast bridging and routing functionality at the SPBM fabric edge, with the streams mapped to SPBM multicast trees in the fabric.

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

IP Multicast over Fabric Connect and Universal Plug and Play Filtering

When multicast packets are received on IGMP-enabled interfaces and the multicast group matches the range of groups to be filtered, Universal Plug and Play (uPnP) Filtering drops them.

For more information, see [Universal Plug and Play Filtering](#) on page 1588.

How IP Multicast over Fabric Connect works

The BEBs act as the boundary between the multicast domain (currently only IGMP dynamic or static) and the SPBM domain. Multicast senders (sources) and receivers connect directly or indirectly (using Layer 2 switches) to the BEBs. You can enable IP Multicast over Fabric Connect services at the Layer 2 VSN level or the Layer 3 VSN level (including the GRT).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

Figure 146: IP Multicast over Fabric Connect streams

The following list describes how multicast senders and receivers connect to the SPBM cloud using BEBs in the preceding diagram:

1. The sender transmits multicast traffic with group IP address 233.252.0.1.
2. After the BEB receives the IP multicast stream from the sender, the BEB allocates data I-SID 16000001 for the S,G multicast stream. The BEB sends an LSP with the TLV 185 (for Layer 2 VSN multicast and Layer 3 VSN multicast) or TLV 186 (for IP Shortcuts multicast) with the transmit bit set. The BEB also sends an IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the I-SID is the Data I-SID).
3. The receiver sends a join request to Group 233.252.0.1.
4. The BEB (acting as the IGMP Querier) queries the IS-IS database to find all senders for group 233.252.0.1. If the group exists, the BEB sends an LSP with the IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the nickname is the stream transmitter BEB and the I-SID is the data I-SID).
5. The multicast tree is calculated for the data I-SID and the data starts flowing from the sender.

Scope level

IP Multicast over Fabric Connect constrains all multicast streams within the level in which they originate, which is called the scope level. In other words, if a sender transmits a multicast stream to a BEB on a C-VLAN (a VLAN that is mapped to an I-SID, for instance, a L2 VSN) with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream. Similarly, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT or a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 instance (GRT or L3 VSN) can receive that stream.

Note

In the context of IP Multicast over Fabric Connect, scope is either the Global Routing Table or the I-SID value of the Layer 2 or Layer 3 VSN associated with the local VLAN on which the IP multicast data was received.

Data I-SID

After the BEB receives the IP multicast stream from the sender, a BEB allocates a data Service Identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the S,G, V tuple, which is the source IP address, the group IP address, and the local VLAN the multicast stream is received on.

The BEB propagates this information through the SPBM cloud by using IS-IS TLV updates in LSPs, which results in the creation of a multicast tree for that stream. All BEBs now know what data I-SID to use for that stream and its scope. The data I-SID is a child of the scope or VSN I-SID. If no receiver requests the IP multicast stream, the ingress BEB does not forward the multicast stream.

IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver, and this information is propagated through the SPBM cloud.

IS-IS acts dynamically using the TLV information it receives from BEBs that connect to the sender and the receivers to create a multicast tree between them. IS-IS creates very efficient multicast trees for the data I-SID allocated at the sender edge of the SPBM cloud to transport data between the sender and the receivers. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID. After IS-IS creates the multicast tree, the sender transports data to the receiver across the SPBM cloud using the data I-SID.

The trigger to send IS-IS updates to announce a multicast stream into the SPBM cloud is the multicast traffic arriving at the BEB. Because the BEB only interacts with IGMP and not PIM, all multicast traffic must be drawn towards the BEB for the stream to be announced, which SPBM accomplishes by making the BEB an IGMP Querier. In a VLAN, the IGMP Querier sends out periodic IGMP queries.

Note

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, it causes unexpected behavior, including traffic loss.

BEB as IGMP Querier

The BEB acts as the IGMP Querier and creates tables for links that need IP multicast streams. IGMP and IGMP Snooping cannot work without an IGMP Querier that sends out periodic IGMP queries.

The BEB only interacts with IGMP messages and not PIM. All multicast traffic must enter the BEB for the data stream to be announced.

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, unexpected behavior results, including traffic loss.

The IGMP query message is an IP packet and requires a source IP address. However, Layer 2 IGMP Snooping with SPBM by default turns on the service without the configuration of an IP address on the VLAN. By default, the BEB sends an IGMP query message with an IP source address of 0.0.0.0. If there are interoperability issues with third party vendors as a result of the 0.0.0.0 IP address, then you can configure the querier address under IGMP, without having to configure an IP address for the Layer 2 VSN VLAN.

IGMP Snooping, operating on the Layer 2 VSN, listens to conversations between hosts and routers, and maintains a table for links that need IP multicast streams.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

For more conceptual and configuration information on IGMP, see [IP Multicast](#) on page 1319.

Switch clustering at the edge of the SPBM network

Typical customer deployments require redundancy all the way to the access side of the network. IP Multicast over Fabric Connect supports switch clustering, Split Multilink Trunking (SMLT) technology, at the edge of the SPBM fabric, providing redundancy to the access Layer 2 switch where you can attach multicast senders and receivers. Typical SPBM fabric deployments use two or more B-VLANs for Equal Cost Multipath (ECMP) and resiliency. For simplicity in understanding how the SPBM network works, assume that there are two B-VLANs (primary and secondary).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

Figure 147: IP Multicast over Fabric Connect streams in an SMLT configuration

The following list describes the preceding diagram:

1. The edge switch hashes the sender multicast data to a specific MLT link.
2. A multicast stream received at the edge of the SPBM fabric is mapped to a dedicated multicast data I-SID.
3. For the non-SMLT attached sender 2, the stream is hashed to the primary or secondary B-VLAN based on whether the data I-SID is even or odd numbered. For the SMLT attached to sender 1, IS-IS advertises the stream to the rest of the fabric on the primary B-VLAN and synchronizes information to the vIST peer.
4. The edge switch hashes the receiver IGMP join to a specific MLT link.
5. Both BEBs on both B-VIDs advertise the IGMP join.
6. The multicast tree is built for (S1,G1), which is rooted in the primary sender BEB. The multicast tree is built for (S1,G1), which is rooted in the secondary sender BEB.

IGMP Snooping is widely used on Layer 2 access switches to prune multicast traffic. In IP Multicast over Fabric Connect, BEBs are the IGMP Queriers, therefore access switches forward multicast data from the senders as well as IGMP control messages from receivers to the BEBs.

Multicast sender

When a sender transmits multicast data to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB allocates a data I-SID and sends a TLV update on either the primary B-VLAN or the secondary B-VLAN, depending on whether the BEB is the primary or secondary switch. The primary switch uses the primary B-VLAN, whereas, the secondary switch uses the secondary B-VLAN. This information is propagated through the SPBM fabric so all BEBs are aware of this stream availability.

The sender information is also synchronized over the vIST to the peer switch. Then the peer switch allocates a data I-SID for the multicast stream and sends a TLV update on the appropriate B-VLAN to announce the availability of the stream. The data I-SIDs allocated by the primary and secondary switch cluster peers may be the same or different, as they are allocated independently by each switch.

**Note**

If a sender attaches to only one BEB in a switch cluster, the sender information is not synchronized over the vIST because it is not SMLT attached. The sender information is advertised, and data is sent on either the primary or secondary B-VLAN. The odd-numbered data I-SIDs use the primary B-VLAN, and the even-numbered data I-SIDs use the secondary B-VLAN. The same hashing rules apply to the forwarding of multicast data.

Multicast receiver

When a receiver sends an IGMP join message to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB queries the IS-IS Link State Database (LSDB) to check if a sender exists for the requested stream within the scope of the receiver.

If the requested stream does not exist, the BEB keeps the IGMP information but no further action is taken. If the requested stream exists, the BEB sends an IS-IS Link State Packet (LSP), with TLV update information, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of a receiver. The BEB propagates this information through LSPs through the SPBM cloud. The receiver information is also synchronized over the vIST to the peer switch. The peer switch then queries its IS-IS Link State Database (LSDB) and, if the requested stream exists, it sends an IS-IS LSP, with a TLV update, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of the receiver.

IS-IS uses these TLV updates in LSPs to create multicast shortest path first trees in the SPBM fabric. IS-IS creates a shortest path first tree for the primary and secondary B-VLANs, but only one of the B-VLANs transports multicast data with the other in active standby in case of failures at the SPBM edge. After IS-IS creates the trees, multicast data flows between senders and receivers.

IP Multicast over Fabric Connect and SMLT

The following section summarizes the IP Multicast over Fabric Connect actions in an SMLT environment. The BEBs on the sender side behave as follows:

- Primary SMLT peer BEB always advertises the streams it receives, and sends data for them on the primary B-VLAN.
- Secondary SMLT peer BEB always advertises the streams it receives, and sends data for them on the secondary B-VLAN.
- Non-SMLT BEBs or SMLT BEBs with single attached senders advertise streams, and send data on the primary or secondary B-VLAN based on hash criteria (odd-numbered data I-SIDs use primary B-VLAN; even-numbered data I-SIDs use secondary B-VLAN).

The BEBs on the receiver side behave as follows:

- The primary SMLT peer BEB that receives multicast data on the primary B-VLAN sends it to both SMLT and non-SMLT SPBM access (UNI) links.
- The primary SMLT peer BEB that receives multicast data on the secondary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.

- The secondary SMLT peer BEB that receives multicast data on primary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.
- The secondary SMLT peer BEB that receives multicast data on secondary B-VLAN sends data to both SMLT and non-SMLT SPBM access (UNI) links.
- The non-SMLT BEB that receives multicast data on primary or secondary B-VLAN sends data to all SPBM access (UNI) links.

Layer 2 Querier behavior for a switch cluster

For C-VLANs in an SMLT environment, the vIST ports are not part of the VLAN.

IGMP on a C-VLAN behaves as follows to account for the fact that vIST peers do not see the membership queries of each other:

- The vIST peer with the higher IP address sends the queries out all SMLT and non-SMLT ports on SPBM access links.
- The vIST peer with the lower IP address only sends out queries on its non-SMLT ports. This includes SMLT ports whose remote ports are down (SMLT state of 'norm').
- With the existence of an vIST peer with a higher IP address and an vIST peer with a lower IP address, it means two queriers exist within the C-VLAN. Having two queriers poses no problems in this SPB environment, as all SMLT access devices see the vIST peer with the higher IP address as the querier, and non-SMLT access devices see the directly connected vIST peer as the querier. Non-SMLT access devices that connect on either side of the vIST peers can talk to each other using the SPBM cloud.

Considerations when you connect an IP Multicast over Fabric Connect network to a PIM network

IP Multicast over Fabric Connect does not integrate PIM functionality. Apply the following considerations when you connect to a PIM network:

- You must configure static IGMP receivers on the BEB access interface that faces the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network.

Note

The PIM router must have a configuration option to accept streams with non-local sources or the router drops the packets. The switch does not support a configuration option to accept streams with non-local sources.

You must configure static IGMP receivers on the PIM interface that face the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.

Note

For security reasons and to limit unnecessary multicast streams from being injected into the SPBM domain, you should configure ACLs on the BEB facing the PIM network.

IP Multicast over Fabric Connect restrictions

Review the following restrictions for the IP Multicast over Fabric Connect feature.

IGMP

The BEB must be the only IGMP querier in the network. If the BEB receives an IGMP query from any other device, it causes unpredictable behavior, including traffic loss.

SPBM supports IGMP Snooping on a C-VLAN, but it does not support PIM on a C-VLAN. If you enable IGMP Snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IP Multicast over Fabric Connect.

SPBM supports Network Load Balancing (NLB) unicast and multicast modes. SPBM does not support NLB Multicast operation with IGMP.

Note

The NLB Multicast operation feature is not supported on all hardware platforms. For more information about feature support, see [VLAN Feature Support](#) on page 3814.

You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is either the same as the IGMP version configured on the IGMP Snooping VLAN, or that compatibility mode is enabled.

SSM

If you delete any **ssm-map** in a static range group, the switch deletes the entire static range group. For example, create an ssm-map for 232.122.122.122 to 232.122.122.128 and after that configure this same range in a static group. If you delete any ssm-map between 232.122.122.122. to 232.122.122.128, the switch deletes the entire static range group.

PIM

There can be no interaction with PIM and multicast routers on the access.

The BEB only interacts with IGMP messages and not PIM, so all multicast traffic must be drawn towards the BEB, which acts as the IGMP querier, for the stream to be announced.

IP Multicast over Fabric Connect does not integrate PIM functionality so the following considerations apply when connecting to a PIM network:

- You must configure static IGMP receivers on the BEB access interface facing the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network. Static IGMP receivers make the PIM router accept streams and avoid a Reverse Path Forwarding (RPF) check that can change the source of the stream.
- You must configure static IGMP receivers on the PIM interface facing the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.
- You must configure Access Control Lists (ACLs) on the BEB facing the PIM network for security.

Data I-SID

The BEB matches a single multicast stream to a particular data I-SID. As a result there is a one-to-one mapping between the S,G to data I-SID for each BEB.

Supported services

The switch does not support IP Multicast over Fabric Connect routing on inter-VSN routing interfaces.

The switch supports the following modes of IP Multicast over Fabric Connect:

- Layer 2 VSN multicast service — Multicast traffic remains within the same Layer 2 VSN across the SPBM cloud.
- Layer 3 VSN multicast service — Multicast traffic remains within the same Layer 3 VSN across the SPBM cloud.
- IP Shortcuts multicast service — Multicast traffic can cross VLAN boundaries but remains confined to the subset of VLANs with the Global Routing Table that have IP Multicast over Fabric Connect enabled.

SPBM Multicast FIB

Multicast FIB

SPBM runs all pair Dijkstras to produce the multicast FIB. The computing node loops through each node to run Dijkstra using that node as the root, and then prunes paths to only keep the shortest paths. The computing node then computes the intersection of the set of I-SIDs for which the root node transmits, with the set of I-SIDs for which the path endpoints receive.

The multicast addresses are built out of two pieces: the SPBM Node Nickname and the I-SID ID converted to hexadecimal format to form the multicast MAC address.

| |
|------------------------------------|
| ----- ----- |
| nickname 0x30000 hexadecimal I-SID |

For example, if the nickname is 0.00.10 and the I-SID is 100 (0x64), the multicast address is 03:00:10:00:00:64.

The following text shows an example of the multicast FIB.

```
Switch:1(config)#show isis spbm multicast-fib

Universal Plug and Play Filtering

The switch can filter multicast packets destined for the Universal Plug and Play (uPnP) multicast IP address with a Universal Plug and Play (uPnP) Filtering option. uPnP Filtering drops all incoming multicast packets received by a switch on an IGMP-enabled interface if the destination multicast IP address matches the configured range.

uPnP Filtering applies to both multicast receivers and multicast senders. If you want to use the uPnP Filtering address range for actual multicast streaming, you must disable uPnP Filtering on the IGMP interface.

uPnP Filtering is disabled by default. If you create a new IGMP interface, uPnP Filtering is enabled automatically on the interface for the destination multicast IP address range 239.255.255.250/32. If you enable uPnP Filtering on an existing IGMP-enabled interface with senders and receivers already present, the filter does not delete the existing senders or receivers; the filter begins to drop packets from that point forward. Existing senders and receivers eventually expire and senders are not relearned.

You can use CLI or EDM to configure a different destination multicast IP address range.

uPnP Filtering functions in the following scenarios:

- IGMP snooping is enabled on a VLAN and IP Multicast over Fabric Connect on Layer 2 VSN is configured.
- IP Multicast over Fabric Connect within the Global Routing Table (GRT) is configured.
- IP Multicast over Fabric Connect on a Layer 3 VSN is configured.

IP Multicast over Fabric Connect Configuration using the CLI

Enabling IP Multicast over Fabric Connect globally

Use this procedure to enable IP Multicast over Fabric Connect globally on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose.

Note

IP Multicast over Fabric Connect uses I-SIDs starting at 16,000,000 and above. If Layer 2 or Layer 3 I-SIDs are in this range, the system displays an error message and the switch does not enable IP Multicast over Fabric Connect.

Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must add IST slot/ports to the C-VLAN for an SMLT topology.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Verify no I-SIDs exist in the default reserved range:
 - a. For Layer 2 use the following command:
`show vlan i-sid`
 - b. For Layer 3 use the following command:
`show ip ipvpn vrf WORD<1-16>`
3. Enter IS-IS Router Configuration mode:
`enable`

`configure terminal`

`router isis`
4. Enable IP Multicast over Fabric Connect globally:
`spbm <1-100> multicast enable`

Note

The switch only supports one SPBM instance.

5. (Optional) Disable IP Multicast over Fabric Connect globally:
`no spbm <1-100> multicast enable`

`default spbm <1-100> multicast enable`

Example

Enable IP Multicast over Fabric Connect globally:

```
Switch:1>show vlan i-sid
=====
                Vlan I-SID
=====
VLAN_ID      I-SID      I-SID NAME
-----
1
10           100        Hospital-Server-10
90           1000       ISID-1000

3 out of 3 Total Num of Vlans displayed
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

| Variable | Value |
|----------|---|
| <1-100> | Enables IP Multicast over Fabric Connect globally. The default is disabled. Specifies the SPBM instance. The switch only supports one instance. |

Displaying IP Multicast over Fabric Connect information

Use this procedure to display IP Multicast over Fabric Connect summary information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the status of the global IP Multicast over Fabric Connect configuration:

```
show isis spbm multicast
```
3. Display IP Multicast over Fabric Connect summary information for each S, G, V tuple:

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```
4. Display information about the multicast routes on the switch:

```
show ip mroute route [vrf WORD<0-16>] [vrfrids WORD<0-255>]
```

Example

Display IP Multicast over Fabric Connect global configuration information:

```
Switch:1>enable
Switch:1#show isis spbm multicast

                multicast : enable
                fwd-cache-timeout(seconds) : 210

Switch:1#show isis spb-mcast-summary

=====
                        SPB multicast - Summary
=====
SCOPE   SOURCE          GROUP          DATA          LSP   HOST

```

Variable definitions

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable | Value |
|--|---|
| <i>count</i> | Displays the total number of SPB multicast entries. |
| <i>host-name WORD<0-255></i> | Displays the IP Multicast over Fabric Connect summary information for a specific host-name. |
| <i>lspid <xxx.xxx.xxx.xx-xx></i> | Displays the IP Multicast over Fabric Connect summary information for the specified LSP ID that you enter in xxx.xxx.xxx.xx-xx — 8 byte format. |

The following table defines parameters for the **show ip mroute route** command.

| Variable | Value |
|---------------------------------|----------------------|
| <i>vrf WORD<1-32></i> | Specifies a VRF. |
| <i>vrfids WORD<0-255></i> | Specifies the VRF ID |

Job aid

The following table describes the fields in the output for the **show isis spbm multicast** command.

| Parameter | Description |
|-----------------------------|---|
| multicast | Specifies if multicast is enabled. |
| fwd-cache-timeout (seconds) | Specifies the forward cache timeout value in seconds. |

The following table describes the fields in the output for the **show isis spb-mcast-summary** command.

| Parameter | Description |
|----------------|--|
| SCOPE I-SID | Indicates the I-SID that specifies the multicast streams when the scope is either the Layer 3 VSN or the Layer 2 VSN or any combination. |
| SOURCE ADDRESS | Indicates the IP multicast source address that maps to the I-SID. |
| GROUP ADDRESS | Indicates the IP multicast group address that maps to the I-SID. |
| DATA I-SID | Indicates the data I-SID for the IP multicast route, which includes the source IP address, group IP address, and the local VLAN that the stream is received on (S,G,V tuple). SPBM uses the data I-SID to create the multicast tree. |
| BVID | Indicates the ID of the SPBM backbone VLAN (B-VLAN) on which the multicast stream forwards in the SPBM cloud. |
| LSP FRAG | Indicates the fragment number of the LSP ID. |
| HOST-NAME | Indicates the host name of the router. |

The following table describes the fields in the output for the **show ip mroute route** command.

| Parameter | Description |
|--------------|--|
| GROUP | Indicates the IP multicast group for this multicast route. |
| SOURCE | Indicates the network address that, when combined with the corresponding value of SRCMASK, identifies the sources for this multicast route. |
| SRCMASK | Indicates the network mask that, when combined with the corresponding value of SOURCE, identifies the sources for this multicast route. |
| UPSTREAM_NBR | Indicates the address of the upstream neighbor from which IP datagrams from these sources to this multicast address are received. The field displays the value of 0.0.0.0 if the (S,G) source is local or if the RP for this the (*,G) group is an address on this router. |
| IF | Indicates the value of ifindex for the interface that receives IP datagrams sent by these sources to this multicast address. A value of 0 in a (*,G) route indicates that datagrams are not subject to an incoming interface check, but datagrams can be received on any interface. |
| EXPIR | Indicates the minimum amount of time remaining before this entry ages out. The value 0 indicates that the entry is not subject to aging.

Note:
The value you configure for fwd-cache-timeout applies only to the locally learned sender; it does not apply to SMLT synchronized sender records. |
| PROT | Indicates the multicast protocol through which the switch learned this route. The spb-access and spb-network values indicate the stream learned when IP Multicast over Fabric Connect is configured on the VLAN. The spb-access value indicates that it was learned on the access. The spb-network value indicates it was learned over the SPBM cloud. |

Display the Multicast FIB

About This Task

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

Procedure

1. Enter Privileged EXEC mode:
`enable`

2. Display the SPBM multicast FIB:

```
show isis spbm multicast-fib [vlan <1-4059>] [i-sid <1-16777215>]
[nick-name <x.xx.xx>] [summary]
```

Example

```
Switch#show isis spbm multicast-fib

Variable Definitions

The following table defines parameters for the **show isis spbm multicast-fib** command.

| Variable | Value |
|----------------------------|---|
| <i>vlan</i> <1-4059> | Displays the FIB for the specified SPBM VLAN. |
| <i>i-sid</i> <1-16777215> | Displays the FIB for the specified I-SID. |
| <i>nick-name</i> <x.xx.xx> | Displays the FIB for the specified nickname. |
| <i>summary</i> | Displays a summary of the FIB. |

Job Aid

The following section describes the fields in the output for the SPBM multicast FIB command.

```
show isis spbm multicast-fib
```

The following table describes the fields in the output for the **show isis spbm multicast-fib** command.

| Parameter | Description |
|--------------------|---|
| MCAST DA | Indicates the multicast destination MAC address of the multicast FIB entry. |
| ISID | Indicates the I-SID of the multicast FIB entry. |
| BVLAN | Indicates the B-VLAN of the multicast FIB entry. |
| SYSID | Indicates the system identifier of the multicast FIB entry. |
| HOST-NAME | Indicates the host name of the multicast FIB entry. |
| OUTGOING INTERFACE | Indicates the outgoing port of the multicast FIB entry. |
| INCOMING INTERFACE | Indicates the outgoing port of the multicast FIB entry. |

Configure Universal Plug and Play (uPnP) Filtering

Before You Begin

Create a port-based VLAN.

About This Task

Use the following procedure to enable Universal Plug and Play (uPnP) Filtering on an IGMP-enabled interface. uPnP Filtering is disabled by default.

The default uPnP Filtering multicast group address range is 239.255.255.250/32. If you do not configure the multicast group range, uPnP Filtering filters multicast packets destined for the default multicast group range.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable uPnP Filtering:

```
ip igmp upnp-filter [ip {A.B.C.D/X}]
```

Example

Enable uPnP Filtering on a VLAN using the default multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter
```

Enable uPnP Filtering on a VLAN with configured multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter ip 233.252.0.0/24
```

Variable definitions

The following table defines parameters for the **ip igmp upnp-filter** command.

| Variable | Value |
|--|---|
| <code>gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>ip {A.B.C.D/X}</code> | Configures the multicast destination IP address range to filter for an IGMP interface. The default multicast group address is 239.255.255.250/32. |
| <code>vlan <1-4059></code> | Specifies the VLAN. |

View uPnP Filtering information on an IGMP-enabled interface

Use the following command to display uPnP Filtering information on an IGMP-enabled interface.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about the interfaces where IGMP is enabled:
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]

Example

View the default uPnP Filtering information on an IGMP-enabled interface:

```
Switch:(config)#show ip igmp interface vlan 2
=====
                        Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST  PROXY  SNOOP  SSM  UPnP  FAST  FAST
ID   INTVL MAX   RESP          MEMB  SNOOP  ENABLE SNOOP  SNOOP  FILTER LEAVE LEAVE
                                QUERY ENABLE          ENABLE ENABLE ENABLE PORTS
-----
2    125  100   2      2      10    false  false false  false  false

VLAN SNOOP  SNOOP          DYNAMIC  COMPATIBILITY EXPLICIT UPnP
ID   QUERIER QUERIER        DOWNGRADE  MODE        HOSTS  FILTER
     ENABLE  ADDRESS      VERSION    TRACKING  ADDRESS
-----
2    false  0.0.0.0      enable    disable    disable  239.255.255.250/32
```

View uPnP Filtering information on an IGMP-enabled interface when uPnP Filtering is enabled and a non-default multicast group address is configured:

```
Switch:1(config)#show ip igmp interface vlan 2
=====
                        Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST  PROXY  SNOOP  SSM  UPnP  FAST  FAST
ID   INTVL MAX   RESP          MEMB  SNOOP  ENABLE SNOOP  SNOOP  FILTER LEAVE LEAVE
                                QUERY ENABLE          ENABLE ENABLE ENABLE PORTS
-----
2    125  100   2      2      10    false  false false  true  false
```

| VLAN ID | SNOOP QUERIER ENABLE | SNOOP QUERIER ADDRESS | DYNAMIC DOWNGRADE VERSION | COMPATIBILITY MODE | EXPLICIT HOSTS TRACKING | UPnP FILTER ADDRESS |
|---------|----------------------|-----------------------|---------------------------|--------------------|-------------------------|---------------------|
| 2 | false | 0.0.0.0 | enable | disable | disable | 233.252.0.0/24 |

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable | Value |
|--|---|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059> | Specifies the VLAN. |
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

IP Multicast over Fabric Connect configuration using the EDM

Configure IP Multicast over Fabric Connect Globally

Use this procedure to globally enable IP Multicast over Fabric Connect on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose. IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

Important

IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM** to determine if any I-SIDs are within the default range reserved for multicast..
2. Select the **I-SID** tab to determine if the I-SIDs are within the default range reserved for multicast.
3. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
4. Select the **SPBM** tab.
5. If you want to enable multicast on an SPBM instance that already exists, in the **Mcast** column in the table, select **enable**.
6. If you want to enable multicast on an SPBM instance that does not yet exist, select **Insert**.
7. In the **Mcast** box, select **enable** to enable IP Multicast over Fabric Connect globally.
8. Select **Insert**.
9. Select **Apply**.

SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

| Name | Description |
|--------------------------------------|--|
| Id | Specifies the SPBM instance ID. Only one SPBM instance is supported. |
| NodeNickName | Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>. |
| PrimaryVlan | Specifies the primary SPBM B-VLANs to add to the SPBM instance. |
| Vlans | Specifies the SPBM B-VLANs to add to the SPBM instance. |
| LsdbTrap | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable. |
| IpShortcut | Enables or disables SPBM IP shortcut state. The default is disable. |
| SmltSplitBEB | Specifies whether the switch is the primary or secondary vIST peer. The default is primary. |
| SmltVirtualBmac | Specifies a virtual MAC address that can be used by both peers. |
| SmltPeerSysId | Specifies the system ID of the SPBM SMLT for this SPBM instance. |
| Mcast | Specifies if IP multicast over SPBM is enabled. The default is disabled. |
| McastFwdCacheTimeout | Specifies the global forward cache timeout in seconds. The default is 210 seconds. |
| Ipv6Shortcut | Enables or disables SPBM IPv6 shortcut state. The default is disable. |
| McastSpbPimGwControllerEnable | Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default. |

| Name | Description |
|--|---|
| McastSpbPimGwGatewayEnable | Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default. |
| StpMultiHoming | Enables or disables MSTP-Fabric Connect Multi Homing.
The default is disabled (false). |
| BVlanOrigin

Note:
Exception: not supported on XA1400 Series and VSP 8600 Series. | Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic. |

Displaying IP Multicast over Fabric Connect routes

Use this procedure to display IP Multicast over Fabric Connect routes.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **IpMcastRoutes** tab.

IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name | Description |
|------------------|--|
| Vsnlsid | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID. |
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Source | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| NickName | Specifies the nick name used to filter criteria. |
| SourceBeb | Specifies the source BEB for the IP multicast route. |
| VlanId | Specifies the ID for the C-VLAN. |
| VrfName | Specifies the VRF name. |
| Datalsid | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| Type | Specifies the type for the IP Multicast over Fabric Connect route. |

| Name | Description |
|----------------------|--|
| Bvlan | Specifies the B-VLAN for the IP Multicast over Fabric Connect route. |
| NniInterfaces | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports. |

Displaying the UNI ports for IP multicast routes

Use this procedure to display UNI ports associated with particular IP multicast routes.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **IpMcastRoutes** tab.
3. Select the desired row and click the **UNI Ports** tab to display the UNI ports associated with a particular stream.

IpMcastRoutes Uni Ports field descriptions

Use the data in the following table to use the **IpMcastRoutes Uni Ports** tab.

| Name | Description |
|------------------|--|
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Source | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| Vsnlsid | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID. |
| Datalsid | Specifies the data I-SID for the IP multicast route. After a BEB receives the IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| SourceBeb | Specifies the source BEB for the IP multicast route. |
| VlanId | Specifies the ID for the C-VLAN. |
| VrfName | Specifies the VRF name. |
| NniPorts | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports facing a customer VLAN are user-to-network interface (UNI) ports. |
| Type | Specifies the type for the IP multicast route. |
| Bvlan | Specifies the B-VLANs for the IP multicast route. |

Displaying the multicast FIB

Use the following procedure to display the multicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Multicast FIB** tab.

Multicast FIB field descriptions

Use the data in the following table to use the **Multicast FIB** tab.

| Name | Description |
|---------------------------|--|
| SysId | System ID of the node where the multicast FIB entry originated. |
| Vlan | VLAN of the multicast FIB entry. |
| McastDestMacAddr | Multicast destination MAC Address of the multicast FIB entry |
| Isid | I-SID of the multicast FIB entry. |
| Isid Name | Name assigned to the I-SID. |
| HostName | Host name of the node where the multicast FIB entry originated. |
| OutgoingInterfaces | Specifies the switched UNI port outgoing interface of multicast FIB entry. |
| IncomingInterface | Specifies the incoming interface (port or MLT) of the multicast FIB entry. |

IP Multicast over Fabric Connect configuration examples

IP multicast over Fabric Connect global configuration

The following sections show the steps required to configure IP multicast over Fabric Connect at a global level

SwitchC

```
enable
configure terminal
prompt SwitchC

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

SwitchG

```
enable
configure terminal

IP Multicast over Fabric Connect Services Configuration

Layer 2 VSN Configuration Fundamentals

Layer 2 VSN IP Multicast over Fabric Connect

IP Multicast over Fabric Connect supports Layer 2 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. An application for Layer 2 VSNs using IP Multicast over Fabric Connect is multicast traffic in data centers.

For more information on Layer 2 VSN configuration, see [Layer 2 VSN configuration](#) on page 1141.

After you configure **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN), that VLAN is automatically enabled for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

Multicast traffic remains in the same Layer 2 VSN across the SPBM cloud for Layer 2 VSN IP Multicast over Fabric Connect. IP Multicast over Fabric Connect constrains all multicast streams within the scope level in which they originate. If a sender transmits a multicast stream to a BEB on a Layer 2 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream.

I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 2 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 2 VSN associated with the local VLAN on which the IP multicast data was received.

TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 2 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the request stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Layer 2 VSN Configuration using the CLI

Configuring Layer 2 VSN IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for Layer 2 VSN functionality. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must assign the same I-SID to the C-VLANs on all the BEBs where you configure the C-VLAN.
- You must enable IP Multicast over Fabric Connect globally.

About This Task

Traffic is only delivered to UNIs on the Layer 2 VSN where the switch receives IGMP joins and reports. Traffic does not cross the Layer 2 VSN boundary.

Configuring **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN) automatically enables that VLAN for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

SPBM supports enabling IGMP Snooping on a C-VLAN, but it does not support enabling Protocol Independent Multicast (PIM) on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

The switch only supports IPv4 multicast traffic.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable proxy snoop:

```
ip igmp proxy
```

3. Enable IGMP snooping:

```
ip igmp snooping
```

4. (Optional) If you want to configure an address for the IGMP queries, enter the following command:

```
ip igmp snoop-querier-addr <A.B.C.D>
```

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

5. (Optional) Enable IGMPv3 at a VLAN level by enabling SSM-snooping and IGMPv3:

```
ip igmp ssm-snoop

ip igmp version 3
```

You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Example

Enable IGMPv2 at a VLAN level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#interface vlan 501
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
```

Enable IGMPv3 at a VLAN level:

```
Switch:>enable
Switch:#configure terminal
Switch:1(config)#interface vlan 2256
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1(config-if)#ip igmp version 3
Switch:1(config-if)#ip igmp ssm-snoop
```

Viewing Layer 2 VSN IP Multicast over Fabric Connect information

Use the following options to display Layer 2 VSN information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:
`show isis spbm ip-multicast-route [all]`
3. Display detailed IP Multicast over Fabric Connect route information:
`show isis spbm ip-multicast-route [detail]`
4. Display IP multicast route information by VLAN:
`show isis spbm ip-multicast-route [vlan <1-4059>]`
5. Display IP Multicast over Fabric Connect route information by VSN I-SID:
`show isis spbm ip-multicast-route [vsn-isid <1-16777215>]`
6. Display IP Multicast over Fabric Connect route information by group address:
`show isis spbm ip-multicast-route [group {A.B.C.D}]`
7. Display IP Multicast over Fabric Connect route information by source address:
`show isis spbm ip-multicast-route [source {A.B.C.D}]`

Important

When you use the command `show isis spbm ip-multicast-route` without parameters or use the `detail` or `group` optional parameters without specifying a VLAN ID or VSN-ISID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

8. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid
<xxxx.xxxx.xxxx.xx-xx>]
```

Example

```
Switch:1#show isis spbm ip-multicast-route all

Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable | Value |
|---------------|---|
| <i>all</i> | Displays all IP Multicast over Fabric Connect route information. |
| <i>detail</i> | Displays detailed IP Multicast over Fabric Connect route information. |

| Variable | Value |
|---|---|
| <i>group</i> {A.B.C.D}
<i>source</i> {A.B.C.D} | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. |
| <i>vlan</i> <0-4084> | Displays IP Multicast over Fabric Connect route information by VLAN. |
| <i>vrf</i> WORD<1-16> | Displays IP Multicast over Fabric Connect route information by VRF. |
| <i>vsn-isid</i> <1-16777215> | Displays IP Multicast over Fabric Connect route information by I-SID. |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable | Value |
|-------------------------------------|--|
| <i>count</i> | Displays the total number of SPB multicast entries. |
| <i>host-name</i> WORD<0-255> | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid</i> <xxxx.xxxx.xxxx.xx-xx> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID. |

Job aid

The following table describes the fields for the **show isis spbm ip-multicast-route all** command.

| Parameter | Description |
|------------|--|
| Type | Specifies the type of interface. The options include: <ul style="list-style-type: none"> routed— For IP Shortcuts and Layer 3 VSNs. snoop— For Layer 2 VSNs. |
| VrfName | Specifies the VRF name of the interface. |
| Vlan Id | Specifies the VLAN ID of the interface. |
| Source | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| VSN-ISID | Specifies the VSN I-SID for Layer 2 VSNs and Layer 3 VSNs.
Specifies the GRT for IP Shortcuts with IP Multicast over Fabric Connect because IP Shortcuts IP Multicast over Fabric Connect does not use a VSN I-SID. |
| Data ISID | Specifies the data I-SID for the IP Multicast over Fabric Connect route. After a BEB receives IP multicast data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVLAN | Specifies the B-VLAN for the IP Multicast over Fabric Connect route. |
| Source-BEB | Specifies the source BEB for the IP Multicast over Fabric Connect route. |

The following table describes the fields for the **show isis spbm ip-multicast-route vsn-isisid** command.

| Parameter | Description |
|------------|--|
| Source | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Data ISID | Specifies the data I-SID for the IP Multicast over Fabric Connect route. After a BEB receives the IP Multicast over Fabric Connect data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVLAN | Specifies the B-VLAN for the IP Multicast over Fabric Connect route. |
| Source-BEB | Specifies the source BEB for the IP Multicast over Fabric Connect route. |

The following table describes the fields for the **show isis spbm ip-multicast-route vsn-isisid <1-16777215> detail** command.

| Parameter | Description |
|------------|--|
| Source | Specifies the group IP address for the IP multicast route. |
| Group | Specifies the group IP address for the IP multicast route. |
| Data ISID | Specifies the data I-SID for the IP multicast route. After a BEB receives IP multicast data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVLAN | Specifies the B-VLAN for the IP multicast route. |
| NNI Rcvrs | Specifies the NNI receivers. |
| UNI Rcvrs | Specifies the UNI receivers. |
| Source-BEB | Specifies the source BEB for the IP multicast route. |

The following table describes the fields for the **show isis spb-mcast-summary** command.

| Parameter | Description |
|----------------|--|
| SCOPE I-SID | Specifies the scope I-SID. Layer 2 VSN and Layer 3 VSN each require a scope I-SID. |
| SOURCE ADDRESS | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| GROUP ADDRESS | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| DATA I-SID | Specifies the data I-SID for the IP Multicast over Fabric Connect route. After a BEB receives the IP Multicast over Fabric Connect data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |

| Parameter | Description |
|-----------|--|
| BVID | Specifies the Backbone VLAN ID associated with the SPBM instance. |
| LSP FRAG | Specifies the LSP fragment number. |
| HOST NAME | Specifies the host name listed in the LSP, or the system name if the host is not configured. |

View IGMP Information for Layer 2 VSN Multicast

Use the following commands to display IGMP information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-
512>]
```

Ensure that the output displays snoop-spb under MODE.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}]
[vrf WORD<1-16>][vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:

```
show ip igmp sender [count][group {A.B.C.D}][member-subnet
{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
```

6. Display information about IGMP snoop-trace information:

```
show ip igmp snoop-trace [group {A.B.C.D}][source {A.B.C.D}][vrf
WORD<1-16>][vrfids WORD<0-512>]
```

Example

```
Switch:1#show ip igmp interface

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable | Value |
|--|---|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059> | Specifies the VLAN. |
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp cache** command.

| Variable | Value |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp snoop-trace** command.

| Variable | Value |
|---------------------------|--|
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>source</i> {A.B.C.D} | Specifies the source address. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

Viewing TLV information for Layer 2 VSN IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For Layer 2 VSN with IP multicast over Fabric Connect, TLV 185 on the BEB where the source is located, displays the multicast source and group addresses and has the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by Type-Length-Value (TLV):

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx>tlv <1-236> [sub-tlv <1-3>] [detail]
```

Example

```
Switch:1# show isis lsdb tlv 185 detail

Variable definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable | Value |
|---|---|
| <i>detail</i> | Displays detailed information about the IS-IS Link State database. |
| <i>level {11, 12, 112}</i> | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 and combined Level 1 and 2 (112) function is disabled. |
| <i>local</i> | Displays information on the local LSDB. |
| <i>lspid <xxxx.xxxx.xxxx.xx-xx></i> | Specifies information about the IS-IS Link State database by LSP ID. |
| <i>sub-tlv <1-3></i> | Specifies information about the IS-IS Link State database by sub-TLV. |
| <i>sysid <xxxx.xxxx.xxxx></i> | Specifies information about the IS-IS Link State database by System ID. |
| <i>tlv <1-236></i> | Specifies information about the IS-IS Link State database by TLV. |

Job aid

The following table describes the fields for the **show isis lsdb** command.

| Parameter | Description |
|-----------|--|
| LSP ID | Indicates the LSP ID assigned to external IS-IS routing devices. |
| LEVEL | Indicates the level of the external router: I1, I2, or I12. |
| LIFETIME | Indicates the maximum age of the LSP. If the max-lsp-gen-interval is set to 900 (default) then the lifetime value begins to count down from 1200 seconds and updates after 300 seconds if connectivity remains. If the timer counts down to zero, the counter adds on an additional 60 seconds, and then the LSP for that router is lost. This situation happens because of the zero age lifetime, which is detailed in the RFC standards. |
| SEQNUM | Indicates the LSP sequence number. This number changes each time the LSP is updated. |
| CKSUM | Indicates the LSP checksum. The checksum is an error checking mechanism used to verify the validity of the IP packet. |
| HOST-NAME | Indicates the host-name. |

Layer 2 VSN Configuration using EDM

Viewing the IGMP interface table

Use the Interface tab to view the IGMP interface table. When an interface does not use an IP address, it does not appear in the IGMP table.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Interface** tab.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name | Description |
|-----------------------------|---|
| IfIndex | Shows the interface where IGMP is enabled. |
| QueryInterval | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125. |
| Status | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService. |
| Version | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. |
| OperVersion | Shows the version of IGMP that currently runs on this interface. |
| Querier | Shows the address of the IGMP querier on the IP subnet to which this interface attaches. |
| QueryMaxResponseTime | <p>Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1.</p> <p>Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)</p> <p>Important:
You must configure this value lower than the QueryInterval.</p> |
| WrongVersionQueries | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch. |
| Joins | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time. |
| Robustness | <p>Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.</p> <p>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.</p> |
| LastMembQueryIntvl | <p>Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.</p> <p>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0-255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)</p> |

| Name | Description |
|------------------------------------|--|
| OtherQuerierPresent Timeout | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0. |
| FlushAction | Configures the flush action to one of the following: <ul style="list-style-type: none"> • none • flushGrpMem • flushMrouter • flushSender |
| RouterAlertEnable | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. <p>Important:
To maximize network performance, configure this parameter according to the version of IGMP currently in use.</p> <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |
| SsmSnoopEnable | Enables SSM snoop. |
| SnoopQuerierEnable | Enables IGMP Layer 2 Querier. |
| SnoopQuerierAddr | Specifies the pseudo address of the IGMP snoop querier. |
| ExplicitHostTrackingEnable | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3. |
| McastMode | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> • snoop — Indicates IGMP snooping is enabled on a VLAN. • snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). • pim — Indicates PIM is enabled. • routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts. |
| ExtnUpnpFilterEnable | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled. |
| ExtnUpnpFilterAddress | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32. |
| ExtnUpnpFilterAddressMask | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached. |

Configuring IP Multicast over Fabric Connect on a Layer 2 VSN

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 2 VSN. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

No explicit configuration exists for a Layer 2 VSN. After you configure IP IGMP snooping on a VLAN that has an I-SID configured, the device enables that VLAN for IP Multicast over Fabric Connect services.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

About This Task

SPBM supports enabling IGMP snooping on a C-VLAN, but it does not support enabling PIM on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

This switch only supports IPv4 multicast traffic.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Select the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. (Optional) Select the **SsmSnoopEnable** check box, if you use IGMP version 3.
9. (Optional) Select the **ProxySnoopEnable** check box.
10. (Optional) If you want to enable IGMP version 3, select version3 in the **Version** check box.

You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

11. If you want to enable IGMP version 2, select version2 in the **Version** check box.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

12. (Optional) If you want to enable snoop querier, select **SnoopQuerierEnable**.

- (Optional) If you want to configure an address for IGMP queries, enter the IP address in **SnoopQuerierAddr**. This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

**Note**

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

- Click **Apply**.

Layer 2 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration steps to enable IP Multicast over Fabric Connect support on C-VLAN 1001 that is part of a Layer 2 VSN, including the querier address.

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 9
ip igmp snooping
ip igmp snoop-querier-addr 192.0.2.201
exit
```

When using IGMPv3, the configuration is:

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 19
ip igmp snooping
ip igmp version 3
ip igmp ssm-snoop
```

```
ip igmp snoop-querier-addr 192.0.2.201
exit
```

**Note**

You must enable SSM snoop before you configure IGMP version to version 3, and you must enable both **ssm-snoop** and **snooping** for IGMPv3.

**Note**

You must configure basic SPBM and IS-IS infrastructure.

IP Shortcuts Configuration

This section provides fundamentals concepts for IP Shortcuts configuration. For more information on IP Shortcuts basic configuration, see [IP Shortcuts Configuration](#) on page 1226.

IP Multicast over Fabric Connect within the GRT

IP Multicast over Fabric Connect within the GRT enables you to exchange IP multicast traffic with all or a subset of VLANs that are in the Global Routing Table (GRT). This restriction is called the *scope level*, which IP Multicast over Fabric Connect uses to constrain the multicast streams within the level in which they originate. For example, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT with IP Multicast over Fabric Connect enabled, only receivers that are part of the same GRT can receive that stream.

Applications that can use IP Multicast over Fabric Connect within the GRT include: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.

Both **IP Shortcuts** and **IP Multicast over Fabric Connect within the GRT** use the GRT for the scope level to constrain multicast streams. However, they are separate features that work independently from each other.

**Important**

You do not have to enable IP Shortcuts to support IP Multicast over Fabric Connect within the GRT.

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable **ip spb-multicast** on each of the VLANs within the GRT that need to support IP multicast traffic. Enable IP Multicast over Fabric Connect on all VLANs to which IP multicast senders and receivers attach. IP Multicast over Fabric Connect is typically configured only on BEBs.

**Note**

If no IP interface exists on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

I-SIDs

Unlike IP Shortcuts with unicast, a data I-SID (for mac-in-mac encapsulation of the multicast traffic) is required for IP Multicast over Fabric Connect within the GRT. When the multicast stream reaches the BEB, the BEB assigns a data I-SID to the stream. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

Unlike Layer 2 VSNs and Layer 3 VSNs, IP Multicast over Fabric Connect within the GRT does not have a scope I-SID to determine the scope of the multicast traffic. Instead the scope is the Global Routing Table.

TLVs

The scope and data I-SID information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, and result in the multicast tree creation for that stream. For IP Multicast over Fabric Connect within the GRT, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 186.

IGMP

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, an error message appears.

After you configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

DvR

When you enable **ip spb-multicast** on the Controller nodes, the configuration is automatically pushed to all the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 660.

IP Shortcuts Configuration using the CLI

Configure IP Multicast over Fabric Connect within the GRT

Use this procedure to configure IP Multicast over Fabric Connect within the GRT. The default is disabled.

-  **Note**
 - You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
 - You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.

- You must enable IP Multicast over Fabric Connect globally.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled. After you enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an IP interface on the VLAN:

```
ip address <A.B.C.D/X>
```

3. Enable IP Multicast over Fabric Connect:

```
ip spb-multicast enable
```

Note

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, an error message displays.

Note

When you configure **ip spb-multicast enable** on the Controller node of a DVR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

4. (Optional) Disable IP Multicast over Fabric Connect:

```
no ip spb-multicast enable
```

```
default ip spb-multicast enable
```

5. Ensure IP Multicast over Fabric Connect within the GRT is configured properly:

```
show ip igmp interface
```

If `routed-spb` displays under mode, IP Multicast over Fabric Connect within the GRT is properly enabled on the VLAN.

Example

Enable IP Multicast over Fabric Connect within the GRT:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 500
Switch:1(config-if)#ip address 192.0.2.1 255.255.255.0
Switch:1(config-if)#ip spb-multicast enable
Switch:1(config)#show ip igmp interface
```

```

Variable definitions

The following table defines parameters for the **interface vlan** command.

| Variable | Value |
|----------|------------------------|
| <1-4059> | Specifies the VLAN ID. |

The following table defines parameters for the **interface GigabitEthernet** command.

| Variable | Value |
|--|---|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip address** command.

| Variable | Value |
|--------------------------------|---------------------------------|
| <code><A.B.C.D/X></code> | Specifies the address and mask. |

Configuring the VRF timeout value

Use this procedure to configure the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.

Note

You can use this procedure for Layer 3 VSN with IP Multicast over Fabric Connect services and IP Multicast over Fabric Connect for IP Shortcuts.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Configure the timeout value on the VRF:

```
mvpn fwd-cache-timeout (seconds) <10-86400>
```
3. (Optional) Configure the timeout value to the default value of 210 seconds:

```
no mvpn fwd-cache-timeout

default mvpn fwd-cache-timeout (seconds)
```

Example

Configure the timeout value on the VRF to 500 seconds:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#mvpn fwd-cache-timeout(seconds) 500
```

Variable definitions

The following table defines parameters for the **router vrf** command.

| Variable | Value |
|--------------------|-------------------------|
| <i>WORD</i> <1-16> | Specifies the VRF name. |

The following table defines parameters for the **mvpn fwd-cache-timeout(seconds)** command.

| Variable | Value |
|------------|--|
| <10-86400> | Specifies the timeout value. The default is 210 seconds. |

Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time in seconds. The default timeout value is 210 seconds.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. Enter IS-IS Router Configuration mode:

```
enable

configure terminal

router isis
```
2. Configure the IP Multicast over Fabric Connect forward-cache timeout:

```
spbm <1-100> multicast fwd-cache-timeout(seconds) <10-86400>
```
3. (Optional) Configure the IP Multicast over Fabric Connect forward-cache timeout to the default value of 210 seconds:

```
default spbm <1-100> multicast fwd-cache-timeout(seconds)

no spbm <1-100> multicast fwd-cache-timeout(seconds)
```

Example

Configure the IP Multicast over Fabric Connect forward-cache timeout to 300:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast 1 fwd-cache-timeout 300
```

Variable definitions

The following table defines parameters for the **spbm** command.

| Variable | Value |
|------------|--|
| <1-100> | Specifies the SPBM instance. The switch only supports one instance. |
| <10-86400> | Specifies the IP Multicast over Fabric Connect forward-cache timeout in seconds. The default is 210 seconds. |

Viewing IP Multicast over Fabric Connect within the GRT information

Use the following options to display IP Multicast over Fabric Connect within the GRT information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:

```
show isis spbm ip-multicast-route [all]
```
3. Display detailed IP Multicast over Fabric Connect route information:

```
show isis spbm ip-multicast-route [detail]
```
4. Display the IP Multicast over Fabric Connect multicast group and source address information:

```
show isis spbm ip-multicast-route [group {A.B.C.D}] [source {A.B.C.D}] [source-beb WORD<0-255>]
```
5. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```

Example

Display IP Multicast over Fabric Connect within the GRT information:

```
Switch:1#show isis spbm ip-multicast-route all

Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable | Value |
|---|---|
| <i>all</i> | Displays all IP Multicast over Fabric Connect route information. |
| <i>detail</i> | Displays detailed IP Multicast over Fabric Connect route information. |
| <i>group</i> {A.B.C.D}
<i>source</i> {A.B.C.D}
[<i>source-beb</i> WORD<0-255>] | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address.
Specifies the source BEB name. |
| <i>vlan</i> | Displays IP Multicast over Fabric Connect route information by VLAN. |
| <i>vrf</i> | Displays IP Multicast over Fabric Connect route information by VRF. |
| <i>vsn-isis</i> | Displays IP Multicast over Fabric Connect route information by I-SID. |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable | Value |
|--|--|
| <i>count</i> | Displays the total number of SPB multicast entries. |
| <i>host-name</i> | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid</i>
<xxxx.xxxx.xxxx.xx-xx> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID. |

Job aid

The following table describes the fields for the **show isis spbm ip-multicast-route all** command.

| Parameter | Description |
|------------|--|
| Type | Specifies the type of interface. The options include: <ul style="list-style-type: none"> routed—For GRT and Layer 3 VSN. snoop—For Layer 2 VSN. |
| VrfName | Specifies the VRF name of the interface. |
| Vlan Id | Specifies the VLAN ID of the interface. |
| Source | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| VSN-ISID | Specifies the GRT because IP Multicast over Fabric Connect within the GRT does not use a VSN I-SID. |
| Data ISID | Specifies the data I-SID for the IP Multicast over Fabric Connect route. After a BEB receives IP multicast data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVLAN | Specifies the B-VLAN for the IP Multicast over Fabric Connect route. |
| Source-BEB | Specifies the source BEB for the IP Multicast over Fabric Connect route. |

The following table describes the fields for the **show isis spbm ip-multicast-route detail** command.

| Parameter | Description |
|-----------|--|
| Source | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Group | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| Data ISID | Specifies the data I-SID for the IP Multicast over Fabric Connect route. After a BEB receives IP multicast data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVLAN | Specifies the B-VLAN for the IP Multicast over Fabric Connect route. |

| Parameter | Description |
|------------|--|
| NNI Rcvrs | Specifies the NNI receivers. |
| UNI Rcvrs | Specifies the UNI receivers. |
| Source-BEB | Specifies the source BEB for the IP Multicast over Fabric Connect route. |

The following table describes the fields for the **show isis spb-mcast-summary** command.

| Parameter | Description |
|----------------|---|
| SCOPE I-SID | Specifies the scope I-SID. Layer 2 VSN and Layer 3 VSN each require a scope I-SID. |
| SOURCE ADDRESS | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| GROUP ADDRESS | Specifies the group IP address for the IP Multicast over Fabric Connect route. |
| DATA I-SID | Specifies the data I-SID for the IP multicast route. After a BEB receives IP multicast data from a sender, the BEB allocates a data I-SID in the range of 16,000,000 to 16, 512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| BVID | Specifies the Backbone VLAN ID associated with the SPBM instance. |
| LSP FRAG | Specifies the LSP fragment number. |
| HOST NAME | Specifies the host name listed in the LSP, or the system name if the host is not configured. |

View IGMP Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to display IGMP information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

Ensure that the output displays `routed-spb` under `MODE`.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count] [group {A.B.C.D}] [member-subnet default|
{A.B.C.D/X}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:

```
show ip igmp sender [count] [group {A.B.C.D}] [member-subnet default|
{A.B.C.D/X}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Display IGMP information for IP multicast over Fabric Connect within the GRT:

```
Switch:1#show ip igmp interface

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable | Value |
|--|---|
| <i>gigabitethernet</i> {slot/
port[/sub-port] [-slot/
port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059> | Specifies the VLAN. |
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp cache** command.

| Variable | Value |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group {A.B.C.D}</i> | Specifies the group address. |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask. |
| <i>vrf WORD<1-16></i> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids WORD<0-512></i> | Displays the multicast route configuration for a particular VRF by VRF ID. |

Viewing TLV information for IP Multicast over Fabric Connect within the GRT

Use the following commands to check TLV information.

For IP Multicast over Fabric Connect within the GRT, TLV 186 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set while on all BEB bridges, where a receiver exists, has the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail]
```

Example

Display TLV information:

```
Switch:1# show isis lsdb tlv 186 detail

Variable definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable | Value |
|---|--|
| <i>detail</i> | Displays detailed information about the IS-IS Link State database. |
| <i>level {11, 12, 112}</i> | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i> | Displays information on the local LSDB. |
| <i>lspid <xxxx.xxxx.xxxx.xx-xx></i> | Specifies information about the IS-IS Link State database by LSP ID. |

| Variable | Value |
|---|---|
| <code>sub-tlv <1-3></code> | Specifies information about the IS-IS Link State database by sub-TLV. |
| <code>sysid <xxxx.xxxx.xxxx></code> | Specifies information about the IS-IS Link State database by System ID. |
| <code>tlv <1-236></code> | Specifies information about the IS-IS Link State database by TLV. |

Job aid

The following table describes the fields for the **show isis lsdb tlv** command.

| Parameter | Description |
|-----------|---|
| LSP ID | Indicates the LSP ID assigned to external IS-IS routing devices. |
| LEVEL | Indicates the level of the external router: I1, I2, or I12. |
| LIFETIME | Indicates the maximum age of the LSP. If the max-lsp-gen-interval is set to 900 (default) then the lifetime value begins to count down from 1200 seconds and updates after 300 seconds if connectivity remains. If the timer counts down to zero, the counter adds on an additional 60 seconds, then the LSP for that router is lost. |
| SEQNUM | Indicates the LSP sequence number. This number changes each time the LSP is updated. |
| CKSUM | Indicates the LSP checksum. This is an error checking mechanism used to verify the validity of the IP packet. |
| HOST-NAME | Specifies the host-name. |

IP Shortcuts configuration using the EDM

This section provides procedures to configure IP Shortcuts using the EDM.

Configuring IP Multicast over Fabric Connect on a VLAN within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled.

To configure a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3](#) on page 1654.

Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.

- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing within the GRT does not depend on unicast routing. This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Choose a VLAN, and then click the **IP** button.
4. Click the **SPB Multicast** tab.

Note

After you enable IP Multicast over Fabric Connect, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where SPBM multicast is enabled, an error message appears.

Note

When you enable IP Multicast over Fabric Connect on a Controller switch in a DVR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

5. Click **Enable**.
6. Click **Apply**.

Configuring IP Multicast over Fabric Connect on a brouter port within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port IP interface. The default is enabled.

To configure a brouter port for a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN](#) on page 1656.

**Note**

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. Select an enabled port on the Physical Device View.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB Multicast** tab.
5. Click **Enable**.

**Note**

When you enable IP Multicast over Fabric Connect on a DvR Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

6. Click **Apply**.

SPB Multicast field description

Use the data in the following table to use the SPB Multicast tab.

| Name | Description |
|--------|--|
| Enable | Enables or disables SPB Multicast. The default is disable. |

Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time. The default timeout value is 210 seconds.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **SPBM** tab.
3. Modify the **McastFwdCacheTimeout** value.
4. Click **Apply**.

IP multicast over SPBM within the GRT configuration example

The following example shows the configuration steps to enable IP multicast over SPBM support on VLANs 10 and 11 that are part of the GRT:

```

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION - PHASE I

interface vlan 500
ip address 192.0.2.1 255.255.255.0
ip spb-multicast enable
exit

interface vlan 501
ip address 192.0.2.2 255.255.255.0
ip spb-multicast enable
exit

```

Layer 3 VSN Fundamentals

This section provides fundamentals concepts for Layer 3 VSN configuration. For more information on Layer 3 VSN basic configuration, see [Layer 3 VSN Configuration](#) on page 1296.

Layer 3 VSN with IP Multicast over Fabric Connect

IP Multicast over Fabric Connect supports Layer 3 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. Layer 3 VSN using IP Multicast over Fabric Connect is helpful when you need complete security and total isolation of data. No one outside of the Layer 3 VSN can join or even see the Layer 3 VSN. Applications that can use Layer 3 VSN with IP Multicast over Fabric Connect include: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. This configuration automatically enables IGMP snooping and proxy on those VLANs. IGMPv2 at the VLAN level is the default setting, with no other configuration required. If you want to use IGMPv3, you must configure IGMPv3.

IP Multicast over Fabric Connect is only configured on BEBs.

Note

- You do not need to enable IP Shortcuts to support multicast routing in the Layer 3 VSN using SPBM. IPVPN creation and I-SID assignment for the IPVPN is required, but you do not need to enable IPVPN.
- If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing for Layer 3 VSNs using VRFs, which allows you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

With Layer 3 VSN with IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud. For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that has IP Multicast over Fabric Connect enabled. If a sender transmits a multicast stream to a BEB on a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 VSN can receive that stream.

I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 3 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 3 VSN associated with the local VLAN that the IP multicast data was received on.

TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 3 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

IGMP

After a BEB receives an IGMP join message from a receiver, the BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

DvR

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 660.

Layer 3 VSN Configuration using the CLI

Configuring Layer 3 VSN with IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for a Layer 3 VSN.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. After you enable IP Multicast over Fabric Connect on VRF VLANs, snooping and proxy on those VLANs is enabled. IGMPv2 at the VLAN level is the default setting. No configuration is required.

Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- You must assign an I-SID for the IPVPN.

About This Task

With Layer 3 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud.

For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that have `ip spbm-multicast` enabled. The default is disabled.

All or a subset of VLANs within a Layer 3 VSN can exchange multicast traffic. The BEB only sends out traffic for a multicast stream on which IGMP joins and reports are received.

The switch only supports IPv4 multicast traffic.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
mvpn enable
```

The default is disabled.

3. (Optional) If you want to disable Layer 3 VSN IP Multicast over Fabric Connect, enter:

```
no mvpn enable
```

```
default mvpn enable
```

4. Exit to Global Configuration mode:

```
exit
```

5. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

6. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
ip spb-multicast enable
```

7. (Optional) Disable Layer 3 multicast on the VRF:

```
no ip spb-multicast enable
```

8. (Optional) Enable IGMP version 3:

```
ip igmp snooping

ip igmp ssm-snoop

ip igmp compatibility-mode

ip igmp version 3
```

Note

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to use these commands if you use IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

9. (Optional) Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```

Note

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

Example

Configure IP Multicast over Fabric Connect for a Layer 3 VSN:

```
Switch:>enable
Switch:#configure terminal
Switch:(config)# router vrf green
Switch:(config-vrf)#mvpn enable
Switch:(config)#exit
Switch:(config)#interface vlan 500
Switch:(config-if)#ip spb-multicast enable
```

Variable definitions

The following table defines parameters for the **router vrf** command.

| Variable | Value |
|--------------------|--------------------------------|
| <i>WORD</i> <1-16> | Specifies the name of the VRF. |

The following table defines parameters for the **interface vlan** command.

| Variable | Value |
|-----------------------------|--|
| <code><1-4059></code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

The following table defines parameters for the **GigabitEthernet** command.

| Variable | Value |
|---|---|
| <code>GigabitEthernet{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip igmp** command.

| Variable | Value |
|---|--|
| <code>access-list WORD<1-64> {A.B.C.D/X} <deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both></code> | Specifies the name of the access list from 1-64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic. |
| <code>compatibility-mode</code> | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
<code>default ip igmp compatibility-mode</code>
, or use the no option to disable compatibility mode:
<code>no ip igmp compatibility-mode</code> |
| <code>dynamic-downgrade-version</code> | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
<code>default ip igmp dynamic-downgrade-version</code>
or use the no option to disable downgrade:
<code>no ip igmp dynamic-downgrade-version</code> |
| <code>igmpv3-explicit-host-tracking</code> | Enables explicit host tracking on IGMPv3. The default state is disabled. |

| Variable | Value |
|--|---|
| <code>immediate-leave</code> | Enables fast leave on a VLAN. |
| <code>immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports. |
| <code>last-member-query-interval <0-255></code> | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.
Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. Configure this value between 3-10 (equal to 0.3 - 1.0 seconds). |
| <code>mrdisc [maxadvertinterval <2-180>] [maxinitadvertinterval <2-180>] [maxinitadvertisements <2-15>] [minadvertinterval <3-180>] [neighdeadinterval <2-180>]</code> | Configure the multicast router discovery options to enable the automatic discovery of multicast capable routers. The default parameter values are: <ul style="list-style-type: none"> • maxadvertinterval: 20 seconds • maxinitadvertinterval: 2 seconds • maxinitadvertisements: 3 • minadvertinterval: 15 seconds • neighdeadinterval: 60 seconds |
| <code>mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Adds multicast router ports. |
| <code>proxy</code> | Activates the proxy-snoop option globally for the VLAN. |
| <code>query-interval <1-65535></code> | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds. |
| <code>query-max-response <0-255></code> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).

Important:
You must configure this value lower than the query-interval. |
| <code>robust-value <2-255></code> | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss. |

| Variable | Value |
|---|--|
| <code>router-alert</code> | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.

Important:
To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable |
| <code>snoop-querier</code> | Enables the IGMP Layer 2 Querier feature on the VLAN. The default is disabled. |
| <code>snoop-querier-addr {A.B.C.D}</code> | Specifies the IGMP Layer 2 Querier source IP address. |
| <code>snooping</code> | Activates the snoop option for the VLAN. |
| <code>ssm-snoop</code> | Activates support for SSM on the snoop interface. |
| <code>static-group {A.B.C.D} {A.B.C.D} [port] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static blocked]</code> | Configures IGMP static members to add members to a snoop group.
<code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group.
<code>[port] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry.
<code>[static blocked]</code> configures the route to static or blocked. |
| <code>stream-limit stream-limit-max-streams <0-65535></code> | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4. |
| <code>stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams <0-65535></code> | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4. |
| <code>version <1-3></code> | Configures the version of IGMP that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2). |

Viewing Layer 3 VSN with IP Multicast over Fabric Connect information

Use the following options to display Layer 3 VSN with IP Multicast over Fabric Connect information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all the VRFs that have MVPN enabled and their corresponding forward cache timeout values:
`show ip vrf mvpn`
3. Display IP Multicast over Fabric Connect route information:
`show isis spbm ip-multicast-route [all][detail]`

4. Display IP Multicast over Fabric Connect by group and source address:

```
show isis spbm ip-multicast-route [group {A.B.C.D}] [detail] [source {A.B.C.D}]
```
5. Display IP Multicast over Fabric Connect route information by VRF:

```
show isis spbm ip-multicast-route [vrf WORD<1-16>] [group {A.B.C.D}]
```
6. Display IP Multicast over Fabric Connect route information by VLAN:

```
show isis spbm ip-multicast-route [vlan <1-4059>] [detail] [group {A.B.C.D}]
```
7. Display IP Multicast over Fabric Connect information by VSN I-SID:

```
show isis spbm ip-multicast-route [vsn-isid <1-16777215>] [detail] [group {A.B.C.D}]
```
8. Display summary information for each S, G, V tuple with the corresponding scope, Data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```

Example

Display Layer 3 VSN with IP Multicast over Fabric Connect information:

```
Switch:1>enable
Switch:1#show ip vrf mvpn

                Vrf name : green
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

                Vrf name : 4
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

                Vrf name : blue
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

Switch:1#show isis spbm ip-multicast-route all

Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable | Value |
|-----------------------------------|--|
| <i>all</i> | Displays all IP Multicast over Fabric Connect route information. |
| <i>detail</i> | Displays detailed IP Multicast over Fabric Connect route information. |
| <i>group{A.B.C.D}</i> | Displays information on the group IP address for the IP Multicast over Fabric Connect route. |
| <i>vlan<1-4059></i> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrfWORD<1-16></i> | Displays IP Multicast over Fabric Connect route information by VRF. |
| <i>vsn-isis<1-16777215></i> | Displays IP Multicast over Fabric Connect route information by I-SID. |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable | Value |
|--|---|
| <i>count</i> | Displays the total number of SPB multicast entries. |
| <i>host-nameWORD<0-255></i> | Displays the IP Multicast over Fabric Connect summary information by host-name. |
| <i>lspid<xxxx.xxxx.xxxx.xx-xx></i> | Displays the IP Multicast over Fabric Connect summary information by LSP ID. |

View IGMP Information for Layer 3 VSN Multicast

Use the following commands to check IGMP information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about the interfaces where IGMP is enabled:
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]

Ensure that the output displays routed-spb under MODE.

3. Display information about the IGMP cache:
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
4. Display information about the IGMP group:
show ip igmp group [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
5. Display information about the IGMP sender:
show ip igmp sender [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]

Example

Display IGMP information for Layer 3 VSN with IP multicast over Fabric Connect:

```
Switch:#enable

Switch:1#show ip igmp interface vrf green

=====
                        Igmp Interface - GlobalRouter
=====

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable | Value |
|--|--|
| <i>gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan <1-4059></i> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf WORD<1-16></i> | Specifies the VRF by name. |
| <i>vrfids WORD<0-512></i> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp cache** command.

| Variable | Value |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable | Value |
|----------------------------------|--|
| <i>count</i> | Specifies the number of entries. |
| <i>group</i> {A.B.C.D} | Specifies the group address. |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask. |
| <i>vrf</i> WORD<1-16> | Displays the multicast route configuration for a particular VRF by name. |
| <i>vrfids</i> WORD<0-512> | Displays the multicast route configuration for a particular VRF by VRF ID. |

Viewing TLV information for a Layer 3 VSN with IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For a Layer 3 VSN multicast, TLV 185 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group should have its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> [tlv <1-236>] [sub-tlv <1-3>] [detail]
```

Example

Display TLV information for a Layer 3 VSN with IP Multicast over Fabric Connect:

```
Switch:1# show isis lsdb tlv 185 detail
=====

```

Variable definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable | Value |
|---|--|
| <i>detail</i> | Displays detailed information about the IS-IS Link State database. |
| <i>level {11, 12, 112}</i> | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i> | Displays information on the local LSDB. |
| <i>lspid <xxxx.xxxx.xxxx.xx-xx></i> | Specifies information about the IS-IS Link State database by LSP ID. |
| <i>sub-tlv <1-3></i> | Specifies information about the IS-IS Link State database by sub-TLV. |
| <i>sysid <xxxx.xxxx.xxxx></i> | Specifies information about the IS-IS Link State database by System ID. |
| <i>tlv <1-236></i> | Specifies information about the IS-IS Link State database by TLV. |

Job aid

The following table describes the fields for the **show isis lsdb tlv** and the **show isis lsdb lspid** commands.

| Parameter | Description |
|-----------|---|
| LSP ID | Indicates the LSP ID assigned to external IS-IS routing devices. |
| LEVEL | Indicates the level of the external router: I1, I2, or I12. |
| LIFETIME | Indicates the maximum age of the LSP. If the max-lsp-gen-interval is set to 900 (default), then the lifetime value begins to count down from 1200 seconds and updates after 300 seconds if connectivity remains. If the timer counts down to zero, the counter adds on an additional 60 seconds, then the LSP for that router is lost. This happens because of the zero age lifetime, which is detailed in the RFC standards. |
| SEQNUM | Indicates the LSP sequence number. This number changes each time the LSP is updated. |
| CKSUM | Indicates the LSP checksum. This is an error checking mechanism used to verify the validity of the IP packet. |
| HOST-NAME | Indicates the host-name. |

*Layer 3 VSN Configuration using EDM***Enable MVPN for a VRF**

Use this procedure to enable MVPN for a particular VRF. IP Multicast over Fabric Connect, constrains multicast streams of senders to all receivers in the same Layer 3 VSN. MVPN functionality is disabled by default.

**Note**

VLAN level configuration is also required to turn on the service on each VLAN within the VRF on which this services is required. You can turn it on under the VLAN context or the router context.

Before You Begin

- You must enable IP Multicast over Fabric Connect globally.

Procedure

- In the navigation pane, expand **Configuration > IP**.
- Select **IP-MVPN**.
- Select the **MVPN** tab.
- Double-click in the **Enable** field in the table.
- Select **Enable** from the drop down menu.
- Double-click in the **FwdCacheTimeout** field in the table, and then type the VRF timeout value.
- Select **Apply**.

MVPN Field Descriptions

Use the data in the following table to use the **MVPN** tab.

| Name | Description |
|------------------------|---|
| VrfId | Specifies the VRF ID. |
| Enable | Enables Layer 3 VSN IP Multicast over Fabric Connect services for a particular VRF. The default is disabled. |
| FwdCacheTimeout | Specifies the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.. |

Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 3 VSN. The default is disabled.

To configure a VLAN for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN within the GRT](#) on page 1635.

**Note**

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

About This Task

You must configure VLANs to turn on the service on each VLAN with in the VRF on which the service is required. You can turn it on under the VLAN context or the brouter context.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing (for Layer 3 VSN). This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > VLAN**.
7. Click **VLANs**.
8. Choose a VLAN, and then click the **IP** from under the tab bar.
9. Click the **SPB Multicast** tab.
10. Check the **Enable** box.
11. Click **Apply**.

Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port. The default is disabled.

To configure a brouter port for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port within the GRT](#) on page 1636.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 2 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

About This Task

You must enable IP Multicast over Fabric Connect on each of the VLANs that need to support IP multicast traffic.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > Edit > Port**.
7. Click **IP**.
8. Click the **SPB Multicast** tab.
9. Click **Enable**.
10. Click **Apply**.

Configuring IGMP on a VLAN interface for a Layer 3 VRF

Use this procedure to configure IGMP for each VLAN interface to enable the interface to perform multicast operations.

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to enable IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance with an I-SID on the switch.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect for a Layer 3 VSN.

About This Task

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. In the navigation pane, expand **Configuration > VLAN**.
6. Click **VLANs**.
7. Select the desired VLAN from the listing.
8. Click the **IP** button.
9. Click the **IGMP** tab.
10. (Optional) If you want to enable SsmSnoopEnable, select the **SsmSnoopEnable** box.
11. (Optional) If you want to enable Snoop, select the **SnoopEnable** box.
12. (Optional) In the **Version** box, select the correct IGMP version.
You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.
13. (Optional) Select **SnoopQuerierEnable**, to enable Snoop Querier. Only select this option, if you want to configure an address for the IGMP queries.

14. (Optional) In the **SnoopQuerierAddr** box, type an IP address, if you want to configure a snoop querier address.

Note

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name | Description |
|-----------------------------|---|
| QueryInterval | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1-65535 and the default is 125. |
| QueryMaxResponseTime | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0-255 and the default is 100 tenths of a second (equal to 10 seconds.)

Important:
You must configure this value lower than the QueryInterval. |
| Robustness | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2-255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |
| LastMembQueryIntvl | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0-255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |
| SnoopEnable | Enables or disables snoop. |
| SsmSnoopEnable | Enables or disables support for SSM on the snoop interface. |
| ProxySnoopEnable | Enables or disables proxy snoop. |

| Name | Description |
|-----------------------------------|--|
| Version | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode. |
| FastLeaveEnable | Enables or disables fast leave on the interface. |
| StreamLimitEnable | Enables or disables stream limitation on this VLAN. |
| Maximum Number Of Stream | Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4. |
| Current Number Of Stream | Displays the current number of streams. This value is a read-only value. |
| FastLeavePortMembers | Selects the ports that are enabled for fast leave. |
| SnoopMRouterPorts | Selects the ports in this interface that provide connectivity to an IP multicast router. |
| DynamicDowngradeEnable | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network. |
| CompatibilityModeEnable | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2. |
| ExplicitHostTrackingEnable | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3. |
| SnoopQuerierEnable | Enables Snoop Querier. The default is disabled.
When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups. Enable Layer 2 Querier on only one node in the VLAN. |
| SnoopQuerierAddr | Specifies the pseudo IP address of the IGMP Snoop Querier. The default IP address is 0.0.0.0.
If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPBM bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0. |

Layer 3 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration to enable IP Multicast over Fabric Connect support on VLANs 500 and 501 that are part of VRF Green:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

IPFIX Fundamentals

Internet Protocol Flow Information eXport (IPFIX) is an Internet Engineering Task Force (IETF) standard of export for Internet Protocol flow information.

IPFIX monitors flows that pass an observation point. The switch organizes flows into a flow group, which is contained in an observation domain.

An IPFIX flow is a set of packets that pass an observation point in the network during a certain time interval. Packets that belong to a particular flow have a common set of properties. The switch defines each property using values from the following:

- Source IP address
- Destination IP address
- IP protocol
- L4 source port
- L4 destination port

A packet belongs to a flow if it completely satisfies all defined properties of the flow.

The switch logically organizes flows into a flow group, which corresponds to a single observation point. A flow can belong to only 1 flow group. A flow group is a collection of packet flows that meet match criteria. Examples of flow groups are packets ingressing a specific physical port, or packets with a destination IP address belonging to a specific subnet.

A flow group is contained in an observation domain. The switch assigns the flow group to an observation domain. The observation domain has a unique observation domain ID that you can configure. You can configure only 1 observation domain.

The IPFIX solution consists of the following processes:

- Filtering Rules process: The Filtering Rules process gathers information about flows through different ports, or the observation point. Flow information includes the following:
 - The IPv4 source address.
 - The IPv4 destination address.
 - The L4 source port.
 - The L4 destination port.
 - The transport protocol.
 - The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
 - The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
 - The absolute timestamp of the first packet of this flow.
 - The absolute timestamp of the last packet of this flow.

The Filtering Rules process runs on the switch.

- Exporting process: The Filtering Rules process sends information to the Exporting process. The Exporting process uses the UDP transport protocol for network communication with the Collecting process.

The Exporting process runs on the switch.

- Collecting process: You can view flows and export flow information periodically to a collector. A collector can store a large number of flow records from several devices in the network. The IPFIX standard specifies the protocol for exporting the flows to a collector, including the formatting of flow records and the underlying UDP transport protocol.

Use the collected information for network planning, troubleshooting a live network, and monitoring security threats.

The best practice is to use the ExtremeAnalytics™ solution as the collector. The ExtremeAnalytics™ solution provides an enhanced method of collecting IPFIX flow information.

The external collector for the IPFIX solution must support our IPFIX template, which contains the following element IDs defined by Internet Assigned Numbers Authority (IANA) IPFIX assignments.

Table 199: IPFIX element IDs

| Element ID | Name | Description |
|------------|-------------------------------|---|
| 0 | unknown | Reserved |
| 1 | Custom Timestamp
NewLearn | Exports a record of the packet when it is first leaned. This field is for IPFIX statistics packet, not for IPFIX template packets.

Note:
This element ID applies to 5520 Series only. |
| 2 | Custom Timestamp
FlowStart | The Timestamp that represents the time the flow is first earned, such as when a TCP SIN+ACK is received. This field is for IPFIX statistics packet, not for IPFIX template packets.

Note:
This element ID applies to 5520 Series only. |
| 3 | Custom Timestamp
FlowEnd | The timestamp that represents the time the flow has ended, such as when a TCP FIN is received. This field is for IPFIX statistics packet, not for IPFIX template packets.

Note:
This element ID applies to 5520 Series only. |
| 4 | protocolIdentifier | The value of the protocol number in the IP packet header. |
| 7 | sourceTransportPort | The source port identifier in the transport header. |
| 8 | sourceIPv4Address | The IPv4 source address in the IP packet header. |
| 11 | destinationTransportPort | The destination port identifier in the transport header. |
| 12 | destinationIPv4Address | The IPv4 destination address in the IP packet header. |
| 85 | octetTotalCount | The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point. |
| 86 | packetTotalCount | The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point. |
| 145 | templateId | The local template unique to the observation domain.

Note:
This element ID applies to 5520 Series only. |
| 152 | flowStartMilliseconds | The absolute timestamp of the first packet of this flow.

Note:
This element ID applies to VSP 7400 Series only. |

Table 199: IPFIX element IDs (continued)

| Element ID | Name | Description |
|------------|---------------------|--|
| 153 | flowEndMilliseconds | The absolute timestamp of the last packet of this flow.

Note:
This element ID applies to VSP 7400 Series only. |
| 192 | ipTTL | The value of the time-to-live (TTL) field in the IPv4 packet header.

Note:
This element ID applies to 5520 Series only. |
| 234 | ingressVRFID | The VRF name that receives packets for this flow.

Note:
This element ID applies to 5520 Series only. |
| 243 | dot1qVlanId | The VLAN ID in the Tag Control information of an Ethernet frame.

Note:
This element ID applies to 5520 Series only. |

IPFIX is a push protocol. The Filtering Rules and Exporting processes periodically send IPFIX messages to configured receivers without interaction from the Collecting process.

IPFIX collects IPv4 flow information on the switch and conforms with the following:

- IPFIX supports only 1 collector.
- IPFIX learns only IPv4 flows.
- IPFIX sends and receives only TCP/UDP flows
- IPFIX uses only UDP to export packets.
- You can configure only the template exporting timer.
- The Out-of-Band (OOB) port does not support IPFIX.
- IPFIX exports TCP/UDP IPv4 flows on IS-IS interfaces that are members of a VLAN. IPFIX does not capture Mac-In-Mac encapsulated flows on IS-IS interfaces.

IPFIX processes IPv4 UDP or TCP Mac-in-Mac packet flows that are terminated by the switch. IPFIX does not process Mac-in-Mac packet flows that are only traversing the switch (Layer 2 switching).

- Layer 3 Virtual Services Network (L3 VSN) flow packets on NNI ports are not learned by IPFIX.

**Note**

IPFIX is not supported on OOB, Circuitless IP (CLIP), or VLAN Segmented Management Instance interfaces.

IPFIX Configuration Using CLI

This section provides procedures to configure IPFIX using Command Line Interface (CLI).

Enabling IPFIX Globally

About This Task

Use the following procedure to enable IPFIX globally. IPFIX provides the ability to monitor IPv4 traffic flows.

The default global state is disabled.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable IPFIX:
`ip ipfix enable`
3. (Optional) Configure the flow aging interval:
`ip ipfix aging-interval <1-60>`
4. (Optional) Configure a value for observation domain:
`ip ipfix observation-domain <0-4294967295>`

Example

Enable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix enable
Switch:1(config)#ip ipfix aging-interval 30
Switch:1(config)#ip ipfix observation-domain 1
```

Disable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no ip ipfix enable
```

```
By disabling IPFIX globally, all the processes and traffic
sent to collector(s) will be stopped.Do you agree (y/n) ? y
```

Variable Definitions

Use the data in the following table to use the **ip ipfix** command.

| Variable | Value |
|-----------------------------------|--|
| aging-interval <1-60> | Specifies (in seconds) the flow record aging interval. The aging-interval determines how long a traffic flow that is no longer being received is retained as a flow. The default value is 40 seconds. |
| enable | Enables IPFIX globally. |
| observation-domain <0-4294967295> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |

Displaying IPFIX Global Status

About This Task

Use the following procedure to display global status information for IPFIX.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IPFIX global status:

```
show ip ipfix
```

Example

```
Switch:1#show ip ipfix
=====
                                IPFIX Global
=====
      Global-State : enable
  Observation-Domain ID : 1
        Flow Limit : 20000
        Flow Count  : 0
      Aging Interval : 40
```

Configure the IPFIX Aging Interval

About This Task

Use the following procedure to configure an aging interval for IPFIX. The aging interval determines how long a traffic flow that is no longer being received, is retained as a flow.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a value for the aging interval:

```
ip ipfix aging-interval <interval>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix aging-interval 30
```

Variable Definitions

The following table defines parameters for the **ip ipfix aging-interval** command.

Table 200:

| Variable | Value |
|-------------------------------------|---|
| <i>aging-interval</i>
<interval> | <p>Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch.</p> <p>The default varies depending on the platform:</p> <ul style="list-style-type: none"> • 5520 Series - 10 seconds • VSP 7400 Series - 40 seconds |

Configuring the IPFIX Collector

About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure values for the collector ID, the IP address of the collector, and the IP address of the exporter. Optionally, you can configure values for the source port sending flow information and the destination port receiving flow information:

```
ip ipfix collector <1-1> {A.B.C.D} exporter-ip {A.B.C.D} [dest-port
<1-65535>] [src-port <1-65535>]
```

Note

You cannot configure collector or exporter IP addresses in the following formats:

- 255.255.255.255
- 127. x.x.x
- 0.x.x.x
- 224.0.0.0 to 239.255.255.255

If you configure a collector or exporter IP address in any of these formats, the following error message is displayed:

```
Error: Invalid IP address
```

- (Optional) Configure a value for the export interval:

```
ip ipfix collector 1 export-interval <1-120>
```

- (Optional) Configure a value for the initial burst of template packets:

```
ip ipfix collector 1 initial-burst <1-10>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix collector 1 192.0.2.15 exporter-ip 192.0.2.16
dest-port 2 src-port 4
Switch:1(config)#ip ipfix collector 1 export-interval 40
Switch:1(config)#ip ipfix collector 1 initial-burst 4
```

Variable Definitions

Use the data in the following table to use the **ip ipfix collector** command.

| Variable | Value |
|-----------------------|--|
| <1-1> | Specifies the IPFIX collector ID. |
| {A.B.C.D} | Specifies the IP address of the collector. |
| exporter-ip {A.B.C.D} | Specifies the IP address of the exporter. |
| dest-port <1-65535> | Specifies the destination port receiving flow information. |
| src-port <1-65535> | Specifies the source port sending flow information. |
| export-interval | Specifies, in seconds, the frequency of template packet exports to the collector. The default value is 60 seconds. |
| initial-burst | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5. |

Displaying IPFIX Collector Information

About This Task

Use the following procedure to display information about the IPFIX collector. The IPFIX collector can store flow information from multiple network devices.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the IPFIX collector:

```
show ip ipfix collector [<1-1>]
```

Example

```

=====
                                IPFIX Collector-Info
=====
ID  Collector      Exporter      Source  Destination  Collector  Reachable  Exporting  Initial
   IP Address    IP Address    Port    Port         State     Via        Interval  Burst
-----
1   20.20.20.2     20.20.20.1   2055   2055         Enabled   -          60        5
    
```

Variable Definitions

Use the data in the following table to use the **show ip ipfix collector** command.

| Variable | Value |
|----------|-----------------------------------|
| <1-1> | Specifies the IPFIX collector ID. |

Configuring an IPFIX Observation Domain

About This Task

An observation domain consists of a collection of flow groups. Use this procedure to assign a unique ID to an observation domain. The default value is 0.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the observation domain ID:

```
ip ipfix observation-domain <0-4294967295>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix observation-domain 1
```

Variable Definitions

Use the data in the following table to use the **ip ipfix observation-domain** command.

| Variable | Value |
|--------------------------------------|---|
| observation-domain
<0-4294967295> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |

Display IPFIX Flows

About This Task

Use the following procedure to display information about IPFIX flows. You can display information for all IPFIX flows, or you can specify a single IPFIX flow and display additional information about that flow.

Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about all IPFIX flows:

```
show ip ipfix flows
```
- Display information about an IPFIX flow learned on an ingress port:

Note

This step only applies to VSP 7400 Series.

```
show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-port <rx-nni
| {slot/port[/sub-port]}>
```

- Display information about an IPFIX flow learned on an ingress VRF:

Note

This step only applies to 5520 Series.

```
show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-vrf <0-511>
{in-vlan <1-4095> | untagged} ip-ttl <0-255>
```

Example

Display all IPFIX flows:

```
Switch:1>show ip ipfix flows
```

```
=====
                        IPFIX Flows
=====
Source      Destination  Source  Destination  Protocol  In
IP          IP          Port    Port          IP         Port

Display information about a specific IPFIX flow:

```
Switch:1>#show ip ipfix flows source-addr 203.0.113.2 dest-addr 203.0.113.1 s 63 d 63 p
udp in-port rx-nni
```

```
=====
                                IPFIX Flows
=====
```

| Source IP/
Destination IP | Src Port/
Dest Port | Protocol/
In Port | Start Time/
Observation Time | Byte Count/
Packet Count |
|------------------------------|------------------------|----------------------|---------------------------------|-----------------------------|
| 203.0.113.2 | 63 | UDP | Tue Apr 09 06:48:57 2019 UTC | 352376 |
| 203.0.113.1 | 63 | RX-NNI | Tue Apr 09 06:49:49 2019 UTC | 5182 |

Variable Definitions

The following table defines parameters for the **show ip ipfix flows** command.

| Variable | Value |
|---|---|
| <i>dest-addr</i> {A.B.C.D} | Specifies an IP address for the flow destination. |
| <i>dest-port</i> <1-65535> | Specifies a value for the destination port. |
| <i>in-port</i> <rx-nni {slot/port[/sub-port]}>

Note:
Exception: only supported on VSP 7400 Series. | Specifies the port that learns the flow. |
| <i>in-vlan</i> <1-4095>

Note:
Exception: only supported on 5520 Series. | Specifies an ingress VLAN ID for the flow. |
| <i>in-vrf</i> <0-511>

Note:
Exception: only supported on 5520 Series. | Specifies an ingress VRF ID for the flow. |
| <i>ip-ttl</i> <0-255>

Note:
Exception: only supported on 5520 Series. | Specifies the IP time-to-live (TTL) for the flow. |
| <i>protocol</i> {udp tcp} | Specifies the transport protocol. |
| <i>source-addr</i> {A.B.C.D} | Specifies an IP address for the flow source. |

| Variable | Value |
|---|--|
| <i>source-port</i> <1-65535> | Specifies a value for the source port. |
| <i>untagged</i> | Specifies ingress untagged flows. |
| Note:
Exception: only supported on 5520 Series. | |

IPFIX Configuration Using EDM

This section provides procedures to configure IPFIX in Enterprise Device Manager (EDM).

Enabling IPFIX Globally

About This Task

IPFIX allows you to monitor IPv4 traffic flows. Use the following procedure to enable IPFIX globally.

The default global state is disabled.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **IPFIX**.
3. Click the **Globals** tab.
4. To enable IPFIX, click **enable** in the **ConfState** option box.
5. (Optional) To configure an observation domain ID, type a value in the **ObservationDomainID** field.
6. (Optional) To configure the aging interval, type a value in the **AgingInterval** field.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name | Description |
|----------------------------|--|
| ConfState | Specifies whether IPFIX is enabled or disabled. The default is disabled. |
| ObservationDomainID | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |
| AgingInterval | Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. Depending on the hardware platform, the parameter range and default value can vary.
The default varies depending on the platform: <ul style="list-style-type: none"> • 5520 Series - 10 seconds • VSP 7400 Series - 40 seconds |

Configuring the IPFIX Collector

About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **IPFIX**.
3. Click the **Collector** tab.
4. Click **Insert**.
5. In the **Num** field, specify a value for the collector ID number.
6. In the **AddressType** field, specify a value for the IP address type of the collector.
7. In the **Address** field, specify a value for the IP address of the collector.
8. (Optional) In the **SrcPort** field, specify a value for the source port sending flow information. The default value is 2055.
9. (Optional) In the **DestPort** field, specify a value for the destination port receiving flow information. The default value is 2055.
10. In the **ExporterIpType** field, specify a value for the IP address type of the exporter for the collector.
11. In the **ExporterIp** field, specify the IP address of the exporter for the collector.
12. (Optional) In the **ExportInterval** field, specify the frequency of template packets exports to the collector.
13. (Optional) In the **InitialBurst** field, specify the number of template packets to send when the collector becomes reachable.
14. Click **Insert**.

Collector field descriptions

Use the data in the following table to use the **Collector** tab.

| Name | Description |
|-----------------------|---|
| Num | Specifies the ID number of the collector |
| AddressType | Specifies the IP address type of the collector. |
| Address | Specifies the IP address of the collector. |
| Protocol | Specifies the protocol used to export data from the exporter to the collector. |
| SrcPort | Specifies the source port sending flow information. |
| DestPort | Specifies the destination port receiving flow information. |
| ExporterIpType | Specifies the IP address type of the exporter for the collector. |
| ExporterIp | Specifies the IP address of the exporter for the collector. |
| State | Specifies the state of the collector. The default value is enabled. |
| IsReachable | Specifies whether the collector is reachable. The default value is false (not reachable) |
| ViaNextHopName | Specifies the next-hop through which the collector is reachable. |
| ExportInterval | Specifies, in seconds, the frequency of template packets exports to the collector. The default value is 60 seconds. |
| InitialBurst | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5. |

IPsec Fundamentals

Internet Protocol Security (IPsec) ensures the authenticity, integrity, and confidentiality of data at the network layer of the Open System Interconnection (OSI) stack.

The IPsec feature is a set of security protocols and cryptographic algorithms that protect communication in a network. Use IPsec in scenarios where you need to encrypt packets between two hosts, or two routers, or a router and a host.

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols.

IPsec adds support for OSPF virtual link for the security protection of the communication between the end points. You can also use IPsec with OSPFv3 on a brouter port or VLAN interface, for example, if you want to encrypt OSPFv3 control traffic on a broadcast network. You can also use IPsec with ICMPv6.

Note

- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.
- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

Note

- When an OSPFv3 virtual link between two end points is secured using IPsec, the IPsec status on the IPv6 interfaces is automatically updated. This is applicable only on those interfaces that have no IPSEC policies manually configured on them

The following figure displays the movement of traffic using IPsec.

Figure 148: Internet Protocol Security (IPsec)

The IPsec feature uses security ciphers and encryption algorithms like AES, DES, and 3DES to ensure confidentiality of data, and keyed MAC for authenticity of data. The encryption algorithms require shared keys to secure the communication. The device only supports manual keying and configuration for IPsec. The IPsec feature supports IPv4 and IPv6 interfaces.

To configure IPsec, you create an IPsec policy, and then link the IPsec policy to an interface. You also link each IPsec policy to an IPsec security association. The IPsec policies define the amount of security applied to specific traffic on a specific interface. The IPsec feature supports the following security protocols:

- Encapsulating security payload (ESP)
- Authentication header (AH)

The device restricts IPsec encryption to control traffic through the CPU. The IPsec feature processes either the ingress, the egress, or both the egress and ingress control packets to and from the CPU.

The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to the packet. The device consults the SPD for both ingress and egress traffic. For egress traffic, the device consults the SPD to determine if IPsec needs to apply security considerations. For ingress traffic, the device consults the SPD to determine whether the traffic received with IPsec encapsulation complies with the policies defined in the system.

For more information on IPsec, see [IPsec Support with OSPFv3](#) on page 2353, [View IPsec Statistics](#) on page 3218, and [Display IPsec Interface Statistics](#) on page 1719.

Authentication header

The authentication header (AH) authenticates IP traffic and ensures you connect with who you want to connect. The authentication header can detect if data is altered in transit and protect against replay attacks. The authentication header does not encrypt traffic.

The authentication header provides a small header that precedes the payload with the use of the security parameters index (SPI) and sequence number. The authentication header provides:

- IP datagram sender authentication by HMAC or MAC
- IP datagram integrity assurance by HMAC or MAC
- Replay detection and protection by sequence number

The IPsec feature inserts the AH header after the IP header in transport mode. Transport mode with AH authenticates only the payload of the IP packet.

Tunnel mode authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

You can apply AH alone, or in combination with the Encapsulating Security Payload (ESP).

The following figures show an original IP packet and an IP packet with an AH header.

Figure 149: Original IP packet

Figure 150: AH in transport mode

Encapsulating security payload

The encapsulating security payload (ESP) encrypts traffic with use of encryption algorithms, such as 3DES, AES-CBC, and AES-CTR. The security association specifies the algorithm and key used in ESP.

The encapsulating security payload can protect origin authenticity, integrity, and confidentiality of packets. ESP supports encryption-only and authentication-only configurations. The IPsec feature inserts the ESP header after the IP header and before the next layer protocol header in transport mode. Transport mode with ESP encrypts or authenticates only the payload of the IP packet.

Tunnel mode encrypts or authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

The following figures display the original IP packet and an IP packet with ESP.

Figure 151: Original IP packet

Figure 152: ESP in transport mode

IPsec modes

The IPsec feature security protocols use two different modes to protect the entire IP payload or the upper layer protocols:

- Transport mode
- Tunnel mode

Transport mode IPsec protects the upper layer protocols. In transport mode, IPsec adds an IPsec header between the IP header and upper layer protocol header.

Tunnel mode IPsec protects the whole IP packet. In tunnel mode, IPsec inserts the IPsec header between another IP datagram IP header and inner IP header.

Security association

A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet. IPsec identifies SAs by:

- Security Parameter Index (SPI)
- Protocol value (either AH or ESP)
- Destination address to which the SA applies

Creation of a security association

Typically SAs exist in pairs; one in each direction, either inbound or outbound.

You can create SAs manually or dynamically. After you create an SA manually, the SA has no defined lifetime and the SA exists until you manually delete the SA.

After the device creates the SA dynamically, the SA can have a lifetime value that IPsec peers negotiate through use of a key management protocol. If the device uses the key excessively unauthorized access can occur. You must define the IPsec lifetime and other configurable parameters manually.

Security associations reside in the Security Association Database (SADB), which maintains a list of active SAs. The IPsec feature uses outbound SAs to secure the outgoing traffic and inbound SAs to process the incoming traffic. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature restricts SAs to the source and destination address of the connected router.

Security policy

Use IPsec to create IPsec security policies that define the levels of security for different types of traffic. You can use IPsec security policies to create rules to filter traffic with IPsec. IPsec policies determine what IP traffic to secure. An IPsec security policy typically consists of:

- An IP filter
- Security algorithms for authentication and key exchange
- An action

Creation of a security policy

You can configure IPsec on IPv4/IPv6 interfaces. First, create and configure an IPsec policy, and then add and enable the policy on an interface.

After you enable IPsec, the device encrypts all control traffic on the interface based on the policy. You have to specify individual policies to target a particular interface address or multiple addresses. By default, this implementation does not work on a subnet.

The Security Policy Database (SPD) maintains the IPsec security policies. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature only adds policies if the source address in the policy specified matches an interface IP address.

The IPsec feature restricts the policy match source address to the interface address of the router and destination IPv6 address.

IPsec NAT-T

IP security (IPsec) Network Address Translation Traversal (NAT-T) allows IPsec tunnel traffic through Network Address Translation (NAT) or Port Address Translation (PAT) points in the network. To enable IPsec NAT-T connectivity, you must deploy and configure an IPsec NAT-T supported IPsec logical interface on each side of the IPsec tunnel.

The following terms are specific to the IPsec NAT-T feature:

- IPsec Initiator - The initiator mode of an IPsec tunnel initiates IKE negotiation and rekeying. A supported IPsec logical interface configured as an IPsec Initiator initiates IKE message exchange and IPsec security association (SA) establishment, rekeys IKE, and initiates IPsec SAs. Configure the IPsec Initiator device on the branch side of the tunnel.

Note

IPsec Initiator is the default mode of the logical interface IPsec tunnel.

- IPsec Responder - The responder-only mode of an IPsec tunnel responds to IKE negotiation and rekeying and only responds to IPsec negotiations from an IPsec Initiator. A VOSS device with a logical interface configured as an IPsec Responder does not initiate IKE message exchange and IPsec SA establishment, and does not rekey IKE and IPsec SAs. Configure the IPsec Responder device on the aggregator side of the tunnel.
- IPsec Remote NAT IP - The remote-nat-ip is the public IP address of the NAT router connected to the IPsec Responder device. Only configure an IPsec Initiator with the IPsec Remote NAT IP address when NAT routers are present on both sides of the IPsec tunnel.

Note

Only configure the logical interface of the IPsec Initiator device with the Remote NAT IP address of the responder.

The following diagram illustrates an example of an IPsec NAT-T configuration with both sides of the connection behind NAT:

Figure 153: IPsec NAT-T with NAT router on both sides

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.3
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec remote-nat-ip 203.0.113.1
ipsec
```

The following diagram illustrates an example of an IPsec NAT-T configuration with only 1 side of the connection behind NAT:

Figure 154: IPsec NAT-T with NAT router on one side

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.2
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec
```

IPsec NAT-T Considerations

The following considerations apply to IPsec NAT-T:

- You must configure one side of the IPsec NAT-T tunnel as an IPsec responder. If IPsec is configured on the IPsec Initiator device and subsequently configured on the IPsec Responder device, IPsec must be restarted on the Initiator device. If IPsec is not restarted, it can take approximately 3 minutes for the adjacency to open.
- You must configure the aggregator device as the IPsec Responder device, and configure the branch device as the IPsec Initiator device.
- Among all the IPsec responders, the system uses the lowest configured maximum transmission unit (MTU) value of any responder IPsec tunnel as the MTU value for all IPsec responder-only tunnels. The system uses the lowest configured IPsec tunnel MTU value regardless of manually configured MTU tunnel values, and higher MTU values might be visible in the IPsec information for the logical

interface. For non-responder IPsec tunnels or VXLAN tunnels, the configured and visible MTU value for the tunnel is used for fragmentation and reassembly.

- If both the IPsec Initiator device and the IPsec Responder device are behind NAT, you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.
- You must add route table entries on the IPsec Responder device with the public IP address and private IP address of the remote NAT for the IPsec Initiator device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.
- You must add a route table entry on the IPsec Initiator device with the public IPsec Remote NAT IP address for the IPsec Responder device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.

Digital Certificates for IPsec Authentication

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. The default method for IPsec authentication is a pre-shared key, which is easy to configure, but does not scale well and is less secure than a certificate. You can use a digital certificate, instead of a pre-shared key, to authenticate IPsec for Fabric Extend.

Consider a hub and spoke topology with two branch locations. The network carries both private traffic and encrypted IPsec traffic. To use Public Key Infrastructure (PKI) with IPsec Fabric Extend technology, all devices must acquire the digital-signed certificates. The CA server can be accessed from the devices, a public network, or an internal network. Each device must configure a profile for the CA server. The switch uses Simple Certificate Enrollment Protocol (SCEP) to obtain the trusted, signed certificates.

XA1400 Series

XA1400 Series supports digital certificate configuration through VOSS. VOSS supports both offline and online certificate management; they are mutually exclusive. Use offline certificate management if the switches cannot communicate with the certificate authority (CA).

Digital certificate support for IPsec authentication provides an alternate method to validate the CA certificate chain. You can configure the IPsec authentication type as RSA signature instead of pre-shared key.

VOSS supports only one CA server and one subject certificate.

To use IPsec with Digital Certificates for XA1400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1701.
- Configure certificate information in VOSS.

For information about certificate configuration, see [Security](#) on page 2863.

VSP 4900 Series and VSP 7400 Series

VSP 4900 Series and VSP 7400 Series support digital certificate configuration through the Fabric IPsec Gateway virtual machine. Fabric IPsec Gateway supports both offline and online certificate management simultaneously. Use offline certificate management if the switches cannot communicate with the CA.

Fabric IPsec Gateway supports multiple CA trustpoints and multiple identity subject certificates. You can use different certificates for different IPsec tunnels. Fabric IPsec Gateway acts like a hub to isolate IPsec domains.

To use IPsec with Digital Certificates for VSP 4900 Series and VSP 7400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1701.
- Configure certificate information in Fabric IPsec Gateway.

For information about certificate configuration, see [Extreme Integrated Application Hosting](#) on page 817 for Fabric IPsec Gateway virtual machine configuration.

IPsec Limitations

- The IPsec feature implementation is available only in software. Hardware implementation is not available. Only control packets to and from the CPU are subject to IPsec. IPsec implements IPsec policies in the software on the control path.
- The device does not support address ranges facility for an IPsec policy.
- No fast-path support exists for IPsec.

IPsec configuration using CLI

The following section provides procedures to configure Internet Protocol Security (IPsec).

Creating an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create an IPsec policy:

```
ipsec policy WORD<1-32>
```
3. (Optional) Delete an IPsec policy:

```
no ipsec policy WORD<1-32>
```

Example

Create an IPsec policy named newpolicy:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy
```

Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable | Value |
|-------------------------|----------------------------------|
| <i>WORD<1-32></i> | Specifies the IPsec policy name. |

Enabling an IPsec policy

Use the following procedure to enable an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Before You Begin

- Create an IPsec policy.

About This Task

The IPsec feature adds policies only if the admin status of the policy and the IPsec status on the interface are enabled.

If you disable the IPsec policy on an IPv4 or IPv6 interface, IPsec removes the policy-related information from the security policy database (SPD) and the security association database (SADB), but the information remains on the system. After you re-enable, the information reapplies on the interface.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable an IPsec policy:

```
ipsec policy WORD<1-32> admin enable
```
3. (Optional) Disable an IPsec policy:

```
no ipsec policy WORD<1-32> admin enable
```

Example

Enable an IPsec policy named newpolicy:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy admin enable
```

Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable | Value |
|-------------------------|----------------------------------|
| <i>admin enable</i> | Enables the policy. |
| <i>WORD<1-32></i> | Specifies the IPsec policy name. |

Creating an IPsec security association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create an IPsec security association:

```
ipsec security-association WORD<1-32>
```
3. (Optional) Delete an IPsec security association:

```
no ipsec security-association WORD<1-32>
```

Example

Create an IPsec security association named `newsa`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa
```

Variable Definitions

The following table defines parameters for the `ipsec security-association` command.

| Variable | Value |
|-------------------------------|--|
| <code>WORD<1-32></code> | Specifies the security association identifier. |

Configuring an IPsec security association

Use the following procedure to configure an IPsec security association (SA). An SA is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

Before You Begin

- Create an IPsec security association to configure.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from a policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the IPsec security association key-mode:

```
ipsec security-association WORD<1-32> key-mode <automatic|manual>
```

This device only supports manual mode.

3. Configure the IPsec security association mode:

```
ipsec security-association WORD<1-32> mode <transport|tunnel>
```

This device only supports transport mode.

4. Configure the IPsec security association encapsulation protocol:

```
ipsec security-association WORD<1-32> encap-proto <AH|ESP>
```

5. Configure the IPsec security association security parameters index:

```
ipsec security-association WORD<1-32> spi <1-4294967295>
```

For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.

6. Configure the IPsec security association encryption algorithm:

```
ipsec security-association WORD<1-32> Encrpt-algo <3DES|AES-CBC|AES-CTR|NULL> [EncrptKey WORD<1-256>][KeyLength <1-256>]
```

The encryption algorithm parameters are only accessible if you configure the encapsulation protocol to ESP.

7. Configure the IPsec security association authentication algorithm:

```
ipsec security-association WORD<1-32> auth-algo <AES-XCBC-MAC|MD5|SHA1|SHA2> [auth-key WORD<1-256>][KeyLength <1-256>]
```

8. Configure the IPsec security association lifetime value:

```
ipsec security-association WORD<1-32> lifetime <Bytes<1-4294967295>|seconds<1-4294967295>
```

9. (Optional) Delete the IPsec security association:

```
no ipsec security-association WORD<1-32>
```

Example

Configure an IPsec security association named `new_sa` to have a key-mode of ASCII, an SA mode of transport, and an encapsulation protocol of ESP. Configure the encryption algorithm to 3DES, with an encryption key of 11111111111111111111111111111111, and a keylength of 24. Configure the authorization algorithm to SHA1, the authorization key to 11111111111111111111111111111111, and key length to 20. Configure the SPI to 1 and the lifetime in seconds to 1000.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa mode transport
Switch:1(config)#ipsec security-association newsa encap-proto ESP
Switch:1(config)#ipsec security-association newsa Encrpt-algo 3DES Encrpt-key
1111111111111111111111111111111111111111111111111111111111111111 KeyLength 48
Switch:1(config)#ipsec security-association newsa auth-algo SHA1 auth-key
1111111111111111111111111111111111111111111111111111111111111111 KeyLength 20
Switch:1(config)#ipsec security-association newsa key-mode manual
Switch:1(config)#ipsec security-association newsa spi 1
Switch:1(config)#ipsec security-association newsa lifetime seconds 1000
```

Variable Definitions

The following table defines parameters for the `ipsec security-association` command.

| Variable | Value |
|--|--|
| <i>WORD</i> <1-32> | Specifies the security association. |
| <i>auth-algo</i> <AES-XCBC-MAC MD5 SHA1 SHA2> [<i>auth-key</i> <i>WORD</i> <1-256>] [<i>KeyLength</i> <1-256>] | <p>Specifies the authorization algorithm, which includes one of the following values:</p> <ul style="list-style-type: none"> • AES-XCBC-MAC • MD5 • SHA1 • SHA2 <p>The default authentication algorithm name is MD5.
The parameter <i>auth-key</i> specifies the authentication key.
The <i>KeyLength</i> parameter specifies a string value of 1 to 256 characters in length. The default <i>KeyLength</i> is 128. The <i>KeyLength</i> values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.</p> |
| <i>encap-proto</i> <AH ESP> | <p>Specifies the encapsulation protocol:</p> <ul style="list-style-type: none"> • AH—Specifies authentication header. • ESP—Specifies encapsulation security payload. <p>If you configure the encapsulation protocol as AH, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP.
The default value is ESP.</p> |
| <i>Encrpt-algo</i> <3DES AES-CBC AES-CTR NULL> [<i>EncrptKey</i> <i>WORD</i> <1-256>] [<i>KeyLength</i> <1-256>] | <p>Specifies the encryption algorithm value as one of the following:</p> <ul style="list-style-type: none"> • 3DES-CBC • AES-CBC • AES-CTR • NULL—Only use the NULL parameter to debug. Do not use this parameter in other circumstances. <p>The default encryption algorithm is AES-CBC.
You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP.
The <i>EncrptKey</i> specifies the encryption key.
The <i>KeyLength</i> specifies the key length value in a string from 1 to 256 characters. The default <i>KeyLength</i> is 128. The <i>KeyLength</i> values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.</p> |
| <i>key-mode</i> < <i>automatic</i> <i>manual</i> > | <p>Specifies the key-mode as one of the following:</p> <ul style="list-style-type: none"> • <i>automatic</i> • <i>manual</i> <p>The default is <i>manual</i>.</p> |
| <i>lifetime</i> < <i>Bytes</i> <1-4294967295> <i>seconds</i> <1-4294967295> | <p>Specifies the lifetime value in seconds or bytes.
The default lifetime value in seconds is 28800. The default lifetime value in bytes is 4294966272.</p> |

| Variable | Value |
|--|---|
| <code>mode <transport tunnel></code> | <p>Specifies the mode value as one of the following:</p> <ul style="list-style-type: none"> • <code>transport</code>—Transport mode encapsulates the IP payload and provides a secure connection between two end points. • <code>tunnel</code>—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. <p>The default is transport mode.</p> |
| <code>spi<1-4294967295></code> | <p>Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet.</p> <p>For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.</p> <p>The default value is 0.</p> |

Configuring an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Before You Begin

- Create an IPsec policy.

About This Task

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the remote address:

```
ipsec policy WORD<1-32> raddr WORD<1-32>
```
3. (Optional) Configure the local address:

```
ipsec policy WORD<1-32> laddr WORD<1-32>
```

The `laddr` parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.

4. Configure the protocol:

```
ipsec policy WORD<1-32>[protocol <icmp|icmpv6|ospfv3|tcp|udp>]
[sport<1-65535|any>][dport<1-65535|any>]
```

5. Configure the policy action:

```
ipsec policy WORD<1-32> [action <drop|permit>]
```

Example

Configure the remote address to 2001:db8:0:0:0:0:0:1 and local address to 2001:db8:0:0:0:0:0:15. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to permit.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv6policy raddr 2001:db8:0:0:0:0:0:1
Switch:1(config)#ipsec policy Ipv6policy laddr 2001:db8:0:0:0:0:0:15
Switch:1(config)#ipsec policy Ipv6policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv6policy action permit
```

Configure the remote address to 192.0.1.1 and local address to 192.0.1.2. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to drop.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv4policy raddr 192.0.1.1
Switch:1(config)#ipsec policy Ipv4policy laddr 192.0.1.2
Switch:1(config)#ipsec policy Ipv4policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv4policy action drop
```

Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable | Value |
|---|--|
| <i>action</i> <drop permit> | Specifies the action the policy takes.
The default is permit. |
| <i>laddr</i> WORD<1-32> | Specifies the local address. The <i>laddr</i> parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.
The default is 0::0. |
| <i>protocol</i> <icmp icmpv6 ospfv3 tcp udp>] [<i>sport</i> <1-65535> <i>any</i> >] [<i>dport</i> <1-65535> <i>any</i> >] | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> • ICMP • ICMPv6 • OSPFv3 • TCP • UDP <i>sport</i> — Specifies the source port for TCP and UDP. You can specify any to configure any port as the source port.
<i>dport</i> — Specifies the destination port for TCP and UDP. You can specify any to configure any port as the destination port.
The default protocol is TCP any.
IPv4 only supports ICMP, UDP, and TCP. |

| Variable | Value |
|-------------------------------|---|
| <i>raddr WORD<1-32></i> | Specifies the remote address.
The default is 0::0. |
| <i>WORD<1-32></i> | Specifies the policy name. |

Linking the IPsec security association to an IPsec policy

Use the following procedure to link the security association to an IPsec policy.

Before You Begin

- The IPsec security association and IPsec policy must exist.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

- Enter Global Configuration mode:
`enable`

`configure terminal`
- Link the IPsec security association to the IPsec policy:
`ipsec policy WORD<1-32> security-association WORD<1-32>`
- (Optional) Unlink the IPsec security association to the IPsec policy:
`no ipsec policy WORD<1-32> security-association WORD<1-32>`

Example

Link the IPsec security association named `new_sa` to the IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy security-association newsa
```

Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable | Value |
|--|--|
| <i>WORD<1-32></i> | Specifies the policy ID. |
| <i>security-association WORD<1-32></i> | Specifies the security association ID. |

Enable IPsec on an Interface

Use the following procedure to enable IPsec on an interface. You can configure IPsec on a port, management port, VLAN, or loopback interface.

Note

IPsec support on the management port applies to VSP 8600 Series only.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]}`
- `interface loopback <1-256>`
- `interface mgmtEthernet <mgmt | mgmt2>`
- `interface vlan <1-4059>`

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPsec on an IPv6 interface:

```
ipv6 ipsec enable
```

```
default ipv6 ipsec enable
```

3. Enable IPsec on an IPv4 interface:

```
ip ipsec enable
```

```
default ip ipsec enable
```

4. (Optional) Disable IPsec on an IPv6 interface:

```
no ipv6 ipsec enable
```

5. (Optional) Disable IPsec on an IPv4 interface:

```
no ip ipsec enable
```

Example

Enable IPsec for IPv6 on VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec enable
```

Variable Definition

The following table defines parameters for the **ip ipsec** and **ipv6 ipsec** commands.

| Variable | Value |
|---------------|---------------------------------|
| <i>enable</i> | Enables IPsec on the interface. |

Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

Note

IPsec support on the management port applies to VSP 8600 Series only.

Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]}`
- `interface loopback <1-256>`
- `interface mgmtEthernet <mgmt | mgmt2>`
- `interface vlan <1-4059>`

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Link the IPsec policy to an IPv4 interface:

```
ip ipsec policy WORD<1-32> dir <both|in|out>
```

- Link the IPsec policy to an IPv6 interface:

```
ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv4 interface:

```
no ip ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv6 interface:

```
no ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

Example

Link the IPsec policy newpolicy to the IPv6 interface VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec policy newpolicy dir both
```

Variable Definitions

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

| Variable | Value |
|---|---|
| <i>WORD</i> <1–32> | Specifies the policy ID. |
| <i>dir</i> < <i>both</i> <i>in</i> <i>out</i> > | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> • <i>both</i>—Specifies both ingress and egress traffic. • <i>in</i>—Specifies ingress traffic. • <i>out</i>—Specifies egress traffic. The default is <i>both</i> . |

Enable IPsec on a Management Interface

Use the following procedure to enable IPsec on a management interface.

By default, IPsec is disabled on the management interface.

Note

This procedure applies to VSP 8600 Series only.

Procedure

1. Enter mgmtEthernet Interface Configuration mode:

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Enable IPsec on an IPv6 interface:

```
ipv6 ipsec enable
```
3. Enable IPsec on an IPv4 interface:

```
ip ipsec enable
```

Example

Enable IPsec for IPv4 on the management interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtEthernet mgmt
Switch:1(config-if)#ip ipsec enable
```

Link an IPsec Policy to a Management Interface

Use the following procedure to link an IPsec policy to a management interface, and configure a policy direction. By default, the direction is both.

Note

This procedure applies to VSP 8600 Series only.

Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

Procedure

- Enter mgmtEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface mgmtEthernet <mgmt | mgmt2>
```

- Link the IPsec policy to an IPv4 interface:

```
ip ipsec policy WORD<1-32> dir <both|in|out>
```

- Link the IPsec policy to an IPv6 interface:

```
ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv4 interface:

```
no ip ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv6 interface:

```
no ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

Example

Link the IPsec policy for IPv4 to the management interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtEthernet mgmt
Switch:1(config-if)#ip ipsec policy newpolicy dir both
```

Variable Definitions

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

| Variable | Value |
|--------------------------------|---|
| <i>WORD<1-32></i> | Specifies the policy ID. |
| <i>dir <both in out></i> | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> both—Specifies both ingress and egress traffic. in—Specifies ingress traffic. out—Specifies egress traffic. <p>The default is both.</p> |

Configure the IPsec Initiator with the IPsec Responder Remote NAT IP Address

About This Task

If both the Responder device and the Initiator device are behind Network Address Translation (NAT), you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.

Note

Only perform this procedure on the IPsec Initiator device.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
logical-intf isis <1-255>
```

2. Configure the public IP address of the NAT router connected to the IPsec Responder device:

```
ipsec remote-nat-ip {A.B.C.D}
```

Variable Definitions

The following table defines parameters for the **logical-intf isis** command.

| Variable | Value |
|--|---|
| isis <1-255> | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID. |
| dest-ip {A.B.C.D} | Specifies the destination IP address for the logical interface. |
| name WORD<1-64> | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters. |
| mtu <mtu_value>
Note:
Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch. The default value is 1950. |

The following table defines parameters for the **ipsec remote-nat-ip** command.

| Variable | Value |
|-----------|---|
| {A.B.C.D} | Specifies the public IP address of the NAT router connected to the Responder device in an IPsec Network Address Translation Traversal (NAT-T) connection. |

Configure an IPsec NAT-T Responder

About This Task

One side of an IPsec Network Address Translation Traversal (NAT-T) connection must be a responder device and the other side must be the Initiator device. By default, both sides of an IPsec NAT-T connection are Initiators. Use the following procedure to configure one side of an IPsec NAT-T connection as a Responder device.

Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```

2. Configure an IPsec Responder:

```
ipsec responder-only
```

Variable Definitions

The following table defines parameters for the **logical-intf isis** command.

| Variable | Value |
|---|--|
| isis <1-255> | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID. |
| dest-ip {A.B.C.D} | Specifies the destination IP address for the logical interface. |
| name WORD<1-64> | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters. |
| mtu <mtu_value> | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch.
The default value is 1950. |
| Note:
Exception: only supported on XA1400 Series. | |

Configure Public Key Infrastructure for IPsec Tunnels

Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

Before You Begin

- Configure the Fabric Extend tunnels between the branch and hub switches.
- Configure digital certificates on the switch using either VOSS or the Fabric IPsec Gateway virtual machine, as appropriate.

About This Task

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. You can use a digital certificate to authenticate IPsec for Fabric Extend.

The default IPsec authentication method for Fabric Extend tunnels is a pre-shared key. If you configure the authentication method to RSA signature, the tunnels use the installed digital certificate.

Procedure

1. On XA1400 Series, configure IPsec authentication in the VOSS CLI:
 - a. Enter Layer 3 Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```
 - b. Configure the authentication type as RSA signature:

```
ipsec auth-method rsa-sig
```
2. On VSP 4900 Series and VSP 7400 Series, configure IPsec authentication in the Fabric IPsec Gateway virtual machine:

- a. Enter Fabric IPsec Gateway Configuration mode:

```
enable

virtual-service WORD<1-128> console
```

Note

Type CTRL+Y to exit the console.

- b. Configure the authentication type as RSA signature:

```
set ipsec <1-255> auth-method rsasig
```
- c. Configure the subject identity to use with the IPsec tunnel:

```
set ipsec <1-255> cert-subject <subject-label>
```

Variable Definitions

The following table defines parameters for the **set ipsec** command.

| Variable | Value |
|-----------------|---------------------------------|
| <1-255> | Specifies the tunnel ID. |
| <subject-label> | Specifies the subject identity. |

Display IPsec Information on an Interface

Use the following procedure to display IPsec information on an interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IPsec status on an Ethernet interface:

```
show ipsec interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

3. Display the IPsec status on a VLAN interface:

```
show ipsec interface vlan <1-4059>
```

4. Display the IPsec status on a management interface:

```
show ipsec interface mgmtethernet mgmt
```

Note

This step applies to VSP 8600 Series only.

5. Display the IPsec status on a loopback interface:

```
show ipsec interface loopback <1-256>
```

Example

Display the IPsec status on a VLAN interface.

```
Switch:1>show ipsec interface vlan 22
=====
                        VLAN Interface Policy Table
=====
Vlan Interface      Policy Name          IPsec State          Direction
-----
22                  AAA                  Enable               both
22                  tcp                  Enable               both
22                  icmp                 Enable               both
```

Variable Definitions

The following table defines parameters for the **show ipsec interface** command.

| Variable | Value |
|--|---|
| <i>gigabitethernet</i>
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>mgmtethernet mgmt</i> | Identifies the interface as the management interface.

Note:
Exception: only supported on VSP 8600 Series. |

| Variable | Value |
|-------------------------------------|--|
| <code>loopback <1-256></code> | Specifies the loopback interface. |
| <code>vlan <1-4059></code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

Job aid

The following table describes the fields in the output for the **show ipsec interface vlan** command.

| Parameter | Description |
|----------------|---|
| Vlan Interface | Specifies the VLAN interface. |
| Policy Name | Specifies the IPsec policy that associates with the specific VLAN or VLANs. |
| IPsec State | Specifies whether the IPsec policy is enabled on the VLAN interface. |
| Direction | Specifies the policy direction. |

The following table describes the fields in the output for the **show ipsec interface gigabitethernet** command.

| Parameter | Description |
|-------------|---|
| Interface | Specifies the interface. |
| Policy Name | Specifies the IPsec policy that associates with the specific port or ports. |
| IPsec State | Specifies whether the IPsec policy is enabled on the interface. |
| Direction | Specifies the policy direction. |

The following table describes the fields in the output for the **show ipsec interface mgmtethernet** command.

**Note**

This command applies to VSP 8600 Series only.

| Parameter | Description |
|-------------|--|
| Interface | Specifies the VLAN interface. |
| Policy Name | Specifies the IPsec policy that associates with the management port. |
| IPsec State | Specifies whether the IPsec policy is enabled on the interface. |
| Direction | Specifies the policy direction. |

The following table describes the fields in the output for the **show ipsec interface loopback** command.

| Parameter | Description |
|--------------------|---|
| LoopBack Interface | Specifies the loopback interface. |
| Policy Name | Specifies the IPsec policy that associates with the interface. |
| IPsec State | Specifies whether the IPsec policy is enabled on the interface. |
| Direction | Specifies the policy direction. |

Displaying configured IPsec policies

Use the following procedure to display IPsec policies.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all of the IPsec policies on the switch:
show ipsec policy all
3. Display a specific IPsec policy based on the policy name on the interface:
show ipsec policy interface WORD<1-32>
4. Display the IPsec policy based on the policy name:
show ipsec policy name WORD<1-32>

Example

Display IPsec policy information:

```
Switch:1>show ipsec policy all
=====
                        IPSEC Policy Table
=====
PolicyName           : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable

Switch:1>show ipsec policy interface ospf1
=====
                        IPsec Policy Interface Table
=====
POLICY NAME          InterfaceIndex      Policy State      Direction
-----
ospf1                 2/3                 Enable            both

Switch:1>show ipsec policy name ospf1
=====
                        IPSEC Policy Table
=====
PolicyName           : ospf1
```

```

LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable

```

Variable Definitions

The following table defines parameters for the **show ipsec policy** command.

| Variable | Value |
|-----------------------------------|---|
| <i>all</i> | Displays all of the IPsec policies on the switch. |
| <i>interface WORD<1-32></i> | Displays a specific IPsec policy based on the policy name on the interface. |
| <i>name WORD<1-32></i> | Displays the IPsec policy based on the name of the policy. |

Job aid

The following table describes the fields in the output for the **show ipsec policy all** and **show ipsec policy name** commands.

| Parameter | Description |
|---------------|--|
| PolicyName | Specifies the IPsec policy name. |
| LocalAddress | Specifies the local address. The default is 0::0. |
| RemoteAddress | Specifies the remote address. The default is 0::0. |
| Protocol | Specifies the protocol. |
| src-port | Specifies the source port. |
| dest-port | Specifies the destination port. |
| Action | Specifies the action as either: permit or drop. |
| Admin | Specifies whether the policy is enabled. |

The following table describes the fields in the output for the **show ipsec policy interface** command.

| Parameter | Description |
|----------------|--|
| POLICY NAME | Specifies the IPsec policy name. |
| InterfaceIndex | Specifies the interface. |
| Policy State | Specifies whether the policy is enabled. |

Displaying IPsec security association information

Use the following procedure to display IPsec security association information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all IPsec security associations:
show ipsec sa all
3. Display a specific IPsec security association:
show ipsec sa name WORD<1-32>
4. Display all security associations linked to a specific policy:
show ipsec sa-policy

Example

Display information on IPsec security association policies:

```
Switch:1>enable
Switch:1#show ipsec sa all
=====
IPSEC Security Association Table
=====

Variable Definitions

The following table defines parameters for the **show ipsec sa** command.

| Variable | Value |
|------------------------------|---|
| <i>all</i> | Displays all security associations. |
| <i>name WORD<1-32></i> | Displays a specific security association based on name. |

Use the data in the following table to use the **show ipsec** command.

| Variable | Value |
|------------------|---|
| <i>sa-policy</i> | Displays all security associations linked to a specific policy. |

Job aid

The following table describes the fields in the output for the **show ipsec sa all** and **show ipsec saname** commands.

| Parameter | Description |
|-------------------|---|
| sa-name | Specifies all of the IPsec security association names. |
| key-Mode | Specifies the key mode as manual or automatic. The default is automatic. |
| Encap protocol | Specifies the encapsulation protocol. |
| SPI Value | Specifies the SPI value, which is a tag added to the IP header. For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy. |
| Encrypt Algorithm | Specifies the encrypt algorithm as one of the following: <ul style="list-style-type: none"> • 3DES-CBC • AES-CBC • AES-CTR • NULL—Only used to debug. |
| Encrypt-key | Specifies the encrypt-key parameter for the authentication key in either: <ul style="list-style-type: none"> • hex— Specifies hexadecimal. • ascii—Specifies ASCII, the American Standard Code for Information Interchange character encoding scheme. |
| Encrypt-key-Len | Specifies the key length value in a string from 1 to 256 characters. The default KeyLength is 128. |
| Mode | Specifies the mode value as one of the following: <ul style="list-style-type: none"> • tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. • transport—Transport mode encapsulates the IP payload and provides a secure connection between two endpoints. The default is transport mode. |

| Parameter | Description |
|---------------|---|
| Lifetime-Sec | Specifies the lifetime value in seconds. The default is 28800. |
| Lifetime-Byte | Specifies the lifetime value in bytes. The default is 4294966272. |

The following table describes the fields in the output for the **show ipsec sa-policy** command.

| Parameter | Description |
|----------------------|--|
| Policy Name | Specifies the IPsec policy name. |
| Security Association | Specifies the security association name. |

Display Logical Interface IPsec and Authentication Key

Displays the IS-IS logical interface IPsec ID and authentication keys.

About This Task

Use the following procedure to display the IS-IS logical interface IPsec ID and authentication keys.

Procedure

Display the IS-IS logical interface ID and related IPsec authentication key:

```
show isis logical-interface ipsec
```

Example

```
Switch:1>show isis logical-interface ipsec
=====
                        ISIS Logical Interface IPsec
=====
ID   Auth-Method   Auth-Key   Responder-Only   Remote NAT IP   Auth-Key-Len   Status   Compression
-----
1    RSA-SIG       *        False            -                128            Enable   False
-----
1 out of 1 Total Num of Logical ISIS interfaces
-----

                        IPsec Tunnel General Info
=====
IPsec tunnel source-ip-address :

IPsec configuration using EDM

The following section provides procedures to configure Internet Protocol security (IPsec).

Create an IPsec Policy

Use the following procedure to configure an IPsec policy for an IPv4 or an IPv6 interface. An IPsec policy defines the level of security for different types of traffic.

Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

About This Task

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **IPSec**.
- Click the **Policy** tab.
- Click **Insert**.
- In the **Name** field, type a policy name.
- Complete the remaining optional configuration to customize the policy.
- Click **Insert**.

Policy field descriptions

Use the data in the following table to use the **Policy** tab.

| Name | Description |
|-------------------|---|
| Name | Specifies the IPsec policy name. |
| DstAddress | Specifies the remote address. This field accepts IPv4 and IPv6 address, depending on the selected source address type. |
| SrcAddress | Specifies the local address. The local address is optional that you can configure to have multiple local addresses for each remote (destination) address.
This field accepts IPv4 and IPv6 address, depending on the selected source address type. |

| Name | Description |
|-------------------|--|
| SrcPort | Specifies the source port for TCP and UDP. Leave this field empty to configure any port as the source port. The default value is 1. |
| DstPort | Specifies the destination port for TCP and UDP. Leave this field empty to configure any port as the destination port. The default value is 1. |
| AdminFlag | Enables or disables the policy. The default is disabled. |
| L4Protocol | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> • tcp • udp • icmp • icmpv6 • ospfv3 IPv4 interfaces only support TCP, UDP, and ICMP. The default is TCP. |
| Action | Specifies the action the policy takes. The default is to permit the packet. |

Create an IPsec Security Association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Security Association** tab.
4. Click **Insert**.
5. In the **Name** field, type a name to identify the SA.
6. In the **SPI** field, type the security parameters index.

Note

For IPsec to function, each peer must have the same SPI value configured for a particular policy.

7. Complete the remaining optional configuration.
8. Click **Insert**.

Security Association field descriptions

Use the data in the following table to use the **Security Association** tab.

| Name | Description |
|-------------------------|--|
| Name | Specifies the name of the security association. |
| Spi | Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet.
For IPsec to function, each peer must have the same SPI value configured for a particular policy. The default value is 0. |
| HashAlgorithm | Specifies the authorization algorithm, which includes one of the following values: <ul style="list-style-type: none"> • AESXCBC • MD5 • SHA1 • SHA2 The default authentication algorithm name is MD5. |
| EncryptAlgorithm | Specifies the encryption algorithm value as one of the following: <ul style="list-style-type: none"> • DES3CBC • AES128CBC • AESCTR • NULL—Only use the NULL parameter to debug. Do not use this parameter in any other circumstance. The default encryption algorithm is AES128CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. |
| AuthMethod | Specifies the encapsulation protocol: <ul style="list-style-type: none"> • ah—Specifies authentication header. • es—Specifies encapsulation security payload. If you configure the encapsulation protocol as ah, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to es. The default value is es. |

| Name | Description |
|-------------------------|--|
| Mode | Specifies the mode value as one of the following: <ul style="list-style-type: none"> • transport—Transport mode encapsulates the IP payload and provides a secure connection between two end points. This device only supports transport mode. • tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. This device does not support tunnel mode. The default is transport mode. |
| KeyMode | Specifies the key-mode as one of the following: <ul style="list-style-type: none"> • manual • auto The default is manual. |
| EncryptKeyName | Specifies the encryption key. |
| EncryptKeyLength | Specifies the numbers of bits used in the encryption key. The key length values are as follows: <ul style="list-style-type: none"> • DES3CBC is 48 • AES128CBC is 32, 48, 64 • AESCTR is 32 |
| HashKeyName | Specifies the authentication key. |
| HashKeyLength | Specifies the numbers of bits used in the hash key. The key length values are as follows: <ul style="list-style-type: none"> • AESXCBC is 32 • MD5 is 32 • SHA1 is 40 |
| LifetimeSeconds | Specifies the lifetime value in seconds. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in seconds is 28800. |
| LifetimeKbytes | Specifies the lifetime value in kilobytes. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in bytes is 4294967295. |

Link the IPsec Security Association to an IPsec Policy

Use the following procedure to link the security association to an IPsec policy.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy

does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Before You Begin

- The IPsec security association and IPsec policy must exist.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Policy SA Link** tab.
4. Click **Insert**.
5. In the **PolicyName** field, type the IPsec policy name.
6. In the **SAName** field, type the security association name.
7. Click **Insert**.

Policy SA Link field descriptions

Use the data in the following table to use the **Policy SA Link** tab.

| Name | Description |
|-------------------|---|
| PolicyName | Specifies the name of the IPsec policy. |
| SAName | Specifies the name of the security association. |

Enable IPsec on an IPv6 Interface

Use the following procedure to enable IPsec on an IPv6 interface.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IPSec**.
3. Select the **IPv6 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Select **Apply**.

Enable IPsec on an IPv4 Interface

Use the following procedure to enable IPsec on an IPv4 interface.

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **IPSec**.
3. Click the **IPv4 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Click **Apply**.

IPv4 Interfaces tab field descriptions

Use the data in the following table to use the **IPv4 Interfaces** tab.

| Name | Description |
|--------------------|---|
| Interface | Specifies the interface. |
| IpsecEnable | Specifies if IPsec is enabled on that particular interface. |

Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Interface Policy** tab.
4. Click **Insert**.
5. In the **Name** field, type the name of the IPsec policy.
6. In the **IfIndex** field, click either **Port**, **Vlan**, or **Mgmt Port**, and then select an interface.

Note

The Mgmt Port button only appears for hardware with a dedicated, physical management interface. If you click this button, EDM automatically populates the IfIndex value.

7. Click **Okay**.
8. Complete the remaining optional configuration.
9. Click **Insert**.

Interface Policy field descriptions

Use the data in the following table to use the **Interface Policy** tab.

| Name | Description |
|--------------------|--|
| Name | Specifies the IPsec policy name. |
| IfIndex | Links a policy to either a port, VLAN, loopback, or management interface. |
| IfEnabled | Shows if the IPsec is enabled on the interface and if the administrative state of the policy is enabled. |
| IfDirection | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> inbound—Specifies ingress traffic. outbound—Specifies egress traffic. bothDirections—Specifies both ingress and egress traffic. The default is bothDirections. |

Configure IPsec NAT-T

About This Task

By default, both sides of an IPsec connection are Initiator devices. IPsec Network Address Translation Traversal (NAT-T) connections require that one side of the connection is a Responder device and the other side of the connection is an Initiator device.

If the Responder device and the Initiator device are both behind NAT, the IPsec NAT-T Initiator device requires the public IP address of the Responder device.

Procedure

Perform the following steps to configure one side of an IPsec NAT-T connection as a Responder device:

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **IS-IS**.
3. Select **Logical Interfaces**.
4. Select **Insert**.
5. Select **IpsecNatConfigResponderOnly**.

If required, perform the following steps on the IPsec NAT-T Initiator device to configure the public IP address of the Responder device:

6. In the navigation pane, expand **Configuration > IS-IS**.
7. Select **IS-IS**.
8. Select **Logical Interfaces**.
9. Select **Insert**.
10. For **IpsecNatConfigRemoteNatIPAddr**, enter the public IP address of the Responder device.

Logical Interfaces Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

| Name | Description |
|---|--|
| Id | Specifies the index number that uniquely identifies this logical interface.
This field displays on the Insert Logical Interfaces dialog only. |
| IfIndex | Specifies the index number that uniquely identifies this logical interface. This field is read-only.
This field displays on the Logical Interfaces tab only. |
| Name | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters. |
| Type
Note:
Exception: Type Layer 2 is not supported on XA1400 Series. | Specifies the type of logical interface to create: <ul style="list-style-type: none"> Specify layer 2 for a Layer 2 core network that the tunnel will traverse. Specify ip for a Layer 3 core network that the tunnel will traverse. |
| DestIPAddr | Specifies the destination IP address for the IP-type logical interface. |
| DestIfIndex
Note:
Exception: Not supported on XA1400 Series. | Specifies the physical port or MultiLink Trunking (MLT) that the Layer 2 logical interface is connected to. |
| Vids
Note:
Exception: Not supported on XA1400 Series. | Specifies the list of VLANs that are associated with this logical interface. |
| PrimaryVid
Note:
Exception: Not supported on XA1400 Series. | Specifies the primary tunnel VLAN ID associated with this L2 Intermediate-System-to-Intermediate-System (IS-IS) logical interface. |
| CirclIndex
Note:
Exception: Not supported on XA1400 Series. | Identifies the IS-IS circuit created under the logical interface.
This field displays on the Logical Interfaces tab only. |

| Name | Description |
|---|--|
| <p>NextHopVrf</p> <p>Note:
Exception: Not supported on XA1400 Series.</p> | <p>Identifies the next-hop VRF name to reach the logical tunnel destination IP.
This field displays on the Logical Interfaces tab only.</p> |
| <p>IpssecEnable</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies whether the logical interace should use IPsec.</p> |
| <p>AuthenticationKey</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies the authentication key of this logical interface, which can be up to 32 characters.</p> |
| <p>ShapingRate</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies the value, in Mbps, of the Egress Tunnel Shaper applied to the logical interface.</p> |
| <p>Mtu</p> | <p>Specifies the Maximum Transmission Unit (MTU) size for each logical interface. The default MTU value is 1950.</p> |
| <p>EncryptionKeyLength</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies the IPsec encryption key length for FE tunnel, which can be 128 bit or 256 bit.
The default value is len128bit.</p> |
| <p>IpssecTunnelDestAddress</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies the destination IP address for the IPsec tunnel.</p> |
| <p>BfdEnable</p> <p>Note: Exception: Not supported on VSP 8600 Series or VSP 4450 Series.</p> | <p>Enables or disables BFD on an IS-IS Logical Interface.</p> |
| <p>IpssecResponderOnly</p> <p>Note:
Exception: Only supported on XA1400 Series.</p> | <p>Specifies whether the device is a Responder device in an IPsec Network Address Translation Traversal (NAT-T) connection.</p> |

| Name | Description |
|---|---|
| IpssecRemoteNatIPAddr
Note:
Exception: Only supported on XA1400 Series. | Specifies the public IP address of the NAT router connected to the Responder device in an IPsec NAT-T connection. |
| IpssecAuthMethod
Note:
Exception: Only supported on XA1400 Series. | Configures the IPsec authentication method for the tunnel as either a pre-shared key or RSA signature for digital certificates. The default is pre-shared key. |
| IpssecCompression
Note:
Exception: Only supported on XA1400 Series. | Reduces the size of the IP datagram to improve the communication performance between hosts connected behind Backbone Edge Bridges (BEB).

Tip:
As a best practice, use IPsec compression only for Fabric Extend tunnels where latency is greater than 70ms. |

Display IPsec Interface Statistics

Use this procedure to view IPsec statistics and counter values for each IPsec-enabled interface.

About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.

Interface Stats Field Descriptions

Use the data in the following table to use the **Interface Stats** tab.

| Name | Description |
|-----------------------|--|
| IfIndex | Shows the interface index for which the statistic is captured. |
| InSuccesses | Specifies the number of ingress packets IPsec successfully carries. |
| InSPViolations | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation. |

| Name | Description |
|------------------------------|---|
| InNotEnoughMemories | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available. |
| InAHESPReplays | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails. |
| InESPReplays | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails. |
| InAHFailures | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails. |
| InESPFailures | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails. |
| OutSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| OutSPViolations | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs. |
| OutNotEnoughMemories | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| generalError | Specifies a general error. |
| InAhSuccesses | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds. |
| OutAHSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| InESPSuccesses | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds. |
| OutESPSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| OutKBytes | Specifies the total number of kilobytes on egress. |
| OutBytes | Specifies the total number of bytes on egress. |
| InKBytes | Specifies the total number of bytes on ingress. |
| InBytes | Specifies the total number of bytes on ingress. |
| TotalPacketsProcessed | Specifies the total number of packets processed. |
| TotalPacketsByPassed | Specifies the total number of packets bypassed. |
| OutAHFailures | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails. |

| Name | Description |
|----------------------------|---|
| OutESPFailures | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails. |
| InMD5Hmac | Specifies the number of inbound HMAC MD5 occurrences since boot time. |
| InSHA1Hmac | Specifies the number of inbound HMAC SHA1 occurrences since boot time. |
| InAESXCBCs | Specifies the number of inbound AES XCBC MAC occurrences since boot time. |
| InAnyNullAuth | Specifies the number of inbound null authentication occurrences since boot time. |
| In3DESCBCs | Specifies the number of inbound 3DES CBC occurrences since boot time. |
| InAESCBCs | Specifies the number of inbound AES CBC occurrences since boot time. |
| InAESCTRs | Specifies the number of inbound AES CTR occurrences since boot time. |
| InAnyNullEncrypt | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes. |
| OutMD5Hmac | Specifies the number of outbound HMAC MD5 occurrences since boot time. |
| OutSHA1Hmac | Specifies the number of outbound HMAC SHA1 occurrences since boot time. |
| OutAESXCBCs | Specifies the number of outbound AES XCBC MAC occurrences since boot time. |
| OutInAnyNullAuth | Specifies the number of outbound null authentication occurrences since boot time. |
| Out3DESCBCs | Specifies the number of outbound 3DES CBC occurrences since boot time. |
| OutAESCBCs | Specifies the number of outbound AES CBC occurrences since boot time. |
| OutAESCTRs | Specifies the number of outbound AES CTR occurrences since boot time. |
| OutInAnyNullEncrypt | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

Display Switch Level Statistics for IPsec-Enabled Interfaces

Use this procedure to view IPsec statistics and counter values at the switch level for all IPsec-enabled interfaces.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **IPSec**.
3. Click the **Global Stats** tab.

Global Stats Field Descriptions

Use the data in the following table to use the **Global Stats** tab.

| Name | Description |
|-----------------------------|---|
| InSuccesses | Specifies the number of ingress packets IPsec successfully carries. |
| InSPViolations | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation. |
| InNotEnoughMemories | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available. |
| InAHESPReplays | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails. |
| InESPReplays | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails. |
| InAHFailures | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails. |
| InESPFailures | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails. |
| OutSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| OutSPViolations | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs. |
| OutNotEnoughMemories | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| generalError | Specifies a general error. |
| InAHSuccesses | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds. |
| OutAHSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| InESPSuccesses | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds. |
| OutESPSuccesses | Specifies the number of egress packets IPsec successfully carries since boot time. |
| OutKBytes | Specifies the total number of kilobytes on egress. |

| Name | Description |
|------------------------------|---|
| OutBytes | Specifies the total number of bytes on egress. |
| InKBytes | Specifies the total number of bytes on ingress. |
| InBytes | Specifies the total number of bytes on ingress. |
| TotalPacketsProcessed | Specifies the total number of packets processed. |
| TotalPacketsByPassed | Specifies the total number of packets bypassed. |
| OutAHFailures | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails. |
| OutESPFailures | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails. |
| InMD5Hmacs | Specifies the number of inbound HMAC MD5 occurrences since boot time. |
| InSHA1Hmacs | Specifies the number of inbound HMAC SHA1 occurrences since boot time. |
| InAESXCBCs | Specifies the number of inbound AES XCBC MAC occurrences since boot time. |
| InAnyNullAuth | Specifies the number of inbound null authentication occurrences since boot time. |
| In3DESCBCs | Specifies the number of inbound 3DES CBC occurrences since boot time. |
| InAESCBCs | Specifies the number of inbound AES CBC occurrences since boot time. |
| InAESCTRs | Specifies the number of inbound AES CTR occurrences since boot time. |
| InAnyNullEncrypt | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes. |
| OutMD5Hmacs | Specifies the number of outbound HMAC MD5 occurrences since boot time. |
| OutSHA1Hmacs | Specifies the number of outbound HMAC SHA1 occurrences since boot time. |
| OutAESXCBCs | Specifies the number of outbound AES XCBC MAC occurrences since boot time. |
| OutInAnyNullAuth | Specifies the number of outbound null authentication occurrences since boot time. |
| Out3DESCBCs | Specifies the number of outbound 3DES CBC occurrences since boot time. |
| OutAESCBCs | Specifies the number of outbound AES CBC occurrences since boot time. |

| Name | Description |
|----------------------------|---|
| OutAESCTRs | Specifies the number of outbound AES CTR occurrences since boot time. |
| OutInAnyNullEncrypt | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

Configure IPsec for the OSPF Virtual Link

Use the following procedure to configure and enable IPsec for the OSPF virtual link.

IPsec is disabled by default.

About This Task

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You must disable IPsec before you can perform virtual link policy configuration changes.

Before You Begin

- Configure the OSPF virtual link.
- Create the IPsec security association.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Panel**.
2. Click **IPSec**.
3. Click the **OSPF Virtual Link** tab.
4. Click **Insert**.
5. Specify the area ID.
6. Specify the neighbor address.
7. Complete the remaining optional configuration.
8. Click **Insert**.

OSPF Virtual Link field descriptions

Use the data in the following table to use the **OSPF Virtual Link** tab.

| Name | Description |
|--------------------|--|
| Areald | Identifies the OSPF virtual link area. |
| Neighbor | Identifies the OSPF virtual link neighbor. |
| SAName | Links the security association to the OSPF virtual link. |
| AdminStatus | Enables the policy. The default is disabled. |

| Name | Description |
|-------------------|--|
| Action | Configures the action of the IPsec policy under the OSPF virtual tunnel to one of the following: <ul style="list-style-type: none"> • permit—Permits the IP packets. • drop—Drops the IP packets. The default is permit. |
| Direction | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> • inBound—Specifies ingress traffic. • outBound—Specifies egress traffic. • bothDirections—Specifies both ingress and egress traffic. The default is bothDirections. |
| SrcAddress | Shows the address of the source interface to which the policy applies. |
| DstAddress | Shows the address of the destination interface to which the policy applies. |
| LinkID | Shows a unique ID for the OSPF virtual link. The default is 0. |
| IfIndex | Shows the interface index to which OSPF virtual link the policy applies. |
| OperStatus | Shows the operational status of the link, either up or down. The default is down. |

IPsec configuration examples

The following section provides examples to configure Internet Protocol Security (IPsec).

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

IPsec configuration example

Review the following information to understand IPsec configuration.

Use the following steps to configure IPsec.

1. Create and configure an IPsec policy.
2. Enable the policy.
3. Create an IPsec security association to correspond with the IPsec policy.
4. Configure the key mode format.
5. Configure the security association.
6. Link the IPsec security association to the IPsec policy.
7. Enable the IPsec policy on the interface.

8. Link the IPsec policy with the interface.
9. Enable the IPsec on the interface that links to the IPsec policy.

For an example configuration and for more information on IPsec OSPFv3 and OSPFv3 virtual link, see [OSPF](#) on page 2333.

Create a policy named `newpolicy` with a security association named `new_sa` on VLAN 100.

The following displays the IPsec policy configuration:

```
ipsec policy newpolicy raddr 2001:db8:0:0:0:0:0:1
ipsec policy newpolicy laddr 2001:db8:0:0:0:0:0:15
ipsec policy newpolicy protocol tcp sport 4 dport 5
ipsec policy newpolicy action permit
```

The following example displays the IPsec security association:

```
ipsec security-association new_sa
ipsec security-association new_sa key-mode manual
ipsec security-association new_sa mode transport
ipsec security-association new_sa encap-proto ESP
ipsec security-association new_sa Encrpt-algo 3DES-CBC encrypt-key
11111111111111111111111111111111 KeyLength 24
ipsec security-association new_sa auth-algo SHA1 auth-key 11111111111111111111111111111111 KeyLength
20
ipsec security-association new_sa spi 1
ipsec security-association new_sa lifetime seconds 1000
```

IPsec with ICMPv6 configuration example

The following displays configuration of IPsec with ICMPv6.

Figure 155: IPsec configuration with ICMPv6

Switch 10 security association configuration

The following example displays the configuration of the security association on Switch 10.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
1234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
```

```

12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1

```

Switch 10 policy configuration

The following example displays the configuration of the security policy on Switch 10.

```

ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable

ipsec policy ICMP_Policy laddr 2001::1
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy security-association icmp

```

Switch 10 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```

interface gigabitEthernet 1/10
no shut
interface vlan 3
interface address 2000::1
interface enable
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable

```

Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3 with IPsec.

```

interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
interface enable
interface address 2000::1
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable

```

Switch 30 security association configuration

The following example displays the configuration of the security association on Switch 30.

```

ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key

12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1

```

Switch 30 policy configuration

The following example displays the configuration of the security policy on Switch 30.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::1
ipsec policy ICMP_Policy laddr 2001::2
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy security-association icmp
```

Switch 30 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface enable
ipv6 interface vlan 3
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

Switch 30 VLAN configuration

The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/20
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

OSPFv3 IPsec configuration example

The following example displays a network using IPsec used with OSPFv3.

The following example displays the configuration of IPsec with OSPFv3. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2333.

Switch 10 security associations

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```

```

Switch 10 policy configuration

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as outbound.

```

ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 protocol ospfv3
ipsec policy ospf1 action permit

```

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as inbound.

For a policy direction of inbound, laddr and raddr are reversed before storing to the stack. Because of this, even though the policy requires you to configure the laddr as the remote link local address, you need to configure laddr as the link local address in the configuration.

```

ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit

```

Laddr is configured to the link local and raddr is configured to ff02::05 with the direction configured as outbound.

```

ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit

```

Laddr is configured to the remote link local and raddr is configured to ff02::05 with the direction configured as inbound.

```

ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit

```

Laddr is configured to the link local and raddr is configured to ff02::06 with the direction as outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::06 with the direction configured as inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

Switch 10 link table configuration

The following example displays the linking of the policy with the security association on Switch 10.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf3
ipsec policy ospf4 security-association ospf4
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

Switch 10 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
```

Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out

Switch 30 policy configuration

In the example, the local address is fe80:0:0:0:b2ad:aaff:fe43:4d00, and the remote address is fe80:0:0:0:b2ad:aaff:fe43:100. The policy has the laddr configured to the link local address and the raddr is configured to the remote link local address with the direction configured to outbound.

```

ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 protocol ospv3
ipsec policy ospf1 action permit

```

Laddr is configured to the remote link local address and raddr is configured to the local link local address with the direction configured to inbound.

```

ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit

```

Laddr is configured to the link local address and raddr is configured to ff02::05 with the direction configured to outbound.

```

ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit

```

Laddr is configured to the remote link local address and the raddr is configured to ff02::05 with the direction configured to inbound.

```

ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:100

```

```
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::06 with the direction configured to outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local address and raddr is configured to ff02::06 with the direction configured to inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

Switch 30 link table configuration

The following example displays the linking of the policy with the security association on Switch 30.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf4
ipsec policy ospf4 security-association ospf3
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

Switch 30 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 30.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

Switch 30 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1

```

Switch 30 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
minvlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

OSPFv3 virtual link IPsec configuration example

The following example displays a network using IPsec with OSPFv3 virtual link.

Figure 156: OSPFv3 virtual link with IPsec configuration

The following example displays the configuration of IPsec with OSPFv3 virtual link. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2333.

Switch 10 security association configuration

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

Switch 10 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
ipv6 as-boundary-router
ipv6 area 0.0.0.0
```

Switch 10 virtual link and policy configuration

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 3.3.3.3
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec action permit
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec direction both
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec enable
```

Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 port-member
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 20 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 20.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

Switch 20 interface configuration

The following example displays the interface configuration on slot/port 1/10 and 1/20.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 20 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3 and VLAN 4.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20 portmember
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 40 security association configuration

The following example displays the configuration of security associations for OSPFv3 for Switch 40.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32

Switch 40 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 40.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 3.3.3.3
ipv6 area 0.0.0.1
ipv6 area 0.0.0.2
ipv6 as-boundary-router
```

Switch 40 OSPFv3 virtual link and policy configuration

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 1.1.1.1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec action permit
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec direction both
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec enable
```

Switch 40 interface configuration

The following example displays the interface configuration on slot/port 1/20.

```
interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 40 VLAN interface configuration

The following example displays the creation of VLAN 4 and the configuration of IPsec on VLAN 4.

```
interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

IPsec configuration of TCP

The following example displays the configuration of IPsec for TCP.

Switch 10 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012

ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

Switch 10 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::2
ipsec policy tcp1 raddr 2000::2 laddr 2000::1
ipsec policy tcp1 raddr 2000::2 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::2 action permit
```

Switch 10 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

Switch 10 interface configuration

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 30 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012

ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

Switch 30 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::1
ipsec policy tcp1 raddr 2000::1 laddr 2000::2
ipsec policy tcp1 raddr 2000::1 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::1 action permit
```

Switch 30 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

Switch 30 interface configuration

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 30 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

IPv4 Routing Basics

[IP routing operations fundamentals](#) on page 1742

[IP routing configuration using the CLI](#) on page 1753

[IP routing configuration using Enterprise Device Manager](#) on page 1780

This section provides conceptual information and procedures to configure IP Routing using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

IP routing operations fundamentals

Use the information in this section to understand IP routing.

For more information about Border Gateway Protocol (BGP), see [BGP](#) on page 390.

For more information about Open Shortest Path First (OSPF), see [OSPF](#) on page 2333. For more information about Routing Information Protocol (RIP), see [RIP](#) on page 2656.

IP addressing

An IP version 4 address consists of 32 bits expressed in dotted-decimal format (x.x.x.x). The IP version 4 address space is divided into classes, with classes A, B, and C reserved for unicast addresses and accounting for 87.5 percent of the 32-bit IP address space. Class D is reserved for multicast addressing. The following table lists the breakdown of IP address space by address range and mask.

| Class | Address range | Mask | Number of addresses |
|-------|------------------------|---------------|---------------------|
| A | 1.0.0.0 to 126.0.0.0 | 255.0.0.0 | 126 |
| B | 128.0.0.0 to 191.0.0.0 | 255.255.0.0 | 127 * 255 |
| C | 192.0.0.0 to 223.0.0.0 | 255.255.255.0 | 31 * 255 * 255 |
| D | 224.0.0.0 to 239.0.0.0 | — | — |

To express an IP address in dotted-decimal notation, you convert each octet of the IP address to a decimal number and separate the numbers by decimal points. For example, you specify the 32-bit IP address 10000000 00100000 00001010 10100111 in dotted-decimal notation as 128.32.10.167.

Each IP address class, when expressed in binary, has a different boundary point between the network and host portions of the address as illustrated in the following figure. The network portion is a network number field from 8 through 24 bits. The remaining 8 through 24 bits identify a specific host on the network.

Figure 157: Network and host boundaries in IP address classes

Subnet Addressing

Subnetworks (or subnets) extend the IP addressing scheme an organization uses to one with an IP address range for multiple networks. Subnets are two or more physical networks that share a common network-identification field (the network portion of the 32-bit IP address).

You create a subnet address by increasing the network portion to include a subnet address, thus decreasing the host portion of the IP address. For example, in the address 128.32.10.0, the network portion is 128.32, while the subnet is found in the first octet of the host portion (10). A subnet mask is applied to the IP address and identifies the network and host portions of the address.

The following table illustrates how subnet masks used with class B and class C addresses can create differing numbers of subnets and hosts. This example includes the zero subnet, which is permitted on the switch.

Table 202: Subnet masks for class B and class C IP addresses

| Number of bits | Subnet mask | Number of subnets | Number of hosts for each subnet |
|----------------|---------------|-------------------|---------------------------------|
| Class B | | | |
| 2 | 255.255.192.0 | 2 | 16 382 |
| 3 | 255.255.224.0 | 6 | 8 190 |
| 4 | 255.255.240.0 | 14 | 4 094 |
| 5 | 255.255.248.0 | 30 | 2 046 |
| 6 | 255.255.252.0 | 62 | 1 022 |
| 7 | 255.255.254.0 | 126 | 510 |
| 8 | 255.255.255.0 | 254 | 254 |

Table 202: Subnet masks for class B and class C IP addresses (continued)

| Number of bits | Subnet mask | Number of subnets | Number of hosts for each subnet |
|----------------|-----------------|-------------------|---------------------------------|
| 9 | 255.255.255.128 | 510 | 126 |
| 10 | 255.255.255.192 | 1 022 | 62 |
| 11 | 255.255.255.224 | 2 046 | 30 |
| 12 | 255.255.255.240 | 4 094 | 14 |
| 13 | 255.255.255.248 | 8 190 | 6 |
| 14 | 255.255.255.252 | 16 382 | 2 |
| Class C | | | |
| 1 | 255.255.255.128 | 0 | 126 |
| 2 | 255.255.255.192 | 2 | 62 |
| 3 | 255.255.255.224 | 6 | 30 |
| 4 | 255.255.255.240 | 14 | 14 |
| 5 | 255.255.255.248 | 30 | 6 |
| 6 | 255.255.255.252 | 62 | 2 |

You use variable-length subnet masking (VLSM) to divide your intranet into pieces that match your requirements. Routing is based on the longest subnet mask or network that matches. Routing Information Protocol version 2 and Open Shortest Path First are routing protocols that support VLSM.

Supernet Addressing and CIDR

A supernet, or classless interdomain routing (CIDR) address, is a group of networks identified by contiguous network addresses. IP service providers can assign customers blocks of contiguous addresses to define supernets as needed. You can use supernetting to address an entire block of class C addresses and avoid using large routing tables to track the addresses.

Each supernet has a unique supernet address that consists of the upper bits shared by all of the addresses in the contiguous block. For example, consider the class C addresses shown in the following figure. By adding the mask 255.255.128.0 to IP address 192.32.128.0, you aggregate the addresses 192.32.128.0 through 192.32.255.255 and 128 class C addresses use a single routing advertisement. In the bottom half of the following figure, you use 192.32.0.0/17 to aggregate the 128 addresses (192.32.0.0/24 to 192.32.127.0/24).

9577EA

Figure 158: Class C address supernet

Another example is the block of addresses 192.32.0.0 to 192.32.7.0. The supernet address for this block is 11000000 00100000 000000, with the 21 upper bits shared by the 32-bit addresses.

A complete supernet address consists of an address and mask pair:

- The address is the first 32-bit IP address in the contiguous block. In this example, the address is 11000000 00100000 00000000 00000000 (192.32.0.0 in dotted-decimal notation).
- The mask is a 32-bit string containing a set bit for each bit position in the supernet part of the address. The mask for the supernet address in this example is 11111111 11111111 11111000 00000000 (255.255.248.0 in dotted-decimal notation).

The complete supernet address in this example is 192.32.0.0/21.

Although classes prohibit using an address mask with the IP address, you can use CIDR to create networks of various sizes using the address mask. With CIDR, the routers outside the network use the addresses.

Loopback

Circuitless IP (CLIP) is a virtual (or loopback) interface that is not associated with a physical port. You can use the CLIP interface to provide uninterrupted connectivity to your device as long as a path exists to reach the device.

For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Use an interior Border Gateway

Protocol (iBGP) session between two additional addresses, 195.39.128.1/30 (CLIP 1) and 195.39.281.2/30 (CLIP 2).

CLIP 1 and CLIP 2 represent the virtual CLIP addresses that you configure between R1 and R2. These virtual interfaces are not associated with the physical link or hardware interface, which permits the BGP session to continue as long as a path exists between R1 and R2. An IGP (such as OSPF) routes addresses that correspond to the CLIP addresses. After the routers learn all the CLIP addresses in the AS, the system establishes iBGP and exchanges routes.

The system advertises loopback routes to other routers in the domain either as external routes using the route-redistribution process, or after you enable OSPF in passive mode to advertise an OSPF internal route.

You can also use CLIP for PIM-SM, typically, as a Rendezvous Point (RP), or as a source IP address for sending SNMP traps and Syslog messages.

Figure 159: Routers with iBGP connections

The system treats the CLIP interface as an IP interface. The network associated with the CLIP is treated as a local network attached to the device. This route always exists and the circuit is always up because there is no physical attachment.

Static routes

Table 203: Static routing product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Static routing | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VSP 4000 4.0 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 4.2.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VSP 8200 4.0 |
| | VSP 8400 Series | VOSS 4.2 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | VOSS 8.0.50 |

Note

VSP 8600 Series uses the Layer 3 configuration for management static routes as well as for packet forwarding. For all other platforms, management static routes must use [Segmented Management](#) on page 49.

A static route is a route to a destination IP address that you manually create.

Create static routes to enhance network stability. Use the local next hop option to configure a static route with or without local next hop.

You can configure static routes with a next hop that is not directly connected, but that hop must be reachable. Otherwise, the static route is not enabled.

Layer 3 redundancy supports only address resolution protocol (ARP) and static route. Static ARP must configure the nonlocal next-hop of static routes. No other dynamic routing protocols provide nonlocal next-hop.

Note

Static ARP entries are not supported for NLB Unicast or NLB Multicast operations.

You can use a default static route to specify a route to all networks for which no explicit routes exist in the forwarding information base or the routing table. This route has a prefix length of zero (RFC1812). You can configure the switch with a route through the IP static routing table.

To create a default static route, you must configure the destination address and subnet mask to 0.0.0.0.

Note

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

Static Route Tables

A router uses the system routing table to make forwarding decisions. In the static route table, you can change static routes directly. Although the two tables are separate, the static route table manager entries are automatically reflected in the system routing table if the next-hop address in the static route is reachable, and if the static route is enabled.

The system routing table displays only active static routes with a best preference. A static route is active only if the route is enabled and the next-hop address is reachable (for example, if a valid ARP entry exists for the next hop).

You can enter multiple routes (for example, multiple default routes) that have different costs, and the routing table uses the lowest cost route that is available. However, if you enter multiple next hops for the same route with the same cost, the software does not replace the existing route. If you enter the same route with the same cost and a different next-hop, the first route is used. If the first route becomes unreachable, the second route (with a different next-hop) is activated with no connectivity loss.

Routing Protocols

Routers and routing switches use routing protocols to exchange reachability information. Routers use a routing protocol to advertise available paths on which the router can forward data. The routers use the protocol to determine the most efficient path to use. Routers use dynamic routing protocols to avoid sending data to inoperable links, and to send data to links that generally result in the fastest transmission times.

The switch routes frames using one of the following dynamic unicast IP routing protocols for path selection:

- Routing Information Protocol version 1 (RIPv1) (RFC 1058)
- RIPv2 (RFC 2453)
- Open Shortest Path First version 2 (OSPFv2) (RFC 2328)
- OSPFv3 (RFC 2740)
- Border Gateway Protocol version 4 (BGPv4) (RFC 1771)

Unlike static IP routing, where you must create a manual entry in the routing table to specify a routing path, dynamic IP routing uses a learning approach to determine the paths and routes to other routers. Dynamic routing uses two basic types of routing: distance vector and link-state. Routing Information Protocol (RIP) is a distance vector protocol and Open Shortest Path First (OSPF) is a link-state protocol.

The switch uses routing protocols like OSPF and RIP to populate routing tables. Routers use a routing protocol to exchange network topology information. A router uses the IP address of an incoming data packet to send the packet according to the routing tables.

The most commonly used unicast routing protocols include OSPF, RIP, and BGP. For more information about BGP, see [BGP](#) on page 390. For information about multicast routing protocols, see [IP Multicast](#) on page 1319. For information about OSPFv3 routing protocols, see [OSPF](#) on page 2333.

Black hole static routes

A black hole static route is a route with an invalid next hop, and the device drops data packets destined for this network.

While the router aggregates or injects routes to other routers, the router does not have a path to the aggregated destination. In such cases, the result is a black hole and a routing loop. To avoid routing loops, configure a black hole static route to the destination the router is advertising.

You can configure a preference value for a black hole route. However, you must configure that preference value appropriately so that when you want to use the black hole route, it is elected as the best route.

Before you add a black hole static route, perform a check to ensure that no other static route to that identical destination is enabled. If such a route exists, you cannot add the black hole route and an error message appears.

If you enable a black hole route, you cannot add another static route to that destination. You must first delete or disable the black hole route before you add a regular static route to that destination.

VLANs and routing

When traffic is routed on a virtual local area network (VLAN), an IP address is assigned to the VLAN and is not associated with a particular physical port. Brouter ports are VLANs that route IP packets and bridge nonroutable traffic in a single-port VLAN.

Virtual Routing Between VLANs

The switch supports wire-speed IP routing between VLANs. As shown in the following figure, VLAN 1 and VLAN 2 are on the same device, yet for traffic to flow from VLAN 1 to VLAN 2, the traffic must be routed.

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN (a virtual router interface is not associated with a particular port). You can reach the VLAN IP address through the VLAN ports, and frames are routed from the VLAN through the gateway IP address. Routed traffic is forwarded to another VLAN within the device.

Figure 160: IP routing between VLANs

When Spanning Tree Protocol is enabled in a VLAN, the spanning tree convergence must be stable before the routing protocol begins. This requirement can lead to an additional delay in the IP traffic forwarding.

Because a port can belong to multiple VLANs (some of which are configured for routing on the device and some of which are not), a one-to-one correspondence no longer exists between the physical port and the router interface.

As with an IP address, virtual router interface addresses using Virtual Router Redundancy Protocol (VRRP) are also used for device management. For Simple Network Management Protocol (SNMP) or Telnet management, you can use virtual router interface address to access the device as long as routing is enabled on the VLAN.

Brouter Ports

The switch also supports brouter ports. A brouter port is a single-port VLAN that routes IP packets and bridges all nonroutable traffic. The difference between a brouter port and a standard IP protocol-based VLAN configured to route traffic is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

Because a brouter port is a single-port VLAN, each brouter port decreases the number of available VLANs by one and uses one VLAN ID.

The switch allows IP routing to be enabled on VLANs and brouter ports. For the maximum number of interfaces, see the Software scaling capabilities section of the [Release Notes for VOSS](#).

Equal Cost Multipath

Table 204: Equal Cost Multiple Path for IPv4 product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Equal Cost Multiple Path (ECMP) for IPv4 | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VSP 4000 4.0 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 4.2.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VSP 8200 4.0 |
| | VSP 8400 Series | VOSS 4.2 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | VOSS 8.0.50 |

With Equal Cost Multipath (ECMP), the switch can determine up to eight equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of traffic. These multiple paths provide faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use links between routers more efficiently when sending IP traffic. Equal Cost Multipath is formed using routes from the same source or protocol.

All IP ECMP routes that share the same combination of ECMP next hops consume the same ECMP group resource. The following list illustrates how shared next hops affect resource consumption:

- Prefix 3.1.1.0/16 is learned as an ECMP route with next hops A and B, and consumes one entry in the ECMP GROUP table.
- Prefix 4.1.1.0/16 is learned as an ECMP route with the same next hops, A and B. No additional resource is taken in the ECMP GROUP table.
- Prefix 5.1.1.0/16 is learned as an ECMP route with next hops B and C, and consumes one additional entry in the ECMP GROUP table.

ECMP is supported on both the Global Routing Table (GRT) and Virtual Routing and Forwarding (VRF).

The ECMP feature supports and complements the following protocols and route types:

- Border Gateway Protocol (BGP)
- Default route
- Intermediate System-to-Intermediate System (IS-IS)
- Open Shortest Path First (OSPF)
- Routing Information Protocol (RIP)
- Static route
- VRF

ECMP Pathlist

Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

Note

Product Notice: Not all products support Equal Cost Multipath Pathlist with Fabric Connect. For more information, see [VOSS Feature Support Matrix](#).

IP Source Routing

Table 205: IP Source Routing product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| IP Source Routing enable or disable | 5520 Series | VOSS 8.2.5 |
| | VSP 4450 Series | VOSS 5.1 |
| | VSP 4900 Series | VOSS 8.1 |
| | VSP 7200 Series | VOSS 5.1 |
| | VSP 7400 Series | VOSS 8.0 |
| | VSP 8200 Series | VOSS 5.1 |
| | VSP 8400 Series | VOSS 5.1 |
| | VSP 8600 Series | VSP 8600 4.5 |
| | XA1400 Series | Not Supported |

IP Source Routing allows the sender of a packet to specify the route that the packet must travel through the network. When the Source Route option is not enabled, the router chooses the primary routing path to send the packets. If IP Source Routing flag is on, the source host dictates the datapath for the packet to reach the destination using the information contained in the IP header.

The routing behavior in VSP 8600 Series is controlled by the datapath specified, and not by status of the IP Source Route. VSP 8600 Series inspects the packets only if the router itself is specified in the Source Routing. Otherwise, the switch forwards the packets to another router in the network using IP

Routing, whether or not IP Source Route is enabled. You can use an ACL filter to block the datapath from forwarding any IP Source Routing packets.

IP Source Routing is considered as a security risk because it allows the users to specify their own path through the network outside of the primary forwarding path. This can cause packets to bypass the security devices. Therefore, the Source Routing is disabled by default.

Multihoming

The switch uses the multihoming feature to support clients or servers that have multiple IP addresses associated with a single MAC address. Multihomed hosts can be connected to port-based and policy-based VLANs.

The IP addresses associated with a single MAC address on a host must be in the same IP subnet.

Enabling or Disabling IPv4 ICMP Broadcast

Table 206: Internet Control Message Protocol product support

| Feature | Product | Release introduced |
|--|-----------------|--------------------|
| For configuration details, see VOSS User Guide . | | |
| Internet Control Message Protocol (ICMP) | 5520 Series | VOSS 8.2.5 |

On IPv4 networks, a packet can be directed to an individual machine or broadcast to an entire network. When a packet is sent to an IP broadcast address from a machine on the local network, that packet is delivered to all machines on that network.

If a packet that is broadcast is an ICMP echo request packet, the machines on the network receive this ICMP echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMP echo request, the result can be severe network congestion or outages.

The switch always responds to IPv4 ICMP packets sent to a broadcast address. You can disable the processing of these IPv4 ICMP packets sent to the broadcast address. On disabling the ICMP broadcast processing, all the packets containing ICMP sent to the broadcast addresses will be dropped when the packets reach the control plane.

You can disable or enable the IPv4 ICMP broadcast processing at the VRF level.

IP routing configuration using the CLI

Configure the IP router interface so that you can configure and use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

Enabling routing globally or on a VRF instance

Use IP forwarding (routing) on a global level so that the device supports routing. You can use the IP address of an interface for IP-based network management.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Activate IP forwarding:

```
ip routing
```
3. View the forwarding configuration:

```
show ip routing [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

Activate IP forwarding and view the forwarding configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#ip routing
Switch:1(router-vrf)#show ip routing
```

```
=====
                        IP - GlobalRouter
=====
```

```

IP Forwarding is enabled
IP ECMP feature is disabled
Maximum ECMP paths number is 1
ECMP 1 pathlist :
ECMP 2 pathlist :
ECMP 3 pathlist :
ECMP 4 pathlist :
ECMP 5 pathlist :
ECMP 6 pathlist :
ECMP 7 pathlist :
ECMP 8 pathlist :
Gratuitous-Arp : enable
IP Alternative Route feature is enabled
IP More Specific Non Local Route feature is disabled
IP ICMP Unreachable Message is disabled
IP Supernetting is disabled
IP Icmp-echo-broadcast-request is enabled

IP Default TTL is 255 seconds
IP ARP life time is 360 minutes
IP Source Route Option is disabled

```

Variable definitions

Use the data in the following table to use the `show ip routing` command.

Table 207: Variable definitions

| Variable | Value |
|---------------------------------------|---|
| <code>vrf WORD<0-16></code> | Specifies a VRF instance by VRF name. |
| <code>vrfids WORD<0-512></code> | Specifies a VRF instance by VRF number. |

Enabling routing on an IP interface

About This Task

You can enable or disable routing capabilities on a VLAN or brouter port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Enable routing:

```
routing enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#routing enable
```

Deleting a dynamically learned route**About This Task**

Delete a dynamically learned route from the routing table if you do not want the switch to use the route. Exercise caution when you delete entries from the routing table.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. View IP route information:

```
show ip route [<A.B.C.D>] [-s default|-s <A.B.C.D/X>] [alternative]
[count-summary] [spbm-nh-as-mac][preference] [vrf WORD<0-16>] [vrfids
WORD<0-512>] [static]
```
3. Delete the dynamically learned route:

```
no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> dynamic
```

Example

Delete a dynamically learned route:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip route 192.0.2.32 255.255.255.0 198.51.100.31 dynamic
```

Variable definitions

Use the data in the following table to use the `show ip route` commands.

Table 208: Variable definitions

| Variable | Value |
|-----------------------------------|---|
| <code><A.B.C.D></code> | Specifies the IP address of the route to the network. |
| <code>alternative</code> | Displays the alternative routes. |
| <code>count-summary</code> | Displays a summary of the number of routes learned from each routing protocol for each VRF. |
| <code>preference</code> | Displays the route preference. |
| <code>-s <A.B.C.D/X></code> | Indicates the IP address and subnet mask for which to display routes. |
| <code>-s default</code> | Indicates the default subnet. |
| <code>static</code> | Displays the static route information. |

Table 208: Variable definitions (continued)

| Variable | Value |
|---------------------------------------|---|
| <code>vrf WORD<0-16></code> | Displays the route for a particular VRF. |
| <code>vrfids WORD<0-512></code> | Displays the route for a particular VRF number. |
| <code>spbm-nh-as-mac</code> | Displays the spbm route next hop as mac. |

Use the data in the following table to use the `no ip route` command.

Table 209: Variable definitions

| Variable | Value |
|--|---|
| <code><A.B.C.D> <A.B.C.D>
<A.B.C.D></code> | Specifies the IP address, the subnet mask, and the next-hop IP address, respectively. |
| <code>dynamic</code> | Specifies that a dynamic route is to be deleted. |
| <code>enable</code> | Disables the route. |
| <code>local-next-hop enable</code> | Disables the local-next-hop option. |
| <code>preference</code> | Deletes the value of the route preference. |
| <code>next-hop-vrf WORD<0-16></code> | Specifies the name of the next-hop VRF router. |

Configuring IP route preferences

Before You Begin

- Disable ECMP before you configure route preferences

Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. You must therefore change a prefix list or a routing protocol before you activate the protocols.

About This Task

Configure IP route preferences to give preference to routes learned for a specific protocol. You must disable ECMP before you configure route preferences.

To configure route preferences for a VRF, access VRF Router Configuration mode, rather than Global Configuration mode.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```

- Configure the route preference:

```
ip route preference protocol <static|ospf-intra|ospf-inter|ebgp|ibgp|
rip|ospf-extern1|ospf-extern2|spbm-level1> <0-255>
```

- Confirm that the configuration is correct:

```
show ip route preference [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

Configure the route preference to SPBM Level 1 and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route preference protocol spbm-level1 7
Switch:1(config)#show ip route preference
=====
                        IP Route Preference - GlobalRouter
=====
PROTOCOL      DEFAULT    CONFIG
-----
LOCAL         0          0
STATIC        5          5
SPBM_L1       7          7
OSPF_INTRA    20         20
OSPF_INTER    25         25
EBGP          45         45
RIP           100        100
OSPF_E1       120        120
OSPF_E2       125        125
IBGP          175        175
```

View the route preference configuration for a specific VRF, for example 444.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf test
Switch:1(router-vrf)#show ip route preference vrf 444
=====
                        IP Route Preference - VRF 444
=====
PROTOCOL      DEFAULT    CONFIG
-----
LOCAL         0          0
STATIC        5          5
SPBM_L1       7          7
OSPF_INTRA    20         20
OSPF_INTER    25         25
EBGP          45         45
RIP           100        100
OSPF_E1       120        120
OSPF_E2       125        125
IBGP          175        175
```

Variable definitions

Use the data in the following table to use the **ip route preference protocol** command.

| Variable | Value |
|---------------------|----------------------------|
| <i>ebgp</i> | Protocol type eBGP |
| <i>ibgp</i> | Protocol type iBGP |
| <i>ospf-extern1</i> | Protocol type ospf-extern1 |
| <i>ospf-extern2</i> | Protocol type ospf-extern2 |
| <i>ospf-intra</i> | Protocol type ospf-intra |
| <i>ospf-inter</i> | Protocol type ospf-inter |
| <i>rip</i> | Protocol type rip |
| <i>spbm-level1</i> | Protocol type spbm-level1 |
| <i>static</i> | Protocol type static |

Flushing routing tables by VLAN or port

About This Task

For administrative and troubleshooting purposes, flush the routing tables.

To flush tables on a VRF instance for a port or VLAN, ensure that the VRF is associated with the port or VLAN.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush the routing tables:

```
action flushIp
```

Example

Flush the routing tables:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#action flushIp
```

Assigning an IP address to a port

Assign an IP address to a port so that it supports routing operations.

About This Task

Use a brouter port to route IP packets and to bridge all nonroutable traffic. The routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Use the `vrf` parameter to associate the port or VLAN with a VRF instance.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IP address to the port:

```
brouter port {slot/port [-slot/port] [,...]} vlan <2-4059> subnet  
<A.B.C.D/X> [mac-offset <MAC-offset> | [name WORD <0-64>]
```

3. If required, associate the port with a VRF:

```
vrf WORD<1-16>
```

4. Confirm that the configuration is correct:

```
show brouter [<1-4084>]
```

Example

Assign an IP address to a port:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitethernet 1/11  
Switch:1(config-if)#brouter port 1/11 vlan 2202 subnet 47.17.10.31/255.255.255.0
```

Variable Definitions

Use the data in the following table to use the **brouter port** command.

| Variable | Value |
|---------------------------------|--|
| <i>mac-offset</i> <MAC-offset> | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help. |
| <i>name</i> WORD <0-64> | Specifies the IP address name in the range of 0 to 64 characters. |
| { <i>slot/port</i> [/sub-port]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>subnet</i> <A.B.C.D/X> | Specifies the IP address and subnet mask (0-32). |
| <2-4059> | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged. |

Use the data in the following table to use the **show brouter** command.

| Variable | Value |
|----------|---|
| <1-4084> | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged. |

Configure an IP Address for the Management Port

Note

This procedure only applies to VSP 8600 Series. For information about how to configure an IP address for a Segmented Management Instance, see [Configure an IP Address for a Segmented Management Instance](#) on page 66.

About This Task

Configure the IP address for the management port so that you can remotely access the device using the management port. The management port runs on a dedicated VRF. As a best practice, redirect all commands that are run on the management port to its VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band or out-of-band ports.

Procedure

1. Enter mgmtEthernet Interface Configuration mode:

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the IP address and mask for the management port:

```
ip address <A.B.C.D> <A.B.C.D>
```
3. Show the complete network management information:

```
show interface mgmtEthernet
```
4. Show the management IP interface information:

```
show ip interface vrf mgmtrouter
```

Example

Configure the IP address for the management port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtethernet mgmt
Switch:1(config-if)#ip address 192.0.2.31 255.255.255.0
Switch:1(config-if)#show interface mgmtethernet

=====
                        Port Interface
=====
PORT          LINK  PORT          PHYSICAL  STATUS
NUM  INDEX DESCRIPTION TRAP  LOCK  MTU  ADDRESS  ADMIN  OP
ERATE
-----
mgmt    64    mgmtEthernet true  false 1522 192.0.2.31 up    up
```

Variable definitions

Use the data in the following table to use the **ip address** command.

Table 210: Variable definitions

| Variable | Value |
|---------------------|---|
| <A.B.C.D> <A.B.C.D> | Specifies the IP address followed by the subnet mask. |

Viewing IP addresses for all router interfaces

About This Task

Perform the following procedure to display information about all IP interfaces configured on the device.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Show the IP interfaces and addresses on the device:
`show ip interface`

Example

Show the IP interfaces and addresses on the device:

```
Switch:1>enable
Switch:1#show ip interface
```

```
=====
                        IP Interface - GlobalRouter
=====
```

| INTERFACE | IP ADDRESS | NET MASK | BCASTADDR FORMAT | REASM MAXSIZE | VLAN ID | BROUTER PORT |
|-----------|---------------|---------------|------------------|---------------|---------|--------------|
| Port1/6 | 192.0.2.6 | 255.255.255.0 | ones | 1500 | 200 | true |
| Vlan100 | 192.0.2.5 | 255.255.255.0 | ones | 1500 | 100 | false |
| Vlan4000 | 198.51.100.21 | 255.255.255.0 | ones | 1500 | 4000 | false |

Variable definitions

Use the data in the following table to show `ip interface` command.

Table 211: Variable definitions

| Variable | Value |
|------------------------------|---|
| <code>gigabitethernet</code> | Displays IP interface information for Gigabit Ethernet ports. |
| <code>vrf</code> | Displays interface information for a particular VRF. |
| <code>vrfids</code> | Displays interface information for particular VRF IDs. |

Configure IP Routing Globally or for a VRF

Configure the IP routing protocol stack to specify which routing features the device can use. You can configure global parameters before or after you configure the routing protocols.

About This Task

To configure IP routing globally for a VRF instance, use VRF Router Configuration mode rather than Global Configuration mode.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the default TTL for all routing protocols to use:

```
ip ttl <1-255>
```

This value is placed into routed packets that have no TTL specified.

3. Activate the alternative route feature globally:

```
ip alternative-route
```

4. Configure the remaining global parameters as required.

Variable Definitions

The following table defines parameters for the **ip** command.

| Variable | Value |
|--------------------------------------|---|
| <i>alternative-route</i> | Enables or disables the alternative route feature. The default value is enabled.
If the alternative-route parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readded.
The default form of this command is <code>default ip alternative-route</code> . The no form of this command is <code>no ip alternative-route</code> . |
| <i>max-routes-trap enable</i> | Enables the device to send a trap after the maximum number of routes is exceeded.
The no form of this command is <code>no max-routes-trap enable</code> . The default form of this command is <code>default max-routes-trap enable</code> . |
| <i>more-specific-non-local-route</i> | Enables the more-specific-non-local-route feature. If enabled, the device can enter a more-specific nonlocal route into the routing table. The default is disabled.
The default form of this command is <code>default ip more-specific-non-local-route</code> . The no form of this command is <code>no ip more-specific-non-local-route</code> . |
| <i>routing</i> | Enables routing.
The no form of this command is <code>no ip routing</code> . |

| Variable | Value |
|--------------------------------|--|
| <code>supernet</code> | Enables or disables supernetting.
If you globally enable supernetting, the device can learn routes with a route mask of less than eight bits. Routes with a mask length less than eight bits cannot have ECMP paths, even if the ECMP feature is globally enabled. The default is disabled.
The default form of this command is <code>default ip supernet</code> .
The no form of this command is <code>no ip supernet</code> . |
| <code>ttl <1-255></code> | Configures the default time-to-live (TTL) value for a routed packet. The TTL is the maximum number of seconds before a packet is discarded. The default value of 255 is used whenever a time is not supplied in the datagram header.
The default form of this command is <code>default ip ttl</code> . |

The following table defines parameters for the `ip icmp` commands.

| Variable | Value |
|--------------------------|---|
| <code>unreachable</code> | Enables the device to send ICMP unreachable messages. When enabled, this variable generates Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this router. These messages help determine if the device is reachable over the network. The default is disabled.
The default form of this command is <code>default ip icmp unreachable</code> . |

Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which provides fast convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

About This Task

To configure ECMP for a VRF instance, after you enable ECMP globally, use VRF Router Configuration mode rather than Global Configuration mode.

Different hardware platforms can support a different number of ECMP paths. For more information, see [Release Notes for VOSS](#).

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable ECMP globally:

```
ip ecmp
```
3. (Optional) Configure the maximum number of ECMP paths:

```
ip ecmp max-path <ECMP-Paths>
```

4. (Optional) Configure a prefix-list for the target destination:

```
ip prefix-list WORD<1-64> <A.B.C.D/X> [ge <0-32>] [le <0-32>]
```
5. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths:

```
ip ecmp pathlist-<1-8> WORD<1-64>
```
6. (Optional) Return to Privileged EXEC mode:

```
end
```
7. (Optional) Apply changes to all ECMP pathlist configurations:

```
ip ecmp pathlist-apply [vrf WORD<1-16>]
```

Example

Define which IP prefixes use ECMP and which do not.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ecmp
Switch:1(config)#ip prefix-list ecmpAllowed 192.0.2.0/24 ge 24 le 24
Switch:1(config)#ip prefix-list ecmpDenied 0.0.0.0/0 ge 0 le 32
Switch:1(config)#ip ecmp pathlist-2 ecmpAllowed
Switch:1(config)#ip ecmp pathlist-1 ecmpDenied
Switch:1(config)#end
Switch:1#ip ecmp pathlist-apply
```

Variable Definitions

The following table defines parameters for the **ip ecmp** command.

| Variable | Value |
|------------------------------|--|
| <i>max-path</i> <ECMP-Paths> | Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in Release Notes for VOSS . |
| <i>pathlist-1</i> WORD<0-64> | Specifies one equal-cost path to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-2</i> WORD<0-64> | Specifies up to two equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-3</i> WORD<0-64> | Specifies up to three equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-4</i> WORD<0-64> | Specifies up to four equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-5</i> WORD<0-64> | Specifies up to five equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-6</i> WORD<0-64> | Specifies up to six equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <i>pathlist-7</i> WORD<0-64> | Specifies up to seven equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |

| Variable | Value |
|--|--|
| <code>pathlist-8 WORD<0-64></code> | Specifies up to eight equal-cost paths to the same destination prefix. To remove the policy, enter a blank string. |
| <code>pathlist-apply [vrf WORD<1-16>]</code> | Applies the pathlist configuration changes. You can optionally specify a VRF name. |

The following table defines parameters for the **ip prefix-list** command.

| Variable | Value |
|--------------------------------|--|
| <code>WORD<0-64></code> | Specifies the prefix list name. |
| <code><A.B.C.D/X></code> | Specifies the IP address and network mask in one of the following formats: <ul style="list-style-type: none"> a.b.c.d/x a.b.c.d/x.x.x.x default |
| <code>ge <0-32></code> | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |
| <code>le <0-32></code> | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |

Configuring Static Routes

Before You Begin

- Ensure no black hole static route exists.

About This Task

Configure a static route when you want to manually create a route to a destination IP address.

Note

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept policies.

If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

For route scaling information and for information on the maximum number of static routes supported on your hardware platform, see [Release Notes for VOSS](#).

Note

As a best practice, do not configure static routes on a DVR Leaf node unless the configuration is for reachability to a management network using a Brouter port.

You cannot configure the preference of static routes on a Leaf node.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Create an IP static route:

```
ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> weight <1-65535>
```
3. Enable an IP static route:

```
ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> enable
```
4. Use the following variable definitions table to configure other static route parameters as required.
5. View existing IP static routes for the device, or for a specific network or subnet:

```
show ip route static
```
6. Delete a static route:

```
no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D>
```

Example

Create an IP static route, enable a static route, and view the existing IP static routes for the device, or for a specific network or subnet.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 weight 20 name ExtSer 10 preference 1
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 enable
Switch:1(config)#show ip route static
=====
                        IP Static Route - GlobalRouter
=====
DEST          MASK          NEXT          NH-VRF        COST  PREF  LCLNHOP  STATUS  ENABLE  NAME
-----
192.0.2.2    255.255.255.0 198.51.100.24 GlobalRouter  20    1    TRUE    ACTIVE  TRUE    ExtSer 10
```

Variable definitions

Use the data in the following table to use the `ip route` command.

Table 212: Variable definitions

| Variable | Value |
|--|---|
| <code><A.B.C.D> <A.B.C.D>
<A.B.C.D></code> | The first and second <code><A.B.C.D></code> specify the IP address and mask for the route destination. The third <code><A.B.C.D></code> specifies the IP address of the next-hop router (the next router at which packets must arrive on this route). When you create a black hole static route, configure this parameter to 255.255.255.255 as the IP address of the router through which the specified route is accessible. |
| <code>disable</code> | Disables a route to the router or VRF. |
| <code>enable</code> | Adds a static route to the router or VRF.
The no form of this command is <code>no ip route <A.B.C.D>
<A.B.C.D> <A.B.C.D> enable</code> .
The default form of this command is <code>default ip route
<A.B.C.D> <A.B.C.D> <A.B.C.D> enable</code> . |
| <code>local-next-hop enable</code> | Enables the local next hop for this static route. The default form of this command is <code>default ip route <A.B.C.D>
<A.B.C.D> <A.B.C.D> local-next-hop enable</code> .
The no form of this command is <code>no ip route <A.B.C.D>
<A.B.C.D> <A.B.C.D> local-next-hop enable</code> . |
| <code>next-hop-vrf <WORD 0-16></code> | Specifies the next-hop VRF instance by name.
After you configure the <code>next-hop-vrf</code> parameter, the static route is created in the local VRF, and the next-hop route is resolved in the next-hop VRF instance (<code>next-hop-vrf</code>).
The default form of this command is <code>default ip route
<A.B.C.D> <A.B.C.D> <A.B.C.D> next-hop-vrf
<WORD 0-16></code> .
The no form of this command is <code>no ip route <A.B.C.D>
<A.B.C.D> <A.B.C.D> next-hop-vrf <WORD 0-16></code> . |
| <code>weight <1-65535></code> | Specifies the static route cost.
The default form of this command is <code>default ip route
<A.B.C.D> <A.B.C.D> <A.B.C.D> weight</code> .

Note:
Do not configure a static interface subnet route with a weight of 1. |
| <code>name <1-64></code> | Specifies the name of the static route. You can name the route before or after it is created.
Only 32 characters display. The tilde (~) symbol indicates that the name is truncated. |
| <code>preference <1-255></code> | Specifies the route preference.
The default form of this command is <code>default ip route
<A.B.C.D> <A.B.C.D> <A.B.C.D> preference</code> . |

Use the data in the following table to use the `show ip route static` command.

Table 213: Variable definitions

| Variable | Value |
|---|--|
| <code><A.B.C.D></code> | Specifies the route by IP address. |
| <code>-s { <A.B.C.D> <A.B.C.D>
 default }</code> | Specifies the route by IP address and subnet mask. |
| <code>vrf WORD<0-16></code> | Specifies a VRF by name. |
| <code>vrfids WORD<0-512></code> | Specifies a range of VRF IDs. |
| <code>name <1-64></code> | Specifies the name of the static route. You can name the route before or after it is created. Only 32 characters display. The tilde (~) symbol indicates that the name is truncated. |

Configuring a black hole static route

About This Task

Configure a black hole static route to the destination a router advertises to avoid routing loops after the router aggregates or injects routes to other routers.

If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Create a black hole static route:

```
ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 weight <1-65535>
```

3. Enable a black hole static route:

```
ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 enable [next-hop-vrf  
WORD<0-16>]
```

4. Configure other black hole static route parameters as required.

When you specify a route preference, appropriately configure the preference so that when the black-hole route is used, it is elected as the best route.

Example

Create a black hole static route and enable the black hole static route.

```
Switch:1>enable  
Switch:1#configure terminal
```

```
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 weight 200
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 enable
```

Variable definitions

Use the data in the following table to use the `ip route` command.

Table 214: Variable definitions

| Variable | Value |
|--|--|
| <code><A.B.C.D></code> | The first and second <code><A.B.C.D></code> specify the IP address and mask for the route destination. 255.255.255.255 is the destination of the black hole route. |
| <code>enable</code> | Adds a static route to the router or VRF.
The no form of this command is <code>no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 enable</code> . |
| <code>local-next-hop enable</code> | Enables the local next hop for this static route.
The default form of this command is <code>default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> local-next-hop enable</code> .
The no form of this command is <code>no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 local-next-hop enable</code> . |
| <code>next-hop-vrf WORD<0-16></code> | Specifies the next-hop VRF instance by name.
The default form of this command is <code>default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 next-hop-vrf <WORD 0-16></code> .
The no form of this command is <code>no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 next-hop-vrf <WORD 0-16></code> . |
| <code>weight <1-65535></code> | Specifies the static route cost.
The default form of this command is <code>default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 weight</code> .
Note:
Do not configure a static interface subnet route with a weight of 1. |
| <code>preference <1-255></code> | Specifies the route preference.
The default form of this command is <code>default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 preference</code> . |

Configuring a default static route

About This Task

The default route specifies a route to all networks for which there are no explicit routes in the forwarding information base or the routing table. This route has a prefix length of zero (RFC 1812). You can configure the switch with a static default route, or they can learn it through a dynamic routing protocol.

To create a default static route, you configure the destination address and subnet mask to 0.0.0.0.

Note

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept polices.

Note

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a Brouter port.

You cannot configure the preference of static routes on a Leaf node.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Create a default static route:

```
ip route 0.0.0.0 0.0.0.0 <A.B.C.D> weight <1-65535>
```

3. Enable a default static route:

```
ip route 0.0.0.0 0.0.0.0 <A.B.C.D> enable [next-hop-vrf WORD<0-16>]
```

4. Configure other default static route parameters as required.

Example

Create a default static route and enable the default static route.

```
Switch:1>enable
Switch:1>configure terminal
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 weight 100
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 enable
```

Variable definitions

Use the data in the following table to use the `ip route` command.

Table 215: Variable definitions

| Variable | Value |
|---------------|---|
| <A.B.C.D> | <A.B.C.D> specifies the IP address of the next-hop router (the next router at which packets must arrive on this route). |
| <i>enable</i> | Adds a static or default route to the router or VRF. The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> enable</code> . |

Table 215: Variable definitions (continued)

| Variable | Value |
|--|--|
| <code>local-next-hop enable</code> | Enables the local next hop for this static route.
The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> local-next-hop enable</code> .
The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> local-next-hop enable</code> . |
| <code>next-hop-vrf WORD<0-16></code> | Specifies the next-hop VRF instance by name.
The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> next-hop-vrf WORD<0-16></code> .
The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> next-hop-vrf WORD<0-16></code> . |
| <code>weight <1-65535></code> | Specifies the static route cost.
The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> weight</code> .

Note:
Do not configure a static interface subnet route with a weight of 1. |
| <code>preference <1-255></code> | Specifies the route preference.
The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> preference</code> . |

Enabling ICMP Router Discovery globally

About This Task

Enable Router Discovery globally so that the device supports Router Discovery. Use ICMP Router Discovery to enable hosts attached to the broadcast network to discover the IP addresses of their neighboring routers.

If you enable ICMP Router Discovery globally, you automatically enable it for all VLANs. If you do not require ICMP Router Discovery on a specific VLAN, you must manually disable the feature.

Procedure

- Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
- Enable ICMP Router Discovery on the device:

```
ip irdp
```
- Confirm that Router Discovery is enabled:

```
show ip irdp [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

Enable ICMP router discovery on the device and confirm that router discovery is enabled.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip irdp
Switch:1(config)#show ip irdp
      VRF "GlobalRouter" (Global Routing Table) : Router Discovery Enabled
```

Variable definitions

Use the data in the following table to show `ip irdp` command.

Table 216: Variable definitions

| Variable | Value |
|---------------------------------|--|
| <i>interface</i> | Displays route discovery interface information. |
| <i>vrf WORD<0-16></i> | Displays route discovery for particular VRF. |
| <i>vrfids WORD<0-512></i> | Displays route discovery for particular VRF IDs. |

Enabling or disabling IPv4 ICMP broadcast globally

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the global router.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable IPv4 ICMP broadcast feature, enter:

```
ip icmp echo-broadcast-request
```
3. Disable IPv4 ICMP broadcast feature, enter:

```
no ip icmp echo-broadcast-request
```
4. Set the IPv4 ICMP broadcast feature to default state, enter:

```
default ip icmp echo-broadcast-request
```

Note

By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:

```
show ip routing
```

Enabling or disabling IPv4 ICMP broadcast per VRF

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the VRF router.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Enable IPv4 ICMP broadcast feature, enter:

```
ip icmp echo-broadcast-request
```

3. Disable IPv4 ICMP broadcast feature, enter:

```
no ip icmp echo-broadcast-request
```

4. Set the IPv4 ICMP broadcast feature to default state, enter:

```
default ip icmp echo-broadcast-request
```

Note

By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:

```
show ip routing
```

Configuring Router Discovery on a port or VLAN

Enable Router Discovery so that the device forwards Router Discovery Advertisement packets to the VLAN or port.

Procedure

1. Enter Interface Configuration mode:

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Specify the address placed in advertisement packets:

```
ip irdp address <A.B.C.D>
```

3. Enable the interface to send the advertisement packets:

```
ip irdp multicast
```
4. Configure other Router Discovery parameters for the interface as required.

Example

Log on to the GigabitEthernet Interface mode:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/16
```

Specify the address placed in advertisement packets to the all-systems multicast address:

```
Switch:1(config-if)# ip irdp address 244.0.0.1
```

Enable the interface to send the advertisement packets:

```
Switch:1(config-if)# ip irdp multicast
```

Configure the lifetime for advertisements:

```
Switch:1(config-if)# ip irdp holdtime 180
```

Variable definitions

Use the data in the following table to use the `ip irdp` command.

Table 217: Variable definitions

| Variable | Value |
|---|---|
| <code>address <A.B.C.D></code> | Specifies the IP destination address use for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address, 224.0.0.1, or the limited-broadcast address, 255.255.255.255. The default address is 255.255.255.255. The default form of this command is <code>default ip irdp address</code> . |
| <code>holdtime <4-9000></code> | Configures the lifetime for advertisements. The default form of this command is <code>default ip irdp holdtime</code> . |
| <code>maxadvertinterval <4-1800></code> | Specifies the maximum time (in seconds) that elapses between unsolicited router advertisement transmissions from the router interface. The default is 600 seconds. The default form of this command is <code>default ip irdp maxadvertinterval</code> . |
| <code>minadvertinterval <3-1800></code> | Specifies the minimum time (in seconds) that elapses between unsolicited router advertisement transmissions from the interface. The range is 3 seconds to <code>maxadvertinterval</code> . The default is 450 seconds. The default form of this command is <code>default ip irdp minadvertinterval</code> . |

Table 217: Variable definitions (continued)

| Variable | Value |
|---|---|
| <i>multicast</i> | Specifies if multicast advertisements are sent. The no form of this command is <code>no ip irdp multicast</code> . |
| <i>preference</i>
<-2147483648-2147483647> | Specifies the preference (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The default is 0. The default form of this command is <code>default ip irdp preference</code> . |

Configuring a CLIP Interface

About This Task

Configure a circuitless IP (CLIP) interface to provide a virtual interface that is not associated with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your device.

For scaling information and for information on the maximum number of CLIP interfaces you can configure on your device, see [Release Notes for VOSS](#).

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create or access a CLIP interface:

```
interface loopback <1-256>
```

<1-256> indicates the identification number for the CLIP.

The command prompt changes to indicate you now access the Loopback Interface Configuration mode.

3. Configure an IP address and name for the interface:

```
ip address [<1-256>] <A.B.C.D/X> [vrf WORD<0-16>] [name WORD <0-64>]
```

4. Enable OSPF on the CLIP interface:

```
ip ospf [<1-256>] [vrf WORD<1-16>]
```

You can configure other protocols on the CLIP interface; OSPF is the most common. See the following variable definitions table for other options.

5. View the IP address on the CLIP interface:

```
show ip interface
```

Example

Create a CLIP interface, and enable OSPF on the CLIP interface.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 3
```

```

Switch:1(config-if)#ip address 23.23.23.23 255.255.255.0 name Canada

Variable Definitions

Use the data in the following table to use the ip commands.

Table 218: Variable definitions

| Variable | Value |
|---|---|
| <code>address [<1-256>]
<A.B.C.D/X> [vrf
WORD<0-16>] [name
WORD<0-64]</code> | Specifies the IP address for the CLIP interface.
<1-256> specifies the interface.
<A.B.C.D/X> specifies the IP address and mask (0-32).
vrf WORD<0-16> specifies an associated VRF by name.
The no form of this command is <code>no ip address [<1-32>]
<A.B.C.D> [vrf WORD<0-16>]</code> .
name WORD<0-16> specifies a name for the IP address. |
| <code>area <1-256> <A.B.C.D>
[vrf WORD<0-16>]</code> | Designates an area for the CLIP interface.
vrf WORD<0-16> specifies an associated VRF by name
The default form of this command is <code>default ip area
<1-256> <A.B.C.D> [vrf WORD<0-16>]</code> . The no form of
this command is <code>no ip area <1-256> vrf WORD<0-16>]</code> . |

Display BFD Configurations on the Loopback Interface

About This Task

Use the following procedure to display all BFD configurations on the loopback interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:

```
show ip bfd interfaces loopback
```

Example

The following example displays BFD configurations on the Loopback Interface:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
=====
                        Circuitless IP Interface Bfd
=====
INTF ID   STATUS    MIN_RX   INTERVAL  MULTIPLIER  VRF-ID
-----
1         enable   200      200       3           0
2         enable   200      200       3           2
```

Viewing TCP and UDP information

Use this procedure to view TCP and UDP configuration information for IPv4.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View the IPv4 TCP connection information:
show ip tcp connections
3. View the IPv4 TCP connection information for a specific vrf or vrfids:
show ip tcp connections vrf WORD<0-16>

show ip tcp connections vrfids WORD<0-512>
4. View IPv4 TCP properties:
show ip tcp properties
5. View IPv4 TCP statistics
show ip tcp statistics
6. View IPv4 udp endpoints
show ip udp endpoints
7. View IPv4 udp statistics
show ip udp statistics

Example

```
Switch:1#show ip tcp connections
=====
                        TCP connection table info
=====
LOCALPORT  LOCALADDR      REMOTEPORT  REMOTEADDR    STATE        VRF ID
-----
21         0.0.0.0        0           0.0.0.0       listen       0
22         0.0.0.0        0           0.0.0.0       listen       0
23         0.0.0.0        0           0.0.0.0       listen       0
80         0.0.0.0        0           0.0.0.0       listen       0
443        0.0.0.0        0           0.0.0.0       listen       0
```

```

23          192.0.2.146      52583      198.51.100.30      established      0

Switch:1#show ip tcp properties

show ip tcp global properties command:
