Some software files have been licensed under certain open source or third-party licenses. End-user license agreements and open source declarations can be found at: <https://www.extremenetworks.com/support/policies/open-source-declaration/>

About this Document

[Purpose](#) on page 3

[Conventions](#) on page 3

[Documentation and Training](#) on page 5

[Getting Help](#) on page 6

[Providing Feedback](#) on page 7

This section discusses the purpose of this document, ways to provide feedback, additional help, and information regarding other Extreme Networks publications.

Purpose

This document provides information on features in VSP Operating System Software (VOSS). VOSS runs on the following product families:

- ExtremeSwitching 5520 Series
- ExtremeSwitching VSP 4450 Series
- ExtremeSwitching VSP 4900 Series
- ExtremeSwitching VSP 7200 Series
- ExtremeSwitching VSP 7400 Series
- ExtremeSwitching VSP 8000 Series (includes VSP 8200 Series and VSP 8400 Series)
- ExtremeSwitching VSP 8600 Series
- ExtremeSwitching XA1400 Series

Note

VOSS is licensed on the XA1400 Series as a Fabric Connect VPN (FCVPN) application, which includes a subset of VOSS features. FCVPN transparently extends Fabric Connect services over third-party provider networks.

Conventions

To help you better understand the information presented in this guide, the following topics describe the formatting conventions used for notes, text, and other elements.

Text Conventions

The following tables list text conventions that can be used throughout this document.

Table 1: Notes and warnings

Icon	Notice type	Alerts you to...
	Tip	Helpful tips and notices for using the product.
	Note	Useful information or instructions.
	Important	Important features or instructions.
	Caution	Risk of personal injury, system damage, or loss of data.
	Warning	Risk of severe personal injury.

Table 2: Text Conventions

Convention	Description
Angle brackets (< >)	Angle brackets (< >) indicate that you choose the text to enter based on the description inside the brackets. Do not type the brackets when you enter the command. If the command syntax is <code>cfm maintenance-domain maintenance-level <0-7></code> , you can enter <code>cfm maintenance-domain maintenance-level 4</code> .
Bold text	Bold text indicates the GUI object name you must act upon. Examples: <ul style="list-style-type: none"> Click OK. On the Tools menu, choose Options.
Braces ({ })	Braces ({ }) indicate required elements in syntax descriptions. Do not type the braces when you enter the command. For example, if the command syntax is <code>ip address {A.B.C.D}</code> , you must enter the IP address in dotted, decimal notation.

Table 2: Text Conventions (continued)

Convention	Description
Brackets ([])	Brackets ([]) indicate optional elements in syntax descriptions. Do not type the brackets when you enter the command. For example, if the command syntax is <code>show clock [detail]</code> , you can enter either <code>show clock</code> or <code>show clock detail</code> .
Ellipses (...)	An ellipsis (...) indicates that you repeat the last element of the command as needed. For example, if the command syntax is <code>ethernet/2/1 [<parameter> <value>] . . .</code> , you enter <code>ethernet/2/1</code> and as many parameter-value pairs as you need.
Italic Text	Italics emphasize a point or denote new terms at the place where they are defined in the text. Italics are also used when referring to publication titles that are not active links.
Plain Courier Text	Plain Courier text indicates command names, options, and text that you must enter. Plain Courier text also indicates command syntax and system output, for example, prompts and system messages. Examples: <ul style="list-style-type: none"> <code>show ip route</code> <code>Error: Invalid command syntax [Failed] [2013-03-22 13:37:03.303 -04:00]</code>
Separator (>)	A greater than sign (>) shows separation in menu paths. For example, in the Navigation tree, expand the Configuration > Edit folders.
Vertical Line ()	A vertical line () separates choices for command keywords and arguments. Enter only one choice. Do not type the vertical line when you enter the command. For example, if the command syntax is <code>access-policy by-mac action { allow deny }</code> , you enter either <code>access-policy by-mac action allow</code> or <code>access-policy by-mac action deny</code> , but not both.

Documentation and Training

Find Extreme Networks product information at the following locations:

[Current Product Documentation](#)

[Release Notes](#)

[Hardware and software compatibility](#) for Extreme Networks products
[Extreme Optics Compatibility](#)
[Other resources](#) such as white papers, data sheets, and case studies

Extreme Networks offers product training courses, both online and in person, as well as specialized certifications. For details, visit www.extremenetworks.com/education/.

Getting Help

If you require assistance, contact Extreme Networks using one of the following methods:

Extreme Portal

Search the GTAC (Global Technical Assistance Center) knowledge base; manage support cases and service contracts; download software; and obtain product licensing, training, and certifications.

The Hub

A forum for Extreme Networks customers to connect with one another, answer questions, and share ideas and feedback. This community is monitored by Extreme Networks employees, but is not intended to replace specific guidance from GTAC.

Call GTAC

For immediate support: (800) 998 2408 (toll-free in U.S. and Canada) or 1 (408) 579 2826. For the support phone number in your country, visit: www.extremenetworks.com/support/contact

Before contacting Extreme Networks for technical support, have the following information ready:

- Your Extreme Networks service contract number, or serial numbers for all involved Extreme Networks products
- A description of the failure
- A description of any actions already taken to resolve the problem
- A description of your network environment (such as layout, cable type, other relevant environmental information)
- Network load at the time of trouble (if known)
- The device history (for example, if you have returned the device before, or if this is a recurring problem)
- Any related RMA (Return Material Authorization) numbers

Subscribe to Product Announcements

You can subscribe to email notifications for product and software release announcements, Field Notices, and Vulnerability Notices.

1. Go to [The Hub](#).
2. In the list of categories, expand the **Product Announcements** list.
3. Select a product for which you would like to receive notifications.
4. Select **Subscribe**.
5. To select additional products, return to the **Product Announcements** list and repeat steps 3 and 4.

You can modify your product selections or unsubscribe at any time.

Providing Feedback

The Information Development team at Extreme Networks has made every effort to ensure the accuracy and completeness of this document. We are always striving to improve our documentation and help you work better, so we want to hear from you. We welcome all feedback, but we especially want to know about:

- Content errors, or confusing or conflicting information.
- Improvements that would help you find relevant information in the document.
- Broken links or usability issues.

If you would like to provide feedback, you can do so in three ways:

- In a web browser, select the feedback icon and complete the online feedback form.
- Access the feedback form at <https://www.extremenetworks.com/documentation-feedback/>.
- Email us at documentation@extremenetworks.com.

Provide the publication title, part number, and as much detail as possible, including the topic heading and page number if applicable, as well as your suggestions for improvement.

New in this Document

[Notice about Feature Support on page 13](#)

The following sections detail what is new in this document.

[Network Operating System Personalities](#)

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. These hardware products ship with a default NOS personality but you can select a non-default personality.

The primary method to select a NOS personality for the hardware is by using ExtremeCloud IQ. If the network is not accessible, or if you do not use Extreme Networks management software, you can change the NOS personality by using CLI commands in the running NOS. For more information about ExtremeCloud IQ, go to <https://www.extremenetworks.com/extremecloud-iq/>.

The first universal hardware product to support more than one NOS personality is the 5520 Series.

For more information, see [Network Operating System Personalities](#) on page 2304.

[256-bit IPsec Encryption for Fabric Extend Tunnels on XA1400 Series and Fabric IPsec Gateway](#)

This release adds support to configure the IPsec encryption key length as either 128 bit or 256 bit.

This enhancement was originally available as a demonstration feature in VOSS 8.2. This enhancement is generally available in VOSS Release 8.3.

For more information, see the following sections:

- [Configure IPsec Tunnels on Fabric IPsec Gateway VM](#) on page 847
- [Configure Fabric Extend Over IPsec](#) on page 1007
- [Display IS-IS Logical Interfaces](#) on page 1013
- [Configure Fabric Extend Logical Interfaces](#) on page 1085

5520 Series

5520 Series is a new hardware family of switches that supports both ExtremeXOS and VOSS. VOSS 8.2.5 supports the following models:

- 5520-24T: 24 10/100/1000BASE-T full-duplex (FDX), half-duplex (HDX), MACsec-capable ports and 2 QSFP28 Universal Ethernet ports
- 5520-24W: 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports and 2 QSFP28 Universal Ethernet ports
- 5520-48T: 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports, and 2 QSFP28 Universal Ethernet ports
- 5520-48W: 48 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports and 2 QSFP28 Universal Ethernet ports
- 5520-12MW-36W: 12 100 Mbps/1 Gbps/2.5 Gbps/5 Gbps 802.3bt Type 4 PoE MACsec-capable ports, 36 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports, and 2 QSFP28 Universal Ethernet ports
- 5520-24X: 24 100/1000BASE-X/10GBASE-X SFP+ ports and 2 QSFP28 Universal Ethernet ports
- 5520-48SE: 48 100/1000BASE-X MACsec-capable SFP ports and 2 QSFP28 Universal Ethernet ports

Each model provides one Versatile Interface Module (VIM) slot. You can install any one of the following VIMs in the VIM slot to provide flexible linkage to other switches or devices over a range of media:

- 5520-VIM-4X: Four 1 Gbps/10 Gbps SFP+ ports
- 5520-VIM-4XE: Four 1 Gbps/10 Gbps LRM/MACsec-capable SFP+ ports
- 5520-VIM-4YE: Four 10 Gbps/25 Gbps MACsec-capable SFP28 ports

Feature documentation is updated to include support statements specific to the new hardware.

Certificate Enhancements

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels using pre-shared keys for authentication. This release introduces a more secure authentication method through digital certificate support for IPsec.

This release enhances digital certificate support on all switches. You can configure an encrypted SHA-256 fingerprint to validate the certificate authority (CA) certificate chain and to avoid manual transfer of the root certificate file.

For more information, see [Digital Certificates for IPsec Authentication](#) on page 1686 and [Digital Certificate/PKI](#) on page 2875.

DvR One IP Enhancement

This enhancement was originally available as a demonstration feature in VOSS 8.2; this enhancement is now generally available and can be used in production environments. You can now use a single IP address in a subnet shared by all Controllers by configuring the DvR IP to be the same as the DvR gateway IP.

This feature does not apply to VSP 4450 Series or XA1400 Series.

For more information, see [Distributed Virtual Routing](#) on page 660.

Dynamic Nickname Assignment Enhancement

This release extends the Dynamic Nickname Assignment behavior, and provides the user with a *prefix* parameter to assign up to 256 groups with 4,096 nicknames each.

For more information, see [Dynamic Nickname Assignment](#) on page 904.

Extreme Integrated Application Hosting (IAH) Enhancements

Extreme Integrated Application Hosting (IAH) enhancements were originally available as a demonstration feature in VOSS 8.2; these enhancements are now generally available and can be used in production environments. The enhancements are provided on the following platforms:

- VSP4900-24XE
- VSP4900-12MXU-12XE
- VSP 7432CQ
- VSP 7400-48Y

You can configure the following enhancements:

- IAH ports 1/s1 and 1/s2 to accommodate different connect types.
- VT-d connect type on either 1/s1 or 1/s2 IAH ports.
- Up to two VT-d connect types.
- The Network Interface Card (NIC) type of the virtual port.

For more information, see [Extreme Integrated Application Hosting](#) on page 817.

Fabric Extend Enhancements

For XA1400 Series, to improve throughput of an FE tunnel over a WAN circuit, VOSS added IPsec compression and the ability to adjust the TCP maximum segment size (MSS).

For more information, see the following:

- [IPsec Compression](#) on page 914
- [Adjust the TCP Maximum Segment Size](#) on page 1011 (using CLI)
- [Adjust the TCP Maximum Segment Size](#) on page 1090 (using EDM)

Fabric IPsec Gateway

The Fabric IPsec Gateway feature introduces a Virtual Machine that supports aggregation of Fabric Extend Tunnels with fragmentation, reassembly, and Internet Protocol Security (IPsec) encryption functions. Starting with VOSS 8.3, the Fabric IPsec Gateway feature is available for VSP 4900 Series switches. The same virtual machine continues to be available for VSP 7400 Series switches.

For more information, see [Fabric IPsec Gateway Fundamentals](#) on page 823.

MAC Security Limit-Learning

VSP 4900 Series and 5520 Series add support for MAC security limit-learning. Use this feature to limit the number of MAC addresses a port can learn.

For more information, see [VLAN MAC-layer Filtering Database and MAC Security](#) on page 3819.

Mask Password for SNMPv3 and Web Server Commands

This release modifies the following commands, which previously displayed the password in clear text as part of the configuration method, to instead prompt for the password and hide the characters as you type them:

- **web-server password**
- **snmp-server user**

For more information, see the following sections:

- [Enable the Web Management Interface](#) on page 143
- [Command Line Interface](#) on page 238
- [Creating a user](#) on page 2982 or [Add a User to a Group](#) on page 2987

PoE Support for Classes 5 and 6 on VSP 4900

VOSS Release 8.3 provides 60W PoE support for classes 5 and 6 on VSP 4900-12MXU-12XE.

For more information, see [Power over Ethernet Fundamentals](#) on page 2488.

VLAN IP Address as Fabric Extend Tunnel Source

Fabric Extend (FE) enables the extension of Fabric Connect networking over Layer 2 or Layer 3 core IP networks. You can configure a VLAN IP interface as the FE tunnel source IP address on a device. You must configure the VLAN in the same VRF as the ISIS tunnel source IP address.

Note

This feature is generally available for the following products in VOSS Release 8.3:

- 5520 Series
- VSP 4450 Series
- VSP 4900 Series
- VSP 7200 Series
- VSP 7400 Series
- VSP 8200 Series
- VSP 8400 Series

This feature was previously generally available on XA1400 Series only.

For more information, see the following sections:

- [Fabric Extend](#) on page 908
- [Configure Fabric Extend](#) on page 1003

- [Configure Fabric Extend Tunnels](#) on page 1083

VOSS Switch Support on the Network Edge

This release expands support for VOSS switches to the network edge and simplifies deployment and network operation processes. For information about feature support, see [VOSS Feature Support Matrix](#).

The system implements a port-based Auto-sense functionality to support zero touch capabilities when deploying a fabric-based network. Auto-sense introduces a port state machine that allows the port to change its state based on sensing what it is connected to. Port states can be IS-IS links, FA links, IP Phone links, and user links with or without network access control enabled. Additionally, Auto-sense establishes an automatic onboarding I-SID 15999999 on VLAN 4048 for automatic reachability of the network management segment.

Note

For bridged or routed reachability of the management servers (DHCP, RADIUS, Extreme Management Center, or ExtremeCloud IQ) the onboarding I-SID must be manually mapped to the management segment on at least one BEB in the network prior to zero touch deployments of new switches. Additionally, you must enable a Dynamic Nickname server on at least one node.

The following features and enhancements are introduced to support VOSS switches on the network edge and to support network automation:

- IP Phone Support as part of Auto-sense
 - This feature focuses on automating IP Phone connectivity on the network to the VOSS switches.

For more information, see [IP Phone Support](#) on page 30.

- RADIUS and EAP Enhancements
 - Enhancements to EAP and RADIUS-based authentication and attribute exchange automates the movement, addition, or changes of hosts at the VOSS network edge.

For more information, see the following sections:

- [EAP Functionality on Flex UNI Ports](#) on page 746
 - [EAP and Fabric Attach](#) on page 747
 - [MAC Move Detection on EAP Ports](#) on page 748
 - [RADIUS Attributes](#) on page 750
 - [Auto-sense Ports](#) on page 748
 - [Wake On LAN](#) on page 766
 - [EAP Auto-ISID-Offset](#) on page 766
 - [Guest I-SID](#) on page 764
 - [Fail Open I-SID](#) on page 766
 - [EAPoL configuration using CLI](#) on page 767
 - [EAP configuration using Enterprise Device Manager](#) on page 791
- RADIUS Dynamic User-Based Policies

RADIUS Dynamic User-Based Policies are an addition to the Extensible Authentication Protocol (EAP) feature. RADIUS Dynamic User-Based Policies implement a dynamic method to apply filter ACL rules to EAP and NEAP authenticated user traffic.

For more information, see [RADIUS Dynamic User-Based Policies](#) on page 755.

- UPnP Filtering
 - This feature provides an easy way to filter out Universal Plug-and-Play (uPnP) traffic without having to configure an ACL. uPnP Filtering drops all incoming multicast packets received by a switch on an IGMP-enabled interface if the multicast destination IP address is 239.255.255.250.

uPnP Filtering is disabled by default. When an IGMP interface is created, uPnP Filtering is enabled automatically on the interface for the destination multicast IP address range 239.255.255.250/32. You can use CLI or EDM to configure a different destination multicast IP address range.

For more information, see the following sections:

- [Universal Plug and Play Filtering](#) on page 1588
- [Configure Universal Plug and Play \(uPnP\) Filtering](#) on page 1595
- [Configuring the IGMP interface](#) on page 1504
- [View uPnP Filtering information on an IGMP-enabled interface](#) on page 1596
- [View IGMP Interface Information](#) on page 3733

- Zero Touch Fabric Configuration Enhancements
 - Zero Touch Fabric Configuration enhancements remove support for the *fabric* parameter from the **boot config flags factorydefaults** command in this release. Now, when you boot a switch without an existing primary or secondary configuration file, the system initiates zero touch functionality, that triggers Zero Touch Fabric Configuration.

For more information, see the following sections:

- [Zero Touch Fabric Configuration](#) on page 45
- [Auto-sense](#) on page 18
- [Auto-sense Configuration using CLI](#) on page 23

Notice about Feature Support

This document includes content for multiple hardware platforms across different software releases. As a result, the content can include features not supported by your hardware in the current software release.

If a documented command, parameter, tab, or field does not display on your hardware, it is not supported.

For information about physical hardware restrictions, see your hardware documentation.

Installation and Commissioning Documentation

Use installation and commissioning documentation to install the product hardware and software, and perform the initial configuration.

Table 3: Installation and commissioning documents

Zero Touch Capabilities

[Auto-sense on page 18](#)

[IP Phone Support on page 30](#)

[Zero Touch Deployment on page 40](#)

[Zero Touch Provisioning Plus on page 42](#)

[Zero Touch Fabric Configuration on page 45](#)

VOSS supports the following zero touch capabilities:

- Auto-sense support for the following features:
 - Fabric Attach (FA)
 - Extensible Authentication Protocol (EAP) and non-EAPoL (NEAP)
 - IP Phones
- Zero Touch Deployment
- Zero Touch Provisioning Plus (ZTP+)
- Zero Touch Fabric Configuration including Auto-sense for network-to-network (NNI) interfaces

Note

For bridged or routed reachability of the management servers (DHCP, RADIUS, Extreme Management Center, or ExtremeCloud IQ) the onboarding I-SID must be manually mapped to the management segment on at least one BEB in the network prior to zero touch deployments of new switches. Additionally, you must enable a Dynamic Nickname server on at least one node. For more information, see [Release Notes for VOSS](#).

Auto-sense

Table 5: Auto-sense product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Auto-sense	5520 Series	VOSS 8.3
	VSP 4450 Series	VOSS 8.3
	VSP 4900 Series	VOSS 8.3
	VSP 7200 Series	VOSS 8.3
	VSP 7400 Series	VOSS 8.3
	VSP 8200 Series	VOSS 8.3
	VSP 8400 Series	VOSS 8.3
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Auto-sense is a port-based functionality to support zero touch capabilities on the VOSS switches. When you enable Auto-sense on a port, the system dynamically configures the port to act as a Switched UNI, IS-IS, Fabric Attach (FA) or voice (IP phone) interface, based on the Link Layer Discovery Protocol (LLDP) events. Auto-sense provides a global configuration option for IS-IS authentication, FA authentication, and voice configuration for IP phones, on the switch. For more information about IP Phone Support, see [IP Phone Support](#) on page 30.

When a switch boots in Zero Touch Fabric Configuration mode, all ports on the switch automatically operate in Auto-sense mode, until you manually change the port configuration. For more information on Zero Touch Fabric Configuration, see [Zero Touch Fabric Configuration](#) on page 45.

When you manually disable Auto-sense on a specific port, the switch removes the dynamic configuration on that port unless you use an optional parameter to convert the dynamic configuration to a manual configuration.

With Auto-sense functionality, ports on a switch can detect whether they connect to an SPB device, an FA client, FA Proxy, Voice IP devices, or an undefined host.

- If a port connects to an SPB device or an FA client, then the system establishes Fabric architecture.
- If a port connects to any undefined host, then the system moves all untagged traffic on the port to an onboarding service network, also known as the onboarding I-SID.

- If a port is operating in Auto-sense mode then the system automatically activates EAP and NEAP authentication on them, for untagged traffic.

Note

If a port operates in Auto-sense mode, you cannot change the following configurations on it:

- IS-IS interface
- Fabric Attach
- Flex-UNI*
- The port is part of a VLAN or a private VLAN*
- Extensible Authentication Protocol over LAN (EAPoL) status is set to auto
- EAPoL Remote Authentication Dial-In User Service (RADIUS) non-EAP authentication
- EAPoL guest I-SID
- EAPoL guest VLAN
- EAPoL mode is set to Multi Host Single Authentication (MHSA)
- EAPoL voice LLDP authentication
- QoS
- Encapsulation*
- Private VLAN role
- LACP and VLACP
- MLT or SMLT

* If the Auto-sense port state is PORT DOWN or UNI, you can make these changes. The system disables Auto-sense on the port and applies the new configuration. For more information about Auto-sense port states, see [Auto-sense Port States](#) on page 20.

Implementation on Existing Switches

If the switch does not boot in Zero Touch Fabric Configuration mode and you wish to use Auto-sense functionality with an existing switch configuration, you must configure the following items:

- Create a new, private VLAN 4048. If the existing configuration uses VLAN 4048, you must configure a new VLAN for those original purposes.
- Configure I-SID 15999999 as the Auto-sense onboarding I-SID.
- Assign onboarding I-SID 15999999 to private VLAN 4048.

IS-IS Authentication

Auto-sense supports global configuration of IS-IS authentication key on the switch. All ports operating in Auto-sense mode use the global IS-IS authentication key that you configure using the **auto-sense isis hello-auth type** command. For more information, see [Configure Auto-sense IS-IS Authentication](#) on page 27.

Fabric Attach Authentication

Auto-sense supports FA message authentication on switches. You can enable FA message authentication globally on a switch, using the **auto-sense fa message-authentication** command. All ports operating in Auto-sense mode use the global authentication key. A preconfigured authentication key exists on the switch, by default, which you can change. For more information, see [Configure Auto-sense Fabric Attach Authentication](#) on page 25.

Auto-sense Voice Capabilities

Auto-sense voice capabilities are based on the events when the switch detects an IP phone in the network. For more information, see [Auto-sense Voice](#) on page 32.

Loop Prevention

To avoid a loop between two devices that attempt to join the network at the same time and have at least two links between them, the systems include the system ID in the LLDP Fabric Connect TLV. Each time a port receives an LLDP packet with the Fabric Connect TLV, the system inspects the forwarding information base (FIB) and if it finds the neighbor system ID, transitions the port to an NNI loop prevention state. The port is not part of the onboarding I-SID, which prevents it from forwarding or looping traffic between the neighbors. For more information about the LLDP Fabric Connect TLV, see [Establishing IS-IS Adjacencies](#) on page 47.

After the IS-IS adjacency is established, the port transitions to the IS-IS state. If more than one adjacency exists between two neighbors, one of them is active and all others behave like a backup. To detect loops quickly, the LLDP TX frequency is changed when you enable Auto-sense on a port; the port sends the first 5 packets at 2 second intervals.

To avoid a loop with edge devices, when a port is in the Auto-sense UNI, Fabric Attach (FA), or Voice states, and there is at least one IS-IS adjacency up, the port sends fake Bridge Protocol Data Unit (BPDU) packets to the edge switch to claim the Spanning Tree Protocol (STP) root and to put one of the edge switch ports in an STP-blocking state.

For more information on the port states, see [Auto-sense Port States](#) on page 20.

Running Configuration

If you view the running configuration, the global Auto-sense configuration displays under the port module. Use the command **show running-config module port**.

Auto-sense Port States

The system uses a per-interface state to adapt to all Auto-sense events. Each state transition determines background configuration on the port. These configurations do not appear in the output of the **show running-config** command or in the saved configuration file but if you disable Auto-sense on the port and use the *convert-to-config* parameter, the dynamic configuration becomes a manual configuration and is visible in the **show running-config** output.

Port Down State

If you run the **auto-sense enable** command on a port that is disabled or has an inactive link, the port transitions to the Auto-sense Port Down state. This state transitions to the Auto-sense Wait state after the port becomes operational or the link becomes active.

Wait State

If you run the **auto-sense enable** command on a port that is operationally available, the port transitions to the Auto-sense Wait state and starts a 10 second timer to send the first Link Layer Discovery Protocol (LLDP) packets for loop prevention.

The port modifies outgoing LLDP packets to represent the enhanced properties of the port and analyzes incoming LLDP packets for possible transitions to advanced states like NNI, FA, or VOICE. If the port does not receive LLDP packets, the port transitions to the UNI state.

UNI State

This state grants onboarding and data connectivity to the port if you configure the onboarding I-SID or data I-SID in the global Auto-sense configuration. The system prioritizes the data I-SID over the onboarding I-SID. The system also applies the trusted and untrusted Auto-sense global configuration. As with the Wait state, the port continues to monitor received LLDP packets for transitions to other states.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
[qos 802.1p-override enable]
[access-diffserv enable]
on port X interface, if onboarding I-SID Y is configured without data I-SID:
eapol guest i-sid Y
on onboarding I-SID interface, if it is configured without data I-SID:
untagged-traffic port X
on data I-SID interface, if it is configured:
untagged-traffic port X
```

NNI States

The NNI states are as follows:

- NNI
- NNI onboarding
- NNI IS-IS
- NNI loop

If, while in the Wait state, the port receives a Fabric Connect LLDP packet, the port transitions to the NNI state and adds the IS-IS SPBM instance on the interface. The system tries to establish an IS-IS adjacency and, if successful, transitions the port to the NNI IS-IS state. The port remains in the NNI IS-IS state until the adjacency fails, at which time it returns to the NNI state.

The system performs the following background configurations on port x:

```
isis
isis spbm 1
```

```
isis enable
[isis hello-auth ...] inherited from global configuration
```

If the system cannot establish the adjacency, it transitions the port to the NNI onboarding state. The system creates a Switched UNI (S-UNI) with the onboarding I-SID.

The system performs the following background configurations:

```
flex-uni enable
isis
isis spbm 1
isis enable
[isis hello-auth ...] inherited from global configuration
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

When a port is in the Auto-sense NNI state, if an already known system ID is discovered through LLDP on a different port, the port transitions to the NNI loop state.

The NNI loop state is similar to the NNI onboarding state except that creating a secondary S-UNI results in a loop, which occurs if the neighboring system ID is already present in the SPB forwarding information base (FIB). The system tries to establish the adjacency and transition the port to the NNI IS-IS state. If the port receives a new LLDP Fabric Connect packet, it transitions back to the NNI state. If the system cannot establish the adjacency, the port returns to the NNI loop state.

Fabric Attach States

The Fabric Attach (FA) states are as follows:

- FA WAP (Access Point)
- FA PROXY
- FA PROXY NOAUTH

LLDP uses the FA TLV to detect FA-capable neighbors.

The port enters the FA WAP state after LLDP detects an access point, an FA client that is not another switch.

The system performs the following background configurations on port x:

```
flex-uni enable
eapol status auto
eapol multihost radius-non-eap-enable
eapol multihost eap-oper-mode mhmv
eapol guest i-sid X
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

If LLDP detects an FA client switch that uses FA message authentication, the port transitions to the FA PROXY state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
fa message-authentication
fa management-isis
```

If the FA client switch does not use FA message authentication, the port transitions to the FA PROXY NOAUTH state.

The system performs the following background configurations on port x:

```
flex-uni enable
fa enable
on onboarding i-sid interface, if it exists:
untagged-traffic port X
```

Voice State

If the port detects an LLDP packet from a phone, the port transitions to the VOICE state. A global Auto-sense voice configuration is not required to transition to the VOICE state.

For more information on Auto-sense voice, see [Auto-sense Voice](#) on page 32.

Auto-sense Configuration using CLI

To change the Auto-sense configuration on a port using EDM, see [Configure Basic Port Parameters](#) on page 579.

Enable Auto-sense on Port(s)

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to manually enable Auto-sense on a specific port.

Note

After a switch boots without a configuration file, Auto-sense is enabled on all ports, by default.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-sense on the port:

```
auto-sense enable
```

Example

Enabling Auto-sense on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#auto-sense enable
```

Disable Auto-sense on Port(s)

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to disable Auto-sense on a specific port. You also have the option to disable Auto-sense on the port but retain the configuration that the system applied dynamically.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable Auto-sense on the port:

```
no auto-sense enable [convert-to-config]
```

Example

Disable Auto-sense on port 1/2 but retain the configuration. The dynamic configuration becomes a manual configuration and is visible in the **show running-config** output.:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface interface gigabitEthernet 1/2
Switch:1(config-if)#no auto-sense enable convert-to-config
```

Variable Definitions

The following table defines parameters for the **no auto-sense enable** command.

Variable	Value
<i>convert-to-config</i>	Retains the Auto-sense configuration that the system applies dynamically on the specific port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.

Configure Auto-sense Fabric Attach Authentication

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure Fabric Attach authentication for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the Fabric Attach authentication key:

```
auto-sense fa authentication-key WORD<0-32>
```
3. Enable Fabric Attach message authentication:

```
auto-sense fa message-authentication
```

Example

Configuring Fabric Attach message authentication globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense fa message-authentication
```

Variable Definitions

The following table defines parameters for the **auto-sense fa** command.

Variable	Value
<i>authentication-key WORD<0-32></i>	Specifies the authentication key value.
<i>message-authentication</i>	Enables Fabric Attach message authentication globally, for ports that operate in Auto-sense mode.

Configure the Auto-sense Data I-SID on the Switch**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this task to configure Auto-sense data traffic information for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the data I-SID:

```
auto-sense data i-sid <1-16777215>
```

Example

Configuring the Auto-sense data I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense data i-sid 1000
```

Variable Definitions

The following table defines parameters for the **auto-sense data** command.

Variable	Value
<i>i-sid</i> <1-16777215>	Specifies the service instance identifier (I-SID).

Configure the Auto-sense Onboarding I-SID on the Switch**Note**

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure the onboarding I-SID for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Configure the onboarding I-SID:

```
auto-sense onboarding i-sid <1-16777215>
```

Example

Configuring the Auto-sense onboarding I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense onboarding i-sid 15000000
```

Variable Definitions

The following table defines parameters for the **auto-sense onboarding** command.

Variable	Value
<i>i-sid</i> <1-16777215>	Specifies the service instance identifier (I-SID). The default onboarding I-SID value is 15999999.

Configure Auto-sense IS-IS Authentication

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

Enable IS-IS globally.

About This Task

Perform this procedure to configure a global IS-IS authentication key for ports that are operating in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the authentication type for IS-IS hello packets on Auto-sense ports:

```
auto-sense isis hello-auth type {none|simple|hmac-md5|hmac-sha-256}
[key WORD<1-16>] [key-id <1-255>]
```

Example

Configuring simple authentication for IS-IS hello packets on Auto-sense ports:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense isis hello-auth type simple key Secure
```

Variable Definitions

The following table defines parameters for the **auto-sense isis hello-auth type** command.

Variable	Value
<code>{none simple hmac-md5 hmac-sha-256}</code>	<p>Specifies the authentication type for IS-IS hello packets on Auto-sense ports:</p> <ul style="list-style-type: none"> • none • simple - simple password authentication uses a text password in the transmitted packet. The receiving router uses an authentication key (password) to verify the packet. • hmac-md5 - MD5 authentication creates an encoded checksum in the transmitted packet. The receiving router uses an authentication key (password) to verify the MD5 checksum of the packet. • hmac-sha-256 - with SHA-256 authentication, the switch adds an hmac-sha-256 digest to each Hello packet. The switch that receives the Hello packet computes the digest of the packet and compares it with the received digest. <p>Note: Secure Hashing Algorithm 256 bits (SHA-256) is a cipher and a cryptographic hash function of SHA2 authentication. You can use SHA-256 to authenticate ISIS Hello messages. This authentication method uses the SHA-256 hash function and a secret key to establish a secure connection between switches that share the same key. This feature is in full compliance with RFC 5310.</p> <p>The default authentication type is none.</p>
<code>key WORD<1-16></code>	Specifies the authentication key (password) used by the receiving router to verify the packet.
<code>key-id <1-255></code>	Specifies the key ID.

Display Auto-sense Configuration on the Switch

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to display the Auto-sense configuration on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Auto-sense configuration:

```
show auto-sense [access-differv] [data] [eapol] [fa] [isis]
[onboarding] [qos] [voice]
```
3. Display the Auto-sense status and state on a port:

```
show interfaces gigabitEthernet auto-sense [{slot/port[/sub-port]}[-slot/port[/sub-
port]][,...]]
```

Examples

Display the Auto-sense configuration related to voice:

```
Switch:1>show auto-sense voice
=====
                        AUTO-SENSE VOICE Config
=====
I-SID      C-VID      DSCP      PRIORITY
-----
2000      2000      46        6
-----
1 out of 1 Total Num of AUTO-SENSE entries displayed
=====
```

Display the Auto-sense status and state on a range of ports:

```
Switch:1>#show interfaces gigabitethernet auto-sense 1/1-1/5
=====
                        Port Auto-sense
=====
PORT      AUTO-SENSE  AUTO-SENSE
NUM      STATUS      STATE
-----
1/1      Enable      UNI-ONBOARDING
1/2      Disable     OFF
1/3      Disable     OFF
1/4      Disable     OFF
1/5      Disable     OFF
```

Configure Auto-sense Access Ports

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to configure ports operating in Auto-sense mode to determine the Layer 3 QoS actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure Auto-sense access ports:

```
auto-sense access-diffserv [enable]
```

Example

Configure the Auto-sense access ports:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#auto-sense access-diffserv enable
```

Variable Definitions

The following table defines parameters for the **auto-sense access-diffserv** command.

Variable	Value
<i>enable</i>	Configures the ports operating in Auto-sense mode to determine the Layer 3 QoS actions the switch performs. The Auto-sense access ports override the Differentiated Services Code Point (DSCP) markings. The default configuration is enabled.

Configure Layer 2 Trusted Auto-sense Ports

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

About This Task

Perform this procedure to override incoming 802.1p bits on ports that operate in Auto-sense mode.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure Auto-sense ports as Layer 2 untrusted:

```
auto-sense qos 802.1p-override
```

Example

Configure Auto-sense ports as Layer 2 trusted:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#auto-sense qos 802.1p-override
```

IP Phone Support

Table 6: IP Phone product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
IP Phone Support	5520 Series	VOSS 8.3
	VSP 4450 Series	VOSS 8.3
	VSP 4900 Series	VOSS 8.3
	VSP 7200 Series	VOSS 8.3
	VSP 7400 Series	VOSS 8.3
	VSP 8200 Series	VOSS 8.3
	VSP 8400 Series	VOSS 8.3
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The IP phone support feature focusses on the following key points:

- Works only on the Flex UNI-enabled ports.
- For Avaya phones, you can choose to configure and send call server and file server Link Layer Discovery Protocol (LLDP) Type-Length-Value (TLV) options through the **lldp vendor-specific** CLI command.
- To reduce configuration overhead, this feature includes the Auto-sense voice mechanism to detect IP phones from LLDP signalling. After the switch detects the phone, this mechanism manages the following tasks:
 - Provides the voice VLAN to the phone, tagging, Differentiated Services Code Point (DSCP), and priority parameters through the LLDP Media Endpoint Discovery (MED) signaling options.
 - Configures a switched UNI for phone traffic and sends it to the Service Instance Identifier (I-SID) that is associated with the voice VLAN.
 - Handles the configuration, whether “trusted” or “untrusted” on the port and priority re-markings.
 - Integrates with the Auto-sense functionality. For more information on Auto-sense, see [Auto-sense](#) on page 18.

**Note**

This feature does not support auto-creation of voice VLAN and MultiLink Trunking (MLT) or Split Multi-Link Trunking (SMLT).

This feature has the following connectivity models:

- Standalone IP phone, which connects to a switch port.
- IP Phone with PC behind it, where the IP Phone has a small inbuilt bridge, and a PC connects to that bridge port.

**Note**

Phone traffic is tagged with the voice VLAN whereas the PC traffic is untagged. However, you can configure the phone to send the traffic as untagged.

The IP phone connectivity supports the following scenarios:

- Call server and file Server LLDP TLV options—These TLVs are Avaya proprietary. Use them only with the Avaya IP phones to detect the IP addresses of a Call server and File Server.
- Phone detection through LLDP messaging—Use the Capabilities and Enabled Capabilities field in the LLDP packet to detect a phone. A “T” capability identifies a phone.
- Auto-sense voice option, without NAC—Use this functionality to specify the voice VLAN and voice I-SID in a single CLI command.
- Auto-ISID-Offset—Use this functionality if the voice VLAN is received without an I-SID from a Radius response. The Auto-ISID-Offset functionality determines an I-SID automatically to send the data traffic.
- Auto-sense voice, LLDP authentication, and NEAP (MAC authentication) connectivity—If you have enabled NEAP, it authorizes all the MAC addresses received on the port and IP phone. With the LLDP authentication option, a device, such as phone, is trusted and does not require a RADIUS authentication. For this authentication, the EAP is notified after a phone is detected and the port is in the Auto-sense voice state. Then, the MAC address of the phone is added to EAP or NEAP host table.

Auto-sense Voice

The Auto-sense voice feature is an addition to the Auto-sense module. Based on the events of the phone discovery in the network, you can use this feature to configure phone devices without manual intervention.

After the switch discovers an LLDP packet with phone capabilities, the port transitions to the “voice” state. The port receives a message on the voice event details.

With the Auto-sense voice feature, you can configure the voice I-SID and the voice VLAN. If you configure the I-SID as untagged, the phone receives VLAN as zero. When you configure Auto-sense voice, switched UNI is configured in VOICE I-SID for each port that is in “voice” state. The switch adds the LLDP MED policies for voice and voice-signaling TLVs to the LLDP packet and sends LLDP packets to the phone. It uses the configured voice VLAN and default values for DSCP (46) and priority (6). After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to traffic that reaches the VOICE I-SID, which implies the voice traffic.

Note

To change the Auto-sense voice configuration on the switch, delete the earlier configured voice I-SID and VLAN entry.

After you configure auto-sense voice, following tasks take place:

- The I-SID <I-SID value> and C-VID <C-VID value> are saved in the control plane.
- The voice I-SID is created.
- The ports that are in the “voice” state process the voice configuration message and begin the dynamic configuration. This configuration includes the following tasks:
 - Creation of voice Switched UNI (S-UNI).
 - Deletion of onboarding and data I-SID, or S-UNI, if you configured auto-sense as “untagged”.

- Addition of LLDP MED voice and voice-signaling TLVs to the LLDP packet and sending of LLDP packets to the phone.
- The voice filter is updated. After you run the **auto-sense voice** command, a filter is installed to prioritize the traffic that passes through the configured I-SID. The filter applies to the traffic in Voice I-SID. The traffic that passes through this I-SID is internally prioritized with level 6 and forwarded with a dot1p value of 6, for tagged packets. For the IP packets, the DSCP value of 46 is forwarded.

Note

- To disable Auto-sense on the port but keep the dynamic configurations made by Auto-sense, use the command **no auto-sense enable convert-to-config**. The voice S-UNI loses its Auto-sense origin and has a config origin instead. The LLDP MED policies installed by Auto-sense are preserved.
- If you use the **no auto-sense voice** command, the system removes the voice S-UNI and the LLDP MED policies. The voice I-SID is removed if it was installed by using the **auto-sense voice** command. If the I-SID existed before you used the **auto-sense voice** command, the system does not remove the I-SID but the I-SID does lose its Auto-sense origin.
- A port exits the voice state in one of the following scenarios:
 - If the port is down
 - If the LLDP session fails between the switch and the phone
 - If Auto-sense is disabled on the port that is connected to the IP phone.

After a port exits the voice state, the switched UNI, LLDP voice and voice-signaling are deleted.

IP Phone Configuration using CLI

Configure Auto-sense Voice Information for IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

The switch applies the Auto-sense voice configuration on specific port(s), after it discovers IP phones on the port through LLDP packets.

Before You Begin

If you boot the switch with a configuration file, and not through Zero Touch Fabric Configuration, you must manually enable Auto-sense on specific port(s).

About This Task

Perform this procedure to configure Auto-sense voice information for IP phones.

A global Auto-sense voice configuration does not require Auto-sense LLDP authentication.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the customer VLAN ID:

```
auto-sense voice i-sid <1-16777215> c-vid <c-vid>
```
3. Configure the traffic as untagged:

```
auto-sense voice i-sid <1-16777215> untagged
```

Note

The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Example

Configure VLAN tagging as untagged:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#auto-sense voice i-sid 1234 untagged
```

Variable Definitions

The following table defines parameters for the **auto-sense voice** command.

Variable	Value
<i>i-sid</i> <1-16777215>	Specifies the service instance identifier (I-SID).
<i>c-vid</i> < <i>c-vid</i> >	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
<i>untagged</i>	Specifies the VLAN tagging type as untagged. Note: The phone receives VLAN ID as 0 and the tagging is configured as "untagged".

Configure LLDP Vendor Specific Information

About This Task

Use this procedure to configure the LLDP vendor-specific information on a call server or a file server.

Note

After you configure LLDP vendor specific call server information, the SIP Proxy of the phone is configured as transport type TLS port 5061. This option is available depending on the operating system of the call server.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. To configure LLDP vendor-specific information for a call server server, enter:

```
lldp vendor-specific call-server <1-8> <A.B.C.D>
```
3. To configure LLDP vendor-specific information for a file server, enter

```
lldp vendor-specific file-server <1-4> <A.B.C.D>
```

Example

Configure the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#lldp vendor-specific call-server 1 192.0.2.0
```

Variable Definitions

The following table defines parameters for the **lldp vendor-specific** command.

Variable	Value
<i>call-server</i> <1-8> <A.B.C.D>	Specifies the LLDP vendor specific information on the call server number and the IP address.
<i>file-server</i> <1-4> <A.B.C.D>	Specifies the LLDP vendor specific information on the file server number and the IP address.

View LLDP Vendor Specific Information

About This Task

Use this procedure to view the LLDP vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. To view LLDP vendor-specific information for a call server, enter:

```
show lldp vendor-specific call-server
```
3. To configure LLDP vendor-specific information for a file server, enter

```
show lldp vendor-specific file-server
```

Example

Display the LLDP vendor-specific information on a call server:

```
Switch:1>enable
Switch:1#show lldp vendor-specific call-server
=====
                        LLDP Call-Server
=====
```

```

NUM          IP
-----
1           192.0.2.0
2           198.51.100.0
-----
All 2 out of 2 Total Num of call-server entries displayed

```

View LLDP Neighbor Vendor Specific Information

About This Task

Use this procedure to view the remote LLDP vendor-specific information on a call server or a file server.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. To view remote LLDP vendor-specific information for a call server, enter:
`show lldp neighbor vendor-specific call-server`
3. To view remote LLDP vendor-specific information for a file server, enter:
`show lldp neighbor vendor-specific file-server`

Example

Display remote LLDP vendor-specific information on a file server:

```

Switch:1>enable
Switch:1#show lldp neighbor vendor-specific file-server
=====
Remote LLDP File-Server IP Addresses
=====
PORT      IP
-----
203      192.0.2.0, 198.51.100.0, 203.0.113.0
-----
All 3 out of 3 Total Num of remote file-server entries displayed

```

Enable LLDP Authentication of IP Phones

Note

This procedure does not apply to VSP 8600 Series and XA1400 Series.

Before You Begin

- You must enable EAPoL globally.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) authentication of IP phones. The switch authenticates the phone after it receives LLDP packets from the phone.

Auto-sense LLDP authentication applies to Auto-sense ports in the VOICE state. Auto-sense LLDP authentication does not require a global Auto-sense voice configuration.

The **no auto-sense eapol voice lldp-auth** command removes all Auto-sense LLDP sessions and removes the Auto-sense LLDP authentication configuration.

The system removes the LLDP session for the following reasons:

- You disable EAPoL globally.
- You disable Auto-sense on the port.
- The LLDP neighbor is removed.

If the LLDP authentication configuration exists and one of the following situations occur, the LLDP session is recreated:

- You enable EAPoL globally.
- You enable Auto-sense on the port.
- The LLDP neighbor is recreated.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable LLDP authentication:

```
auto-sense eapol voice lldp-auth
```

Example

Enabling LLDP authentication on the switch:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#auto-sense eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **auto-sense eapol voice** command.

Variable	Value
<i>lldp-auth</i>	Enables LLDP authentication of IP phones. By default, LLDP authentication of IP phones is enabled on the switch.

Enable LLDP Voice Authentication on a Specific Port

Note

This procedure does not apply to VSP 4450 Series, VSP 8600 Series, or XA1400 Series.

About This Task

Perform this procedure to enable Link Layer Discovery Protocol (LLDP) voice authentication of IP phones on a specific port. If the system detects a phone through LLDP, then “eapol voice lldp-auth” configuration is applied on the port that is connected to the phone.

If you run the **no auto-sense enable convert-to-config** command, the system preserves the LLDP authentication configuration.

You cannot perform this configuration on Auto-sense ports. Use Auto-sense LLDP authentication to apply LLDP authentication on all Auto-sense ports in the VOICE state.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable LLDP voice authentication on a specific port:

```
eapol voice lldp-auth
```

Example

Enabling LLDP voice authentication on a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#eapol voice lldp-auth
```

Variable Definitions

The following table defines parameters for the **eapol voice** command.

Variable	Value
<i>lldp-auth</i>	Enables LLDP voice authentication of IP phones on the selected port. By default, LLDP authentication of IP phones is enabled on the switch.

IP Phone Configuration using EDM

View Vendor Specific Call Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific call server information.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics > 802_1ab**.
2. Select **Vendor Specific**.
3. Select the **Call Server** tab.

Vendor Specific Call Server Field Descriptions

Use the data in the following table to use the **Call Server** tab.

Name	Description
CallServerNum	Specifies the call server ID.
CallServerAddressType	Specifies the IP address type of the call server.
CallServerAddress	Specifies the IP address of the call server.

View Vendor Specific File Server Information

About This Task

Perform this procedure to view inventory attributes for vendor-specific file server information.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics > 802_1ab**.
2. Select **Vendor Specific**.
3. Select the **File Server** tab.

Vendor Specific File Server Field Descriptions

Use the data in the following table to use the **File Server** tab.

Name	Description
FileServerNum	Specifies the file server ID.
FileServerAddressType	Specifies the IP address type of the file server.
FileServerAddress	Specifies the IP address of the file server.

Zero Touch Deployment

Table 7: Zero Touch Deployment product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Zero Touch Deployment	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.2
	VSP 4900 Series	VOSS 8.2 VIMs: VIM5-4YE, VIM5-4X, VIM5-4XE, and VIM5-2Y only
	VSP 7200 Series	VOSS 8.2
	VSP 7400 Series	VOSS 8.2
	VSP 8200 Series	VOSS 8.2
	VSP 8400 Series	VOSS 8.2
	VSP 8600 Series	Not supported
	XA1400 Series	VOSS 8.2

For the most current information on switches supported by ExtremeCloud™ IQ, see [ExtremeCloud™ IQ Learning What's New](#).

Zero Touch Deployment enables a VOSS switch to be deployed automatically with ExtremeCloud IQ but you still need to onboard the switch on the ExtremeCloud IQ side. When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP Server, and discovers the Domain Name Server, connecting the switch automatically to Extreme Management Center or to ExtremeCloud IQ cloud management application.

VOSS integrates with ExtremeCloud IQ using IQAgent. When you enable IQAgent, you can configure and monitor VOSS devices using ExtremeCloud IQ.

Zero Touch Provisioning Plus (ZTP+) provides Extreme Management Center connectivity to VOSS switches.

For more information about ExtremeCloud IQ Agent, see [ExtremeCloud IQ Agent](#) on page 807. For more information about ZTP+, see [Zero Touch Provisioning Plus](#) on page 42.

To use zero touch functionality, your switch must be in a Zero Touch Deployment-ready configuration mode, which means the switch cannot have existing primary or secondary configuration files loaded. Factory shipped switches are Zero Touch Deployment ready because they deploy without configuration files. However, existing switches require manual preparation before Zero Touch Deployment can function.

To prepare an existing switch for Zero Touch Deployment, the switch must boot without a configuration file. Perform one of the following actions:

- Rename existing primary and secondary configuration files. Use the **mv** command to rename the existing configuration files. For example, **mv config.cfg config.cfg.backup**.

This is the preferred option as it ensures that the primary and secondary files are removed while making a backup of them at the same time. This option also ensures that the switch uses the default config.cfg file for the final configuration after it has successfully onboarded.

- Boot from non-existent configuration files. Use the **boot config choice** command to configure the primary and backup configuration files to reference files that do not exist on the switch:

```
boot config choice primary config-file nonexistent1.cfg
```

```
boot config choice primary backup-config-file nonexistent2.cfg
```

This option also works, however, after the switch has successfully onboarded, it does not use the default config.cfg file but uses the alternative configuration file name provided instead, which might not be desired.

- Delete the existing primary and secondary configuration files. Create a backup of these files before you delete them.

Configuration Considerations

The switch configuration depends on whether you use factory default mode or Zero Touch Deployment.

Zero Touch Deployment Configuration

With Zero Touch Deployment, the switch configuration consists of the following:

- The ssh and sshd boot configuration flags are enabled by default.
- All ports are Private VLAN isolated ports, except on the XA1400 Series.
- VLAN 4048 is created as an *onboarding-vlan* for host-only connectivity for In Band management. On all other platforms, except the XA1400 Series, all front panel ports are members of VLAN 4048.
- In Band management is enabled.
- DHCP client requests are cycled between In Band and Out of Band ports, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- Out of Band management is enabled, except on the XA1400 Series and VSP 4450 Series. XA1400 Series and VSP 4450 Series support In Band management only.
- All ports are administratively enabled, except on the XA1400 Series. Only Port 1/8 is administratively enabled on the XA1400 Series, which means the administrator must plug in and use only port 1/8 for Zero Touch Deployment on an XA1400 Series.
- IQAgent is enabled by default.
- ZTP+ for XMC onboarding is enabled by default.
- Initiates Zero Touch Fabric Configuration.

For information about IQAgent, see [ExtremeCloud IQ Agent](#) on page 807.

Factory Default Mode

The switch continues to support the boot configuration flag **boot config flags factorydefaults** to return an existing switch to factory default configuration.

**Note**

Zero Touch Deployment does not run on a switch returned to factory default configuration in this manner.

For more information, see [Boot Sequence](#) on page 116.

Zero Touch Provisioning Plus

Table 8: Zero Touch Provisioning Plus product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Zero Touch Provisioning Plus	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.2.5
	VSP 4900 Series	VOSS 8.2.5

	VSP 8200 Series	VOSS 8.2.5
	VSP 8400 Series	VOSS 8.2.5
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.2.5

With zero touch functionality, VOSS switches are automatically discovered on the network the moment they are connected.

Zero Touch Provisioning Plus (ZTP+) enables you to deploy and configure VOSS switches in Extreme Management Center with minimal server configuration and intervention. ZTP+ enabled switches send information, such as the serial number, software version, MAC, management IP, and port information to Extreme Management Center automatically.

When the switch powers on, the DHCP Client obtains the IP address and gateway from the DHCP server, discovers the Domain Name Server, and connects the switch to Extreme Management Center.

ZTP+ uses HTTPS for communication between the switch and the Extreme Management Center server. The switch discovers the Extreme Management Center server by resolving the DNS name *extremecontrol.<domain-name>*.

**Important**

This feature requires a Zero Touch Deployment-ready configuration. For more information, see [Zero Touch Deployment](#) on page 40.

ZTP+ Phases of Operation

ZTP+ auto-provisioning occurs in phases after you connect the switch to the network, if the switch is in factory ship state with no valid configuration saved on the device.

Connect

The Connect phase is the first phase of ZTP+ during which the switch connects to the Extreme Management Center server on the network. The Extreme Management Center server is discovered by resolving the DNS name *extremecontrol.<domain-name>*.

If the attempt is successful, the Extreme Management Center server responds with an **Accept** message. When connectivity is established, the switch communicates with the Extreme Management Center server securely and transmits information, such as its serial number, model number. The switch then progresses to the next phase of ZTP+.

Upgrade

After a successful connect to the Extreme Management Center server, the next phase of ZTP+ is the Upgrade phase. This phase verifies that the switch is running the image file version that is currently selected as the reference version on the Extreme Management Center server.

Image file validation is initiated by the switch. After a successful connect, the switch sends an image file upgrade request to the Extreme Management Center server with details on the current image file version. If the image file versions on the switch and the Extreme Management Center server match, no upgrade is initiated, and the switch moves to the next phase of ZTP+. If the Extreme Management Center server detects a different image file version, ZTP+ initiates the .tgz image file download from a specified URL location.

After a successful image upgrade, the switch reboots and reconnects to the Extreme Management Center server. If there are errors in the image upgrade process, an event is added to the server log. The switch then retries the image upgrade.

Configuration

The next phase after the image upgrade is ZTP+ Configuration phase. During this phase, the switch queries the Extreme Management Center server for configuration updates, and initiates auto-provisioning by transmitting information, such as the image version, model name, and serial number. The switch then attempts to apply the configuration that is pushed from the Extreme Management Center server.

If the switch can still communicate with the Extreme Management Center server after the configuration is applied, the new configuration is automatically saved on the switch. The switch can be managed through the Extreme Management Center using SNMP. However, if the configuration that is pushed from the Extreme Management Center server breaks switch connectivity to the Extreme Management

Center server, the switch reboots without saving the configuration. After the switch reboots, the ZTP+ onboarding restarts.

**Note**

Any configurations pushed from the Extreme Management Center server to VOSS devices using the initial ZTP+ configuration push are not displayed in the **show log file detail** command output. The logs associated with the Cloud connector are logged internally to `state_machine.txt` and `ztp_plus.txt` files located in `/intflash/cc/cc_logs/`.

ZTP+ Considerations

The following considerations apply to ZTP+:

- Only SNMP, Login, VLANs, and Ports configuration are supported for Extreme Management Center registration.

**Note**

ZTP+ cannot manage VLAN port membership. With ZTP+, new VLANs are created with no ports. Ports cannot be removed from the onboarding VLAN. Ports cannot be added to another VLAN. VLAN port membership is managed through Auto-sense functionality or through manual configuration after initial onboarding is complete.

- Only LLDP neighbor discovery is supported. Based on the LLDP discovery, port templates can be used on the Extreme Management Center server. Enabling or disabling LLDP is not supported.
- Fabric configurations are not supported with ZTP+. After ZTP+ is configured, Extreme Management Center server can use Simple Network Management Protocol (SNMP) to remotely configure Fabric-related configurations on the switch using SNMP MIBs.
- Only the OOB port or the Management VLAN interface are used to connect the Extreme Management Center server.

**Note**

ZTP+ cannot change the Management VLAN interface. If onboarding started on the Management onboarding VLAN, this cannot be changed while using ZTP+.

Configuring ZTP+ using the CLI

This section provides procedures to configure and manage ZTP+ using the Command Line Interface (CLI).

After your VOSS device is onboarded, you have access to Extreme Management Center.

**Note**

You must configure a Segmented Management Instance to use ZTP+. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 64.

For information about onboarding switches, see <https://www.extremenetworks.com/support>.

*View ZTP+ Status***About This Task**

Use this procedure to verify the status of ZTP+ on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify that ZTP+ is enabled:

```
show application auto-provision
```

Example

The following is an example output of the **show application auto-provision** command:

```
Switch:1>show application auto-provision

Admin state      : Enabled
Operational state : Running
```

Zero Touch Fabric Configuration

Table 9: Zero Touch Fabric Configuration product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Zero Touch Fabric Configuration	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 7.0
	VSP 7400 Series	VOSS 8.0.5
	VSP 8200 Series	VOSS 7.0
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

You can use Zero Touch Fabric Configuration to deploy Fabric-capable switches in a plug and play manner with no initial configuration. The switches form a new Fabric automatically or they can connect to an existing Fabric that is Auto-sense-capable, obtain an IP address and DNS information from a DHCP server using the onboarding I-SID/VLAN, which then permits the system to automatically onboard to the management servers, such as ExtremeCloud IQ or Extreme Management Center, to conduct actual provisioning deployment of the switch. For more information about Auto-sense, see [Auto-sense](#) on page 18.

Zero Touch Fabric Configuration automatically configures SPBM and IS-IS without user intervention if you boot the switch in Zero Touch Deployment-ready configuration mode, meaning you boot without a configuration file. For more information, see [Zero Touch Deployment](#) on page 40.

Important

To add new Zero Touch Fabric Configuration devices or implement Zero Touch Fabric Configuration on existing devices, the network requires a nickname server and reachability to the DHCP server. How you implement this depends on if the network is a new deployment or an existing Fabric network that you upgrade. In a new deployment, you can meet the network requirements with one node, known as a seed node. In an existing network, functions may already exist on different nodes. For more information, see [Release Notes for VOSS](#).

Zero Touch Fabric Configuration uses the port-based Auto-sense features, that enables all ports on the switch, by default, and all ports operate in Auto-sense mode. With the support of Auto-sense, Zero Touch Fabric Configuration onboards all ports on the switch to an existing network, without having to manually enable each port. Auto-sense automatically detects neighbor capabilities and performs the configuration on the port to reach the desired connectivity with the neighbor without user invention.

With Auto-sense functionality, ports on a switch can detect whether they connect to an SPB device, an FA client, FA Proxy, Voice IP devices, or an undefined host, and then make the necessary configuration. For more information about Auto-sense, see [Auto-sense](#) on page 18.

If you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration, through Auto-sense, dynamically establishes an IS-IS adjacency between them. For more information, see [Establishing IS-IS Adjacencies](#) on page 47.

Default IS-IS Parameters

Zero Touch Fabric Configuration automatically configures the Shortest Path Bridging (SPB) and Intermediate System-to-Intermediate System (IS-IS) infrastructure to enable Fabric architecture on a switch. The system initializes the following items after you start the switch in Zero Touch Fabric Configuration mode:

- Enables Shortest Path Bridging MAC (SPBM).
- Creates a private VLAN 4048.
- Creates the Auto-sense onboarding I-SID 15999999.
- Assigns the Auto-sense onboarding I-SID 15999999 to private VLAN 4048 and also includes the management VLAN.

Note

As a best practice, use the onboarding I-SID for onboarding purposes and, whenever possible, configure a management VLAN or management CLIP on a different I-SID after the onboarding procedures have been successfully completed.

- Enables Auto-sense on all ports.
- Configures Auto-sense access ports and layer 2 trusted Auto-sense ports.

- Creates an SPBM instance.
- Enables IS-IS globally.

Parameter	Default value
SPBM instance	1
Primary B-VLAN	4051
Secondary B-VLAN	4052
Manual area	Initialize to 00.1515.fee1.900d.1515.fee1.900d Note: You can change the manual area dynamically, without disabling IS-IS, only when the area is the Zero Touch Fabric Configuration area. When IS-IS is enabled, you cannot delete the last manual area.
Auto-sense onboarding I-SID	15999999

Establishing IS-IS Adjacencies

Zero Touch Fabric Configuration automatically triggers when the switch boots without a configuration file, the platform enables Intermediate System-to-Intermediate System (IS-IS) without a configured nickname or manual area. The system creates default backbone VLANs (B-VLAN) (4051 and 4052) and IS-IS manual area values. As a result, if you start two nodes in a network without an existing configuration file, then Zero Touch Fabric Configuration dynamically establishes an IS-IS adjacency between them.

The switch uses the Auto-sense functionality with the Zero Touch Fabric Configuration feature to establish the adjacency between two nodes. For more information about how and when the system tries to establish the adjacency, see [Auto-sense Port States](#) on page 20 .

- If you manually configure an SPBM instance on a node, then the system removes the SPBM instance that is dynamically created by Zero Touch Fabric Configuration. The system uses the LLDP Fabric Connect TLV to send user-defined B-VLANs to other nodes in the network. Only the first pair of B-VLANs is learned. If the switch already learned the B-VLANs from neighbor_A, the switch ignores the B-VLANs received from neighbor_B, if those are different.
- If a switch operating in Zero Touch Fabric Configuration mode in the network receives B-VLANs from a neighboring switch, which do not match the default B-VLANs configured through Zero Touch Fabric Configuration, then the switch will perform the following actions:
 - Disables ISIS.
 - Deletes its VLANs.
 - Unassigns the B-VLANs.
 - Assigns the values received through LLDP Fabric Connect TLV.
 - Creates the corresponding VLANs.
 - Re enables ISIS and log a message on the console.

LLDP Fabric Connect TLV

The system uses an LLDP Fabric Connect TLV to communicate B-VLANs, system IDs, Fabric Attach and EAP events between nodes in the SPB cloud.

Table 10: LLDP Fabric Connect TLV Format

TLV Type	TLV Length	OUI	Subtype	Fabric Connect Capabilities	B-VLANs Number	B-VLAN-1	B-VLAN-2	System ID Length	System ID
7 bits	9 bits	3 octets	1 byte	1 byte	1 byte	2 bytes	2 bytes	1 byte	6 bytes

Table 11: LLDP Fabric Connect TLV Field Descriptions

TLV Field	Description
Fabric Connect capability	Fabric Connect capability is enabled on all nodes that support Zero Touch Fabric Configuration. The value is 0 if the LLDP Fabric Connect TLV is not carrying any information in it. By default, the value is set to 1 on all ports.
B-VLANs number	Specifies the number of B-VLANs that the TLV can carry. The LLDP Fabric Connect TLV supports an unlimited number of B-VLANs, but Zero Touch Fabric Configuration sends 2 B-VLANs through the TLV. The value is 0 if the node is sending default B-VLAN values.
B-VLANs	Specifies the B-VLAN that is user-configured or dynamically learned from a neighbor node in the network.
System ID Length	Specifies the length (in bytes) of the System ID.
System ID	Specifies the IS-IS system ID.
OUI	Specifies the Extreme OID value (0xd88466).

This section details administrative tasks to configure a Segmented Management Instance. A Management Instance is required to provide access to specific management applications.

With Segmented Management, the Management plane (management protocols) is separated from the Control Plane (routing plane) from a process and data-path perspective. Segmented Management is the

only method to management switches. One or a combination of the following management interface/management instance types can be used:

- Out-of-Band (OOB) management IP address (IPv4 and/or IPv6)
- In-band Loopback/circuitless IP (CLIP) management IP address (IPv4 and/or IPv6)
- In-band management VLAN IP address (IPv4 and/or IPv6)

Segmented Management provides better security because you cannot reach the management instance from outside the VRF (in case of CLIP) or outside VLAN/I-SID (in case of management VLAN) and because it has a built-in firewall for the management plane. There is also more predictability with symmetric traffic flows for management traffic originating from and terminating on the switch, for instance:

- Sessions originated from switch (client mode) - Source IP of packets is determined based on Management IP stack routing table weights (configurable).
- Sessions connecting to switch (server mode) - Source IP is derived from session connection and reply will go out on management interface packet.

Segmented Management Instance Overview

The Segmented Management Instance provides support for management interfaces that transmit and receive packets directly to and from the system native Linux IP stack. The management interfaces do not route packets through the VOSS networking IP stack.

Management Applications

The following management applications use the Segmented Management Instance directly to transmit or receive packets with segmented management interfaces and addresses.

Note:

The VSP 8600 Series only supports Ping, Traceroute, and NTPv4.

Segmented Management Instance Applications and Protocols	Client	Server	IPv4	IPv6
Digital Certificates	Yes		Yes	
DHCP Client	Yes		Yes	
DNS	Yes		Yes	Yes
FTP	Yes	Yes	Yes	Yes
HTTP/HTTPS		Yes	Yes	Yes
IQAgent	Yes		Yes	
NTPv4	Yes	Yes	Yes	Yes
OVSDB protocol support for VXLAN Gateway	Yes	Yes	Yes	

Segmented Management Instance Applications and Protocols	Client	Server	IPv4	IPv6
Ping	Yes	Yes	Yes	Yes
RADIUS	Yes		Yes	Yes
RADIUS Security (RADSec)	Yes		Yes	Yes
Representational State Transfer Configuration Protocol (RESTCONF)		Yes	Yes	
SSH/SCP/SFTP	Yes (SSH only)	Yes	Yes	Yes
Syslog	Yes		Yes	Yes
TACACS+	Yes		Yes	
Telnet	Yes	Yes	Yes	Yes
TFTP	Yes	Yes	Yes	Yes
Traceroute	Yes	Yes	Yes	Yes

The following management applications do not use the Segmented Management Instance directly to transmit or receive packets, but can integrate with segmented management interfaces and addresses.

Segmented Management Instance Applications and Protocols	IPv4	IPv6
Link Layer Discovery Protocol (LLDP)	Yes	Yes
SynOptics Network Management Protocol (SONMP)	Yes	
Sampled Flow (sFlow)	Yes	
Remote Network Monitoring version 2 (RMON2)	Yes	

Note

The following management applications do not use the Segmented Management Instance and are deprecated in VOSS.

- NTPv3
- Remote Login (rlogin)
- Remote Shell (RSH)

Segmented Management Instance Migration

Important

VOSS 8.2 introduced changes to Segmented Management Instance that required migration of legacy management interfaces. Before you upgrade to VOSS 8.2 or later from an earlier release, you must consider your management interface configuration and migration scenario requirements. Backup and save your configuration files off the switch before upgrading to this release.

If the switch already runs VOSS 8.2 or later, you can ignore this section. This section does not apply to VSP 8600 Series.

Note

Management interface access to the switch can be lost if you do not perform the applicable migration scenarios before upgrading to this release. Loss of management access after an upgrade can result in an automatic roll-back to the previous software version.

You must perform a manual software commit after upgrading from VOSS Release 8.1.5.0 or earlier to VOSS 8.2 or later. Management interface access is required to input the `software commit` CLI command within 10 minutes after the upgrade. If the time expires the system initiates an automatic roll-back to the previous release.

You must ensure the switch runs one of the following VOSS releases before you upgrade to VOSS 8.2 or later to support the **migrate-to-mgmt** functionality:

- VOSS 8.1.0.0 or later for switches running VOSS 8.1.x releases.
- VOSS 8.0.1.0 or later for switches running VOSS 8.0.x releases.
- VOSS 7.1.3.0 or later for switches running VOSS 7.1.x releases.

Note

If the network environment must migrate static IPv6 routes, the switches must run VOSS Release 8.1.2.0 or later before you upgrade to VOSS 8.2 or later.

Not all upgrade paths are validated by Extreme Networks for each new software release. Always refer to [Release Notes for VOSS](#) to understand the validated upgrade paths.

You must consider the following legacy management interface migration scenarios before you upgrade to VOSS 8.2 or later:

Table 13: Management Interface Migration Scenarios

Mgmt Interface	Mgmt Scenario	Migration Description
DVR leaf	Automatic migration during upgrade.	DvR leaf settings migrate automatically during the software upgrade process. Note: Leaf nodes only support the management CLIP as part of the Global Routing Table (GRT).
OOB	Automatic migration during upgrade.	Out-of-Band management settings migrate automatically during the software upgrade process.
CLIP	Specify a Circuitless IP (CLIP) interface for migration to management interface before upgrading.	Use the migrate-to-mgmt command in the Loopback interface configuration CLI to specify the CLIP interface for management before starting the software upgrade process. The loopback IP to migrate can include the configured ISIS IP shortcuts. Save the configuration before upgrading. A Fabric or legacy Layer 3 network typically uses the CLIP management interface. Important: Ensure that the management CLIP IP address does not fall into the range of a configured VLAN IP address range as this is not allowed.
VLAN	Specify a VLAN interface for migration to management interface before upgrading.	Use the migrate-to-mgmt command in the VLAN interface configuration CLI mode to specify the VLAN interface for management before starting the software upgrade process. Save the configuration before upgrading. A Layer 2 network typically uses the VLAN management interface, or for restricting management access to a specific subnet or I-SID.

Automatic Migration

Out-of-Band management interface and DVR leaf configurations automatically migrate during the upgrade process. The management port interface, and all associated applications are moved to the Segmented Management Instance .

A DVR leaf has a single management interface that also automatically migrates during the upgrade process to the Segmented Management Instance.

Static Route Migration

When a VLAN designated as management interface or an Out-of-Band management interface migrates to the Segmented Management Instance, static routes might be required for IP reachability. Static routes are always required for Out-of-Band management interfaces but can also be used with in-band VLAN management.

Static route migration is completed by the upgrade process and no commands are necessary to prepare for the migration. The following logic is applied during the upgrade process to the static routes:

- Out-of-Band management interfaces
 - All IPv4 routes in the VRF 512 / mgmtrouter context are moved to the Segmented Management Instance.
 - All IPv6 routes in GRT with a nexthop IP address that exists in the same subnet as the IPv6 address are moved to the Segmented Management Instance.
- In-Band VLAN management
 - All IPv4 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv4 address being migrated are moved to the Segmented Management Instance.
 - All IPv6 routes from the VRF bound to the migrated VLAN and that have a nexthop IP address in the same subnet as the IPv6 address being migrated are moved to the Segmented Management Instance.

Consider the following example of In-Band VLAN management. The static route configuration listed below is in the GRT:

```
ip route 192.168.20.0 255.255.255.0 192.168.10.2 weight 1
ip route 192.168.30.0 255.255.0.0 192.168.10.50 weight 1
ip route 192.168.40.0 255.255.255.0 192.168.20.99 weight 1
ip route 192.168.50.0 255.255.255.0 192.168.10.2 weight 1
no ip route 192.168.50.0 255.255.255.0 192.168.10.2 enable
```

The GRT is associated with VLAN 10 with an IP address of 192.168.10.1. This is the VLAN to be migrated. After the upgrade, the 192.168.20.0, 192.168.30.0, and, 192.168.50.0 routes are migrated to the management instance because their nexthop IP address is associated with the 192.168.10.0/24 subnet.

Note

All routes with a nexthop IP address associated with the subnet are migrated. This includes administratively disabled routes. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

ECMP static route migration is not supported for the Segmented Management Instance. For an ECMP static route, only the first path in the configuration file migrates.

After upgrading to VOSS Release 8.1.60 or later, any administratively disabled static routes that migrated to the OOB or VLAN Segmented Management Instance subnet become active. Administratively disabled routes must be manually deleted after the upgrade if the route is not needed.

The static route configuration in the Management VLAN configuration block will be the following after the upgrade:

```
mgmt vlan 10
ip address 192.168.10.1/24
ip route 192.168.20.0/24 next-hop 192.168.10.2
ip route 192.168.30.0/16 next-hop 192.168.10.50
ip route 192.168.50.0/24 next-hop 192.168.10.2
```

Segmented Management Instance Migration

Beginning in VOSS 8.2, you can use the **migrate-to-mgmt** command to move a management VLAN to a different VLAN ID, or a management CLIP to a different VRF. After you complete the command and save the configuration, the migration to management of the selected interface occurs during the next switch reboot. The following is an outline of the steps required for management migration:

- Configure a new or existing VLAN or CLIP management interface using Interface Configuration mode in the CLI (**interface vlan <vlan_id>** or **interface loopback <clip_id>**) or EDM.
- Add required routes to reach management services and subnets from the new interface.
- Test connectivity to the new interface using ping and traceroute, and from the switch to management stations and servers.
- Use the **migrate-to-mgmt** command from the new interface CLI mode.
- Save the configuration and reboot.

Note

During boot, the migrate-to-mgmt settings are parsed and override the existing management interface with the new interface.

- Access and manage the switch from the new interface.

XA1400 Series Management Migration with a Fabric Extend Source IP VLAN

Before VOSS Release 8.1.60, a single IP address could be used for both routing or management, however Segmented Management Instance separates the routing and management networking stacks. Because **migrate-to-mgmt** can only move an IP from the routing stack to the management stack, see the following scenario for a before and after upgrade process required to manage a XA1400 Series with the Fabric Extend (FE) tunnel Source IP using Segmented Management Instance:

Before upgrading to VOSS Release 8.1.60 or later:

- Configure a CLIP Management Instance or designate an existing loopback IP for migration.
- Save configuration and reboot.

After upgrading to VOSS Release 8.1.60 or later:

- Manage the XA1400 Series using the CLIP Management Instance.
- Create the VLAN Management Instance with the same VLAN ID and IP address as the FE tunnel source VLAN.
- Modify the default route or create static routes to the VLAN Management Instance.
- Manage the XA1400 Series with the VLAN or CLIP Management Instance.

DHCP Client

To support Zero Touch Deployment, a DHCP Client is used for the Segmented Management Instance VLAN management interface or Out-of-Band (OOB) management interface. The DHCP Client configuration supports a VLAN mode, OOB mode, and a cycle mode. DHCP Client cycle mode alternates IP address requests between the VLAN management interface and OOB management interface until an IP address is obtained on one of the interfaces. Priority is given to the OOB management interface.

You can also manually configure the DHCP Client to request an IPv4 address from a DHCP server for the In-band VLAN management interface, or the OOB management interface, or to cycle requests until an IP address is obtained on a VLAN or OOB management interface. The DHCP Client supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously.

Note

If a default route is configured on an OOB or VLAN management interface, and then you configure DHCP so that it replaces the default route, the original default route is restored if you disable DHCP.

However, if the DHCP default route is updated or deleted after it is created by DHCP, the default route will not be replaced by the original route when DHCP is disabled.

DHCP Option 43

DHCP option 43 requests specific vendor options from the DHCP server. Only sub-option 226 (EXTREME.cloudiq-ip) is supported to change the value of the ExtremeCloud IQ server IP address on the switch.

With the support of DHCP option 43, DHCP can dynamically configure the IP address of a private/non-public ExtremeCloud IQ server for zero touch deployments when the default ExtremeCloud IQ server (hac.extremecloudiq.com) is not desired.

For information about configuring the switch to support ExtremeCloud IQ, see [ExtremeCloud IQ Agent](#) on page 807.

DHCP Option 43 Configuration Examples

This section provides examples to configure DHCP Option 43 on a Linux server and on Windows Server.

ISC DHCP Server configuration on Linux:

```
/etc/dhcp/dhcpd.conf
default-lease-time 60;
max-lease-time 7200;
option space EXTREME;
option EXTREME.cloudiq-ip code 226 = ip-address;

class "Edge-without-POE" {
    match if (option vendor-class-identifier = "EXTREME");
    vendor-option-space EXTREME;
    option EXTREME.cloudiq-ip 10.16.231.131;
}

subnet 30.30.30.0 netmask 255.255.255.0 {
    pool {
        range 30.30.30.10 30.30.30.20;
```

```

        allow members of "Edge-without-POE";
    }
    option domain-name-servers 10.1.10.1;
    option domain-name "labs.extremenetworks.com";
    option routers 30.30.30.250;
    default-lease-time 3600;
}

```

Windows Server configuration:

1. Go to scope options for defined DHCP pool.
2. Enter the following for Option 43: e2 04 0a 10 e7 83

Value	Description
e2 04	vendor ID prefix (e2 is the hexadecimal value of the code 226 used to identify sub-option EXTREME.cloudiq-ip and 04 the hexadecimal value of the length of an IP address in bytes)
0a 10 e7 83	IP address 10.16.231.131 converted to hexadecimal

Segmented Management Instance Interface Types

The Management Instance supports the following interface types:

- Management Instance CLIP
 - You can assign a circuitless management IP (CLIP) address bound to a VRF.
 - The IP address is not bound to a physical network; it does not transmit nor receive IPv4 Address Resolution Protocol (ARP) or IPv6 Neighbor Discovery (ND) messages.
 - You do not need to configure a default or static route. This interface type uses all routing information learned by protocols attached to the VRF.
 - Packets can ingress on any port or VLAN in the VRF. You can configure accept policies to access the Management Instance CLIP from other VRF. Inter-VRF access is not permitted with traditional IP routing using OSPF, BGP, or RIP. Packets ingressing the switch from a VLAN belonging to a different VRF without a configured accept policy will not reach the Management Instance CLIP IP address.
 - You can use this interface type for CLIP management network routing in a Fabric network or Layer 3 routing network.
- Management Instance OOB
 - You can assign a management IP address bound to the Out-of-Band (OOB) interface.
 - The Dynamic Host Configuration Protocol (DHCP) Client can request an IPv4 address for the Management Instance OOB interface.
 - You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.
 - You can use this interface type for OOB management network routing, as an alternative to in-band network routing management.
- Management Instance VLAN
 - You can assign a Management Instance IP address to an inband VLAN.
 - The DHCP Client can request an IPv4 address for the Management Instance VLAN interface.
 - The interface resides on the physical VLAN segment, behaving as a host for sending and receiving IPv4 ARP and IPv6 ND messages.

- You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link (other subnets) networks.
- No internal routing occurs between other non Management Instance VLANs. Packets must ingress on one of the ports in the VLAN.
- You can use the Management Instance VLAN for management network routing, such as binding the Management Instance VLAN to an I-SID, which routes all management traffic to a single I-SID in a Fabric network. Also, other normal VLAN related operations such as VLAN port member changes are valid.

You can create only one of each interface type.

Segmented Management Instance Considerations and Restrictions

This section identifies considerations and restrictions for the Segmented Management Instance.

You can configure a maximum of three Management Instance interfaces, one of each type; an Out-of-Band (OOB) management interface, a Circuitless IP (CLIP) management interface, and a VLAN management interface.

You can configure the route priority for the Segmented Management Instance. The Source IP default route priority is management CLIP (weight 100), then management VLAN (weight 200), then management OOB interface (weight 300). You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

Note

The VSP 8600 Series Segmented Management Instance does not support ACL based filters or use of ping with -Q option to change the internal priority of management traffic.

You can configure the default topology IP for LLDP and SONMP advertisements. Both LLDP and SONMP advertise the same topology IP. SONMP supports only IPv4 addresses. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

IPSec is not supported on Segmented Management Instance management interfaces.

DHCP Client for Segmented Management Instance

DHCP Client for the Segmented Management Instance supports IPv4 addresses only, and cannot be enabled on multiple management interfaces simultaneously. The DHCP Client only supports the in-band

VLAN management interface, or the OOB management interface, or to cycle requests on the the VLAN then OOB management interface until an IP address is obtained on one of the interfaces.

**Note**

The DHCP Client is disabled by default on previously configured or upgraded switches. The DHCP Client is enabled by default in cycle mode when:

- The switch ships directly from manufacturing with VOSS Release 8.1.60 or later.

The primary and secondary configuration file is not on the switch.

The primary and secondary configuration file fail to load on the switch.

The DHCP Client is not available if RMON2 is configured on a Management Instance, and RMON2 is not available if the DHCP Client is configured on a Management Instance.

When DHCP is enabled on a Management Instance interface, the DHCP Client initial broadcast discovery packet and initial response from the DHCP server are not counted or shown in KHI management statistics for the management interface. Only the packets after the DHCP IP address assignment completes are counted and shown. After an IP address is assigned, a UDP socket opens and packets are counted on the interface.

If you change the DHCP Client configuration between management VLAN, OOB, or cycle, the default route provided by the DHCP server might delete and add with a different nexthop or network. DHCP Client configuration changes can cause interruptions to existing management connections.

DHCP static routes are not saved in the configuration file or displayed in **show running-config**. You can view DHCP static routes with **show mgmt ip route static**. If the DHCP Client adds a default route to an interface, the previous default route is deleted. If you modify a default route created by the DHCP Client, the route type output of **show mgmt ip route static** changes from DHCP to STATIC. You can save the modified to static default route to the configuration file, but on reboot the DHCP Client deletes the modified default route and restores the default static route the DHCP server specifies.

OOB Management Instance

**Note**

OOB Management Instance is not supported on VSP 8600 Series or XA1400 Series.

You can associate only one OOB interface with an OOB Management Instance IP address.

You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

You can only configure Layer 3 networking parameters in **mgmt OOB** interface CLI mode. You can only configure Layer 1 and Layer 2 networking parameters in **interface mgmtEthernet mgmt** CLI mode.

CLIP Management Instance

You can associate only one VRF ID with a CLIP Management Instance IP address.

You must configure a new loopback interface **isis ip-source address** if you migrate the current ISIS IP address to the CLIP Management Instance when the IP address is the same as a previously configured IP shortcut.

Advertisement of the IPv4 or IPv6 address in the GRT for the CLIP Management Instance to ISIS occurs automatically. Advertisement of the IPv4 or IPv6 address in the VRF Layer 3 VSN bound to the CLIP Management Instance occurs automatically. You must configure route redistribution to advertise the CLIP Management Instance to different protocols.

You must configure accept policies or configure inter-VRF route redistribution to access the CLIP Management Instance from a different VRF.

Packets sent to the CLIP Management Instance IP address must ingress the switch from a VLAN associated with the VRF associated with the CLIP Management Instance.

UDP server applications such as TFTP or RADIUS dynamic server or SMMP can have limitations when multiple Segmented Management Instances are configured with overlapping or asymmetrical routing:

**Note**

The limitations listed do not apply to TCP applications or if a single Management Instance is configured.

- Client communication to the CLIP Management Instance IP address is from the same subnet as the VLAN Management Instance.
- Client communication to the CLIP Management Instance IP address when specific static routes or default route with higher preference back to the client network exist on OOB Management Instance or VLAN Management Instance.
- Client communication to the OOB Management Instance IP address or VLAN Management Instance IP address that relies on a default route with a lower preference than the internal default route used by the CLIP Management Instance.
- Client communication to the CLIP Management Instance IP address is from the same subnet as the OOB Management Instance (even if the OOB port is down).

Asymmetrical routing can occur in any of these three scenarios. For the first two scenarios you can use the OOB or VLAN Management Instance IP address instead of the CLIP Management Instance IP address. Also, use FTP or SCP file transfer as an alternative since those protocols are TCP based.

The third scenario, you can configure more specific static routes for networks originating UDP client communication to the OOB or VLAN Management Instance IP address if the CLIP Management Instance is also configured.

VLAN Management Instance

**Note**

VLAN Management Instance is not supported on VSP 8600 Series.

You can associate only one VLAN ID with a VLAN Management Instance IP address.

You must configure a default or static route to reach the next-hop gateway; no routing protocol information is used to access off-link networks.

For the VLAN Management Instance to take route priority when used in conjunction with the CLIP Management Instance, you must configure a default route for the VLAN Management Instance with a value lower than 100, or configure static routes for direct communication over the VLAN Management Instance and management networks.

Packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the VOSS routing VLAN and the VLAN Management Instance.

If you configure the same VLAN ID for VOSS routing and for the VLAN Management Instance, the VOSS routing stack transmits and receives all ARP, ND, and ICMP packets. In this scenario, the packets are only counted and shown in the VOSS routing KHI port statistics. The management statistics and KHI management statistics do not count or show the packets.

IPv4 and IPv6 address co-existence for both VOSS routing VLAN and VLAN Management Instance is supported, however you must manually match both IP address configurations between the VLANs. For example, the following configuration is not supported:

- VLAN Management Instance with both IPv4 and IPv6 address routing but only the IPv4 or IPv6 address configured for VOSS routing VLAN.

If you configure the VLAN Management Instance with a manual IPv4 address and a DHCP IPv4 address first, you cannot add a IPv4 address to a VOSS routing VLAN.

If you configure the VLAN Management Instance with an IPv6 address first, you can only add one IPv6 global address to a VOSS routing VLAN.

Configuration Example - Coexistence with Port-Based VLAN

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a routing port-based VLAN.

You can configure the VOSS VLAN first and then configure the VLAN Management Instance or vice versa. You can remove or readd the coexistence at anytime.

Note

With the coexistence between VOSS routing stack and the VLAN Management Instance, packets sent to the VLAN Management Instance IP address must ingress the switch from a VLAN port (or contain the VLAN ID) associated with the VLAN Management Instance. The system does not route packets between the VOSS routing VLAN and the VLAN Management Instance.

IPv4

```
vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ip address 192.0.2.0/24
exit
mgmt vlan 10
ip address 192.0.2.0/24
ip route 0.0.0.0/0 next-hop 192.0.2.1
enable
```

IPv6

```

vlan create 10 type port-mstprstp 0
vlan members add 10 1/1
interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
exit
mgmt vlan 10
ipv6 address 2001:DB8::/32
ipv6 route 0::0/0 next-hop 2001::1
enable

```

Configuration Example - Coexistence with Brouter Port

The following example shows how the VLAN Management Instance can be configured to share the same IP address as a brouter interface.

You must configure the brouter interface before you enable the VLAN Management Instance. When the VLAN Management Instance is enabled, you must disable the VLAN Management Instance before you disable the brouter port.

IPv4

```

interface GigabitEthernet 1/1
no shutdown
brouter port 1/1 vlan 10 subnet 192.0.2.0/24
mgmt vlan 10
ip address 192.0.2.0/24
enable

```

IPv6

```

interface GigabitEthernet 1/1
no shutdown
ipv6 interface vlan 10
ipv6 interface address 2001:DB8::/32
ipv6 interface enable
mgmt vlan 10
ipv6 address 2001:DB8::/32
enable

```

Considerations and Restrictions

The following considerations and restrictions apply when a VLAN Management Instance coexists with a port-based VLAN or with a brouter port.

- If you want a dual stack IPv4 and IPv6 coexistence between VOSS and VLAN Management Instance, you must configure the same IPv4 and IPv6 addresses on the VLAN Management Instance and on the VOSS VLAN.

You cannot configure VLAN Management Instance with both IPv4 and IPv6 and configure the VOSS VLAN with IPv4 or IPv6 only.

- If you disable VOSS routing for IPv4, then you must disable routing for IPv6, and vice versa.

Segmented Management Instance Configuration using the CLI

This section provides procedures to configure segmented management instance using the command line interface (CLI).

Create a Segmented Management Instance

You must create a Management Instance to gain access to specific management applications. After you create the Management Instance, you can add an IP address to it and configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

A management VLAN is used for Layer 2 deployments. In a Layer 3 routing or Fabric deployment, use a management CLIP. For Out-of-band Management, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create the Management Instance required for your deployment:

- a. To create a management CLIP:

```
mgmt clip [vrf WORD<1-16>]
```

Note

If you do not specify a VRF, the management CLIP uses the GRT. You cannot use mgmtrouter as the VRF.

OR

- b. To create a management OOB:

```
mgmt oob
```

OR

- c. To create a management VLAN and associate it with an existing port-based VLAN:

```
mgmt vlan <2-4059>
```

3. Enable the Management Instance:

```
enable
```

Example

Create and enable a Management CLIP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#enable
```

Create and enable a Management OOB:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#enable
```

Create and enable a Management VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan 20
Switch:1(mgmt:vlan)#enable
```

Delete a Segmented Management Instance

Use this task to delete a Management Instance. Deleting the Management Instance removes the IP address, and changes the associated VRF for a management CLIP.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Delete the Management Instance:
`no mgmt {clip | oob | vlan}`

Configure the DHCP Client for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure the DHCP Client to obtain an IPv4 address for the Management Instance VLAN interface or Out-of-Band interface.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`

2. Enable and configure the DHCP Client for a management interface:
`mgmt dhcp-client {cycle | oob | vlan}`
3. Disable and clear the DHCP Client configuration for a management interface:
`no mgmt dhcp-client`

Example

The following example configures the DHCP Client to cycle IPv4 requests for the management OOB interface, and then the In-Band management VLAN interface; priority is given to the OOB interface. The system cycles attempts until one management interface receives an IP address from the DHCP server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt dhcp-client cycle
```

Variable Definitions

The following table defines parameters for the **mgmt dhcp-client** command.

Variable	Value
<i>cycle</i>	DHCP Client cycles IP requests for in-band VLAN and Out-of-Band management interfaces.
<i>oob</i>	DHCP Client requests an IP address for the Out-of-Band management interface.
<i>vlan</i>	DHCP Client requests an IP address for the VLAN management interface.

Configure an IP Address for a Segmented Management Instance

Use this task to add an IPv4 or IPv6 address to a Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enter the configuration mode for the Management Instance:
`mgmt {clip | oob | vlan}`
3. Add an IPv4 address:
`ip address {A.B.C.D [A.B.C.D] | A.B.C.D/X}`
4. Add an IPv6 address:
`ipv6 address WORD<0-255>`

Example

Add an IPv4 address to the VLAN Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip address 192.0.2.12/24
```

Add an IPv4 address to the OOB Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt oob
Switch:1(mgmt:oob)#ip address 192.0.2.12 255.255.255.0
```

Add an IPv6 address to the CLIP Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#ipv6 address 2001:DB8::1/128
```

Configure a Segmented Management Instance Interface as Default Topology IP

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure a Management Instance with a default topology IP.

Note

You can only configure one Management Instance interface as the default topology IP.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enter the configuration mode for the Management Instance:
`mgmt {clip | oob | vlan}`
3. Configure the Management Instance as the default topology IP.
`force-topology-ip`

Example

The following example configures the Segmented Management Instance VLAN as the default topology IP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#force-topology-ip
```

Configure Static Routes for a Management Instance

Use this task to configure static routes for Management Instances.

Note

Up to 100 IPv4 and IPv6 static routes can be configured.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the configuration mode for the Management Instance:

```
mgmt {clip | oob | vlan}
```

3. (Optional) Configure a static route:

```
ip route <A.B.C.D A.B.C.D | A.B.C.D/X> next-hop <A.B.C.D> [weight <1-65535>]
```

OR

```
ipv6 route WORD<0-255> [next-hop WORD<0-255>] [weight <1-65535>]
```

Example

Add a static route to configure routing for a Management Instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip route 192.0.2.2/24 next-hop 198.51.100.1
```

Variable definitions

The following table defines parameters for the **ip route** and **ipv6 route** commands.

Variable	Value
<A.B.C.D A.B.C.D A.B.C.D/X>	Specifies the IP address and mask in one of the following formats: <ul style="list-style-type: none"> • A.B.C.D A.B.C.D • A.B.C.D/X
next-hop <A.B.C.D> Or next-hop WORD<0-255>	Specifies the next hop address for the static route. Use an IP in the same subnet as the management VLAN IP address.

Variable	Value
<code>weight <1-65535></code>	Specifies the static route cost. The default is 100 for CLIP, 200 for VLAN, and 300 for OOB. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
<code>WORD<0-255></code>	Specifies the IPv6 address.

Configure MAC-offset for a Management VLAN Instance

Use this task to configure MAC-offset for a Management VLAN instance.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enter the MAC-offset for a Management VLAN instance:
`mgmt vlan mac-offset <MAC-offset>`

Note

Different hardware platforms support different ranges.

Example

Configure the MAC-offset for the Management VLAN instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#mac-offset <0-511>
```

Variable Definitions

The following table defines parameters for the **mgmt vlan** interface.

Variable	Value
<code>mac-offset <MAC-offset></code>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

Migrate a VLAN or CLIP IP address to the Segmented Management Instance

Use this procedure to designate an existing VLAN or loopback IP address to the Segmented Management Instance during an upgrade. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

About This Task

Note

Do not migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance during the upgrade to this release.

Procedure

1. Enter Interface Configuration mode for either a VLAN or loopback interface:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059> or interface loopback <1-256>
```

2. Select the interface address for migration:

```
migrate-to-mgmt
```

3. View the designated interface addresses selected for migration:

```
show mgmt migration
```

4. Save the configuration selected for migration:

```
save config
```

Example

Identify an IP address currently assigned to an inband VLAN to migrate to the Management VLAN. The example assumes you already identified a CLIP address. The VRF column in **show mgmt migration** indicates where the interface is being moved from.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 20
Switch:1(config-if)#migrate-to-mgmt
Switch:1(config-if)#show mgmt migration

View Segmented Management Instance Information

Use this task to view Management Instance information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View general configuration information:
show mgmt interface [clip | oob | vlan]
3. View operational routes for the Management Instance:
show mgmt ip route [clip | oob | vlan]

OR

show mgmt ipv6 route [clip | oob | vlan]

**Note**

Routes with a type of LOCAL have a metric equal to 1.

4. View configured static routes for the Management Instance:
show mgmt ip route static [vlan | oob | clip]

OR

show mgmt ipv6 route static [vlan | oob | clip]

**Note**

Routes with a type of LOCAL have a metric equal to 256.

5. View the ARP or Neighbor Discovery cache information for the Management Instance:
show mgmt ip arp [clip | oob | vlan]

OR

show mgmt ipv6 neighbor [clip | oob | vlan]

Example

```
Switch:1>show mgmt interface vlan

Redistribution of CLIP Segmented Management Instance Examples

The CLIP Management Instance is added as a LOCAL route in the Control Processor Route Table Manager table and change list infrastructure. Existing route redistribution mechanisms redistribute local routes into the desired routing protocols within the associated VRF or across VRF instances.

Redistribute IPv4 CLIP Management Instance to OSPF in GRT

```

router ospf
 redistribute direct
 redistribute direct enable
 exit
 ip ospf apply redistribute direct

```

Redistribute IPv6 CLIP Management Instance to OSPF in GRT

```

router ospf
 ipv6 redistribute direct
 ipv6 redistribute direct enable
 ipv6 ospf apply redistribute direct

```

Redistribute IPv4 CLIP Management Instance to OSPF in VRF

```
router vrf red
ip ospf redistribute direct
ip ospf redistribute direct enable
exit
ip ospf apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to OSPF in VRF

```
router vrf red
ipv6 ospf redistribute direct
ipv6 ospf redistribute direct enable
exit
ipv6 ospf apply redistribute direct vrf red
```

Redistribute IPv4 CLIP Management Instance to BGP in GRT

```
router bgp
redistribute direct
redistribute direct enable
ip bgp apply redistribute direct
```

Redistribute IPv6 CLIP Management Instance to BGP in GRT

```
router vrf
redistribute ipv6-direct
redistribute ipv6-direct enable
ipv6 bgp apply redistribute direct
```

Redistribute IPv4 CLIP Management Instance to BGP in VRF

```
router vrf red
ip bgp redistribute direct
ip bgp redistribute direct enable
exit
ip bgp apply redistribute direct vrf red
```

Redistribute IPv6 CLIP Management Instance to BGP in VRF

```
router vrf red
ip bgp redistribute ipv6-direct
ip bgp redistribute ipv6-direct enable
exit
ipv6 bgp apply redistribute direct vrf red
```

Accept Policy for IPv4 CLIP Management Instance in GRT to VRF Red (I-SID 200)

```
#grt-->vrf
router vrf red
isis accept i-sid 0
isis accept i-sid 0 enable
isis redistribute direct
isis redistribute direct enable
exit
isis apply accept vrf red
isis apply redistribute direct vrf red

#vrf-->grt
router isis
accept i-sid 200

Configure a Segmented Management Instance Using quick-config-mgmt Utility

Use the following procedure to run the quick-config-mgmt utility script to ease the transition to the Segmented Management Instance.

Note

XA1400 Series does not support the OOB Management Instance.

Note

Product Notice: quick-config-mgmt is not supported on VSP 8600 Series.

The quick-config-mgmt utility recognizes existing configuration. For the OOB Management Instance, you can overwrite the existing configuration only. However, for the VLAN Management Instance, you can overwrite the existing configuration, or you can migrate the existing configuration to a coexistence of IP on both VOSS VLAN and management VLAN.

The quick-config-mgmt utility supports the following:

- IPv4 only
- only one interface at one time
- Out-of-Band management and In-Band VLAN management

About This Task

You can use this procedure to help you transition to a new Segmented Management Instance. You can configure IPv4, static routes, and DHCP support for the Out-of-Band (OOB) Management Instance or for the In-Band VLAN Management Instance. If configuration exists for the interface type you selected, you are prompted to replace the configured interface or to quit the utility.

Important

If you configure DHCP, any other running DHCP instance is stopped and a new DHCP instance is created on the interface. This might cause loss of connectivity.

The default values are given in square brackets. You can input your values at the prompt or you can press `Enter` to accept the default values.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enter the following command to start the utility:
`quick-config-mgmt`

Important

If DHCP mode cycle is enabled, the following warning message displays to inform you that DHCP client will be disabled, if you continue.

```
Continuing will disable dhcp and may affect your connectivity  
to the DUT. Do you want to continue? y/n [n]:
```

Example

The following examples show outputs from the **quick-config-mgmt** utility.

Configure the OOB Management Instance:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Replace an existing OOB Management Instance configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]:
MGMT OOB is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [y]:
Please enter management interface type or "q" to quit. [1]:
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by removing parts of or all of the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
```

```
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [n]
This option will remove all current config on VLAN 2.
Please enter port to be added to the in-band management VLAN or "q" to quit [1/1]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
  1 - Out of band management port
  3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit [: 1/1
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully
```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured and coexistence of mgmt and routing on same VLAN is desired:

```
Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
```

```

1 - Out of band management port
3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [y]
Please enter the Management Address IPv4 address, "d" for DHCP configuration or "q" to
quit [192.0.2.2]:
Please enter the Management Address Mask IPv4 address or "q" to quit [255.255.255.0]:
Please enter the Default Gateway Address IPv4 address, 0.0.0.0 for no default gateway,
or "q" to quit [192.0.2.5] :
Management interface created successfully

```

Configure the In-band port-based VLAN Management Instance by reusing the existing VLAN configuration when IP address is configured but coexistence of mgmt and routing on same VLAN is not desired:

```

Switch:1(config)#quick-config-mgmt
Welcome to the management interface setup utility.
You will be requested for information to initially configure the switch.
When finished the information will be applied and stored as a part of the
configuration.

Once the basic parameters are configured, additional configuration can proceed using
other management interfaces.
Press q to abort at any time.
Management interface types:
1 - Out of band management port
3 - In-band port-based VLAN
Please enter management interface type or "q" to quit. [1]: 3
MGMT VLAN is already configured.
Continuing may remove parts or all of current config.
Do you want to continue? y/n [n]: y
Please enter VLAN ID (2-4059) or "q" to quit [4059]: 2
VLAN 2 is already in use.
Do you want to re-use existing vlan configuration? y/n/q: [y]
Please enter port to be appended to the in-band management VLAN or leave empty
to keep currently configured ports or "q" to quit []: 1/1
IP address is already configured on VLAN 2.
Do you want to configure co-existence of mgmt and routing on the same vlan? y/n/q: [n]
Management interface created successfully

```

Segmented Management Instance Configuration for VOSS using EDM

Note

This section does not apply to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

Configure a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 2 routing deployment, use a management VLAN. In a Layer 3 routing or Fabric deployment, use a management CLIP. To separate management network from Layer 2 and Layer 3, use a management OOB.

Each Management Instance supports a IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Interface** tab.
5. Select **Insert**.
6. In the **InstanceId** field, select the type of Management Instance to create.
7. (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

Note

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use mgmtrouter as the VRF.

8. For a VLAN Management Instance, in the **VlanId** field, type the VLAN ID to associate the management VLAN with an existing port-based VLAN.
9. For an OOB Management Instance, in the **OOBIndex** field, select the interface port number to associate for Out-of-Band management.
10. Select the **State** check box to enable the instance.
11. To specify the interface as the default topology IP for LLDP advertisements, select **InterfaceTopologyIpFlag**.
12. To administratively enable RMON for the interface, select **RmonAdminEnable**.
13. Select **Insert**.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
InstanceId	Indicates the Management Instance type associated with this entry.
InterfaceType	Indicates the interface type.
VlanId	Specifies the VLAN ID to associate with the management VLAN.
OoBIndex	Specifies the interface ID to associate with the management OOB.
VrfName	Specifies the VRF name to associate with the management CLIP .
State	Indicates if the interface is enabled for this instance. The default is disabled.
InterfaceMacAddr	Indicates the MAC address for the interface.
InterfaceName	Indicates the interface name.
InterfaceTopologyIpFlag	Specifies if the interface is the default topology source IP.
ZtpOn	Identifies the Zero Touch Provisioning status for the interface.
RmonAdminEnable	Specifies if RMON is administrative enabled for the interface.
RmonOperEnable	Indicates the RMON operational status for the interface.
RmonIpAddress	Indicates the RMON IP address for the interface.
MacOffset	Translates the IP address into a MAC address.

Configure DHCP Client for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to configure a DHCP Client on a management interface.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Dhcp** tab.
5. In the **Client** field, select an option to configure the DHCP Client.
6. Select **Apply**.

Dhcp Field Descriptions

Use the data in the following table to use the **Dhcp** tab.

Name	Description
Client	Specifies the DHCP client configuration: <ul style="list-style-type: none"> • oob - DHCP Client on the Out-of-Band management interface. • vlan - DHCP Client on the VLAN management interface. • cycle - DHCP Client cycles between in-band and Out-of-Band management interfaces until an IP address is obtained on one management interface. • disable - DHCP Client is disabled.
ClientPreferredInterface	Shows the DHCP Client preferred management interface when in cycle mode. On reboot, the system first attempts to acquire a DHCP IP address on the preferred interface.

View IPv4 ARP Information for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 Address Resolution Protocol (ARP) information.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpArp** tab.

IpArp Field Descriptions

Use the data in the following table to use the **IpArp** tab.

Name	Description
Address	Shows the IPv4 address of the ARP entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the ARP entry.
MacAddr	Shows the MAC address for the ARP entry.
State	Shows the state of the ARP entry. The state can be one of the following: <ul style="list-style-type: none"> • reachable • stale • permanent • failed • delay

View IPv6 ND Information for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 Neighbor Discovery (ND) information.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Neighbor** tab.

Ipv6Neighbor Field Descriptions

Use the data in the following table to use the **Ipv6Neighbor** tab.

Name	Description
Addr	Shows the IPv6 address of the neighbor entry.
Instance	Shows the Management Instance ID.
IntfName	Shows the Management Instance interface name for the neighbor entry.
MacAddr	Shows the MAC address for the neighbor entry.
State	Shows the state of the neighbor entry. The state can be one of the following: <ul style="list-style-type: none"> • reachable • stale • permanent • failed • delay

Configure IPv4 Static Routes for a Management VLAN

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure static routes for the management VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpStaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select **vlan**.

7. Type the destination IP address and mask.
8. Type the next hop IP address.
9. Type a metric value.
10. Select **Insert**.

IpStaticRoute Field Descriptions

Use the data in the following table to use the **IpStaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestMask	Specifies the destination mask.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

Configure IPv6 Static Routes for a Management VLAN

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure static routes for the management VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Expand **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6StaticRoute** tab.
5. Select **Insert**.
6. For the **Instance**, select **vlan**.
7. Type the destination IPv6 address and prefix length.
8. Type the next hop IPv6 address.
9. Type a metric value.
10. Select **Insert**.

Ipv6StaticRoute Field Descriptions

Use the data in the following table to use the **Ipv6StaticRoute** tab.

Name	Description
Instance	Specifies the Management Instance.
DestAddr	Specifies the destination IP address.
DestPrefixLen	Specifies the destination prefix length.
NextHop	Specifies the next hop address for the static route. Use an IP address in the same subnet as the management VLAN IP address.
IntfName	Specifies the Management Instance interface name for the route entry.
Metric	Specifies the static route cost. The default is 200. The management CLIP uses an internal static route with a weight of 100. If you use both CLIP and VLAN and need to force all default traffic out the management VLAN interface, configure a default static route with a weight lower than 100.
State	Shows if the route is active or inactive.

View IPv4 Operational Routes for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv4 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpRoute** tab.

IpRoute Field Descriptions

Use the data in the following table to use the **IpRoute** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
DestMask	Shows the destination mask of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 1.

Name	Description
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View IPv6 Operational Routes for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Route** tab.

Ipv6Route Field Descriptions

Use the data in the following table to use the **Ipv6Route** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
PrefixLen	Shows the destination prefix length of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

Migrate an IP Address to a Segmented Management Instance

Note

This procedure is not applicable for VOSS release 8.1.60 or later. You can only configure the migrate to management for a pre-existing VLAN or loopback management interface before you upgrade to this release.

Note

This procedure does not apply to VSP 8600 Series.

Use this procedure to designate an existing VLAN or loopback IP address as a Segmented Management Instance. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Migrate** tab.
5. Select **Insert**.
6. Select the instance type, either **clip** or **vlan**.
7. Specify the existing VLAN or loopback ID.
8. Select **Insert**.

Migrate field descriptions

Use the data in the following table to use the **Migrate** tab.

Name	Description
Instanceld	Specifies the interface instance to migrate.
InterfaceIndex	Shows the interface index of the identified interface.
InterfaceType	Shows the interface type.
Description	Shows the interface description.
VlanId	Specifies the VLAN ID for a port-based VLAN.
LoopbackId	Specifies the loopback ID.

Name	Description
VrfName	Shows the VRF associated with the loopback interface.
IpAddress	Shows the IPv4 address to migrate.
IpMask	Shows the subnet mask for the IPv4 address.
Ipv6Address	Shows the IPv6 address to migrate.
Ipv6PrefixLength	Shows the prefix length for the IPv6 address.

View Topology IP for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view the default topology IP address for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **TopologyIp** tab.

TopologyIp Field Descriptions

Use the data in the following table to use the **TopologyIp** tab.

Name	Description
AddrType	Shows the IP address type for the topology IP.
Addr	Shows the IP address for the topology IP.
InterfaceName	Shows the interface name of the identified interface for the topology IP.
Instanceld	Specifies the interface instance for the topology IP.

Configure an IP Address for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to configure and view IPv4 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **IpAddress** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

IpAddress Field Descriptions

Use the data in the following table to use the **IpAddress** tab.

Name	Description
Instanceld	Specifies the interface instance.
Address	Shows IPv4 address for the interface instance.
Mask	Specifies the subnet mask of the IP address.
AddrOrigin	Shows the IP address origin.
IntfName	Shows the interface name.

Configure an IPv6 Address for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to configure or view IPv6 address information for a Segmented Management Instance.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Mgmt**.
4. Select the **Ipv6Address** tab.
5. Select **Insert**.
6. Select the Segmented Management Instance interface type.
7. Type the address information.
8. Select **Insert**.

Ipv6Address Field Descriptions

Use the data in the following table to use the **Ipv6Address** tab.

Name	Description
Instanceld	Specifies the interface instance.
Address	Shows IPv6 address for the interface instance.
PrefixLength	Specifies the prefix length for the IPv6 address.
AddrOrigin	Shows the IPv6 address origin.
IntfName	Shows the interface name.
DadStatus	Shows the IPv6 DAD status of the address.

View IP Address Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IP address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP Field Descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNotRoutes	Shows the outbound packets with no routes statistics.
ForwDatagrams	Shows the forwarded datagram packets statistics.

Name	Description
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IPv6 Address Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

Use this task to view IPv6 address statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6 Field Descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
InReceives	Shows the inbound packet statistics.
InHdrErrors	Shows the inbound packets with header errors statistics.
InAddrErrors	Shows the inbound packets with address errors statistics.
InUnknownProtos	Shows the inbound packets with unknown protocols statistics.
InDiscards	Shows the inbound packets discarded statistics.
InDelivers	Shows the inbound packets delivered statistics.
InTooBigErrors	Shows the inbound packets too big errors statistics.
InNoRoutes	Shows the inbound packets with no routes statistics.

Name	Description
InTruncatedPkts	Shows the inbound packets truncated statistics.
InMcastPkts	Shows the inbound multicast packets statistics.
InOctets	Shows the inbound octets statistics.
InMcastOctets	Shows the inbound multicast octets statistics.
InBcastOctets	Shows the inbound broadcast octets statistics
InNoECTPkts	Shows the inbound packets with no Explicit Congestion Notification (ECN) statistics.
InECT1Pkts	Shows the inbound packets with ECT(1) statistics.
InECT0Pkts	Shows the inbound packets with ECT(0) statistics.
InCEPkts	Shows the inbound packets with Congestion Ecountered (CE) statistics.
OutRequests	Shows the outbound packet requests statistics.
OutDiscards	Shows the outbound packets discarded statistics.
OutNoRoutes	Shows the outbound packets with no routes statistics.
OutForwDatagrams	Shows the forwarded datagram packets statistics.
OutMcastPkts	Shows the outbound multicast packets statistics.
OutOctets	Shows the outbound octets statistics.
OutMcastOctets	Shows the outbound multicast octets statistics.
OutBcastOctets	Shows the outpound broadcast octets statistics.
ReasmTimeout	Shows the packet reassembly timeouts statistics.
ReasmReqds	Shows the packet reassembly requests statistics.
ReasmOKs	Shows the successfully reassembled packets statistics.
ReasmFails	Shows the failed reassembled packets statistics.
FragOKs	Shows the successfully fragmented packets statistics.
FragFails	Shows the failed fragmented packets statistics.
FragCreates	Shows the fragments created statistics.

View IP ICMP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IP ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IP-ICMP Field Descriptions

Use the data in the following table to use the **IP-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InSrcQuenchs	Shows the inbound source quenchs statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.
InEchoReps	Shows the inbound echo replies statistics.
InTimestamps	Shows the inbound timestamps statistics.
InTimestampsReps	Shows the inbound timestamp replies statistics.
InAddrMasks	Shows the inbound address masks statistics.
InAddrMaskReps	Shows the inbound address mask replies statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.
OutParmProbs	Shows the outbound parameter problems statistics.
OutSrcQuenchs	Shows the outbound source quenchs statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutTimestamps	Shows the outbound timestamps statistics.
OutTimestampReps	Shows the outbound timestamps replies statistics.
OutAddrMasks	Shows the outbound address masks statistics.

Name	Description
MsgInType0	Shows the inbound Type0 messages statistics.
MsgOutType8	Shows the outbound Type8 messages statistics.

View IPv6 ICMP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view IPv6 ICMP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IPv6-ICMP** tab.
5. To clear IP statistics, select **Clear Stats**.
6. To clear IP counters, select **Clear Counters**.

IPv6-ICMP Field Descriptions

Use the data in the following table to use the **IPv6-ICMP** tab.

Name	Description
InMsgs	Shows the inbound messages statistics.
InErrors	Shows the inbound errors statistics.
InCsumErrors	Shows the inbound checksum errors statistics.
InDestUnreachs	Shows the inbound destination unreachable statistics.
InTimeExcds	Shows the inbound time exceeded statistics.
InParmProbs	Shows the inbound parameter problems statistics.
InPktTooBigs	Shows the inbound packets too big statistics.
InRedirects	Shows the inbound redirects statistics.
InEchos	Shows the inbound echos statistics.
InEchoReplies	Shows the inbound echo replies statistics.
InGroupMembQueries	Shows the inbound group member queries statistics.
InGroupMembResponses	Shows the inbound group member responses statistics.
InGroupMembReductions	Shows the inbound group member reductions statistics.
InRouterSolicits	Shows the inbound router solicits statistics.

Name	Description
InRouterAdvertisements	Shows the inbound router advertisements statistics.
InNeighborSolicits	Shows the inbound neighbor solicits statistics.
InNeighborAdvertisements	Shows the inbound neighbor advertisements statistics.
InMLDv2Reports	Shows the inbound MLDv2 reports statistics.
InType134	Shows the inbound type134 statistics.
InType136	Shows the inbound type136 statistics.
OutMsgs	Shows the outbound messages statistics.
OutErrors	Shows the outbound errors statistics.
OutDestUnreachs	Shows the outbound destination unreachable statistics.
OutTimeExcds	Shows the outbound time exceeded statistics.
OutParmProbs	Shows the outbound parameter problems statistics.
OutPktTooBigs	Shows the outbound packets too big statistics.
OutRedirects	Shows the outbound redirects statistics.
OutEchos	Shows the outbound echos statistics.
OutEchoReps	Shows the outbound echo replies statistics.
OutGroupMembQueries	Shows the outbound group member queries statistics.
OutGroupMembResponses	Shows the outbound group member responses statistics.
OutGroupMembReductions	Shows the outbound group member reductions statistics.
OutRouterStatistics	Shows the outbound router statistics
OutRouterAdvertisements	Shows the outbound router advertisements statistics.
OutNeighborSolicits	Shows the outbound neighbor solicits statistics.
OutNeighborAdvertisements	Shows the outbound neighbor advertisements statistics.
OutMLDv2Reports	Shows the outbound MLDv2 reports statistics.
OutType133	Shows the outbound Type133 statistics.
OutType135	Shows the outbound Type135 statistics.
OutType143	Shows the outbound Type143 statistics.

View UDP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view UDP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 UDP** tab.

IP/IPv6 UDP Field Descriptions

Use the data in the following table to use the **IP/IPv6 UDP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
InDatagrams	Shows the input datagram statistics.
NoPorts	Shows the number of ports statistics.
InErrors	Shows the input errors statistics.
OutDatagrams	Shows the output datagram statistics.
IgnoredMulti	Show the ignored multiport statistics.
RcvbufErrors	Shows the received buffer errors statistics.
SndbufErrors	Shows the send buffer errors statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Statistics for a Segmented Management Instance

Note

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 TCP** tab.

IP/IPv6 TCP Field Descriptions

Use the data in the following table to use the **IP/IPv6 TCP** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
ActiveOpens	Shows the active open TCP connections statistics.
PassiveOpens	Shows the passive open TCP connections statistics.
AttemptFails	Shows the TCP connection attempt failures statistics.
EstabResets	Shows the TCP connection established resets statistics.
InSegs	Shows the input segments statistics.
OutSegs	Shows the output segments statistics.
RetransSegs	Shows the retransmit segments statistics.
InErrs	Shows the input checksum errors statistics.
OutRsts	Shows the output resets statistics.
InCsumErrors	Shows the input checksum errors statistics.
Clear	Specifies to clear the statistics. Default is false.

View TCP Connections and UDP Endpoints Statistics for a Segmented Management Instance

**Note**

This procedure does not apply to VSP 8600 Series.

Use this task to view TCP connections and UDP endpoints statistics for a Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select **Stats**.
4. Select the **IP/IPv6 Socket (TCP/UDP)** tab.

IP/IPv6 Socket (TCP/UDP) Field Descriptions

Use the data in the following table to use the **IP/IPv6 Socket (TCP/UDP)** tab.

Name	Description
IPVersion	Shows the IP address version as ipv4 or ipv6.
Type	Shows the connection type as tcp or udp.
Index	Shows the index ID for the connection.

Name	Description
State	Shows the link state for the connection.
RecvQ	Shows the connection received quantity.
SendQ	Shows the connection sent quantity.
LocalAddressAndPort	Shows the local IP address and port.
PeerAddressAndPort	Shows the peer IP address and port.

Segmented Management Instance Configuration for VSP 8600 Series using EDM

Note

This section only applies to VSP 8600 Series.

This section provides procedures to configure segmented management instance using the EDM.

Configure a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

You must create a Management Instance to gain access to specific management applications.

About This Task

The Management Instance supports different management interface types. When you create the Management Instance, you specify the interface type and the switch automatically creates the appropriate instance ID for that type.

In a Layer 3 routing or Fabric deployment, use a management CLIP.

Each Management Instance supports a single IPv4 and IPv6 (global scope) management address for use by management applications.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtInterface** tab.
4. Select **Insert**.
5. In the **InterfaceType** field, select the type of Management Instance to create.

- (Optional) For a CLIP Management Instance, in the **VrfName** field, type the VRF name to associate with the CLIP instance.

**Note**

If you want to associate the GRT with the CLIP instance, type **GlobalRouter** in the **VrfName** field. You cannot use **mgmtrouter** as the VRF.

If you specify a non-default VRF, you must enable Layer 3 VSN to achieve IPv6 CLIP connectivity.

- Select the **State** check box to enable the instance.
- Select **Insert**.

MgmtInterface field descriptions

Use the data in the following table to use the **MgmtInterface** tab.

Name	Description
InstanceId	Shows a value that identifies the Management Instance type associated with this entry.
InterfaceType	Indicates the interface type.
VrfName	Specifies the VRF name to associate with the management CLIP .
State	Indicates if the interface is enabled for this instance. The default is disabled.
InterfaceMacAddr	Shows the MAC address for the interface.
InterfaceName	Shows the interface name.

Configure a Segmented Management Instance IP Address

**Note**

This procedure only applies to VSP 8600 Series.

After you create the Management Instance, you can add an IP address to it, and then configure route redistribution to advertise reachability of the Management Instance to the rest of the network.

Before You Begin

- Ensure the IP address you plan to assign is not in use by an existing VLAN or CLIP IP subnet configured on the switch.

Procedure

- In the navigation pane, expand **Configuration > Edit**.
- Select **Mgmt Instance**.
- Select the **MgmtAddress** tab.

**Tip**

If you create the interface and assign an IP address during the same EDM session, you may need to select **Refresh** on the **MgmtAddress** tab before you see the new interface to configure.

4. To assign an IPv4 address:
 - a. Select the **IpAddress** field, and then type the IPv4 address value.
 - b. Select the **IpMask** field, and then type the IPv4 Mask value.
5. To assign an IPv6 address:
 - a. Select the **Ipv6Address** field, and then type the IPv6 address value.
 - b. Select the **Ipv6PrefixLength** field, and then type the IPv6 prefix value.
6. Select **Apply**.

MgmtAddress Field Descriptions

Use the data in the following table to use the **MgmtAddress** tab.

Name	Description
InstanceId	Shows a value that identifies the Management Instance type associated with this entry.
IpAddress	Specifies the IPv4 management address.
IpMask	Specifies the subnet mask of the IPv4 management address.
Ipv6Address	Specifies the IPv6 management address. Each Management Instance supports a single IPv6 management address for use by management applications.
Ipv6PrefixLength	Specifies the prefix length of the IPv6 management address. It is /128 for a loopback interface.
Ipv6LinkLocalAddr	Shows the automatically generated link local address.
InterfaceName	Shows the interface name.

View IPv4 Operational Routes for a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

Use this task to view IPv4 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpRoute** tab.

MgmtIpRoute Field Descriptions

Use the data in the following table to use the **MgmtIpRoute** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
DestMask	Shows the destination mask of the route entry.

Name	Description
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

View IPv6 Operational Routes for a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

Use this task to view IPv6 operational routes.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtIpv6Route** tab.

MgmtIpv6Route Field Descriptions

Use the data in the following table to use the **MgmtIpv6Route** tab.

Name	Description
DestAddr	Shows the destination address of the route entry.
PrefixLen	Shows the destination prefix length of the route entry.
Metric	Shows the metric, or cost, assigned to the route entry. If multiple entries exist to the same destination, the metric determines which route is used. Routes with a type of LOCAL have a metric equal to 256.
Instance	Shows the Management Instance ID.
NextHop	Shows the next hop for the route entry.
IntfName	Shows the Management Instance interface name for the route entry.
Type	Shows the type of route entry.

Migrate an IP Address to a Segmented Management Instance

Note

This procedure only applies to VSP 8600 Series.

Use this procedure to designate an existing VLAN or loopback IP address as a Segmented Management Instance. This action moves the IP interface from the VOSS routing stack to the management stack to use with management applications.

About This Task

You cannot migrate interfaces used for routing purposes, for example, where you configure Layer 3 routing protocols.

This command does not apply to the OOB or mgmtEthernet interface. Releases that support this migration procedure automatically move the IP address on the mgmtEthernet interface from the routing stack to the Segmented Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **MgmtMigrate** tab.
4. Select **Insert**.
5. Select the instance type, either **clip** or **vlan**.
6. Specify the existing VLAN or loopback ID.
7. Select **Insert**.

MgmtMigrate field descriptions

Use the data in the following table to use the **MgmtMigrate** tab.

Name	Description
Instanceld	Specifies the interface instance to migrate.
InterfaceIndex	Shows the interface index of the identified interface.
InterfaceType	Shows the interface type.
Description	Shows the interface description.
VlanId	Specifies the VLAN ID for a port-based VLAN.
LoopbackId	Specifies the loopback ID.
VrfName	Shows the VRF associated with the loopback interface.
IpAddress	Shows the IPv4 address to migrate.
IpMask	Shows the subnet mask for the IPv4 address.
Ipv6Address	Shows the IPv6 address to migrate.
Ipv6PrefixLength	Shows the prefix length for the IPv6 address.

View Segmented Management Instance Statistics

Note

This procedure only applies to VSP 8600 Series.

View operational statistics for the Management Instance.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Mgmt Instance**.
3. Select the **Mgmt Instance** tab.
4. Select a Management Instance by placing the cursor in a cell within the applicable row.
5. Select **Graph**.

Interface Counters Field Descriptions

Use the data in the following table to use the **Interface Counters** tab.

Name	Description
RxPkts	Counts the packets received on the Segmented Management Instance.
RxError	Counts the packets received with errors on the Segmented Management Instance.
RxDrop	Counts the packets received and dropped on the Segmented Management Instance.
TxPkts	Counts the packets transmitted on the Segmented Management Instance.
TxError	Counts the packets transmitted with errors on the Segmented Management Instance.
TxDrop	Counts the packets dropped before transmission on the Segmented Management Instance.

Basic Administration

[Basic Configuration](#) on page 134

[Verification](#) on page 155

[Basic Administration Procedures using CLI](#) on page 159

[Basic administration procedures using EDM](#) on page 175

[Boot parameter configuration using the CLI](#) on page 177

[Run-time process management using CLI](#) on page 200

[Hardware status using EDM](#) on page 210

[CLI show command reference](#) on page 216

This section provides instructions to perform basic configuration of, and administrative tasks for, the chassis and software.

Examples and network illustrations in this section can illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Fundamentals

This section includes the minimum, but essential, configuration steps to:

- provide a default, starting point configuration
- establish basic security on the node

For more information about hardware specifications and installation procedures, see the following documents:

advanced-feature-bandwidth-reservation Boot Flag

Table 14: Advanced Feature Bandwidth Reservation product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Advanced Feature Bandwidth Reservation Note: If your switch does not have this boot flag, it is because the hardware reserves the bandwidth automatically with no user interaction.	5520 Series	VOSS 8.2.5
	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	Not Supported
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.0.50 XA1480 only- demonstration feature

Use the **boot config flags advanced-feature-bandwidth-reservation** command to enable advanced features on the switch. If the **boot config flags advanced-feature-bandwidth-reservation** command is disabled and you attempt to enable an advanced feature, the switch displays an error message to explain why the advanced feature failed to start, and to remind you that you must enable this boot flag for that advanced feature.

Important

If you change the configuration, you must save the configuration, and then reboot the switch for the change to take effect.

If you disable this feature and save the configuration, any configuration for advanced features remains saved in the configuration file but is not used.

5520 Series and VSP 7400 Series

By default, this boot configuration flag is enabled with the low level option for 5520 Series and VSP 7400 Series.

When disabled, you can use all ports for Layer 2 or Layer 3 forwarding of standard unicast and multicast features. Use this mode if you are not configuring advanced features. The syntax for disabling this boot configuration flag is **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, also known as Full Feature mode, the switch supports advanced features by reassigning some of the front panel ports to be loopback ports. The following advanced features require loopback ports:

- Fabric Extend
- SPB
- SMLT

- vIST
- VXLAN Gateway
- Fabric RSPAN (Mirror to I-SID)
- Application Telemetry
- IS-IS Accept Policies
- Segmented Management Instance CLIP interface

**Note**

Full Feature mode does not support PIM.

The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation [low | high]**.

The *high* level means that the switch reserves the maximum bandwidth for the advanced features.

The *low* level means that the switch reserves less bandwidth to support minimum functionality for advanced features.

**Note**

Product Notice: 5520 Series only supports the *low* level.

After the switch reserves the appropriate ports to become loopback ports, the ports are no longer visible in the output when you enter **show interfaces gigabitEthernet**.

The following list identifies ports reserved as loopback ports:

- 5520 Series reserves the following ports:
 - 5520-12MW-36W reserves ports 1/49 and 1/50.
 - 5520-24T reserves ports 1/25 and 1/26.
 - 5520-24W reserves ports 1/25 and 1/26.
 - 5520-24X reserves ports 1/25 and 1/26.
 - 5520-48SE reserves ports 1/49 and 1/50.
 - 5520-48T reserves ports 1/49 and 1/50.
 - 5520-48W reserves ports 1/49 and 1/50.
- VSP 7432CQ
 - Low reserves ports 1/31 and 1/32.
 - High reserves ports 1/29, 1/30, 1/31, and 1/32.
- VSP 7400-48Y
 - Low reserves ports 1/55 and 1/56.
 - High reserves ports 1/53, 1/54, 1/55, and 1/56

**Important**

You must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

XA1400 Series**Note**

Product Notice: This feature is available in demo mode only on XA1480 and supports low level parameter configuration automatically, which cannot be modified.

When disabled, all I-SID bindings are removed and the switch can only operate as a Backbone Core Bridge (BCB). The syntax for disabling this boot configuration flag is: **no boot config flags advanced-feature-bandwidth-reservation**.

When enabled, the switch reserves CPU cores for Backbone Edge Bridge (BEB) functionality. The syntax for enabling the boot flag for this mode is: **boot config flags advanced-feature-bandwidth-reservation low**.

spbm-config-mode boot flag

Table 15: spbm-config-mode product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
spbm-config-mode (boot config flags spbm-config-mode)	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, the software uses a boot flag called **boot config flags spbm-config-mode**.

- The **boot config flags spbm-config-mode** flag is enabled by default. This enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface.
- If you disable the boot flag, save the configuration, and then reboot with the saved configuration. When the flag is disabled, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

**Important**

After you change the **boot config flags spbm-config-mode** flag, you must save the configuration, and then reboot the switch for the change to take effect.

For more information about this boot flag and Simplified vIST, see [IP Multicast](#) on page 1319.

nni-mstp boot config flag

Table 16: nni-mstp boot flag product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
nni-mstp boot flag (boot config flags nni-mstp)	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

The nni-mstp boot flag changes the default behavior of the MSTP on SPBM NNI ports. The Common and Internal Spanning Tree (CIST) is disabled automatically on the NNI, and the NNI ports can only be members of backbone VLANs (B-VLAN).

- During startup, if you have non-B-VLAN on SPBM NNI ports in your configuration file, the system sets the nni-mstp flag to true (if it was not already set to true) and enables MTSP on SPBM NNI ports, and all other configurations remain the same. Save your configuration file. If you do not save your configuration, you continue to see the following message on reboot:

```
Warning
Detected brouter and/or vlans other than BVLANS on NNI ports. Setting the boot config
flag nni-mstp to true. Saving configuration avoids repetition of this warning on
reboot.
```

**Note**

When the nni-mstp flag is set to true, only MSTI 62 is disabled on the SPBM NNI ports. You can add the SPBM NNI ports to any VLAN.

- If you configure the nni-mstp boot configuration flag to false (default), the system checks to make sure that the SPBM NNI ports do not have brouter (IPv4 or IPv6) or non-SPBM VLANs configured. The nni-mstp flag is then set to false. Save your configuration file, and reboot the switch for the configuration change to take effect.

**Note**

Ensure that all SPBM NNI ports in non-B-VLAN are removed prior to setting the nni-mstp flag to false.

Example: Configuring nni-mstp to true

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags nni-mstp
Warning: Please save the configuration and reboot the switch for this configuration to
```

```
take effect.  
Switch:1(config)#
```

System Connections

Connect the serial console interface (an RJ-45 jack) to a PC or terminal to monitor and configure the switch. The port uses a RJ-45 connector that operates as data terminal equipment (DTE). Some switches also provide a USB port or micro USB port for serial console interface connectivity. See your hardware documentation for available ports.

The default communication protocol settings for the console port are:

- Baud rate:
 - 5520 Series — 115200
 - VSP 4450 Series — 9600
 - VSP 4900 Series — 115200
 - VSP 7200 Series — 9600
 - VSP 7400 Series — 115200
 - VSP 8000 Series — 9600
 - VSP 8600 Series — 115200
 - XA1400 Series — 115200
- 8 data bits
- 1 stop bit
- No parity
- No flow control.

To use the console port, you need a terminal or teletypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software. Depending on the hardware platform, the console port can display as console port or 10101.

Boot Sequence

Table 17: Linux kernel version product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Important: For VSP 4450 Series, VSP 7200 Series, VSP 8200, and VSP 8400 Series, kernel version 4.9 has special upgrade considerations the first time you upgrade to a release that supports it. You must first upgrade to a stepping-stone release, 6.1.x , before you upgrade to the release with the new kernel.	5520 Series	4.14 as of VOSS 8.2.5
	VSP 4450 Series	4.9 as of VOSS 7.0
	VSP 4900 Series	4.14 as of VOSS 8.1
	VSP 7200 Series	4.9 as of VOSS 7.0
	VSP 7400 Series	4.14 as of VOSS 8.0
	VSP 8200 Series	4.9 as of VOSS 7.0
	VSP 8400 Series	4.9 as of VOSS 7.0
	VSP 8600 Series	4.9 as of VSP 8600 8.0
	XA1400 Series	4.14 as of VOSS 8.1

The switch goes through a boot sequence before it becomes fully operational. After you turn on power to the switch, the system starts.

The boot sequence consists of the following stages:

- [Loading Linux](#) on page 117
- [Loading the Primary Release](#) on page 118
- [Deploying Zero Touch](#) on page 118 or [Loading the Configuration File](#) on page 118

Note

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. The first time you start a universal hardware product, the boot sequence can be different from what is documented in this section. The boot sequence documented in this section assumes a NOS selection of VOSS is already established. For more information on NOS personalities, see [Network Operating System Personalities](#) on page 2304.

The following figure shows a summary of the boot sequence.

Figure 1: Boot Sequence

Loading Linux

Depending on the Linux kernel used, the boot image is stored either in a boot flash partition, Secure Digital (SD), or Solid State Drive (SSD) flash card. The boot image includes the boot loader, and the Linux kernel and applications.

The boot location contains two versions of the boot image: a committed version (the primary release) and a backup version. A committed version is one that is marked as good (if you can start the system using that version). The system automatically uses the backup version if the system fails the first time you start with a new version.

Loading the Primary Release

The switch can install a maximum of six releases but can only load one of two—a primary (committed) release or a backup release.

The system saves software image files to the `/intflash/release/` directory.

After loading the primary release, the CPU and basic system devices, such as the console port, initializes. Depending on the hardware platform, the console port displays as console or 10101. At this stage, the I/O ports are not available; the system does not initialize the I/O ports until the port sends configuration data.

Deploying Zero Touch

Important

Zero Touch Deployment does not function if primary or secondary configuration files exist.

After the system loads the primary release and the switch is in a Zero Touch Deployment-ready configuration mode, the switch automatically deploys without intervention.

For more information, see [Zero Touch Deployment](#) on page 40.

Loading the Configuration File

After the system loads the primary release, it identifies the location and file name of the primary configuration file. You can save this file in internal flash.

If the primary configuration file does not exist, the system looks for the backup configuration file, as identified by `version.cfg`. If this file does not exist, the system initiates Zero Touch functionality on the switch that enables Zero Touch Fabric Configuration. For more information, see [Zero Touch Fabric Configuration](#) on page 45.

Note

Exception: for VSP 8600 Series and XA1400 Series, if the configuration file does not exist, the system loads the factory-default configuration, which is the equivalent of using the **boot config flags factorydefaults** command.

The switch configuration consists of higher-level functionality, including:

- Chassis configuration
- Port configuration
- Virtual LAN (VLAN) configuration
- Routing configuration
- IP address assignments
- Remote monitoring (RMON) configuration

The default switch configuration in Zero Touch Fabric Configuration mode includes the following:

- Shortest Path Bridging MAC (SPBM) instance is created.
- Intermediate System-to-Intermediate System (IS-IS) is enabled.

- All ports are enabled and operating in Auto-sense mode.
- The switch issues DHCP requests on the out-of-band (OOB) management port and the management VLAN.

The default switch configuration in factory default mode includes the following:

- A single, port-based default VLAN with a VLAN identification number of 1
- No interface assigned IP addresses
- Traffic priority for all ports configured to normal priority
- All ports as untagged ports
- Default communication protocol settings for the console port. For more information about these protocol settings, see [System Connections](#) on page 115.

Configuration File Statements

In the configuration file, statements preceded by both the number sign (#) and exclamation point (!) load prior to the general configuration parameters. Statements preceded by only the number sign are comments meant to add clarity to the configuration; they do not load configuration parameters. The following table illustrates the difference between these two statement formats.

Table 18: Configuration file statements

Sample statement	Action
# software version : 4.0.0.0	Adds clarity to the configuration by identifying the software version.
#!no boot config flags sshd	Configures the flag to the false condition, prior to loading the general configuration.

Boot Sequence Modification

You can change the boot sequence in the following ways:

- Change the primary designations for file sources.
- Change the file names from the default values. You can store several versions of the configuration file and specify a particular one by file name. The specified configuration file only gets loaded when the chassis starts. To load a new configuration file, you need to restart the system.
- Start the system without loading an existing configuration file so that the system uses the factory default configuration. Bypassing the system configuration does not affect saved system configuration; the configuration simply does not load. You can do this by running the **boot config flags factorydefaults** command.
- Start the system in Zero Touch Deployment mode, which includes Zero Touch Fabric Configuration. For more information, see [Zero Touch Deployment](#) on page 40.

Run Time

After the switch is operational, you can use the run-time commands to perform configuration and management functions necessary to manage the system. These functions include the following

- Resetting or restarting the switch
- Adding, deleting, and displaying address resolution protocol (ARP) table entries
- Pinging another network device

- Viewing and configuring variables for the entire system and for individual ports
- Configuring and displaying MultiLink Trunking (MLT) parameters
- Creating and managing port-based VLANs or policy-based VLANs

To access the run-time environment you need a connection from a PC or terminal to the switch. You can use a direct connection to the switch through the console port or remotely through Telnet, rlogin, or Secure Shell (SSH) sessions.

Note

rlogin is only supported on VSP 8600 Series.

Important

Before you attempt to access the switch using one of the preceding methods, ensure you first enable the corresponding daemon flags.

System logon

After the platform boot sequence is complete, a logon prompt appears. The following table shows the default values for logon and password for console and Telnet sessions.

Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

Table 19: Access levels and default logon values

Access level	Description	Default logon	Default password
Read-only	Permits view-only configuration and status information. Is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read/write	View most switch configuration and status information and change physical port settings.	l1	l1
Layer 2 read/write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read/write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3

Table 19: Access levels and default logon values (continued)

Access level	Description	Default logon	Default password
Read/write	View and change configuration and status information across the switch. You cannot change security and password settings. This access level is equivalent to SNMP read/write community access.	rw	rw
Read/write/all	Permits all the rights of read/write access and the ability to change security settings, including CLI and Web-based management user names and passwords and the SNMP community strings.	rwa	rwa

System flags

After you enable or disable certain modes and functions, you need to save the configuration and restart the switch for your change to take effect. This section lists parameters and indicates if they require a switch restart.

The following table lists parameters you configure in CLI using the **boot config flags** command. For information on system flags and their configuration, see [Configure Boot Flags](#) on page 187.

Note

Flag support can vary across hardware models.

Table 20: Boot config flags

CLI flag	Restart
<i>advanced-feature-bandwidth-reservation</i>	Yes
Note: Exception: only supported on 5520 Series, VSP 7400 Series and XA1480.	
<i>block-snmp</i>	No
<i>debug-config</i>	Yes
<i>debugmode</i>	Yes
<i>dvr-leaf-mode</i>	Yes
<i>enhancedsecure-mode</i>	Yes
<i>factorydefaults</i>	Yes
<i>flow-control-mode</i>	Yes
Note: Exception: not supported on VSP 8600 Series.	

Table 20: Boot config flags (continued)

CLI flag	Restart
<i>ftpd</i>	No
<i>ha-cpu</i> Note: Exception: only supported on VSP 8600 Series.	Yes, the standby CPU restarts automatically. Modifying this flag does not require a system restart.
<i>hsecure</i>	Yes
<i>linate-directed-broadcast</i>	Yes
<i>ipv6-egress-filter</i> Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Yes
<i>ipv6-mode</i> Note: Exception: not supported on VSP 4450 Series, VSP 8600 Series or XA1400 Series.	Yes
<i>logging</i>	No
<i>nmi-mstp</i> Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Yes
<i>reboot</i>	No
<i>rlogind</i> Note: Exception: only supported on VSP 8600 Series.	No
<i>savetostandby</i>	No
<i>spanning-tree-mode</i>	Yes
<i>spbm-config-mode</i>	Yes
<i>sshd</i>	No
<i>telnetd</i>	No
<i>tftpd</i>	No
<i>trace-logging</i>	No
<i>urpf-mode</i> Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Yes
<i>verify-config</i>	Yes

Table 20: Boot config flags (continued)

CLI flag	Restart
<i>vrf-scaling</i>	Yes
<i>vxlan-gw-full-interworking-mode</i> Exception: only supported on VSP 7200 Series, VSP 7400 Series , VSP 8200 Series, and VSP 8400 Series.	Yes

Secure and Nonsecure Protocols

The following table describes the secure and nonsecure protocols that the switch supports.

Table 21: Secure and nonsecure protocols for IPv4 and IPv6

Nonsecure protocols	Default status	Equivalent secure protocols	Default status
FTP and Trivial FTP	Disabled	Secure Copy (SCP) and Secure File Transfer Protocol (SFTP)	Disabled
<p>Note: File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.</p>			
Telnet	Disabled	Secure Shell version 2 (SSHv2)	Disabled
SNMPv1, SNMPv2	Enabled	SNMPv3	Enabled
rlogin	Disabled	SSHv2	Disabled
<p>Note: Exception: only supported only on VSP 8600 Series.</p>			
HTTP	Disabled	HTTPS	Enabled
<p>Important: Take the appropriate security precautions within the network if you use HTTP.</p> <p>You must use the web-server enable command in CLI before you can access EDM.</p>			

Client and Server Support

	XA1400 Series	VOSS 8.1

The client-server model partitions tasks between servers that provide a service and clients that request a service.

For active CLI clients, users initiate a client connection from the switch to another device.

Note

Both FTP and TFTP clients are supported by the switch. The switch does not launch FTP and TFTP clients explicitly as a separate command; you can launch them through the CLI **copy** command. If you have configured the username through the **boot config host** command, the FTP client is used to transfer files to and from the switch using the CLI **copy** command; If you have not configured the username, the TFTP client is used to transfer files to and from the switch using the CLI **copy** command.

Configuring the `boot config flags ftpd` or `boot config flags tftpd` enables the FTP or TFTP Servers on the switch.

For non-active clients, the client exists on the switch and the switch console initiates the request, with no intervention from users after the initial setup. For instance, Network Time Protocol (NTP) is a non active client. The switch initiates the client request to the central server to obtain the up-to-date time.

Password encryption

The platform stores passwords in encrypted format and not in the configuration file.

Important

For security reasons, configure the passwords to values other than the factory defaults.

Enterprise Device Manager

The switch includes Enterprise Device Manager (EDM), an embedded graphical user interface (GUI) that you can use to manage and monitor the platform through web-based access without additional installations.

For more information about EDM, see [Enterprise Device Manager](#) on page 258.

Enterprise Device Manager access

To access EDM, enter one of the following addresses in your web browser:

- `http://<A.B.C.D>`
- `https://<A.B.C.D>`

Where <A.B.C.D> is the device IP address.

Ensure you use a supported browser version. For more information about supported browsers, see [Supported Browsers](#) on page 259.

Important

- You must enable the Web server from CLI to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. Take the appropriate security precautions within the network if you use HTTP.
- EDM access is available to read-write users only.

If you experience any issues while connecting to the EDM, check the proxy settings. Proxy settings may affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device. This should resolve the issue.

Default user name and password

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Change Passwords](#) on page 2927.

Table 24: EDM default username and password

Username	Password
admin	password

Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Change Passwords](#) on page 2927.

TLS server for secure HTTPS

Table 25: TLS server for secure HTTPS product support

Feature	Product	Release introduced
For configuration details, see VOSS User Guide .		
Note: VOSS Releases 6.0 and 6.0.1 do not support this feature.	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	VSP 8600 6.1
XA1400 Series	VOSS 8.0.50	

This feature enhances communications security by implementing Mocana NanoSSL to secure HTTPS server using Transport Layer Security (TLS) cryptographic protocol.

The following are the key properties of Secure Web server with TLS:

- This feature can be implemented on a maximum of only 10 concurrent client connections.
- The switch supports version TLS 1.2 and above by default. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI or EDM.
- This feature replaces SSL 3.0 with TLS. SSL 3.0 is not supported.

- TLS server does not support RC4, DES, TDES, and MD5 based cipher suites.
- The minimum password length for the web server is 8 characters, by default. You can change this using CLI or EDM.

For information about the certificate order priority when the Transport Layer Security (TLS) server and switch connect, see [Certificate Order Priority](#) on page 2878.

IP Address for the Management Port

At startup, the system loads the runtime configuration file, which is stored in the internal flash of the CPU. If the file is present, the system assigns the IP address for the management port from that file.

You can configure an IP address for the management port if one is not in the configuration file. For more information, see [Configure an IP Address for the Management Port](#) on page 549. This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 49.

Basic Configuration

Connect a Terminal

Before You Begin

- To use the console port, you need the following equipment:
 - A terminal or TeleTypewriter (TTY)-compatible terminal, or a portable computer with a serial port and terminal-emulation software.
 - A specific cable with an RJ-45 or USB connector for the console port on the switch. The other end of the cable must use a connector appropriate to the serial port on the computer or terminal.
- To comply with emissions regulations and requirements, you must shield the cable that connects to the console port.

Note

If you are using the VSP 4900 Series USB console port with a terminal running Windows 10, you must install the CP210x USB to UART Bridge Virtual COM Port (VCP) driver from Silicon Labs before you connect to the terminal.

About This Task

Connect a terminal to the serial console interface to monitor and configure the system directly.

Procedure

1. Configure the terminal protocol as follows:
 - 9600 baud or 115200 baud, depending on the hardware platform.
 - 8 data bits
 - 1 stop bit
 - No parity
 - No flow control

2. Connect the RJ-45 or USB cable to the console port on the switch.
3. Connect the other end of the cable to the terminal or computer serial port.
4. Turn on the terminal.
5. Log on to the switch.

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

If you enable the `hsecure` flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

If you enable enhanced secure mode with the `boot config flags enhancedsecure-mode` command, you enable new access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System access fundamentals](#) on page 3306.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Change a password:

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
```
3. Enter the old password.
4. Enter the new password.
5. Re-enter the new password.
6. Configure password options:

```
password [access-level WORD<2-8>] [aging-time day <1-365>] [default-lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-passwd-len <10-20>] [password-history <3-32>]
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Change a password:
```

```
Switch:1(config)# cli password rwa read-write-all
```

Enter the old password: ***

Enter the new password: ***

Re-enter the new password: ***

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#password access-level rwa aging-time 60
```

Variable definitions

Use the data in the following table to use the `cli password` command.

Table 26: Variable definitions

Variable	Value
<code>layer1 layer2 layer3 read-only read-write read-write-all</code>	Changes the password for the specific access level.
<code>WORD<1-20></code>	Specifies the user logon name.

Use the data in the following table to use the `password` command.

Table 27: Variable definitions

Variable	Value
<code>access-level WORD<2-8></code>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • layer1 • layer2 • layer3 • read-only • read-write • read-write-all
<code>aging-time day<1-365></code>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<code>default-lockout-time <60-65000></code>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.
<code>lockout WORD<0-46> time <60-65000></code>	Configures the host lockout time. <ul style="list-style-type: none"> • <code>WORD<0-46></code> is the host IPv4 or IPv6 address. • <code><60-65000></code> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.

Table 27: Variable definitions (continued)

Variable	Value
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configuring system identification

Configure system identification to specify the system name, contact person, and location of the switch.

Procedure

1. Log on as rwa.
2. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
3. Change the system name:

```
sys name WORD<0-255>
```
4. Configure the system contact:

```
snmp-server contact WORD<0-255>
```
5. Configure the system location:

```
snmp-server location WORD<0-255>
```

Example

Change the system name, configure the system contact, and configure the system location:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys name Floor3Lab2
Floor3Lab2:1(config)#snmp-server contact http://companyname.com
Floor3Lab2:1(config)#snmp-server location "12 Street, City, State, Zip"
```

Variable definitions

Use the data in the following table to use the system-level commands.

Table 28: Variable definitions

Variable	Value
<code>contact WORD<0-255></code>	Identifies the contact person who manages the node. To include blank spaces in the contact, use quotation marks ("") around the text. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.
<code>location WORD<0-255></code>	Identifies the physical location of the node. To include blank spaces in the location, use quotation marks ("") around the text. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.
<code>name WORD<0-255></code>	Configures the system or root level prompt name for the switch. <code>WORD<0-255></code> is an ASCII string from 1-255 characters (for example, LabSC7 or Closet4).

Configuring the CLI Banner

Configure the logon banner to display a message to users before authentication and configure a system login message-of-the-day in the form of a text banner that appears after each successful logon.

About This Task

You can use the custom logon banner to display company information, such as company name and contact information. For security, you can change the default logon banner of the switch, which contains specific system information, including platform type and software release.

Use the custom message-of-the-day to update users on a configuration change, a system update or maintenance schedule. For security purposes, you can also create a message-of-the-day with a warning message to users that, "Unauthorized access to the system is forbidden."

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the switch to use a custom banner or use the default banner:

```
banner <custom|static>
```

3. Create a custom banner:

```
banner WORD<1-80>
```

Note

To enter multiple lines for a message, use the **banner** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

4. Create the message-of-the-day:

```
banner motd WORD<1-1516>
```

Note

To enter multiple lines for a message, use the **banner motd** command before each new line of the message. To provide a string with spaces, include the text in quotation marks.

5. Enable the custom message-of-the-day:

```
banner displaymotd
```

6. Save the configuration:

```
save config
```

7. Display the banner information:

```
show banner
```

8. Logon again to verify the configuration.

9. (Optional) Disable the banner:

```
no banner [displaymotd] [motd]
```

Example

Configure the custom banner to “Company, www.Companyname.com.” and configure the message of the day to “Unauthorized access to this system is forbidden. Please logout now.”

```
Switch:1> enable
Switch:1#configure terminal
Switch:1(config)# banner custom
Switch:1(config)# banner Company
Switch:1(config)# banner www.Companyname.com
Switch:1(config)# banner motd "Unauthorized access to this system is forbidden"
Switch:1(config)# banner motd "Please logout now"
Switch:1(config)#banner displaymotd
Switch:1(config)#show banner
Company
www.company.com
        defaultbanner : false
        custom banner :

        displaymotd : true
        custom motd :
Unauthorized access to this system is forbidden
Please logout now
```

Variable definitions

Use the data in the following table to use the **banner** command.

Variable	Value
<i>custom</i>	Disables the use of the default banner.
<i>static</i>	Activates the use of the default banner.
<i>WORD</i> <1-80>	Adds lines of text to the CLI logon banner.
<i>motd WORD</i> <1-1516>	Create the message of the day. To provide a string with spaces, include the text in quotation marks ("").
<i>displaymotd</i>	Enable the custom message of the day.

Configuring the date

About This Task

Configure the calendar time in the form of month, day, year, hour, minute, and second.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Configure the date:

```
clock set <MMddyyyyhhmmss>
```

3. Verify the configuration:

```
show clock
```

Example

Configure the date and time, and then verify the configuration.

```
Switch:1>enable
Switch:1#clock set 19042014063030
Switch:1#show clock
Wed Mar 19 06:30:32 2014 EDT
```

Variable definitions

Use the data in the following table to use the `clock set` command.

Table 29: Variable definitions

Variable	Value
<i>MMddyyyyhhmmss</i>	Specifies the date and time in the format month, day, year, hour, minute, and second.

Enable Remote Access Services

Before You Begin

- When you enable the rlogin flag, you must configure an access policy to specify the user name of who can access the switch. For more information about the access policy commands, see [Access Policies for Services](#) on page 2866.

Note

Rlogin is only supported on VSP 8600 Series.

About This Task

Enable the remote access service to provide multiple methods of remote access.

File Transfer Protocol (FTP), Trivial File Transfer Protocol (TFTP) and Telnet server support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Enable the access service:

```
boot config flags {ftpd | rlogind | sshd | telnetd | tftpd}
```
- Repeat as necessary to activate the desired services.
- Save the configuration.

Example

Enable the access service for Telnet:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags telnetd
```

Variable Definitions

The following table defines parameters for the **boot config flags** command.

Table 30: Variable definitions

Variable	Value
<i>ftpd</i>	Enables the File Transfer Protocol remote-access service type. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.
<i>rlogind</i> Note: Exception: only supported on VSP 8600 Series.	Enables the rlogin remote-access service type. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.

Table 30: Variable definitions (continued)

Variable	Value
<i>spbm-config-mode</i>	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. Use the no operator so that you can configure PIM and IGMP. The boot flag is enabled by default. To set this flag to the default value, use the default operator with the command.
<i>sshd</i>	Enables the Secure Shell remote-access service type. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.
<i>telnetd</i>	Enables the Telnet remote-access service type. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.
<i>tftpd</i>	Enables the Trivial File Transfer Protocol remote-access service type. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.

Using Telnet to log on to the device

About This Task

Use Telnet to log on to the device and remotely manage the switch.

Procedure

1. From a PC or terminal, start a Telnet session:
`telnet <ipv4 or ipv6 address>`
2. Enter the logon and password when prompted.

Example

```
C:\Users\jsmith>telnet 192.0.2.40
Connecting to 192.0.2.40.....
Login:rwa
Password:rwa
```

Enable the Web Management Interface

About This Task

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Enable the web management interface to provide management access to the switch using a web browser.

HTTP and HTTPS, and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Important

If you want to allow HTTP access to the device, then you must disable the web server secure-only option. If you want to allow HTTPS access to the device, the web server secure-only option is enabled by default. The TFTP server supports both IPv4 and IPv6 TFTP clients.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the web server:

```
web-server enable
```
3. To enable the secure-only option (for HTTPS access), enter:

```
web-server secure-only
```
4. (Optional) To disable the secure-only option (for HTTP access), enter:

```
no web-server secure-only
```
5. Configure the username and the access password:

```
web-server password rwa WORD<1-20>
```

Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on.

6. Enter and confirm your password.
7. Enable read-only user:

```
web-server read-only-user enable
```
8. Save the configuration:

```
save config
```
9. Display the web server status:

```
show web-server
```

Example

Enable the secure-only web-server. Configure the Read-Write-All access level username to smith2 and the password to 90Go2437. Enable read-only-user for the web server. Configure the read-only-user username to jones6 and the password to G69s8672.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#show web-server

Web Server Info :

      Status                : on
      Secure-only            : enabled
      TLS-minimum-version    : tlsv12
      RO Username Status     : enabled
      RO Username            : jones6
      RO Password            : *****
      RWA Username           : smith2
      RWA Password           : *****
      Def-display-rows       : 30
      Inactivity timeout     : 900 sec
      Html help tftp source-dir :
      HttpPort               : 80
      HttpsPort              : 443
      NumHits                 : 0
      NumAccessChecks        : 0
      NumAccessBlocks        : 0
      NumRxErrors            : 0
      NumTxErrors            : 0
      NumSetRequest          : 0
      Minimum password length : 8
      Last Host Access Blocked : 0.0.0.0
      In use certificate      : Self signed
```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
<i>def-display-rows</i> <10-100>	Configures the number of rows each page displays, between 10 and 100.
<i>enable</i>	Enables the Web interface. To disable the web server, use the no form of this command: no web-server [enable]

Variable	Value
<code>help-tftp <WORD/0-256></code>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/help • 192.0.2.1/
<code>http-port <80-49151></code>	Configures the web server HTTP port. The default port is 80.
<code>https-port <443-49151></code>	Configure the web server HTTPS port. The default port is 443.
<code>inactivity-timeout<30-65535></code>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
<code>password {ro rwa} WORD<1-20></code>	Configures the logon and password for the web interface.
<code>password min-passwd-len<1-32></code>	Configures the minimum password length. By default, the minimum password length is 8 characters.
read-only-user	Enables read-only user for the web server. Note: read-only-user enable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .
secure-only	Enables secure-only access for the web server.
<code>tls-min-ver<tlsv10 tlsv11 tlsv12></code>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> • tlsv10 - Configures the version to TLS 1.0. • tlsv11 - Configures the version to TLS 1.1. • tlsv12 - Configures the version to TLS 1.2 The default is tlsv12.

Enable the Web Server RO User

About This Task

Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable the web server RO user, which is disabled by default after a software upgrade.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the read-only user:

```
web-server read-only-user enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable the default ro username:

```
Switch1:(config)#web-server read-only-user enable
```

Display the output of the **show web-server** command with the ro username enabled:

```
Switch:1(config)#show web-server
Web Server Info :

      Status                : on
      Secure-only           : enabled
      TLS-minimum-version   : tlsv12
      RO Username Status    : enabled
      RO Username           : jones6
      RO Password           : *****
      RWA Username          : smith2
      RWA Password          : *****
      Def-display-rows      : 30
      Inactivity timeout    : 900 sec
      Html help tftp source-dir :
      HttpPort              : 80
      HttpsPort             : 443
      NumHits                : 87
      NumAccessChecks        : 4
      NumAccessBlocks        : 0
      NumRxErrors            : 73
      NumTxErrors            : 0
      NumSetRequest          : 0
      Minimum password length : 8
      Last Host Access Blocked : 0.0.0.0
      In use certificate     : Self signed
```

Setting the TLS protocol version

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support using CLI.

About This Task

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected from changing to a different version after you run the **tls-min-ver** command.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Disable the Web server:
`no web-server enable`
3. Set the TLS protocol version:
`web-server tls-min-ver [tlsv10 | tlsv11 | tlsv12]`
4. Enable the Web server:
`web-server enable`
5. Verify the protocol version:
`show web-server`

Example

```
Switch> enable
Switch# configure terminal
Switch(config)# web-server tls-min-ver tlsv11
```

Verify the protocol version.

```
Switch> show web-server

Web Server Info :

      Status                : on
      Secure-only           : disabled
      TLS-minimum-version   : tlsv11
      RWA Username          : admin
      RWA Password          : *****
      Def-display-rows     : 30
      Inactivity timeout    : 900 sec
      Html help tftp source-dir :
      HttpPort              : 80
      HttpsPort             : 443
      NumHits               : 198
      NumAccessChecks       : 8
      NumAccessBlocks       : 0
      NumRxErrors           : 198
      NumTxErrors           : 0
      NumSetRequest         : 0
      Minimum password length : 8
      Last Host Access Blocked : 0.0.0.0
      In use certificate     : Self signed
```

Variable Definitions

Use the data in the following table to use the **web-server** command.

Variable	Value
<code>def-display-rows <10-100></code>	Configures the number of rows each page displays, between 10 and 100.
<code>enable</code>	Enables the Web interface. To disable the web server, use the no form of this command: <code>no web-server [enable]</code>
<code>help-tftp <WORD/0-256></code>	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d;/peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/help • 192.0.2.1/
<code>http-port <80-49151></code>	Configures the web server HTTP port. The default port is 80.
<code>https-port <443-49151></code>	Configure the web server HTTPS port. The default port is 443.
<code>inactivity-timeout<30-65535></code>	Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).
<code>password {ro rwa} WORD<1-20></code>	Configures the logon and password for the web interface.
<code>password min-passwd-len<1-32></code>	Configures the minimum password length. By default, the minimum password length is 8 characters.
<code>read-only-user</code>	Enables read-only user for the web server. Note: read-only-user enable is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix .
<code>secure-only</code>	Enables secure-only access for the web server.
<code>tls-min-ver<tlsv10 tlsv11 tlsv12></code>	Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> • tlsv10 – Configures the version to TLS 1.0. • tlsv11 – Configures the version to TLS 1.1. • tlsv12 – Configures the version to TLS 1.2 The default is tlsv12.

Access the Switch Through the Web Interface

Before You Begin

You must enable the Web server using CLI.

About This Task

Monitor the switch through a Web browser from anywhere on the network. The Web interface uses a 15-minute timeout period. If no activity occurs for 15 minutes, the system logs off the switch Web interface, and you must reenter the password information.

Hypertext Transfer Protocol (HTTP) and Hypertext Transfer Protocol Secure (HTTPS) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

By default the Web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option. For more information about configuring the secure-only option, see [Enable the Web Management Interface](#) on page 143.

Procedure

1. Start your Web browser.
2. Type the switch IP address as the URL in the Web address field.
3. In the **User Name** box, type `admin` and in the **Password** box, type `password`.
4. Select **Login**.

Configuring the minimum version of the TLS protocol

Use the following procedure to configure the minimum version of the TLS protocol.

Earlier releases used a self-signed certificate generated using the OpenSSL API, and this self-signed certificate was installed in `/inflash/.ssh`. The self-signed certificate is now generated with the Mocana API.

Disable the web server before changing the TLS version. By disabling the web server, other existing users with a connection to the web server are not affected by changing to a different version.

The switch by default supports version TLS 1.2 and above. You can explicitly configure TLS 1.0 and TLS 1.1 version support.

Procedure

1. In the navigation tree, open the following folders: **Configuration** > **Security** > **Control Path**.
2. Click **General** and select **Web** tab.
3. In the **TlsMinimumVersion** field, select the TLS version you want to configure as the minimum on the system.

Web Field Descriptions

Use the data in the following table to use the **Web** tab.

Name	Description
WebRWAUserName	Specifies the RWA username from 1–20 characters. The default is admin.
WebRWAUserPassword	Specifies the password from 1–32 characters. The default is 12345678.
WebROEnable Note: Exception: not supported on VSP 8600 Series.	Enables the web server read-only (RO) user, which is disabled by default after a software upgrade.
WebROUserName	Specifies the RO username from 1–20 characters. The default is user. Note: Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.
WebROUserPassword	Specifies the password from 1–32 characters. The default is password.
MinimumPasswordLength	Configures the minimum password length. By default, the minimum password length is 8 characters.
HttpPort	Specifies the HTTP port for web access. The default value is 80.
HttpsPort	Specifies the HTTPS port for web access. The default value is 443.
SecureOnly	Controls whether the secure-only option is enabled. The default is enabled.
InactivityTimeout	Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).
TlsMinimumVersion	Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: <ul style="list-style-type: none"> • <code>tlsv10</code> – Configures the version to TLS 1.0. • <code>tlsv11</code> – Configures the version to TLS 1.1. • <code>tlsv12</code> – Configures the version to TLS 1.2 The default is <code>tlsv12</code> .
InUseCertType Note: Exception: not supported on VSP 8600 Series.	Shows if the certificate is self-signed or user-installed. Note: Product Notice: For VSP 8600 Series use the <code>show web-server</code> command in CLI to view this information.

Name	Description
HelpTftp/Ftp_SourceDir	Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d:/peer:/ [<dir>]. The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> • 192.0.2.1:/Help • 192.0.2.1/
DefaultDisplayRows	Configures the web server display row width between 10–100. The default is 30.
LastChange	Shows the last web-browser initiated configuration change.
NumHits	Shows the number of hits to the web server.
NumAccessChecks	Shows the number of access checks performed by the web server.
NumAccessBlocks	Shows the number of access attempts blocked by the web server.
LastHostAccessBlockedAddressType	Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server.
LastHostAccessBlockedAddress	Shows the IP address of the last host access blocked by the web server.
NumRxErrors	Shows the number of receive errors the web server encounters.
NumTxErrors	Shows the number of transmit errors the web server encounters.
NumSetRequest	Shows the number of set-requests sent to the web server.

Saving the configuration

Save the configuration to a file to retain the configuration settings.

About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

Note

If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the running configuration:

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

Example

```
Switch:1> enable
```

Save the file to the default location:

```
Switch:1# save config
```

Variable definitions

Use the data in the following table to use the `save config` command.

Table 31: Variable definitions

Variable	Value
<i>backup</i> WORD<1-99>	Saves the specified file name and identifies the file as a backup file. WORD uses one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
<i>file</i> WORD<1-99>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> • a.b.c.d:<file> • /intflash/<file> The file name, including the directory structure, can include up to 99 characters.
<i>verbose</i>	Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.

Backing up configuration files

Before and after you upgrade your switch software, make copies of the configuration files. If an error occurs, use backup configuration files to return the switch to a previous state.

Before You Begin

- If you use File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP), ensure that you enable the FTP or TFTP server. File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

About This Task

Keep several copies of backup files.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Determine the configuration file names:
`show boot config choice`
3. Save the configuration files. Assuming the files use the default file names, enter:
`save config`
4. Copy the files to a safe place:
`copy /intflash/config.cfg /intflash/config_backup.cfg`
`copy /intflash/config.cfg a.b.c.d:/dir/config_backup.cfg`

Example

Determine the configuration file names, save the configuration files, and copy the files to a safe place.

```
Switch:1>enable
Switch:1#show boot config choice
choice primary config-file "/intflash/config.cfg"
choice primary backup-config-file "/intflash/config.cfg"
Switch:1#save config
Switch:1#copy /intflash/config.cfg 00:11:f9:5b:10:42/dir/config_backup.cfg
Do you want to continue? (y/n)
y
```

Resetting the platform

About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Reset the switch:
`reset [-y]`

Example

Reset the switch:

```
Switch:1>enable
Switch:1#reset
Are you sure you want to reset the switch? (y/n)
y
```

Variable definitions

Use the data in the following table to use the `reset` command.

Table 32: Variable definitions

Variable	Value
<code>-y</code>	Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets.

Install a New Software Build

Use the following procedure to install a new software build for the switch.

For full software upgrade instructions, see [Image Upgrade](#) on page 277.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Extract the release distribution files to the `/intflash/release/` directory:
`software add WORD<1-99>`
3. Install the image:
`software activate WORD<1-99>`
4. Restart the switch:
`reset`

Example

Extract the release distribution files to the `/intflash/release/` directory, extract the module files to the `/intflash/release` directory, and install the image.

```
Switch:1>enable
Switch:1#software add VSPX.X.X.X.X.tgz
Switch:1#software activate VSPX.X.X.X.X
Switch:1#reset
```

Removing a software build

Use the following procedure to remove a software build for the switch.

Important

A maximum of 6 software distributions can be installed. Once the limit is reached, one or more distributions must be removed to accommodate new distributions.

Procedure

1. Enter Privileged EXEC mode:
`enable`

2. Remove the software build:
`software remove WORD<1-99>`

Example

Remove the software build:

```
Switch:1>enable
Switch:1#software remove w.x.y.z
```

Verification

Verify Boot Configuration Flags

Verify the boot configuration flags to verify boot configuration settings. Boot configuration settings only take effect after you reset the system. Verification of these parameters is essential to minimize system downtime and the resets to change them.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Verify the flags:
`show boot config flags`

Example

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags ha-cpu true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags rlogind false
flags savetostandby true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
```

```

flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

Verifying the software release

About This Task

Use CLI to verify your installed software. It is important to verify your software version before you place a device into a production environment.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Verify the software release:

```
show software detail
```

Example

The following is an example of the output of the `show software detail` command.

```

Switch:1#show software detail

=====
                        software releases in /intflash/release/

Verifying the software version on the slots

Note

This procedure only applies to VSP 8600 Series.

About This Task

Use CLI to verify the software version running on each slot.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Verify the software version running on each slot:
show software slot

Example

The following is an example of the output of the **show software slot** command.

```
Switch:1#show software slot
```

```
=====
Software running on chassis
=====
```

```

SF 2      VOSS8600.voss_4.5.0.0int011
```

Displaying local alarms

View local alarms to monitor alarm conditions.

Local alarms are raised and cleared by applications running on the switch. Local alarms are an automatic mechanism run by the system that do not require any additional user configuration. The raising and clearing of local alarms also creates a log entry for each event. Check alarms occasionally to ensure no alarms require additional operator attention.

For more information, see [Alarm Database](#) on page 3552.

Procedure

- Display local alarms:
- ```
show alarm database
```

### Example

Display local alarms:

#### Note

The switches that support SF cards display warning messages when SFIs are down.

```
Switch:1#show alarm database
```

## Basic Administration Procedures using CLI

The following section describes common procedures that you use while you configure and monitor the switch operations using the Command Line Interface (CLI).

### Note

Unless otherwise stated, to perform the procedures in this section, you must log on to the Privileged EXEC mode in the CLI. For more information about how to use CLI, see [CLI procedures](#) on page 249.

## Restarting the platform

### Before You Begin

### Note

The command mode is key for this command. If you are logged on to a different command mode, such as Global Configuration mode, rather than Privileged EXEC mode, different options appear for this command.

### About This Task

Restart the switch to implement configuration changes or recover from a system failure. When you restart the system, you can specify the boot config file name. If you do not specify a boot source and file, the boot command uses the configuration files on the primary boot device defined by the `boot config choice` command.

After the switch restarts normally, it sends a cold trap within 45 seconds after the restart.

### Procedure

1. Enter Privileged EXEC mode:  
enable

- Restart the switch:

```
boot [config WORD<1-99>] [-y]
```

### Important

If you enter the `boot` command with no arguments, you cause the switch to start using the current boot choices defined by the `boot config choice` command.

If you enter a boot command and the configuration file name without the directory, the device uses the configuration file from `/intflash/`.

### Example

```
Switch:1> enable
```

Restart the switch:

```
Switch:1# boot config /intflash/config.cfg
```

```
Switch:1# Do you want to continue? (y/n)
```

```
Switch:1# Do you want to continue? (y/n) y
```

### Variable Definitions

The following table defines parameters for the **boot** command.

| Variable                             | Value                                                                                                                                                                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>config WORD&lt;1-99&gt;</code> | Specifies the software configuration device and file name in one of the following formats: <ul style="list-style-type: none"> <li><code>/intflash/ &lt;file&gt;</code></li> </ul> The file name, including the directory structure, can include up to 99 characters. |
| <code>-y</code>                      | Suppresses the confirmation message before the switch restarts. If you omit this parameter, you must confirm the action before the system restarts.                                                                                                                  |

## Resetting the platform

### About This Task

Reset the platform to reload system parameters from the most recently saved configuration file.

### Procedure

- Enter Privileged EXEC mode:

```
enable
```
- Reset the switch:

```
reset [-y]
```

**Example**

```
Switch:1> enable
```

Reset the switch:

```
Switch:1# reset
```

```
Are you sure you want to reset the switch? (y/n) y
```

*Variable Definitions*

The following table defines parameters for the **reset** command.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| -y       | Suppresses the confirmation message before the switch resets. If you omit this parameter, you must confirm the action before the system resets. |

**Shutting Down the System**

Use the following procedure to shut down the system.

**Caution**

Before you unplug the AC power cord, always perform the following shutdown procedure.

This procedure:

- Flushes any pending data to ensure data integrity.
- Ensures the completion of recent configuration save actions, thus preventing the system from inadvertently booting up with incorrect configuration.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Shut down the system:  
`sys shutdown`
3. Before you unplug the power cord, wait until you see the following message:  
`System Halted, OK to turn off power`

**Example**

Shut down a running system.

```
Switch:1#sys shutdown
Are you sure you want shutdown the system? Y/N (y/n) ? y
CP1 [05/08/14 15:47:50.164] 0x00010813 00000000 GlobalRouter HW INFO System shutdown
initiated from CLI

## Configure the Default Ping and Traceroute Context

### About This Task

Ping commands and traceroute commands execute in Global Router (GRT) context by default. You can configure ping commands and traceroute commands to execute in management (mgmt) context or in Virtual Router Forwarding (vrf) context.

#### Note

This procedure is not supported on VSP 8600 Series.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the default ping command and traceroute command context:  

```
sys default-ping-context {grt | mgmt | vrf}
```

*Variable Definitions*

The following table defines parameters for the **sys default-ping-context** command.

**Note**

The **sys default-ping-context** command is not supported on VSP 8600 Series.

| Variable | Value                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| grt      | Specifies Global Routing Table (grt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.      |
| mgmt     | Specifies management (mgmt) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context.               |
| vrf      | Specifies Virtual Router Forwarding (vrf) context as the default context for ping commands and traceroute commands. The default configuration is grt as the default context. |

## Calculate and Verify the MD5 Checksum for a File on the Switch

Perform this procedure to verify that the software files are downloaded properly to the switch. The MD5 checksum for each release is available on the Extreme Networks Support website.

### About This Task

Calculate and verify the MD5 checksum after you download software files.

### Before You Begin

- Download the MD5 checksum to an intermediate workstation or server where you can open and view the contents.
- Download the image file to the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the list of files:

```
ls *.tgz
```

OR

```
ls *.voss
```

3. Calculate the MD5 checksum for the file:
 

```
file-checksum md5 WORD<1-99>
```
4. Compare the number generated for the file on the switch with the number that appears in the MD5 checksum on the workstation or server. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

### Example

View the contents of the MD5 checksum on the workstation or server:

```
3242309ad6660ef09be1b945be15676d VSP8200.4.0.0.0_edoc.tar
d000965876dee2387f1ca59cf081b9d6 VSP8200.4.0.0.0_mib.txt
897303242c30fd944d435a4517f1b3f5 VSP8200.4.0.0.0_mib.zip
2fbd5eab1c450d1f5feae865b9e02baf VSP8200.4.0.0.0_modules.tgz
a9d6d18a979b233076d2d3de0e152fc5 VSP8200.4.0.0.0_OpenSource.zip
8ce39996a131de0b836db629b5362a8a VSP8200.4.0.0.0_oss-notice.html
80bfe69d89c831543623aaad861f12aa VSP8200.4.0.0.0.tgz
a63a1d911450ef2f034d3d55e576eca0 VSP8200.4.0.0.0.zip
62b457d69cadd44c21c395505dcf4a80 VSP8200v400_HELP_EDM_gzip.zip
```

Calculate the MD5 checksum for the file on the switch:

```
Switch:1>ls *.tgz
-rw-r--r-- 1 0 0 44015148 Dec 8 08:18 VSP8200.4.0.0.0.tgz
-rw-r--r-- 1 0 0 44208471 Dec 8 08:19 VSP8200.4.0.1.0.tgz
Switch:1>file-checksum md5 VSP8200.4.0.0.0.tgz
MD5 (VSP8200.4.0.0.0.tgz) = 80bfe69d89c831543623aaad861f12aa
```

### Variable Definitions

The following table defines parameters for the **file-checksum md5** command:

| Variable                | Value                    |
|-------------------------|--------------------------|
| <i>WORD&lt;1-99&gt;</i> | Specifies the file name. |

## Calculate and Verify the MD5 Checksum for a File on a Client Workstation

Perform this procedure on a Unix or Linux machine to verify that the software files downloaded properly. The MD5 checksum for each release is available on the Extreme Networks Support website.

### About This Task

Calculate and verify the MD5 checksum after you download software files.

### Procedure

1. Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum <downloaded software-filename>
```

Typically, downloaded software files are in the form of compressed Unix file archives (.tgz files) or .voss files.

2. Verify the MD5 checksum of the software suite:

```
$ more <md5-checksum output file>
```

3. Compare the output that appears on the screen. Ensure that the MD5 checksum of the software suite matches the system output generated from calculating the MD5 checksum from the downloaded file.

## Example

Calculate the MD5 checksum of the downloaded file:

```
$ /usr/bin/md5sum VSP4K.4.0.40.0.tgz
02c7ee0570a414becf8ebb928b398f51 VSP4K.4.0.40.0.tgz
```

View the MD5 checksum of the software suite:

```
$ more VSP4K.4.0.40.0.md5
285620fdclce5ccd8e5d3460790c9fe1 VSP4000v4.0.40.0.zip

02c7ee0570a414becf8ebb928b398f51 VSP4K.4.0.40.0.tgz
```

## Calculating the File Checksum

### About This Task

Perform the following procedure to calculate or compare the MD5 or SHA512 digest for a specific file. The **file-checksum** command calculates the MD5 or SHA512 digest for files on the internal flash and either shows the output on screen or stores the output in a file that you specify. The **file-checksum** command compares the calculated MD5 or SHA512 digest with that in a checksum file on flash, and the compared output appears on the screen. By verifying the MD5 or SHA512 checksum, you can verify that the file is transferred properly to the switch.

#### Important

- If the MD5 key file parameters change, you must remove the old file and create a new file.
- Use the **file-checksum** command with reserved files (for example, a password file) only if you possess sufficient permissions to access these files.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Calculate the file checksum:

```
file-checksum {md5 | sha512} WORD<1-99> [-a] [-c] [-f WORD<1-99>] [-r]
```

### Example

```
Switch:1>file-checksum md5 password -a -f password.md5
```

## Variable Definitions

The following table defines parameters for the **file-checksum** command.

| Variable                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>md5</i>              | Calculates or compares the MD5 digest for a specific file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>sha512</i>           | Calculates or compares the SHA512 digest for a specific file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>-a</i>               | Adds data to the output file instead of overwriting it.<br>You cannot use the <i>-a</i> option with the <i>-c</i> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>-c</i>               | Compares the checksum of the specified file with the MD5 checksum present in the checksum file name. You can specify the checksum file name using the <i>-f</i> option. If the checksum filename is not specified, the file <code>/intflash/checksum.md5</code> is used for comparison.<br>If the supplied checksum filename and the default file are not available on flash, the following error message appears:<br>Error: Checksum file <i>&lt;filename&gt;</i> not present.<br>The <i>-c</i> option also <ul style="list-style-type: none"> <li>calculates the checksum of the specified files</li> <li>compares the checksum with all keys in the checksum file, even if filenames do not match</li> <li>displays the output of comparison</li> </ul> |
| <i>-f</i>               | Stores the result of MD5 checksum to a file on internal flash.<br>If the output file specified with the <i>-f</i> option is reserved filenames on the switch, the command fails with the error message:<br>Error: Invalid operation.<br>If the output file specified with the <i>-f</i> option is files for which to compute MD5 checksum, the command fails with the error message:<br>Switch:1# md5 *.cfg -f config.cfg Error: Invalid operation on file <i>&lt;filename&gt;</i><br>If the checksum filename specified by the <i>-f</i> option exists on the switch (and is not one of the reserved filenames), the following message appears on the switch:<br>File exists. Do you wish to overwrite? (y/n)                                             |
| <i>-r</i>               | Reverses the output. Use with the <i>-f</i> option to store the output to a file.<br>You cannot use the <i>-r</i> option with the <i>-c</i> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>WORD&lt;1-99&gt;</i> | Specifies the file name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Resetting system functions

### About This Task

Reset system functions to reset all statistics counters on the console port. Depending on your hardware platform, the console port displays as console or 10101.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Reset system functions:  

```
sys action reset {console|counters}
```

### Example

```
Switch:1> enable
```

Reset the statistics counters:

```
Switch:1# sys action reset counters
```

```
Are you sure you want to reset system counters (y/n)? y
```

### Variable Definitions

The following table defines parameters for the **sys action** command.

| Variable                              | Value                                                                                                                                                                                                                                       |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>reset {console counters}</code> | Reinitializes the hardware universal asynchronous receiver transmitter (UART) drivers. Use this command only if the console connection does not respond. Resets all the statistics counters in the switch to zero. Resets the console port. |

## Sourcing a Configuration

Source a configuration to merge a script file into the running configuration or verify the syntax of a configuration file.

### About This Task

The **source** cli command is intended for use with a switch that is running with a factory default configuration to quick load a pre-existing configuration from a file. If you source a configuration file to merge that configuration into a running configuration, it can result in operational configuration loss if the sourced configuration file contains any configuration that has dependencies on or conflicts with the running configuration. Use the source command to merge smaller portions of a configuration into the existing configuration.

Not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands. Ensure that you understand what configuration options are included or not included in a configuration file, when you use that file to build new configurations.

The operational modes in the boot configuration file must be configured for some features (for example, **spbm-config-mode true/false**). Before sourcing a configuration file, you need to configure the **boot config flag**, save the configuration, and reboot the system. After the reboot, you can source the configuration file without fail.

### Important

Do not source a verbose configuration (`verbose.cfg`) with the `debug stop` option. The sourcing process cannot complete if you use these two options with a verbose configuration.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Source a configuration:
 

```
source WORD<1-99> [debug] [stop] [syntax]
```

### Example

```
Switch:1> enable
```

Debug the script output:

```
Switch:1# source testing.cfg debug
```

### Variable Definitions

The following table defines parameters for the **source** command.

| Variable           | Value                                                                     |
|--------------------|---------------------------------------------------------------------------|
| <code>debug</code> | Debugs the script by outputting the configuration commands to the screen. |
| <code>stop</code>  | Stops the sourcing of a configuration if an error occurs.                 |

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>syntax</code>           | Checks the syntax of the configuration file. This parameter does not load the configuration file; only verifies the syntax.<br>If you use this parameter with the <code>stop</code> parameter ( <b>source WORD&lt;1-99&gt; stop syntax</b> ), the output appears on screen and verification stops if it encounters an error.<br>If you use this parameter with the <code>debug</code> parameter ( <b>source WORD&lt;1-99&gt; debug syntax</b> ), the output does not stop if it encounters an error; you must review the on-screen output to verify if an error exists.<br>If you use this parameter by itself, it does not output to the screen or stop on error; it shows an error message, <code>syntax errors in script</code> , to indicate if errors exist in the configuration file. |
| <code>WORD&lt;1-99&gt;</code> | Specifies a filename and location in one of the following format: <ul style="list-style-type: none"> <li>• <code>a.b.c.d:&lt;file&gt;</code></li> <li>• <code>/intflash/&lt;file&gt;</code></li> </ul> <file> is a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Using the USB Device

The following sections describe common procedures that you can use with the USB device.

### Save a File to an External USB Device

Use the following procedure to save the configuration file or log file to an external USB device.

#### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Save the file to an external USB device:
  - a. To save the configuration file to an external USB device, enter:

```
save config file WORD<1-99>
```
  - b. To save the log file to an external USB device, enter:

```
save log file WORD<1-99>
```

#### Example

```
Switch:1#save config file /usb/test.cfg
CP-1: Save config to file /usb/test.cfg successful.
WARNING: Choice Primary Node Config file is "/intflash/soak.cfg".
```

```
Switch:1#
Switch:1#save log file /usb/test.log

Save log to file /usb/test.log successful.
Save log to file /usb/test.log successful.
Switch:1#
```

## Variable definitions

The following table defines parameters for the save command.

| Variable                          | Value                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| config file<br><i>WORD</i> <1-99> | Specifies the software configuration device and configuration file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> <p>The file name, including the directory structure, can include up to 99 characters.</p> |
| log file<br><i>WORD</i> <1-99>    | Specifies the software configuration device and log file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> <p>The file name, including the directory structure, can include up to 99 characters.</p>           |

## Back Up and Restore the Compact Flash to an External USB Device

Perform this procedure to back up and restore the contents of the internal compact flash to a USB flash device without entering multiple **copy** commands. This procedure is useful if you want to copy the complete compact flash contents to another chassis.

### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

## Before You Begin

-  **Important**  
Disable logging using the command: `no boot config logging`.
- You must have a USB storage device ready to use that is at least 2 GB. The switch supports USB 1 and 2.

## About This Task

The system verifies that the USB flash device has enough available space to perform the backup operation. If the USB flash device does not have enough available space, an error message appears. The backup command uses the following filepath on the USB flash device: `/usb/intflash/intflashbackup_yyyymmddhhmmss.tgz`.

The backup action can take up to 10 minutes.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Backup the internal flash to USB:  
backup intflash
3. Restore the data to the internal flash:  
restore intflash

**Example**

```
Switch:1#backup intflash
```

```
Warning: Command will backup all data from /intflash to /usb/intflash.
 It will take a few minutes and may cause high CPU utilization.

 Are you sure you want to continue? (y/n) ? y

For file system /intflash:
 7252475904 total bytes on the filesystem
 990920704 used bytes on the filesystem
 6261555200 free bytes on the filesystem

For file system /usb:
 2021216256 total bytes on the filesystem
 12038144 used bytes on the filesystem
 2009178112 free bytes on the filesystem

cd /intflash ; /bin/tar -czvf /usb/intflash/intflashbackup_20140610074501.tgz *
; /bin/sync

Info: Backup /intflash to filename /usb/intflash/intflashbackup_20140610074501.tgz is
complete!

Do you want to stop the usb? (y/n) ? n
```

*Copy Configuration and Log Files from a USB Device to Intflash*

Copy configuration and log files from an external USB device to the internal Flash memory.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Copy configuration or log files from the USB device to Intflash:  
copy /usb/<srcfile> /intflash/<destfile>

**Example**

```
Switch:1#enable
```

```
Switch:1#copy /usb/test.cfg /intflash/test.cfg
```

## Variable Definitions

The following table defines parameters for the `copy` command.

| Variable   | Value                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <destfile> | Specifies the name of the configuration or log file when copied to the internal Flash memory. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log.<br>The file name, including the directory structure, can include up to 255 characters. |
| <srcfile>  | Specifies the name of the configuration or log file on the USB device. For example, test.cfg or test.log.<br>The file name, including the directory structure, can include up to 255 characters.                                                                                                                |

### Display the Contents of a USB File

Use the following procedure to view content of a USB file.

#### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display content of a USB file:  
`more WORD<1-99>`

#### Example

```
Switch:1#enable
```

```
Switch:1#more /usb/test.cfg
```

## Variable definitions

The following table defines parameters for the `more` command.

| Variable   | Value                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<1-99> | Specifies the file name in the following format: <ul style="list-style-type: none"> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters. |

### Move a File to or from a USB Device

Use the following procedure to move a file from the internal Flash memory (Intflash) to an external USB device, or from a USB device to Intflash.

#### Caution

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Move a file to a safe location:
  - a. To move a file from Intflash to a USB device:
 

```
mv /intflash/<srcfile> /usb/<destfile>
```
  - b. To move a file from a USB device to Intflash:
 

```
mv /usb/<srcfile> /intflash/<destfile>
```

**Example**

```
Switch:1#enable
Switch:1#mv /intflash/test.cfg /usb/test.cfg
Switch:1#enable
Switch:1#mv /usb/test.cfg /intflash/test.cfg
```

**Variable Definitions**

The following table defines parameters for the `mv` command.

| Variable   | Value                                                                                                                                                                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <destfile> | Specifies the name of the configuration or log file when moved to the USB device. The destination file name must be lower case and have a file extension of .cfg or .log. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters. |
| <srcfile>  | Specifies the name of the configuration or log file on the internal flash memory. For example, test.cfg or test.log. The file name, including the directory structure, can include up to 255 characters.                                                                                         |

*Delete a file from a USB Device*

Use the following procedure to delete a file from an external USB device.

**Caution**

Always use the `usb-stop` command to safely unplug the USB drive from the USB slot.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Delete a file from a USB device:
 

```
delete WORD<1-255>
```

**Example**

```
Switch:1#enable
Switch:1#delete /usb/test.cfg
Are you sure (y/n) ? y
```

**Variable Definitions**

The following table defines parameters for the `delete` command.

| Variable                       | Value                                                                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-255&gt;</code> | Specifies the file name in the following format: <ul style="list-style-type: none"> <li><code>/usb/&lt;file&gt;</code></li> </ul> |

Back Up Configuration Files to ZIP

**Table 33: Extreme Management Center backup configuration ZIP file product support**

| Feature                                                                                                                       | Product         | Release introduced |
|-------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| Extreme Management Center backup configuration ZIP file<br>For more information, see Extreme Management Center documentation. | 5520 Series     | VOSS 8.2.5         |
|                                                                                                                               | VSP 4450 Series | VOSS 6.1.2         |
|                                                                                                                               | VSP 4900 Series | VOSS 8.1           |
|                                                                                                                               | VSP 7200 Series | VOSS 6.1.2         |
|                                                                                                                               | VSP 7400 Series | VOSS 8.0           |
|                                                                                                                               | VSP 8200 Series | VOSS 6.1.2         |
|                                                                                                                               | VSP 8400 Series | VOSS 6.1.2         |
|                                                                                                                               | VSP 8600 Series | VSP 8600 6.1       |
|                                                                                                                               | XA1400 Series   | VOSS 8.0.50        |

Extreme Management Center (XMC) has a configuration backup feature with a requirement to be able to backup configuration related files. Release 6.1.2 introduces new CLI commands to backup configuration related files and package them into a single zip file, or to restore configuration files that were backed up.

**Note**

License files are not backed up.

*Backing up configuration files to a ZIP file*

**About This Task**

Use this procedure to back up configuration files.

**Important**

Only the RWA user can use the **backup** command.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Use the backup command:
 

```
backup configure WORD<1-99>
```

**Example**

```
Switch:1>enable
Switch:1#backup configure /intflash/backup02072018

Successfully backed up config /intflash to /intflash/backup02072018.tgz
```

*Restoring configuration files from a ZIP file***About This Task**

Use the following procedure to restore previously backed up configuration files.

**Before You Begin**

- Download the backup file to the /intflash directory.
- If restoring the configuration files on a new switch, you must do one of the following:
  - Disable ISIS on the old switch .
  - Power the old switch down.
  - Remove the old switch from the network.
- If restoring the configuration files on a different switch, use the “isis dup-detection-temp-disable” command on the new switch to suspend duplicate detection prior to its insertion into the existing SPBM topology.

**Important**

This must be done after the original unit has been completely removed or isolated from the SPBM topology.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Run the restore command to restore the configuration files.
 

```
restore configure WORD<1-99>
```

**Example**

```
Switch:1>enable
Switch:1#restore configure /intflash/backup02072018.tgz

Warning: Command will restore your backup setup and access files
The current files will be overwritten.

Are you sure you want to continue? (y/n) ?y

Restore /intflash from /intflash/backup02072018.tgz is complete!
Reboot is required for the new configuration to be effective
```

**Basic administration procedures using EDM**

The following section describes common procedures that you use while you configure and monitor the switch operations using Enterprise Device Manager (EDM).

## Reset the Platform

### About This Task

Reset the platform to reload system parameters from the most recently saved configuration file. Use the following procedure to reset the device using EDM.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.
5. Locate **ActionGroup4** near the bottom of the screen.
6. Select **softReset** from **ActionGroup4**.
7. Click **Apply**.

## Show the MTU for the System

### About This Task

Perform this procedure to show the MTU configured for the system.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click on the **Chassis** tab.
5. Verify the selection for the MTU size.

## Save the Configuration

### About This Task

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

#### Note

When you logout of the EDM interface, a dialog box automatically prompts if you want to save the configuration. If you want to save the configuration, click **OK**. If you want to close without saving the configuration, click **Cancel**. If you no longer see the prompt, clear your browser cache, restart your browser and reconnect.

### Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System** tab.

5. (Optional) Specify a filename in **ConfigFileName**.  
If you do not specify a filename, the system saves the information to the default file.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Click **Apply**.

## View UBoot Version and Status

### Note

This procedure only applies to 5520 Series.

### About This Task

Use this information to verify the integrity of the software and hardware. A representative from Customer Support will instruct you to obtain this information when required.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **UBoot** tab.

### *UBoot Field Descriptions*

Use the data in the following table to use the **UBoot** tab.

| Name                         | Description                                                                 |
|------------------------------|-----------------------------------------------------------------------------|
| <b>DefaultVersion</b>        | Displays the default UBoot version.                                         |
| <b>AlternateVersion</b>      | Displays the alternate UBoot version.                                       |
| <b>VersionUsed</b>           | Displays the UBoot version in use, either the default or alternate.         |
| <b>TrustedDeliveryStatus</b> | Displays the status of the chain of trust image signature validation steps. |

## Boot parameter configuration using the CLI

Use the procedures in this section to configure and manage the boot process.

### Modify the Boot Sequence

#### About This Task

Modify the boot sequence to prevent the switch from using the factory default settings or, conversely, to prevent loading a saved configuration file.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Bypass the loading of the switch configuration file and load the factory defaults:

```
boot config flags factorydefaults
```

3. Use a configuration file and not the factory defaults:

```
no boot config flags factorydefaults
```

### Important

If the switch fails to read and load a saved configuration file after it starts, check the log file to see if the log file indicates that the factorydefaults setting was enabled, before you investigate other options.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags factorydefaults
```

## Configuring the remote host logon

### Before You Begin

- The FTP server must support the FTP passive (PASV) command. If the FTP server does not support the passive command, the file transfer is aborted, and then the system logs an error message that indicates that the FTP server does not support the passive command.

### About This Task

Configure the remote host logon to modify parameters for FTP and TFTP access. The defaults enable TFTP transfers. If you want to use FTP as the transfer mechanism, you need to change the password to a non-null value.

### Important

tftp-debug should be used exclusively to transfer small files less than 1MB in size. Using it for larger files might cause unwanted behavior, such as transfer failure.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Define conditions for the remote host logon:

```
boot config host {ftp-debug|password WORD<0-16>|tftp-debug|tftp-hash|
tftp-rexmit <1-120>|tftp-timeout <1-120>|user WORD<0-16>}
```

3. Save the changed configuration.

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Enable console tftp/tftpd debug messages:

```
Switch:1#boot config host tftp-debug
```

```
Switch:1# save config
```

## Enable Remote Access Service

Enable the remote access service to provide multiple methods of remote access.

### Before You Begin

- When you enable the rlogin flag, you must configure an access policy to specify the user name of who can access the switch. For more information about the access policy commands, see [System Access](#) on page 3306.

#### Note

Rlogin is only supported on VSP 8600 Series.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the access service:

```
boot config flags {ftpd|rlogind|sshd|telnetd|tftpd}
```

3. Save the configuration.

### Example

Enable the access service to SSHv2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags sshd
```

### Variable Definitions

The following table defines parameters for the **boot config flags** command.

| Variable                                                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>advanced-feature-bandwidth-reservation [low   high]</i></p> <p><b>Note:</b><br/>Exception: only supported on 5520 Series, VSP 7400 Series and XA1480.<br/>Exception: only low level supported on 5520 Series.</p> | <p>Enables the switch to support advanced features by reserving ports as loopback ports. The default is enabled with low level configuration. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <p>The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features.</p> <p>If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>block-snmp</i>                                                                                                                                                                                                       | <p>Activates or disables Simple Network Management Protocol management. The default value is false (disabled), which permits SNMP access.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>debug-config [console]   [file]</i>                                                                                                                                                                                  | <p>Enables you to debug the configuration file during loading configuration at system boot up. The default is disabled. You do not have to restart the switch after you enable debug-config, unless you want to immediately debug the configuration. After you enable debug-config and save the configuration, the debug output either displays on the console or logs to an output file the next time the switch reboots.</p> <p>The options are:</p> <ul style="list-style-type: none"> <li>• debug-config [console]—Displays the line-by-line configuration file processing and result of the execution on the console while the device loads the configuration file.</li> <li>• debug-config [file]— Logs the line-by-line configuration file processing and result of the execution to the debug file while the device loads the configuration file. The system logs the debug config output to /intflash/debugconfig_primary.txt for the primary configuration file. The system logs the debug config output to /intflash/debugconfig_backup.txt for the backup configuration, if the backup configuration file loads.</li> </ul> |

|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>debugmode</i>                             | <p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter unless directed by technical support.</p>                                                                                                                                                                                                                                                                                                |
| <i>dvr-leaf-mode</i>                         | <p>Enables an SPB node to be configured as a DvR Leaf.<br/>A node that has this flag set cannot be configured as a DvR Controller.<br/>The boot flag is disabled by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>enhancedsecure-mode {jitc   non-jitc}</i> | <p>Enables enhanced secure mode in either the JITC or non-JITC sub-modes.</p> <p><b>Note:</b><br/>As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.</p> <p>When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.</p> |
| <i>factorydefaults</i>                       | <p>Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| <i>flow-control-mode</i>                     | <p>Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.<br/>The default is disabled.</p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series.</p>                                                                                                                                                                                   |
| <i>ftpd</i>                                  | <p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the <i>tfootpd</i> flag is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Variable                                                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>ha-cpu</i></p> <p><b>Note:</b><br/>Exception: only supported on VSP 8600 Series.</p>                                      | <p>Activates or disables High Availability-CPU (HA-CPU) mode. Switches with two CPUs use HA mode to recover quickly from a failure of one of the CPUs.</p> <p>If you enable or disable HA mode, the secondary CPU resets automatically to load settings from the saved configuration file.</p>                                                                                                                                                                                                                                                                                                                                                                    |
| <p><i>hsecure</i></p>                                                                                                           | <p>Activates or disables High Secure mode. The hsecure command provides the following password behavior:</p> <ul style="list-style-type: none"> <li>• 10 character enforcement</li> <li>• The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters.</li> <li>• Aging time</li> <li>• Failed login attempt limitation</li> </ul> <p>The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.</p>       |
| <p><i>ipv6-egress-filter</i></p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series and XA1400 Series.</p>         | <p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>verify-config</i>                                                                                                                                                       | <p>Activates syntax checking of the configuration file. The default is enabled.</p> <ul style="list-style-type: none"> <li>Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file.</li> </ul> <p>If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file.</p> <ul style="list-style-type: none"> <li>Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file.</li> </ul> <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p> |
| <i>vrf-scaling</i>                                                                                                                                                         | <p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p><b>Important:</b><br/>If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <a href="#">Release Notes for VOSS</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <p><i>vxlan-gw-full-interworking-mode</i></p> <p><b>Note:</b><br/>Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p> | <p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see <a href="#">VOSS Feature Support Matrix</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Changing the primary or secondary boot configuration files

### About This Task

Change the primary or secondary boot configuration file to specify which configuration file the system uses to start.

Configure the primary boot choices.

You have a primary configuration file that specifies the full directory path and a secondary configuration file that also contains the full directory path.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change the primary boot choice:  

```
boot config choice primary {backup-config-file|config-file} WORD<0-255>
```
3. Save the changed configuration.
4. Restart the switch.

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Specify the configuration file in internal flash memory as the primary boot source:

```
Switch:1(config)# boot config choice primary config-file /intflash/
config.cfg
```

```
Switch:1(config)# save config
```

```
Switch:1(config)# reset
```

## Variable Definitions

The following table defines parameters for the **boot config** command.

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{backup-config-file config-file}</i> | Specifies that the boot source uses either the configuration file or a backup configuration file.                                                                                                                                                                                                                                                                                                                  |
| <i>WORD&lt;0-255&gt;</i>                | <p>Identifies the configuration file. <i>WORD&lt;0-255&gt;</i> is the device and file name, up to 255 characters including the path, in one of the following format:</p> <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> </ul> <p>To set this option to the default value, use the <b>default</b> operator with the command.</p> |

## Configure Boot Flags

### Before You Begin

- If you enable the hsecure flag, you cannot enable the flags for the Web server or SSH password-authentication.

#### Important

After you change certain configuration parameters using the **boot config flags** command, you must save the changes to the configuration file.

### About This Task

Configure the boot flags to enable specific services and functions for the chassis.

#### Note

Flag support can vary across hardware models.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable boot flags:

```
boot config flags <advanced-feature-bandwidth-reservation [low | high]
| block-snmp | debug-config [file] | debugmode | dvr-leaf-mode |
enhancedsecure-mode <jitc|non-jitc> | factorydefaults | flow-control-
mode | ftpd | ha-cpu | hsecure | ipv6-egress-filter | ipv6-mode |
linerate-directed-broadcast | logging | nni-mstp | reboot | rlogind |
savetostandby | spanning-tree-mode <mstp|rstp> | spbm-config-mode |
sshd | syslog-rfc5424-format | telnetd | tftpd | trace-logging | urpf-
mode | verify-config | vrf-scaling | vxlan-gw-full-interworking-mode>
```

## 3. Disable boot flags:

```
no boot config flags <advanced-feature-bandwidth-reservation | block-
snmp | debug-config [file] | debugmode | enhancedsecure-mode <jitc|
non-jitc> | dvr-leaf-mode | factorydefaults | flow-control-mode | ftpd
| ha-cpu | hsecure | ipv6-egress-filter | ipv6-mode | linerate-
directed-broadcast | logging | nni-mstp | reboot | rlogind |
savetostandby | spanning-tree-mode <mstp|rstp> | spbm-config-mode |
sshd | syslog-rfc5424-format | telnetd | tftpd | trace-logging | urpf-
mode | verify-config | vrf-scaling | vxlan-gw-full-interworking-mode>
```

## 4. Configure the boot flag to the default value:

```
default boot config flags <advanced-feature-bandwidth-reservation |
block-snmp | debug-config [file] | debugmode | enhancedsecure-mode
<jitc|non-jitc> | dvr-leaf-mode | factorydefaults | flow-control-mode
| ftpd | ha-cpu | hsecure | ipv6-egress-filter | ipv6-mode | linerate-
directed-broadcast | logging | nni-mstp | reboot | rlogind |
savetostandby | spanning-tree-mode <mstp|rstp> | spbm-config-mode |
sshd | syslog-rfc5424-format | telnetd | tftpd | trace-logging | urpf-
mode | verify-config | vrf-scaling | vxlan-gw-full-interworking-mode>
```

## 5. Save the changed configuration.

## 6. Restart the switch.

*Examples*

```
Switch:1>enable
Switch:1#configure terminal
```

## Activate High Secure mode:

```
Switch:1(config)# boot config flags hsecure
Switch:1(config)# save config
Switch:1(config)# reset
```

## Activate High Availability mode:

```
Switch:1(config)#boot config flags ha-cpu
Switch:1(config)#save config
```

## Variable Definitions

The following table defines parameters for the **boot config flags** command.

| Variable                                                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><i>advanced-feature-bandwidth-reservation [low   high]</i></p> <p><b>Note:</b><br/>Exception: only supported on 5520 Series, VSP 7400 Series and XA1480.<br/>Exception: only low level supported on 5520 Series.</p> | <p>Enables the switch to support advanced features by reserving ports as loopback ports. The default is enabled with low level configuration. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <p>The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features.</p> <p>If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>block-snmp</i>                                                                                                                                                                                                       | <p>Activates or disables Simple Network Management Protocol management. |----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>debugmode</code>                             | <p>Enables a TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. Works on console connection only. The default is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter unless directed by technical support.</p>                                                                                                                                                                                                                                                                                                |
| <code>dvr-leaf-mode</code>                         | <p>Enables an SPB node to be configured as a DvR Leaf.<br/>A node that has this flag set cannot be configured as a DvR Controller.<br/>The boot flag is disabled by default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>enhancedsecure-mode {jitc   non-jitc}</code> | <p>Enables enhanced secure mode in either the JITC or non-JITC sub-modes.</p> <p><b>Note:</b><br/>As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.</p> <p>When you enable enhanced secure mode in either the JITC or non-JITC sub-modes, the switch provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.</p> |
| <code>factorydefaults</code>                       | <p>Specifies whether the switch uses the factory default settings at startup. The default value is disabled. This flag is automatically reset to the default setting after the CPU restarts. If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| <code>flow-control-mode</code>                     | <p>Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.<br/>The default is disabled.</p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series.</p>                                                                                                                                                                                   |
| <code>ftpd</code>                                  | <p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the <code>tftpd</code> flag is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Variable                                                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <i>verify-config</i>                                                                                                                                                       | <p>Activates syntax checking of the configuration file. The default is enabled.</p> <ul style="list-style-type: none"> <li>Primary config behavior: When the verifyconfig flag is enabled, the primary config file is pre-checked for syntax errors. If the system finds an error, the primary config file is not loaded, instead the system loads the backup config file.</li> </ul> <p>If the verify-config flag is disabled, the system does not pre-check syntax errors. When the verify-config flag is disabled, the system ignores any lines with errors during loading of the primary config file. If the primary config file is not present or cannot be found, the system tries to load the backup file.</p> <ul style="list-style-type: none"> <li>Backup config behavior: If the system loads the backup config file, the system does not check the backup file for syntax errors. It does not matter if the verify-config flag is disabled or enabled. With the backup config file, the system ignores any lines with errors during the loading of the backup config file.</li> </ul> <p>If no backup config file exists, the system defaults to factory defaults.</p> <p>As a best practice, disable the verify-config flag.</p> |
| <i>vrf-scaling</i>                                                                                                                                                         | <p>Increases the maximum number of VRFs and Layer 3 VSNs that the switch supports. This flag is disabled by default.</p> <p><b>Important:</b><br/>If you enable both this flag and the spbmconfig-mode flag, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <a href="#">Release Notes for VOSS</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <p><i>vxlan-gw-full-interworking-mode</i></p> <p><b>Note:</b><br/>Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.</p> | <p>Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.</p> <p>The no operator is the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments. For more information about feature support, see <a href="#">VOSS Feature Support Matrix</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Specifying the master CPU and the standby-to-master delay

### Note

This procedure only applies to VSP 8600 Series.

Specify the master CPU to designate which CPU becomes the master after the switch performs a full power cycle. This procedure applies only to hardware with two CPUs.

### About This Task

Configure the standby-to-master delay to set the number of seconds a standby CPU waits before trying to become the master CPU. The standby-to-master delay applies when two CP modules are booting at the same time. The designated standby CP waits for the configured number of seconds before attempting to assert mastership. Only one CP can be master in a chassis.

### Caution

If you configure the master-to-standby delay to too short a value, the configured standby CP can become a master. If you configure the master-to-standby delay to too long, it can delay the backup CP asserting mastership and continue booting when the designated CP is inserted, but fails booting.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. View the current configuration for the master CPU:  
`show boot config master`
3. Specify the slot of the master CPU:  
`boot config master <1-2>`
4. Save the changed configuration.
5. Configure the number of seconds a standby CPU waits before trying to become the master CPU:  
`boot config delay <0-255>`
6. Save the changed configuration.
7. Restart the switch.

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Specify the slot number, either 1 or 2, for the master CPU:

```
Switch:1(config)# boot config master 2
Switch:1(config)# save config
```

Specify the number of seconds a standby CPU waits before trying to become the master CPU:

```
Switch:1(config)# boot config delay 30
Switch:1(config)# save config
Switch:1(config)# reset
```

### Variable Definitions

The following table defines parameters for the **boot config master** command.

| Variable | Value                                                                                      |
|----------|--------------------------------------------------------------------------------------------|
| <1-2>    | Specifies the slot number, either 1 or 2, for the master CPU. The default value is slot 1. |

## Reserving Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable this boot flag, you need to save and reboot with the new configuration.

### Before You Begin

Product Notice: For 5520 Series and VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the boot flag:  

```
boot config flags advanced-feature-bandwidth-reservation [low | high]
```
3. Save the configuration, and then reboot the switch.

#### Important

A change to the advanced-feature-bandwidth-reservation boot flag requires a reboot for the change to take effect.

4. Verify the boot flag configuration:  

```
show boot config flags
```
5. Verify that the switch reserved the ports as loopback ports. Reserved ports are not visible in the output of the following command:

#### Note

This step only applies to 5520 Series and VSP 7400 Series.

```
show interfaces gigabitEthernet
```

### Example

Enable this feature to the low level.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags advanced-feature-bandwidth-reservation low
Warning: Please ensure that your configuration does not include ports 1/55-1/56. If
```

```

the configuration contains ports 1/55-1/56, loading of config will be aborted.
Are you sure you want to continue (y/n) ? y
Warning: Please save the configuration and reboot the switch
for this to take effect.
Flag advanced-feature-bandwidth-reservation is changed to enable (low).

```

## Display Advanced Feature Bandwidth Reservation Ports

### Note

This procedure applies to 5520 Series and VSP 7400 Series.

After you configure the **advanced-feature-bandwidth-reservation** boot flag and reboot with the new configuration, you can use the following procedure to verify that the switch reserved ports for configuring advanced features such as Fabric Extend, SPB, SMLT, vIST, VXLAN Gateway, Fabric RSPAN (Mirror to I-SID), Application Telemetry, or IS-IS Accept Policies.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Advanced Feature Bandwidth Reservation mode and reserved ports:

```
show sys-info
```

### Example

```

Switch# show sys-info

General Info :

SysDescr : Switch1 (w.x.y.z) BoxType: Switch1
SysName : Switch1
.
.
.

Advanced Feature Bandwidth Reservation:

Reservation Mode : low
Port Usage Info : 1/31 and 1/32 are not available to use

```

## Display the Boot Configuration

### About This Task

Display the configuration to view current or changed settings for the boot parameters.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View the configuration:
 

```
show boot config <choice|flags|general|host|master|running-config
[verbose]|sio>
```

## Example

Show the current boot configuration. (If you omit `verbose`, the system only displays the values that you changed from their default value.):

```
Switch:1>enable

Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1#(config)#show boot config running-config
#
#Mon Feb 13 13:32:58 2017 EST
#
boot config flags debug-config file
boot config flags debugmode
boot config flags ftpd
no boot config flags spbm-config-mode
boot config flags sshd
boot config flags telnetd
boot config flags tftpd
no boot config flags verify-config
boot config choice primary backup-config-file "/intflash/config.cfg"
#boot config sio console baud 115200
```

### Variable Definitions

The following table defines parameters for the **show boot config** command.

| Variable                                  | Value                                                                                                                                                                                                                       |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>choice</i>                             | Shows the current boot configuration choices.                                                                                                                                                                               |
| <i>flags</i>                              | Shows the current flag settings.                                                                                                                                                                                            |
| <i>general</i>                            | Shows system information.                                                                                                                                                                                                   |
| <i>host</i>                               | Shows the current host configuration.                                                                                                                                                                                       |
| <i>master</i>                             | Shows the master information.                                                                                                                                                                                               |
| <i>running-config</i><br><i>[verbose]</i> | Shows the current boot configuration. If you use <i>verbose</i> , the system displays all possible information. If you omit <i>verbose</i> , the system displays only the values that you changed from their default value. |
| <i>sio</i>                                | Specifies the current configuration of the serial ports.                                                                                                                                                                    |

## Configuring serial port devices

Configure the serial port devices to define connection settings for the console port. Depending on your hardware platform the console port displays as console or 10101.

### Note

These commands do not appear on all hardware platforms.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. View the current baud rate configuration:  
`show boot config sio`
3. Change the console baud rate:  
`boot config sio console baud <9600-115200> <1-8>|<SF1-SF3>`
4. Save the changed configuration.
5. Restart the switch.

**Example**

```
Switch:1>enable
Switch:1#config terminal
Switch:1(config)#show boot config sio
sio console baud 115200 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

Configure the baud rate to 9600 for the console port in IOC module slot 2:

```
Switch:1(config)#boot config sio console baud 9600 2
Switch:1(config)#show boot config sio
sio console baud 9600 2
sio console baud 115200 5
sio console baud 115200 8
sio console baud 115200 SF1
sio console baud 115200 SF3
```

### Variable Definitions

The following table defines parameters for the **boot config sio console** command.

| Variable                                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Run-time process management using CLI

Configure and manage the run-time process using the Command Line Interface (CLI).

### Configuring the date

#### About This Task

Configure the calendar time in the form of month, day, year, hour, minute, and second.

#### Procedure

1. Log on as rwa to perform this procedure.
2. To enter User EXEC mode, log on to the switch.
3. Configure the date:

```
clock set <MMdyyyyyhmmss>
```

#### Example

```
Switch:1> enable
```

```
Switch:1# clock set 19042014063030
```

*Variable definitions*

The following table defines parameters for the **clock set** command.

| Variable              | Value                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------|
| <i>MMddyyyyhhmmss</i> | Specifies the date and time in the format month, day, year, hour, minute, and second. |

## Configuring the time zone

### About This Task

Configure the time zone to use an internal system clock to maintain accurate time. The time zone data in Linux includes daylight changes for all time zones up to the year 2038. You do not need to configure daylight savings.

The default time zone is Coordinated Universal Time (UTC).

#### Important

In October 2014, the government of Russia moved Moscow from UTC+4 into the UTC+3 time zone with no daylight savings.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the time zone by using the following command:  

```
clock time-zone WORD<1-10> WORD<1-20> WORD<1-20>
```
3. Save the changed configuration.

### Example

Configure the system to use the time zone data file for Vevay:

```
Switch:1(config)# clock time-zone America Indiana Vevay
```

### Variable Definitions

The following table defines parameters for the **clock time-zone** command.

| Variable                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-10&gt;</i>                         | Specifies a directory name or a time zone name in <code>/usr/share/zoneinfo</code> , for example, Africa, Australia, Antarctica, or US. To see a list of options, enter <code>clock time-zone</code> at the command prompt without variables.                                                                                                                                                                                                                                                                                                                       |
| <i>WORD&lt;1-20&gt;</i> <i>WORD&lt;1-20&gt;</i> | The first instance of <i>WORD&lt;1-20&gt;</i> is the area within the timezone. The value represents a time zone data file in <code>/usr/share/zoneinfo/<i>WORD&lt;1-10&gt;</i></code> , for example, Shanghai in Asia. The second instance of <i>WORD&lt;1-20&gt;</i> is the subarea. The value represents a time zone data file in <code>/usr/share/zoneinfo/<i>WORD&lt;1-10&gt;</i>/<i>WORD&lt;1-20&gt;</i></code> , for example, Vevay in America/Indiana. To see a list of options, enter <code>clock time-zone</code> at the command prompt without variables. |

## Configure the Run-time Environment

### About This Task

Configure the run-time environment to define generic configuration settings for CLI sessions.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change the login prompt:  

```
login-message WORD<1-1513>
```
3. Change the password prompt:  

```
passwordprompt WORD<1-1510>
```
4. Configure the number of supported rlogin sessions:  

```
max-logins <0-8>
```

#### Note

This step only applies to VSP 8600 Series.

5. Configure the number of supported inbound Telnet sessions:  

```
telnet-access sessions <0-8>
```
6. Configure the idle timeout period before automatic logoff for CLI and Telnet sessions:  

```
cli timeout <30-65535>
```
7. Configure the number of lines in the output display:  

```
terminal length <8-64>
```
8. Configure scrolling for the output display:  

```
terminal more <disable|enable>
```

**Example**

```
Switch:1> enable
```

```
Switch:# configure terminal
```

Use the default option to enable use of the default logon string:

```
Switch:(config)# default login-message
```

Use the default option before this parameter to enable use of the default string:

```
Switch:(config)# default passwordprompt
```

Configure the allowable number of inbound remote CLI logon sessions:

```
Switch:(config)# max-logins 5
```

Configure the allowable number of inbound Telnet sessions:

```
Switch:(config)# telnet-access sessions 8
```

Configure the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection:

```
Switch:(config)# cli timeout 900
```

Configure the number of lines in the output display for the current session:

```
Switch:(config)# terminal length 30
```

Configure scrolling for the output display:

```
Switch:(config)# terminal more disable
```

*Variable Definitions*

The following table defines parameters for the **login-message** command.

| Variable             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-1513> | Changes the CLI logon prompt. <ul style="list-style-type: none"> <li>• <i>WORD</i>&lt;1-1513&gt; is an American Standard Code for Information Interchange (ASCII) string from 1-1513 characters.</li> <li>• Use the default option before this parameter, <code>default login-message</code>, to enable use of the default logon string.</li> <li>• Use the <code>no</code> operator before this parameter, <code>no login-message</code>, to disable the default logon banner and display the new banner.</li> </ul> |

Use the data in the following table to use the **passwordprompt** command.

| Variable             | Value                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-1510> | Changes the CLI password prompt. <ul style="list-style-type: none"> <li>• <i>WORD</i>&lt;1-1510&gt; is an ASCII string from 1-1510 characters.</li> <li>• Use the default option before this parameter, <code>default passwordprompt</code>, to enable using the default string.</li> <li>• Use the no operator before this parameter, <code>no passwordprompt</code>, to disable the default string.</li> </ul> |

Use the data in the following table to use the **max-logins** command.

| Variable                                                      | Value                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <0-8>                                                         | Configures the allowable number of inbound remote CLI logon sessions. The default value is 8. |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series. |                                                                                               |

Use the data in the following table to use the **telnet-access sessions** command.

| Variable | Value                                                                               |
|----------|-------------------------------------------------------------------------------------|
| <0-8>    | Configures the allowable number of inbound Telnet sessions. The default value is 8. |

Use the data in the following table to use the **cli time-out** command.

| Variable   | Value                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------|
| <30-65535> | Configures the timeout value, in seconds, to wait for a Telnet or CLI login session before terminating the connection. |

Use the data in the following table to use the **terminal** command.

| Variable                       | Value                                                                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <8-64>                         | Configures the number of lines in the output display for the current session. To configure this option to the default value, use the <b>default</b> operator with the command. The default is value 23.                                     |
| <i>disable</i>   <i>enable</i> | Configures scrolling for the output display. The default is enabled. Use the <b>no</b> operator to remove this configuration. To configure this option to the default value, use the <b>default</b> operator with the command.<br><b>no</b> |

## Configuring the logon banner

### About This Task

Configure the logon banner to display a warning message to users before authentication.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the switch to use a custom banner or use the default banner:  

```
banner <custom|static>
```
3. Create a custom banner:  

```
banner WORD<1-80>
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Activate the use of the default banner:

```
Switch:1(config)# banner static
```

### Variable Definitions

The following table defines parameters for the **banner** command.

| Variable                | Value                                            |
|-------------------------|--------------------------------------------------|
| <i>custom static</i>    | Activates or disables use of the default banner. |
| <i>displaymotd</i>      | Enables displaymotd.                             |
| <i>motd</i>             | Sets the message of the day banner.              |
| <i>WORD&lt;1-80&gt;</i> | Adds lines of text to the CLI logon banner.      |

## Configuring the message-of-the-day

### About This Task

Configure a system login message-of-the-day in the form of a text banner that appears after each successful logon.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Create the message-of-the-day:
 

```
banner motd WORD<1-1516>
```
3. Enable the custom message-of-the-day:
 

```
banner displaymotd
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Create a message-of-the-day to display with the logon banner. (To provide a string with spaces, include the text in quotation marks.):

```
Switch:1(config)# banner motd "Unauthorized access is forbidden"
```

Enable the custom message-of-the-day:

```
Switch:1(config)# banner displaymotd
```

### Variable Definitions

The following table defines parameters for the **banner motd** command.

| Variable                        | Value                                                                                                                                                                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-1516&gt;</code> | Creates a message of the day to display with the logon banner. To provide a string with spaces, include the text in quotation marks ("). To set this option to the default value, use the <b>default</b> operator with the command. |

## Configuring CLI logging

### About This Task

Use CLI logging to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

#### Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable CLI logging:
 

```
clilog enable
```

3. Disable CLI logging:  

```
no cliolog enable
```
4. Ensure that the configuration is correct:  

```
show cliolog
```
5. View the CLI log:  

```
show logging file module cliolog
```
6. View the CLI log.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cliolog enable
```

### Variable Definitions

The following table defines parameters for the **cliolog** commands.

| Variable      | Value                                                                              |
|---------------|------------------------------------------------------------------------------------|
| <i>enable</i> | Activates CLI logging. To disable, use the <code>no cliolog enable</code> command. |

## Configure System Parameters

### About This Task

Configure individual system-level switch parameters to configure global options for the switch.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Change the system name:  

```
sys name WORD<0-255>
```
3. Enable support for Jumbo frames:  

```
sys mtu <1522-9600>
```
4. Enable the User Datagram Protocol (UDP) checksum calculation:  

```
udp checksum
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the system, or root level, prompt name for the switch:

```
Switch:1(config)# sys name Floor3Lab2
```

## Variable Definitions

The following table defines parameters for the **sys** command.

| Variable                                                                                      | Value                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>clipId-topology-ip</i><br><b>Note:</b><br>Exception: Only supported on VSP 8600 Series     | Configures the topology ip from the available CLIP.<br><i>WORD</i> <1-256>specifies the Circuitless IP interface id.                                                |
| <i>control tcp-timestamp</i>                                                                  | Enables or disables TCP Timestamp.                                                                                                                                  |
| <i>force-msg</i>                                                                              | Adds forced message control pattern.<br><i>WORD</i> <4-4> Enter force message pattern.                                                                              |
| <i>force-topology-ip-flag</i><br><b>Note:</b><br>Exception: Only supported on VSP 8600 Series | Flags set to force choice of topology flag.<br><i>enable</i>                                                                                                        |
| <i>msg-control</i>                                                                            | Configures system message control feature.                                                                                                                          |
| <i>mtu</i> <1522-9600>                                                                        | Configures Jumbo frame support for the data path. The value can be either 1522, 1950 (default), or 9600 bytes.                                                      |
| <i>name</i> <i>WORD</i> <0-255>                                                               | Configures the system, or root level, prompt name for the switch.<br><i>WORD</i> <0-255> is an ASCII string from 0-255 characters (for example, LabSC7 or Closet4). |
| <i>power</i>                                                                                  | Enables power to specified slot(s).                                                                                                                                 |
| <i>security-console</i>                                                                       | Enables the security console.                                                                                                                                       |
| <i>software</i>                                                                               | Configures software configuration.                                                                                                                                  |
| <i>priv-exec-password</i>                                                                     | Enables authentication for the Privileged EXEC CLI command mode.                                                                                                    |

## Configuring system message control

### About This Task

Configure system message control to suppress duplicate error messages on the console, and to determine the action to take if they occur.

### Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Configure system message control action:  

```
sys msg-control action <both|send-trap|suppress-msg>
```

3. Configure the maximum number of messages:  

```
sys msg-control max-msg-num <2-500>
```
4. Configure the interval:  

```
sys msg-control control-interval <1-30>
```
5. Enable message control:  

```
sys msg-control
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure system message control to suppress duplicate error messages on the console and send a trap notification:

```
Switch:1(config)# sys msg-control action both
```

Configure the number of occurrences of a message after which the control action occurs:

```
Switch:1(config)# sys msg-control max-msg-num 2
```

Configure the message control interval in minutes:

```
Switch:1(config)# sys msg-control control-interval 3
```

Enable message control:

```
Switch:1(config)# sys msg-control
```

### Variable Definitions

The following table defines parameters for the **sys msg-control** command.

| Variable                                    | Value                                                                                                                                                                                |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>action</i> <both send-trap suppress-msg> | Configures the message control action. You can either suppress the message or send a trap notification, or both. The default is suppress.                                            |
| <i>control-interval</i> <1-30>              | Configures the message control interval in minutes. The valid options are 1-30. The default is 5.                                                                                    |
| <i>max-msg-num</i> <2-500>                  | Configures the number of occurrences of a message after which the control action occurs. To configure the maximum number of occurrences, enter a value from 2-500. The default is 5. |

## Extending system message control

### About This Task

Use the force message control option to extend the message control feature functionality to the software and hardware log messages.

To enable the message control feature, you must specify an action, control interval, and maximum message number. After you enable the feature, the log messages, which get repeated and cross the maximum message number in the control interval, trigger the force message feature. You can either suppress the message or send a trap notification, or both.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the force message control option:
 

```
sys force-msg WORD<4-4>
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the force message control option. (If you specify the wildcard pattern (\*\*\*\*), then all messages undergo message control:

```
Switch:1(config)# sys force-msg ****
```

### Variable Definitions

The following table defines parameters for the **sys force-msg** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;4-4&gt;</i> | Adds a forced message control pattern, where <i>WORD&lt;4-4&gt;</i> is a string of 4 characters. You can add a four-byte pattern into the force-msg table. The software and the hardware log messages that use the first four bytes that match one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****) as well. If you specify the wildcard pattern, all messages undergo message control. |

## Hardware status using EDM

This section provides methods to check the status of basic hardware in the chassis using Enterprise Device Manager (EDM).

### Configure Polling Intervals

#### About This Task

Enable and configure polling intervals to determine how frequently EDM polls for port and LED status changes or detects the hot swap of installed ports.

### Procedure

1. In the navigation pane, expand **Configuration > Device**.
2. Click **Preference Setting**.
3. Enable polling or hot swap detection.
4. Configure the frequency to poll the device.
5. Click **Apply**.

### *Preference Setting* field descriptions

Use the data in the following table to use the **Preference Setting** tab.

| Name                                       | Description                                                                                   |
|--------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>Enable</b>                              | Enables polling for port and LED status changes. The default is disabled.                     |
| <b>Poll Interval</b>                       | Specifies the polling interval, if enabled. The default is 60 seconds.                        |
| <b>Enable</b>                              | Detects the hot swap of installed ports. The default is disabled.                             |
| <b>Detection per Status Poll Intervals</b> | Specifies the number of poll intervals for detection, if enabled. The default is 2 intervals. |

## View Module Information

View the administrative status for modules in the chassis.

### About This Task

This command is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

### Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.

### *Card* field descriptions

Use the data in the following table to use the **Card** tab.

| Name                    | Description                                       |
|-------------------------|---------------------------------------------------|
| <b>CardType</b>         | Displays the model number of the module.          |
| <b>CardDescription</b>  | Shows a description of the installed module.      |
| <b>SerialNum</b>        | Shows the serial number for the installed module. |
| <b>PartNumber</b>       | Shows the part number.                            |
| <b>CardAssemblyDate</b> | Shows the date the module was assembled.          |

| Name                           | Description                                                             |
|--------------------------------|-------------------------------------------------------------------------|
| <b>CardHWConfig</b>            | Shows the hardware revision.                                            |
| <b>AdminStatus</b>             | Changes the administrative status for the module.                       |
| <b>OperStatus</b>              | Shows the operational status for the module.                            |
| <b>PowerManagementPriority</b> | Specifies the slot priority for power management as either high or low. |

## View Module Storage Usage

View the storage usage for modules in the chassis.

### About This Task

You cannot perform this procedure on hardware platforms with fixed configurations. It is only available for platforms where you can install modules in slots.

### Procedure

1. In the Device Physical View tab, select a module slot.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Storage Usage** tab.

### **Storage Usage** Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IntflashBytesUsed</b> | Specifies the number of bytes used in internal flash memory.              |
| <b>IntflashBytesFree</b> | Specifies the number of bytes available for use in internal flash memory. |
| <b>IntflashNumFiles</b>  | Specifies the number of files in internal flash memory.                   |
| <b>UsbBytesUsed</b>      | Specifies the number of bytes used in USB device.                         |
| <b>UsbBytesFree</b>      | Specifies the number of bytes available for use in USB device.            |
| <b>UsbNumFiles</b>       | Specifies the number of files in USB device.                              |

## View Power Supply Parameters

Perform this procedure to view information about the operating status of the power supplies.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Power Supply**.

**Details** Field Descriptions

Use the data in the following table to use the **Details** tab.

| Name                         | Description                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                    | Specifies the ID number.<br>This field is not supported on all hardware platforms.                                                                                                                                                                                                   |
| <b>Type</b>                  | Describes the type of power used.                                                                                                                                                                                                                                                    |
| <b>Description</b>           | Provides a description of the power supply.                                                                                                                                                                                                                                          |
| <b>SerialNumber</b>          | Specifies the power supply serial number.                                                                                                                                                                                                                                            |
| <b>HardwareRevision</b>      | Specifies the hardware revision number.                                                                                                                                                                                                                                              |
| <b>PartNumber</b>            | Specifies the power supply part number.                                                                                                                                                                                                                                              |
| <b>PowerSupplyOperStatus</b> | Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> <li>on (up)</li> <li>off (down)</li> </ul>                                                                                                                                      |
| <b>InputLineVoltage</b>      | Displays the input line voltage: <ul style="list-style-type: none"> <li>low 110v—power supply connected to a 110 Volt source</li> <li>high 220v—power supply connected to a 220 Volt source</li> <li>ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source</li> </ul> |
| <b>OutputWatts</b>           | Displays the output power of this power supply.                                                                                                                                                                                                                                      |
| <b>InputOperLineVoltage</b>  | Displays the operating input line voltage.<br>If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value.<br>This field is not supported on all hardware platforms.                                      |
| <b>InputPower</b>            | Displays the input power of this power supply.<br>This field is not supported on all hardware platforms.                                                                                                                                                                             |

## View Power Supply Information

Perform this procedure to view information about the operating status of the power supplies.

**About This Task**

This tab does not appear in all hardware platforms.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Power Supply Information**.

**Details** Field Descriptions

Use the data in the following table to use the **Details** tab.

| Name                         | Description                                                                                                                                                                                                                                                                          |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                    | Specifies the ID number.<br>This field is not supported on all hardware platforms.                                                                                                                                                                                                   |
| <b>Type</b>                  | Describes the type of power used.                                                                                                                                                                                                                                                    |
| <b>Description</b>           | Provides a description of the power supply.                                                                                                                                                                                                                                          |
| <b>SerialNumber</b>          | Specifies the power supply serial number.                                                                                                                                                                                                                                            |
| <b>HardwareRevision</b>      | Specifies the hardware revision number.                                                                                                                                                                                                                                              |
| <b>PartNumber</b>            | Specifies the power supply part number.                                                                                                                                                                                                                                              |
| <b>PowerSupplyOperStatus</b> | Specifies the status of the power supply as one of the following: <ul style="list-style-type: none"> <li>on (up)</li> <li>off (down)</li> </ul>                                                                                                                                      |
| <b>InputLineVoltage</b>      | Displays the input line voltage: <ul style="list-style-type: none"> <li>low 110v—power supply connected to a 110 Volt source</li> <li>high 220v—power supply connected to a 220 Volt source</li> <li>ac110vOr220v—power supply connected to a 110 Volt or 220 Volt source</li> </ul> |
| <b>OutputWatts</b>           | Displays the output power of this power supply.                                                                                                                                                                                                                                      |
| <b>InputOperLineVoltage</b>  | Displays the operating input line voltage.<br>If the power supplies in a chassis are not of identical input line voltage values, the operating line voltage shows the low 110v value.<br>This field is not supported on all hardware platforms.                                      |
| <b>InputPower</b>            | Displays the input power of this power supply.<br>This field is not supported on all hardware platforms.                                                                                                                                                                             |

## View System Temperature Information

View information about the temperature for each sensor on the device.

The system triggers an alarm when one of the zones exceeds the threshold temperature value.

**Note**

This procedure does not apply to all hardware models.

**Procedure**

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **System Temperature** tab.

**System Temperature** field descriptions

Use the data in the following table to use the **System Temperature** tab.

| Name                                 | Description                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SensorIndex</b>                   | Specifies the range of sensors on the device.                                                                                                                                                                            |
| <b>SensorDescription</b>             | Specifies the name of the sensor.                                                                                                                                                                                        |
| <b>Temperature (degrees celsius)</b> | Specifies the sensor temperature measured in Celsius degrees.                                                                                                                                                            |
| <b>WarningThreshold</b>              | Specifies the temperature value of the warning threshold for the sensor. When the temperature crosses the warning threshold a warning message is generated.                                                              |
| <b>CriticalThreshold</b>             | Species the temperature value of the critical threshold for the sensor. When the temperature crosses the critical threshold, a critical message is generated or the system shuts down, depending on hardware capability. |
| <b>Status</b>                        | Specifies the current temperature status based on the warning and critical thresholds.                                                                                                                                   |

## View Temperature on the Chassis

You can view information about the temperature on the chassis.

**Note**

This tab appears only on the VSP 8600 Series switch.

**About This Task**

The system triggers an alarm when one of the zones exceeds the threshold temperature value, and clears the alarm after the zone temperature falls below the threshold value.

When an elevated temperature triggers a temperature alarm, the fan speed increases, and the LED color changes on the front panel of the switch.

**Procedure**

1. In the Device Physical View tab, select the chassis.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Temperature** tab.

**Temperature** field descriptions

Use the data in the following table to use the **Temperature** tab.

| Name                   | Description                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------|
| <b>CpuTemperature</b>  | Current CPU temperature in Celsius.                                                                   |
| <b>MacTemperature</b>  | Current MAC component temperature in Celsius.                                                         |
| <b>Phy1Temperature</b> | Current PHY 1 component temperature in Celsius. This field does not appear on all hardware platforms. |
| <b>Phy2Temperature</b> | Current PHY 2 component temperature in Celsius. This field does not appear on all hardware platforms. |

## CLI show command reference

The following reference information provides show commands to view the operational status of the switch.

### Access, logon names, and passwords

Use the **show cli password** command to display the access, logon name, and password combinations. The syntax for this command is as follows.

#### **show cli password**

The following example shows output from the **show cli password** command if enhanced secure mode is disabled.

```
Switch:1#show cli password
 access-level
 aging 90

 min-passwd-len 10
 password-history 3

 ACCESS LOGIN STATE
 13 13 ena
 12 12 ena
 11 11 ena
 Default Lockout Time 60
 Default Lockout Retries 3
 Lockout-Time:
 IP Time
```

The following example shows output from the **show cli password** command if enhanced secure mode is enabled.

### Note

After you enable enhanced secure mode, the parameters in the output for the **show cli password** command apply to all of the role-based users, except for the admin user. So for instance, the system mandates that the admin user must have a password length of 15, and a password with two of each of the following characters: uppercase, lowercase, numeric and special character. However, the admin user can then configure this differently for the other user access levels. The following values that display for min-passwd-len and password-rule are those configured by admin, and they apply to the privilege, operator, security, and auditor access levels.

```
Switch:1#show cli password
change-interval 24
min-passwd-len 8
password-history 3
password-rule 1 1 1 1
pre-expiry-notification-interval 1 7 30
post-expiry-notification-interval 1 7 30
access-level
ACCESS LOGIN AGING MAX-SSH-SESSIONS STATE
admin rwa 90 3 ena
privilege rwa 90 3 dis
operator oper1 90 3 ena
security security 90 3 ena
auditor auditor 90 3 ena
Default Lockout Time 60
Lockout-Time:
```

## Basic switch configuration

Use the **show basic config** command to display the basic switch configuration. The syntax for this command is as follows.

### **show basic config**

The following example shows the output of this command.

```
Switch:1#show basic config
setdate : N/A
auto-recover-delay : 30
```

## Current Switch Configuration

Use the **show running-config** command to display the current switch configuration. The syntax for this command is as follows.

```
show running-config [verbose] [module <app-telemetry | boot | cfm | cli
| diag | dvr | eap | endpoint-tracking | energy-saver | fa | fhs |
filter | ike | ip | ipfix | ipsec | ipv6 | iqagent | isis | i-sid | lacp
| license | lldp | lst | macsec | mlt | naap | nls | ntp | ovssdb | port
| qos | radius | restconf | rmon | sflow | security | slamon | slpp |
sntp | spbm | stg | sys | tacacs | virtualservice | vlan | web | vxlan>]
```

The following table explains parameters for this command.

**Table 34: Command parameters**

| Parameter                                                                                                                                                                                                                                                                                                                                                                                                                     | Description                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| <code>module &lt;app-telemetry   boot   cfm   cli   diag   dvr   eap   endpoint-tracking   energy-saver   fa   fhs   filter   ike   ip   ipfix   ipsec   ipv6   iqagent   isis   i-sid   lacp   license   lldp   lst   macsec   mlt   naap   nls   ntp   ovsdb   port   qos   radius   restconf   rmon   sflow   security   slamon   slpp   smtp   spbm   stg   sys   tacacs   virtualservice   vlan   web   vxlan&gt;</code> | Specifies the command group for which you request configuration settings.    |
| <code>verbose</code>                                                                                                                                                                                                                                                                                                                                                                                                          | Specifies a complete list of all configuration information about the switch. |

If you make a change to the switch, it appears under the specific configuration heading. The following example shows a subset of the output of this command.

```
Switch:1#show running-config
Preparing to Display Configuration...
#
Sun Dec 18 14:04:23 2016 UTC
box type : VSP-8608
software version : 4.5.0.0
cli mode : CLI
--More-- (q = quit)
```

#### Note

The output from the **show running-config** command displays an "end statement" near the end of the config file. This statement means that the script is exiting the Global Configuration mode and loading the rest of the configuration in Privileged EXEC mode, which is a requirement when loading the IP redistribution commands.

If you add **verbose** to the **show running-config** command, the output contains current switch configuration including software (versions), performance, VLANs (numbers, port members), ports (type, status), routes, memory, interface, and log and trace files. With the verbose command, you can view the current configuration and default values.

## CLI Settings

Use the **show cli info** command to display information about the CLI configuration. The syntax for this command is as follows.

#### **show cli info**

The following example shows sample output from the **show cli info** command.

Command output can vary across hardware models.

```
Switch:1#show cli info

cli configuration

more : true
screen-lines : 23
telnet-sessions : 8
rlogin-sessions : 8
timeout : 900 seconds
monitor duration: 300 seconds
monitor interval: 5 seconds

use default login prompt : true
default login prompt : Login:
custom login prompt : Login:
use default password prompt : true
default password prompt : Password:
custom password prompt : Password:
prompt : Switch
```

## Ftp-access sessions

Use the **show ftp-access** command to display the total sessions allowed. The syntax for this command is as follows.

### **show ftp-access**

The following example shows output from the **show ftp-access** command.

```
Switch:1#show ftp-access
max ipv4 sessions : 4
max ipv6 sessions : 4
```

## Hardware information

To display system status and technical information about the switch hardware components, use the **show sys-info** command. The command displays several pages of information, including general information about the system (such as location), chassis (type, serial number, and base MAC address), cpld, temperature, power supplies, fans, cards, system errors, port locks, topology status, and message control information.

You can identify a port-licensed switch with its part number. Use the command **show sys-info** to view the part number of the switch. For the list of part numbers of VSP 7200 Series switches with the option of port licensing, see [Installing the Virtual Services Platform 7200 Series](#).

The syntax for this command is as follows:

```
show sys-info {card | cpld | fan | led | power | ssd | temperature |
uboot | usb}
```

The following table defines parameters for the **show sys-info** command.

**Table 35: Command parameters**

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>card</i>        | Specifies information about the device. Includes type, serial number, and assembly date.<br><br><b>Note:</b><br>Not all hardware platforms support removable cards or modules. If a platform does not support removable cards or modules, the output provides information on the chassis as a whole. For more information, see the hardware documentation for your platform. |
| <i>cpld</i>        | Specifies information about field programmable gate arrays (FPGA) and complex programmable logic devices (CPLD).<br><br><b>Note:</b><br>This parameter is not supported on all hardware platforms.                                                                                                                                                                           |
| <i>fan</i>         | Specifies information about installed cooling ports.                                                                                                                                                                                                                                                                                                                         |
| <i>led</i>         | Specifies LED information in detail.                                                                                                                                                                                                                                                                                                                                         |
| <i>power</i>       | Specifies information about installed power supplies.                                                                                                                                                                                                                                                                                                                        |
| <i>ssd</i>         | Specifies information about installed modular Solid State Drives (SSD).<br><br><b>Note:</b><br>This parameter is not supported on all hardware platforms.                                                                                                                                                                                                                    |
| <i>temperature</i> | Specifies temperature information.                                                                                                                                                                                                                                                                                                                                           |
| <i>uboot</i>       | Specifies uboot details.                                                                                                                                                                                                                                                                                                                                                     |
| <i>usb</i>         | Specifies information about cached USB information.                                                                                                                                                                                                                                                                                                                          |

The following examples show partial output from the **show sys-info** command for various switches. The output for this command will vary on switches because of hardware differences.

The following example shows partial output from the **show sys-info** command for a VSP 8284XSQ switch.

```
Switch:1>show sys-info

General Info :

 SysDescr : VSP-8284XSQ (w.x.y.z)
 SysName : Switch
```

```

SysUpTime : 0 day(s), 15:49:09
SysContact : http://www.extremenetworks.com/contact/
SysLocation : 9 Northeastern Blvd, Salem, NH. 03079

```

## Chassis Info:

```

Chassis : 8284XSQ
ModelName : 8284XSQ
BrandName : Extreme Networks
Serial# : 14JP174C1013
H/W Revision : 1
H/W Config :
Part Number : EC8200A01-E6
NumSlots : 2
NumPorts : 85
BaseMacAddr : b0:ad:aa:43:48:00
MacAddrCapacity : 1024
MgmtMacAddr : b0:ad:aa:43:48:81
System MTU : 1950

```

Current FPGA/CPLD Info :

 MODULE VERSION

 CPU CPLD : 1.1.18
 SYSTEM FPGA : 1.2.41
 PORT1 PLD : 1.1.08

```

To display port information for a switch, use the **show interfaces gigabitethernet** command.

On a VSP 7200 Series switch that is port licensed, use the command **show interfaces gigabitethernet** to view the licensed status of the ports on the switch.

The syntax for this command is as follows:

```
show interfaces gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

The following example shows output for the **show interfaces gigabitethernet 1/41 - 1/42** command. Slot and port information can differ depending on hardware platform. For more information, see your hardware documentation.

```

Switch:1#show interfaces gigabitEthernet 1/41-1/42
=====
Interface Port
=====
PORT LINK PORT
PHYSICAL STATUS
NUM INDEX DESCRIPTION TRAP LOCK MTU ADDRESS
ADMIN OPERATE

1/41 232 40GbNone true false 1950 b0:ad:aa:41:34:28 down down
1/42 233 40GbNone true false 1950 b0:ad:aa:41:34:29 down down

```

The following example shows the partial output of the **show interfaces gigabitEthernet** command for the VSP 7254XSQ switch. View the `LICENSE STATUS` field. It can have one of the following values:

- `n/a`: Indicates that it is not a port that is activated by a port license.
- `locked`: Indicates that the port is locked and non-operational because the switch is port licensed and a valid port license is not present.

Attempting to enable a locked port, for example port 1/25, displays the error message `Error: port 1/25, Port License is required to enable this port.`

- `unlocked`: Indicates that the port is unlocked and is operational, because a valid port license is present.

```
Switch:1#show interfaces gigabitEthernet
```

| Port Interface |       |             |              |              |      |                     |                 |         |                   |

## High Availability State

Use the **show ha-state** command to view detailed information on High Availability (HA) state of the system.

The syntax for this command is as follows.

### **show ha-state**

The following example shows sample command output.

```
Switch:1(config)#show ha-state
Current CPU State : Initialization state.
```

#### Note

Use the **show sys-info** command to view the slots of the master CPU and the standby CPU. You can also check whether the standby CPU is running in hot standby mode or warm standby mode.

## NTP server statistics

Use the **show ntp statistics** command to view the following information:

- number of NTP requests sent to this NTP server
- number of times this NTP server updated the time
- number of times the client rejected this NTP server while attempting to update the time
- stratum
- version
- sync status
- reachability
- root delay
- precision

The syntax for this command is as follows.

**show ntp statistics**

The following example shows sample command output.

```
Switch:1##show ntp statistics
N NTP Server : 192.0.2.187

 Stratum : unknown
 Version : unknown
 Sync Status : unknown
 Reachability : unknown
 Root Delay : unknown
 Precision : unknown
 Access Attempts : 0
 Server Synch : 0
 Server Fail : 0
 Fail Reason : unknown
```

## Power summary

Use the **show sys power** command to view a summary of the power information for the chassis.

The syntax for this command is as follows.

**show sys power [global] [power-supply] [slot]**

The following example shows sample command output.

```
Switch:1#show sys power
=====
 Chassis Power Information
=====

Chassis Power Status: redundant

Chassis Total Required Max
Type Chassis Redundant Allocated Available Reserved Required

SwitchXYZ 4200 1400 1851 2349 1411 1851
=====
```

**Note**

Power information can differ by hardware platform. For more information, see the hardware documentation for your platform.

## Power management information

Use the **show sys power global** command to view a summary of the power redundancy settings.

The syntax for this command is as follows.

**show sys power global**

The output varies according to platform. The following example shows sample command output for one hardware platform.

```
Switch:1#show sys power global
 slot 1 : critical
 slot 2 : critical
 slot 3 : high
 slot 4 : high
 slot 5 : high
 slot 6 : high
 slot 7 : high
 slot 8 : high
 slot SF1 : critical
 slot SF2 : critical
 slot SF3 : critical
```

## Power information for power supplies

Use the **show sys power power-supply** command to view detailed power information for each power supply.

The syntax for this command is as follows.

**show sys power power-supply**

The following example shows sample command output.

```
Switch:1#show sys power power-supply

=====
 Power Supply Information
=====
Power Type Input Serial Part Oper Max
Supply Voltage Num Num Status Power

PS#2 AC 110/220 GWXD1349000116- DPS-800RB up 800

```

### Note

Power information can differ depending on hardware platform. For more information, see the hardware documentation for your platform.

## Slot power details

Use the **show sys power slot** command to view detailed power information for each slot.

The syntax for this command is as follows.

**show sys power slot**

The following example shows sample command output.

```
Switch:1#show sys power slot

=====
 Slot Power Consumption
=====
```

| Slot No. | Present | CardType    | Priority | Power Status | Max Allocated Power |
|----------|---------|-------------|----------|--------------|---------------------|
| 1        | YES     | 8624XS      | CRITICAL | ON           | 310                 |
| 2        | YES     | 8624XS      | CRITICAL | ON           | 310                 |

| 8        | NO      | Not Present | HIGH     | OFF          | 0                   |
| SF 1     | YES     | 8600SF      | CRITICAL | ON           | 157                 |
| SF 1     | YES     | 8600SF      | CRITICAL | ON           | 157                 |
| SF 1     | YES     | 8600SF      | CRITICAL | ON           | 157                 |

--More-- (q = quit)

## System Information

Use the **show sys** command to display system status and technical information about the switch hardware components and software configuration. The command shows several pages of information, including general information about the system (such as location), chassis (type, serial number, and base MAC address), temperature, power supplies, fans, cards, system errors, port locks, topology status, and message control information. The syntax for this command is as follows.

```
show sys <control | dns | force-msg | locator-led | mgid-usage | msg-control | mtu | power | priv-exec-password | setting | software | stats | topology-ip | vim-speed>
```

The following table explains parameters for this command.

**Table 36: Command parameters**

| Parameter                   | Description                                                                |
|-----------------------------|----------------------------------------------------------------------------|
| <i>control</i>              | Shows system control settings.                                             |
| <i>default-ping-context</i> | Specifies the default context for ping and traceroute commands.            |
| <i>dns</i>                  | Shows the DNS default domain name.                                         |
| <i>force-msg</i>            | Shows the message control force message pattern settings.                  |
| <i>locator-led</i>          | Shows the locator LED status.                                              |
| <i>mgid-usage</i>           | Shows the multicast group ID (MGID) usage for VLANs and multicast traffic. |
| <i>msg-control</i>          | Shows the system message control function status (activated or disabled).  |
| <i>mtu</i>                  | Shows system maximum transmission unit (MTU) information.                  |

**Table 36: Command parameters (continued)**

| Parameter                 | Description                                                                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>power</i>              | Shows power information for the chassis. Command options are: <ul style="list-style-type: none"> <li>• <i>global</i>—power management settings</li> <li>• <i>power-supply</i>—power information for each power supply</li> <li>• <i>slot</i>—power information for each slot</li> </ul> |
| <i>priv-exec-password</i> | Shows whether authentication is enabled for the Privileged EXEC CLI command mode.                                                                                                                                                                                                       |
| <i>setting</i>            | Shows system settings.                                                                                                                                                                                                                                                                  |
| <i>software</i>           | Shows the version of software running on the switch, the last update of that software, and the Boot Config Table. The Boot Config Table lists the current system settings and flags.                                                                                                    |
| <i>stats</i>              | Shows system statistics.<br>This parameter does not apply to all hardware platforms.                                                                                                                                                                                                    |
| <i>topology-ip</i>        | Shows the circuitless IP set.                                                                                                                                                                                                                                                           |
| <i>vim-speed</i>          | Shows the speed of all ports of the VIM.                                                                                                                                                                                                                                                |

The following example shows output from the **show sys control** command.

```
Switch:1>show sys control
=====
 System Control Settings
=====
 tcp-timestamp : enable
 tcp-keepalive-time : 60
 tcp-keepalive-interval : 10
 tcp-keepalive-probes : 5
 mac-move-protection : on
```

**Note**

The *tcp-keepalive-time*, *tcp-keepalive-interval*, *tcp-keepalive-probes*, and *mac-move-protection* fields are not supported on VSP 8600 Series.

The following example shows output from the **show sys dns** command. The same output applies from the **show ip dns** command.

```
Switch:1>show sys dns
DNS Default Domain Name : test.company.com
DNS Default Domain Name Origin: DHCP
DNS Host Name: voss10cdae6bd000
Primary dynamic DNS server details:
=====
 IP address : 192.0.2.11
 Status : active
 Total DNS Number of request made to this server : 0
 Number of Successful DNS : 0

Secondary dynamic DNS server details:
```

```

=====
IP address : 192.0.2.12
Status : active
Total DNS Number of request made to this server : 0
Number of Successful DNS : 0

Tertiary dynamic DNS server details:
=====
IP address : 192.0.2.13
Status : active
Total DNS Number of request made to this server : 0
Number of Successful DNS : 0

```

The following example shows output from the **show sys mgid-usage** command.

```

Switch:1#show sys mgid-usag
Number of MGIDs used for VLANs : (6)
Number of MGIDs used for multicast : (0)
Number of MGIDs used for SPBM : (0)
Number of MGIDs remaining for VLANs : (4089)
Number of MGIDs remaining for multicast : (6976)
Number of MGIDs remaining for SPBM : (1024)

```

The following example shows output from the **show sys msg-control** command.

```

Switch:1#show sys msg-control

Message Control Info :
 action : suppress-msg
 control-interval : 5
 max-msg-num : 5
 status : disable

```

The following example shows output from the **show sys setting** command.

```

Switch:1#show sys setting

 udp-checksum : enable
 mroute-stream-limit : disable
 contact : http://www.company.com/
 location : Anywhere, USA

EnableRloginServer : false
EnableFtpServer : true
EnableTftpServer : false

```

The following example shows output from the **show sys priv-exec-password** command.

```

Switch:1#show sys priv-exec-password
 Privileged exec password status : enabled

```

## System status (detailed)

Use the **show tech** command to display technical information about system status and information about the hardware, software, and operation of the switch.

The information available from the **show tech** command includes general information about the system (such as location), hardware (chassis, power supplies, fans, and ports), system errors, boot configuration, software versions, memory, port information (locking status, configurations, names, interface status), VLANs and STGs (numbers, port members), Virtual Router Redundancy Protocol (VRRP), and log and trace files. This command displays more information than the similar **show sys-info** command. The syntax for this command is as follows.

### show tech

The following example shows representative output from the **show tech** command.

```

Switch:1#show tech

Sys Info:

General Info :

 SysDescr : VSP-8284XSQ (4.0.0.0)
 SysName : VSP-8284XSQ
 SysUpTime : 3 day(s), 14:22:52
 SysContact : support@extremenetworks.com
 SysLocation :

Chassis Info:

 Chassis : 8284XSQ
 ModelName : 8284XSQ
 BrandName : Extreme Networks
 Serial# : 12JP442H70YC
 H/W Revision : 10

```

```

H/W Config : none
NumSlots : 1
NumPorts : 50
BaseMacAddr : 24:d9:21:e2:e0:00
MacAddrCapacity : 256

--More-- (q = quit)

```

## Telnet-access sessions

Use the **show telnet-access** command to display to show the total sessions allowed. The syntax for this command is as follows.

### **show telnet-access**

The following example shows output from the **show telnet-access** command.

```

Switch:1#show telnet-access
max ipv4 sessions : 8
max ipv6 sessions : 8

```

## Users logged on

Use the **show users** command to display a list of users currently logged on to the system. The syntax for this command is as follows.

### **show users**

The following example shows output from the **show users** command.

```

Switch:1#show users
SESSION USER ACCESS IP ADDRESS
Telnet0 rwa rwa 192.0.2.24 (current)
Console none none -----

```

## Port egress COS queue statistics

Use the **show qos cosq-stats interface** command to retrieve the port egress COS queue statistics. The syntax for this command is as follows:

```
show qos cosq-stats interface {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Note

The show output displays either unicast packet stats for each port or all stats based on your hardware platform.

The following example shows output from the **show qos cosq-stats interface** command.

```

Switch:1#show qos cosq-stats interface 1/42

=====
Port:1/42 QOS CoS Queue Stats

```

```

Switch:1#

```

## CPU Queue Statistics

Use the **show qos cosq-stats cpu-port** command to display the statistics of the forwarded packets and bytes, and the dropped packets and bytes, for the traffic sent toward the CP. The queue assignment is based on the protocol types, not on the internal COS value. These statistics are useful for debugging purposes.

The syntax for this command is as follows:

**show qos cosq-stats cpu-port**

### Note

The first column of the show output can display either protocol type or show queue number depending on your hardware platform.

The following example shows output from the **show qos cosq-stats cpu-port** command.

```
Switch:1#show qos cosq-stats cpu-port
```

```
=====
QoS CoS Queue Cpu Port Stats Table
=====
```

| CoS | Out Packets | Out Bytes | Drop Packets | Drop Bytes |
|-----|-------------|-----------|--------------|------------|
| 0   | 0           | 0         | 0            | 0          |
| 1   | 0           | 0         | 0            | 0          |
| 2   | 0           | 0         | 0            | 0          |
| 3   | 0           | 0         | 0            | 0          |
| 4   | 0           | 0         | 0            | 0          |
| 5   | 0           | 0         | 0            | 0          |
| 6   | 414         | 35714     | 0            | 0          |
| 7   | 0           | 0         | 0            | 0          |
| 8   | 561         | 41738     | 0            | 0          |
| 9   | 28740       | 1969460   | 0            | 0          |

## Command Line Interface Fundamentals

---

This section describes the Command Line Interface (CLI).

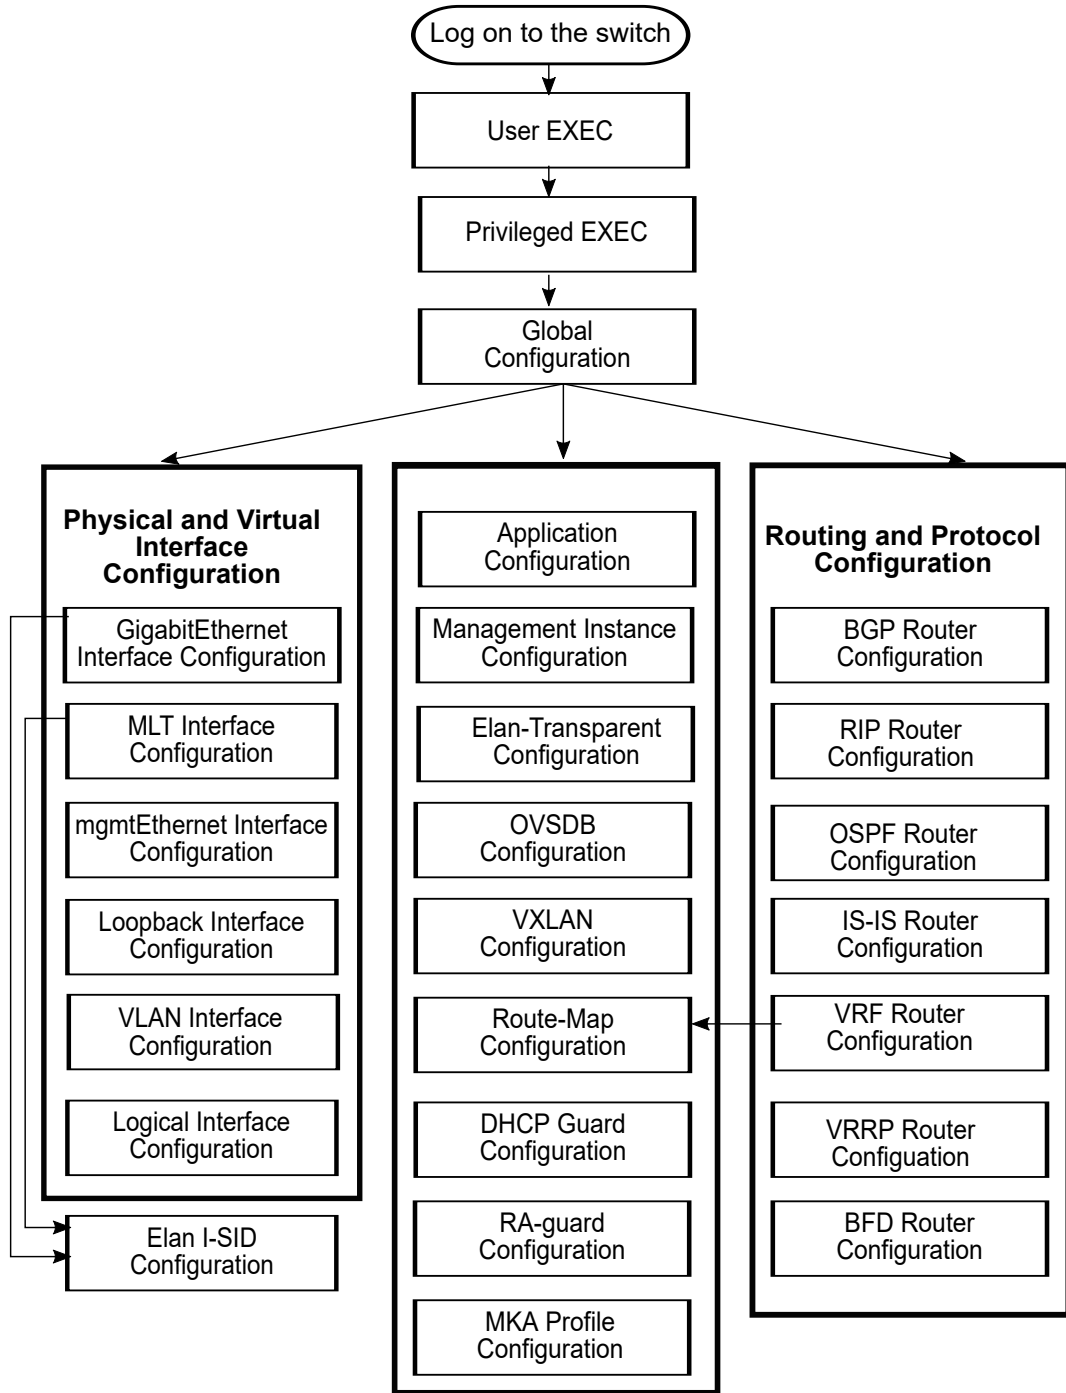

CLI is an industry standard command line interface that you can use for single-device management.

### CLI Command Modes

CLI command modes provide specific sets of CLI commands. When you log onto the switch, you are in User EXEC mode with limited commands. While in a higher mode, you can access most commands from lower modes, except if they conflict with commands of your current mode.

There are two categories of CLI commands: show commands and configuration commands. You can use show commands from multiple command modes with the same results; they show the same configuration information regardless of the command mode. Configuration command results, however, might be dependent on the command mode from which a configuration command is used. For example, an **enable** command used in Global Configuration mode will enable a feature globally for all devices, and the same command used from one of the interface command modes will enable a feature for a specific interface only.

The following figure illustrates the navigation paths for the various command modes:

**Figure 2: CLI Command Mode Navigation**

Your user authorization credentials determine what commands are available to you in Privileged EXEC mode and all higher-level modes. See [System Access](#) on page 3306 for more information.

To navigate from higher-level modes to lower-level modes, use the following commands:

- **exit** to navigate from a higher-level mode to a lower-level mode, down to Privileged EXEC mode
- **end** to navigate from any command mode directly to Privileged EXEC mode
- **disable** to navigate from Privileged EXEC mode to User EXEC mode
- **logout** to terminate the CLI session from any command mode

The following table describes the various command modes, including the CLI command to access each mode, the command prompt that displays in each mode, and a description of the purpose of the mode.

#### Note

Some command modes are hardware dependent. If any of the following commands modes do not display on your hardware, they are not supported or applicable.

**Table 38: CLI Command Mode Summary**

| Command mode                            | Command to access mode                                                                                                                                                                                                                          | Prompt displayed in mode | Description                                                                                                                                          |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| User EXEC                               | None required; default mode                                                                                                                                                                                                                     | >                        | View configuration settings and connection status.                                                                                                   |
| Privileged EXEC                         | enable                                                                                                                                                                                                                                          | #                        | Configure limited device-wide settings.                                                                                                              |
|                                         | <b>Note:</b><br>Depending on feature configuration, you can be prompted to enter a username and password to access Privileged EXEC mode. For more information, see <a href="#">Authentication for Privileged EXEC Command Mode</a> on page 249. |                          |                                                                                                                                                      |
| Global Configuration                    | configure<br>{terminal <br>network}                                                                                                                                                                                                             | (config) #               | From a terminal or TFTP server, configure device-wide global parameters on a running configuration, or specify the filename of a configuration file. |
| GigabitEthernet Interface Configuration | interface<br>GigabitEthernet<br>{slot/port[/sub-<br>port] [-slot/<br>port[/subport]]<br>[, ...]}                                                                                                                                                | (config-if) #            | Configure chassis operations and features on a physical port.                                                                                        |
| MLT Interface Configuration             | interface mlt<br><1-512>                                                                                                                                                                                                                        | (config-mlt) #           | Configure an MLT interface.                                                                                                                          |
| mgmtEthernet Interface Configuration    | interface<br>mgmtEthernet<br><mgmt   mgmt2>                                                                                                                                                                                                     | (config-if) #            | Configure a dedicated physical management port (if supported on your hardware).                                                                      |

**Table 38: CLI Command Mode Summary (continued)**

| Command mode                      | Command to access mode                        | Prompt displayed in mode                                                                                                            | Description                                                                                                           |
|-----------------------------------|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Loopback Interface Configuration  | <code>interface loopback &lt;1-256&gt;</code> | <code>(config-if) #</code>                                                                                                          | Configure a loopback CLIP interface.                                                                                  |
| VLAN Interface Configuration      | <code>interface vlan &lt;1-4059&gt;</code>    | <code>(config-if) #</code>                                                                                                          | Configure port-based, policy-based, private, or SPBM B-VLANs                                                          |
| Logical Interface Configuration   | <code>logical-intf isis &lt;1-255&gt;</code>  | Layer 2:<br><code>(config-isis- &lt;1-255&gt;) #</code><br>Layer 3:<br><code>(config-isis- &lt;1-255&gt;- &lt;A.B.C.D&gt;) #</code> | Configure a logical Layer 2 or Layer 3 interface.                                                                     |
| BGP Router Configuration          | <code>router bgp</code>                       | <code>(router-bgp) #</code>                                                                                                         | Configure device-wide BGP routing protocol settings.                                                                  |
| RIP Router Configuration          | <code>router rip</code>                       | <code>(config-rip) #</code>                                                                                                         | Configure device-wide RIP routing protocol settings.                                                                  |
| OSPF Router Configuration         | <code>router ospf</code>                      | <code>(config-ospf) #</code>                                                                                                        | Configure device-wide OSPF routing protocol settings.                                                                 |
| IS-IS Router Configuration        | <code>router isis</code>                      | <code>(config-isis) #</code>                                                                                                        | Configure device-wide IS-IS routing protocol settings.                                                                |
| VRF Router Configuration          | <code>router vrf WORD&lt;1-16&gt;</code>      | <code>(router-vrf) #</code>                                                                                                         | Configure a VRF instance, including the built-in Management VRF (accessed with <b>router vrf MgmtRouter</b> command). |
| VRRP Router Configuration         | <code>router vrrp</code>                      | <code>(config-vrrp) #</code>                                                                                                        | Configure device-wide VRRP protocol settings.                                                                         |
| Application Configuration         | <code>application</code>                      | <code>(config-app) #</code>                                                                                                         | Configure custom applications, such as SLA Monitor or RESTCONF.                                                       |
| Management Instance Configuration | <code>mgmt &lt;clip   oob   vlan&gt;</code>   | <code>(mgmt:clip) #</code><br>or<br><code>(mgmt:oob) #</code><br>or<br><code>(mgmt:vlan) #</code>                                   | Configure a segmented management CLIP, Out-of-Band (OOB), or VLAN instance.                                           |
| Elan I-SID Configuration          | <code>i-sid &lt;1-16777215&gt; [elan]</code>  | <code>(elan:&lt;1-16777215&gt;) #</code>                                                                                            | Add ports and traffic to a Switched UNI I-SID on a GigabitEthernet or MLT interface.                                  |

**Table 38: CLI Command Mode Summary (continued)**

| Command mode                   | Command to access mode                       | Prompt displayed in mode     | Description                                                                                                                                                              |
|--------------------------------|----------------------------------------------|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Elan-Transparent Configuration | i-sid<br><1-16777215><br>elan-transparent    | (elan-<br>tp:<1-16777215>) # | Add ports and MLT interfaces to an Elan-Transparent based service.                                                                                                       |

| Route-Map Configuration        | route-map<br>WORD<1-64><br><1-65535>         | (route-map) #                | Configure device-wide or VRF instance-specific route map policy settings.                                                                                                |
| DHCP-guard Configuration       | ipv6 fhs dhcp-<br>guard policy<br>WORD<1-64> | (config-<br>dhcpguard) #     | Configure DHCPv6 for advertised address-based, prefix-based, and preference-based filtering.                                                                             |
| RA-guard Configuration         | ipv6 fhs ra-guard<br>policy WORD<1-64>       | (config-raguard) #           | Configure RA Guard for advertised IPv6 and MAC address-based, IPv6 prefix-based, preference-based, hop count limit-based, and default router preference-based filtering. |
| VXLAN Configuration            | vnid <1-16777215><br>i-sid <1-<br>16777215>  | (vxlan:<1-1677721<br>5>) #   | Associate port or MLT interface VLANs, configure VXLAN endpoints and untagged traffic.                                                                                   |
| MKA Profile Configuration      | macsec mka<br>profile<br>WORD<1-16>          | (mka-profile) #              | Configure replay protection and confidentiality offset for an MKA profile.                                                                                               |
| BFD Router Configuration       | router bfd                                   | (router-bfd) #               | Configure device-wide BFD settings.                                                                                                                                      |

*Special CLI Command Modes*

A special CLI command mode provides a set of specific CLI commands that are different from the standard CLI command modes and the CLI commands available in them. For example, a set of CLI commands that are specifically introduced to configure services on a Virtual Machine (VM) through a specific CLI command mode.

**Note**

Special CLI command modes are hardware dependent. If they do not display on your hardware, they are not supported or applicable.

The following table describes the special command mode.

**Table 39: Special CLI Command Mode Summary**

| Special command mode | Command mode navigation         | Command to access mode                                                                            | Prompt displayed in mode | Description                                                                                             |
|----------------------|---------------------------------|---------------------------------------------------------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------|
| Fabric IPsec Gateway | Accessible from Privileged EXEC | virtual-service<br>WORD<1-128><br>console<br><br><b>Note:</b><br>Type CTRL+Y to exit the console. | FIGW>                    | Configure services like IPsec, fragmentation and reassembly, and to manage the Fabric IPsec Gateway VM. |

## Default User Names and Passwords for CLI

The following table contains the default user names and passwords that you can use to log on to the switch using the command line interface (CLI). For more information about how to change passwords, see [Security](#) on page 2863.

**Table 40: CLI default user names and passwords**

| User name | Password | Description    |
|-----------|----------|----------------|
| rwa       | rwa      | read-write-all |
| rw        | rw       | read-write     |
| ro        | ro       | read-only      |
| l1        | l1       | layer 1        |
| l2        | l2       | layer 2        |
| l3        | l3       | layer 3        |

You can create up to a maximum of 10 CLI users for each role. For more information, see [Multiple CLI Users for Each Role](#) on page 3312.

If you enable enhanced secure mode, the user names and passwords are different than the default values documented in the preceding table. For more information on enhanced secure mode, see [Enhanced secure mode authentication access levels](#) on page 3313.

### Important

The default passwords and community strings are documented and well known. As a best practice, change the default passwords and community strings immediately after you first log on. For more information about how to change user names and passwords, see [Security](#) on page 2863.

## Documentation convention for the port variable

Commands that require you to enter one or more port numbers on the switch use the parameter `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}` in the syntax. The following table specifies the rules for using `{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`.

| Syntax                                                             | How to use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}</code>                                | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For example, 1/1 indicates the first port on slot 1. 1/41/1 indicates the first channel on slot 1, port 41.                                                                                                                                                                                                         |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For example, 1/1-1/3 indicates ports 1 to 3 on slot 1, or 1/41/1,1/41/3 indicates the first and third channels of slot 1, port 41. |

## Command completion

The CLI provides potential command completions to the command string. Completions are provided by using a question mark (?) or by using the CLI autocompletion feature.

### ? command completion

The ? command completion is available for any valid command. By typing a command and using a ? as the last argument in the command, the system returns a list of possible command completions from the point of the ?. A short description is provided with each possible completion.

If you enter the following command:

```
Switch:1(config-isis)#redistribute ?
```

CLI provides a list of completions for the **redistribute ?** command.

```
Switch:1(config-isis)#redistribute ?
 direct isis redistribute direct command
 ospf isis redistribute ospf command
 rip isis redistribute rip command
 static isis redistribute static command
```

All the parameters listed under redistribute indicate sub-context commands.

You must use one of the available completions, and if necessary, use the command completion help again to find the next completion.

```
Switch:1(config-isis)#redistribute direct ?
 enable Enable isis redistribute direct command
 metric Isis route redistribute metric
 metric-type Set isis redistribute metric type
 route-map Set isis redistribute direct route-policy
 subnets Set isis redistribute subnets
<cr>
```

When you see `<cr>` (Carriage Return/Enter Key) in the list with the additional choices, this means that no additional parameters are required to execute the CLI command. However, the additional choices listed could be peer commands or sub-context commands.

For example, the parameters listed under **redistribute direct ?** are peer commands. You can enter these peer commands on the same line as the root command, for example **redistribute direct enable**. However, the `<cr>` indicates that you can also enter the **redistribute direct** command only and this command does not require any additional parameters at this level.

### *CLI autocompletion*

CLI autocompletion is a feature that you can use to automatically fill in the unique parts of a command string rather than typing the entire command. Autocompletion makes the CLI experience easier and prevents mistakes in spelling that force you to re-enter the command.

Autocompletion completes the token in the command as soon as it becomes unique.

The `Tab` key autocompletes the command without executing the command, and places the cursor immediately after the last character. The `Enter` key autocompletes the command and executes it.

To enable redistribution of ISIS direct routes,

```
Switch:1(config-isis)#redistribute direct
```

When you use `redistribute ?`, you see four possible sub-context commands.

```
direct
static
ospf
rip
```

If you type the following without pressing `Enter`:

```
Switch:1(config-isis)#redistribute direct m
```

and press the `Tab` key, the system completes the command to the following point:

```
redistribute direct metric
```

Two possible completions exist. You can type `-t`, and then press `Tab` to finish the command:

```
Switch:1(config-isis)#redistribute direct metric-type
```

## default command operator

You can reset the modified configuration of a command to the default configuration by using the default operator. For more information about the default value for each command, see [Command Line Interface Commands Reference for VOSS](#).

Use the `?` command completion along with the default keyword in each configuration mode, to view the list of commands that support the default operator. For more information, see [Command completion](#) on page 244.

Configure **csnp-interval** to its default value. The default value of **csnp-interval** is 10 seconds.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router isis
Switch:1(config-isis)#show isis
```

```

Switch:1(config-mlt)#default ip arp-inspection ?
<cr>
```

## no command operator

You can use the **no** operator in a command to negate a configuration. Based on the functionality of the command, you can perform negations, such as disable, delete, remove, or reset to the default configuration. For more information about the **no** operator for each command, see [Command Line Interface Commands Reference for VOSS](#).

Use the ? command completion along with the **no** keyword to view the list of commands that support the **no** operator in each configuration mode. For more information, see [Command completion](#) on page 244.

Negate the automatic virtual link that provides automatic dynamic backup link for OSPF traffic.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router ospf
Switch:1(config-ospf)#no auto-vlink
```

Remove an IP address configuration from VLAN.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 3
Switch:1(config-if)#no ip address 192.0.2.4
```

View the commands that can negate a configuration in RIP router configuration mode.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#no ?
```

```

Negate a command or set its defaults
ipv6 Disable ipv6 configurations
network Disable rip on an ip network
redistribute To disable/delete redistribute globally
Switch:1(config-rip)#no network ?
 {A.B.C.D} Network ip address
Switch:1(config-rip)#no network 192.0.2.4 ?
<cr>

```

## GREP with CLI show command

You can use Global Regular Expression Print (GREP) with **show** commands to filter the output based on match criteria.

Enter the **show** command followed by the pipe (|) character, followed by the GREP filter command. The **show** command output contains only the lines that match the GREP filter pattern.

### Note

The **show fulltech** command does not support GREP filters.

The following GREP filter commands are supported.

| GREP filter function | Description                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>begin</i>         | Displays the output of a command starting from the first line, which matches the given pattern.                                                                                                                                                                                                                      |
| <i>count</i>         | Counts the number of lines in the output of a command.                                                                                                                                                                                                                                                               |
| <i>exclude</i>       | Displays only the output lines which do not match the given pattern. The lines matching the pattern are discarded.                                                                                                                                                                                                   |
| <i>head</i>          | Limits the output of a command to the first few lines. If a number is not specified then only the first 10 lines display.                                                                                                                                                                                            |
| <i>include</i>       | Displays only the output lines which match the given pattern.                                                                                                                                                                                                                                                        |
| <i>no-more</i>       | Temporarily disables pagination for the output of an CLI command. When the lines of output exceed the terminal length, you are not prompted to continue or quit but the entire output of the command continues to be displayed. The effect is similar to setting terminal length 0 but only for the current command. |
| <i>tail</i>          | Limits the output of a command to the last few lines. If a number is not specified then only the last 10 lines display.                                                                                                                                                                                              |

## Timestamp in show command outputs

The output for all CLI show commands includes a timestamp header to indicate when the command output was generated. This information can be helpful when communicating with Support.

The following command output shows a timestamp example.

```
Switch:1#show alarm statistics

Command Execution Time: Wed Nov 07 19:55:15 2018 UTC

=====
ALARM STATISTICS
=====
PERSISTENT PERSISTENT PERSISTENT PERSISTENT DYNAMIC DYNAMIC DYNAMIC DYNAMIC
ALARM ACTIVE CLEARED WRPRD ALARM ACTIVE CLEARED WRPRD
0 0 0 0 11 8 3 0
```

## Authentication for Privileged EXEC Command Mode

For enhanced security, you can request user authentication to enter Privileged EXEC command mode. When you configure password authentication, the switch prompts you to enter a username and password to access Privileged EXEC command mode from User EXEC command mode. You use the same username and password used to Telnet or SSH to the switch.

For more information about configuring Privileged EXEC authentication, see [Authentication for Privileged EXEC Command Mode](#) on page 2870.

## CLI procedures

This chapter contains information about common CLI tasks. You can access CLI during runtime to manage the switch.

### Logging on to the software

#### Before You Begin

- The first time you connect to the switch, you must log on to CLI using the direct console port.

#### About This Task

After you first connect to CLI you can log on to the software using the default user name and password. For more information about the default user names and passwords, see [Default User Names and Passwords for CLI](#) on page 243.

#### Procedure

1. At the login prompt, enter the user name.
2. At the password prompt, enter the password.

### Viewing configurations

You can view the running configuration using the show command.

#### Procedure

1. Enter Privileged EXEC mode:  
enable

2. View running configuration:

```
show running-config
```

### Example

```
VSP-8284XSQ:1#show running-config
Preparing to Display Configuration...
#
#
Thu Feb 05 18:38:02 2015 UTC
box type : VSP-8284XSQ
software version : 4.2.0.0_B004 (PRIVATE)
cli mode : CLI
#
#
#!end

#
config terminal
#
#
#BOOT CONFIGURATION
#

boot config flags ftpd
boot config flags telnetd
end boot flags
auto-recover-delay 10

#CLI CONFIGURATION
#

telnet-access sessions 3
password password-history 3

#
#SYSTEM CONFIGURATION
#

ip name-server primary 198.51.100.0
sys msg-control control-interval 30
sys msg-control

#
#
```

## Saving the configuration

After you change the configuration, you must save the changes to the module. Save the configuration to a file to retain the configuration settings.

### About This Task

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

## Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Save the running configuration:  

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

## Example

Save the configuration to the default location:

```
Switch:1#save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1#save config backup 198.51.100.1/configs/backup.cfg
```

### Variable definitions

Use the data in the following table to use the **save config** command.

| Variable                  | Value                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>backup</i> WORD<1-99>  | Saves the specified file name and identifies the file as a backup file.<br>WORD<1-99> uses one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters. |
| <i>file</i> WORD<1-99>    | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>• /intflash/&lt;file&gt;</li> <li>• a.b.c.d:&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters.                                                                 |
| <i>verbose</i>            | Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.                                                                                                                                                                                          |
| <i>standby</i> WORD<1-99> | Specifies the standby file name in the following format: <ul style="list-style-type: none"> <li>• /intflash/&lt;file&gt;</li> </ul> The file name, including the directory structure, up to 1 to 99 characters.                                                                                                 |

## Configure the Web Server

### Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

Perform this procedure to enable and manage the web server using the Command Line Interface (CLI). After you enable the web server, you can connect to EDM.

HTTP and FTP support both IPv4 and IPv6 addresses, with no difference in functionality or configuration. The TFTP server supports both IPv4 and IPv6 addresses. The TFTP client is not supported, only the server.

### About This Task

This procedure assumes that you use the default port assignments. You can change the port number used for HTTP and HTTPS.

### Important

If you want to allow HTTP access to the device, you must disable the web server secure-only option. If you want to allow HTTPS access to the device, the web server secure-only option is enabled by default.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable the web server:  
`web-server enable`
3. Disable the secure-only option (for HTTP access) :  
`no web-server secure-only`
4. Enable the secure-only option (for HTTPs access) :  
`web-server secure-only`
5. Enable read-only user:  
`web-server read-only-user enable`
6. Display the web server status:  
`show web-server`

### Example

Enable the secure-only web-server. Configure the Read-Write-All access level username to smith2 and the password to 90Go2437. Enable read-only-user for the web server. Configure the read-only-user username to jones6 and the password to G69s8672.

```
Switch:1>enable
Switch:1#configure terminal
```

```

Switch:1(config)#web-server enable
Switch:1(config)#web-server secure-only
Switch:1(config)#web-server read-only-user enable
Switch:1(config)#web-server password rwa smith2
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#web-server password ro jones6
Enter the New password : *****
Re-enter the New password : *****
Password changed.
Switch:1(config)#show web-server

Web Server Info :

 Status : on

### Variable Definitions

Use the data in the following table to use the **web-server** command.

| Variable                         | Value                                                                                                                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>def-display-rows</i> <10-100> | Configures the number of rows each page displays, between 10 and 100.                                                                                                                                                                                                                                   |
| <i>enable</i>                    | Enables the Web interface. To disable the web server, use the <b>no</b> form of this command:<br>no web-server [enable]                                                                                                                                                                                 |
| <i>help-tftp</i> <WORD/0-256>    | Configures the TFTP or FTP directory for Help files, in one of the following formats: a.b.c.d;/ peer:/ [<dir>]. The path can use 0-256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• 192.0.2.1:/help</li> <li>• 192.0.2.1/</li> </ul> |
| <i>http-port</i> <80-49151>      | Configures the web server HTTP port. The default port is 80.                                                                                                                                                                                                                                            |

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>https-port &lt;443-49151&gt;</code>            | Configure the web server HTTPS port. The default port is 443.                                                                                                                                                                                                                                                                                                                                                |
| <code>inactivity-timeout&lt;30-65535&gt;</code>      | Configures the web-server session inactivity timeout. The default is 900 seconds (15 minutes).                                                                                                                                                                                                                                                                                                               |
| <code>password {ro   rwa} WORD&lt;1-20&gt;</code>    | Configures the logon and password for the web interface.                                                                                                                                                                                                                                                                                                                                                     |
| <code>password min-passwd-len&lt;1-32&gt;</code>     | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                                                                             |
| <code>read-only-user</code>                          | Enables read-only user for the web server.<br><br><b>Note:</b><br><b>read-only-user enable</b> is available for demonstration purposes on some products. For more information, see <a href="#">VOSS Feature Support Matrix</a> .                                                                                                                                                                             |
| <code>secure-only</code>                             | Enables secure-only access for the web server.                                                                                                                                                                                                                                                                                                                                                               |
| <code>tls-min-ver&lt;tlsv10 tlsv11 tlsv12&gt;</code> | Configures the minimum version of the TLS protocol supported by the web-server. You can select among the following: <ul style="list-style-type: none"> <li>• <code>tlsv10</code> - Configures the version to TLS 1.0.</li> <li>• <code>tlsv11</code> - Configures the version to TLS 1.1.</li> <li>• <code>tlsv12</code> - Configures the version to TLS 1.2</li> </ul> The default is <code>tlsv12</code> . |

## Using GREP CLI show command filters

Use the following GREP filters to output only the command lines specified by the filter.

### Procedure

- Count the number of lines in the output:

```
<CLI command> | count
```
- Display the output of a command starting from the first line that matches the given pattern:

```
<CLI command> | begin WORD<0-255> [field <number>] [ignore-case]
[header <number>]
```
- Display only the output lines that match the given pattern:

```
<CLI command> | include <pattern> [field <number>] [ignore-case]
[header <number>]
```
- Display only the output lines that do not match the given pattern:

```
<CLI command> | exclude <pattern> [field <number>] [ignore-case]
[header <number>]
```

- Temporarily disable pagination for the output of a CLI command:

```
<CLI command> | no-more
```

There is no prompt to continue or to quit when the lines of output exceed the terminal length.

- Limit the output of a command to the first few lines:

```
<CLI command> | head [<number>]
```

If a number is not specified, the first 10 lines display.

- Limit the output of a command to the last few lines:

```
<CLI command> | tail [<number>] [from-line <number>] [header <number>]
```

If a number is not specified, the last 10 lines display.

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Count the number of lines in the output:

```
Switch1:#show vlan basic | count
Count: 17 lines
```

Display only the output lines that match the given pattern:

```
Switch:1(config)#show vlan basic | include byPort field 3 header 6
```

```
=====
 Vlan Basic

```

### Variable definitions

The GREP filters use the following parameters:

| Parameter                 | Description                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>field</i> <number>     | Specifies the field in each line to match against the pattern. Fields are separated by white spaces and are counted starting with 1 for the left-most field.<br>If the output is formatted as a table, whitespaces are not counted as fields. |
| <i>from-line</i> <number> | Specifies the remaining output starting with a given line.                                                                                                                                                                                    |
| <i>head</i> <number>      | Specifies the number of lines to keep from the beginning of the output.                                                                                                                                                                       |
| <i>header</i> <number>    | Specifies a number of lines from the start of the output to display unchanged before trying to match the pattern. This parameter is useful to keep the header of a table intact. This filter skips the header lines.                          |
| <i>ignore-case</i>        | Specifies letters to match in the pattern regardless of case.                                                                                                                                                                                 |
| <number>                  | Specifies the number of lines of output to keep, either from the beginning of the output or from the end of the output.                                                                                                                       |
| <pattern>                 | Specifies the regular expression to match against each line of output. Use quotations if the parameter contains spaces.                                                                                                                       |

## Enterprise Device Manager Fundamentals

This section details Enterprise Device Manager (EDM).

EDM is a web-based graphical user interface (GUI) you can use to configure a single switch. EDM runs from the switch and you can access it from a web browser. You do not need to install additional client software, and you can access it with all operating systems.

## Supported Browsers

Use the following browser versions to access Enterprise Device Manager (EDM):

- Microsoft Edge 80+
- Microsoft Internet Explorer 11+
- Mozilla Firefox 74+
- Google Chrome 80+
- Safari 13+

For optimal performance, use Mozilla Firefox or Google Chrome.

## Enterprise Device Manager Access

To access EDM, open `http://<deviceip>/login.html` or `https://<deviceip>/login.html` from Microsoft Edge, Microsoft Internet Explorer, Google Chrome, or Mozilla Firefox. Ensure you use a supported browser version.

### Important

- You must enable the web server from CLI (see [Configure the Web Server](#) on page 252) to enable HTTP access to the EDM. If you want HTTP access to the device, you must also disable the web server secure-only option. The web server secure-only option, allowing for HTTPS access to the device, is enabled by default. As a best practice, take the appropriate security precautions within the network if you use HTTP
- EDM access is available to read-write users only

If you experience issues while connecting to the EDM, check the proxy settings. Proxy settings can affect EDM connectivity to the switch. Clear the browser cache and do not use proxy when connecting to the device.

## Default User Name and Password for EDM

The following table contains the default user name and password that you can use to log on to the switch using EDM. For more information about changing the passwords, see [Security](#) on page 2863.

**Table 42: EDM default username and password**

| Username | Password |
|----------|----------|
| admin    | password |

For information about creating CLI accounts for each user role on the switch, see [Multiple CLI Users for Each Role](#) on page 3312.

### Important

The default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after you first log on. For more information about changing user names and passwords, see [Security](#) on page 2863.

## Device Physical View

After you access EDM, the system displays a real-time physical view of the front panel of the device. From the front panel view, you can view fault, configuration, and performance information for the device or a single port. You can open this tab by clicking the **Device Physical View** tab above the device view.

You can use the device view to determine the operating status of the various ports in your hardware configuration. You can also use the device view to perform management tasks on specific objects. In the device view, you can select a port or the entire chassis. To select an object, click the object. EDM outlines the selected object in yellow, indicating your selection.

The conventions on the device view are similar to the actual device appearance. The port LEDs and the ports are color-coded to provide status. Green indicates the module or port is up and running, red indicates the module or port is disabled, dark pink indicates a protocol is down, and amber indicates an enabled port that is not connected to anything. For information about LED behavior, see your hardware documentation.

## EDM Window

The following list identifies the different sections of the EDM window:

- Navigation pane—Located on the left side of the window, the navigation pane displays all the available command tabs in a tree format. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.
- Content pane—Located on the right side of the window, the content pane displays the tabs and dialog boxes where you can view or configure parameters on the switch.
- Menu bar—Located at the top of the content pane, the menu bar shows the most recently accessed primary tabs and their respective secondary tabs.
- Toolbar—Located just below the menu bar, the toolbar provides quick access to the most common operational commands such as Apply, Refresh, and Help.

The following figure shows an example of the Device Physical View tab within the EDM window.

### Note

The Device Physical View tab on your hardware can appear differently than the following example.

**Figure 3: EDM window**

## Navigation Pane

You can use the navigation pane to see what commands are available and to quickly browse through the command hierarchy. A row of buttons at the top of the navigation pane provides a quick method to perform common functions.

### Note

For module-based chassis, menu options related to a specific module are activated only after you install and select the required module.

The following table describes the buttons that appear at the top of the navigation pane.

**Table 43: Navigation pane buttons**

| Button                                                                              | Name             | Description                                                                                     |
|-------------------------------------------------------------------------------------|------------------|-------------------------------------------------------------------------------------------------|
|  | Save Config      | Saves the running configuration.                                                                |
|  | Refresh Status   | Refreshes the Device Physical View.                                                             |
|  | Edit             | Edits the selected item in the Device Physical View.                                            |
|  | Graph            | Opens the graph options for the selected item in the Device Physical View.                      |
|  | Help Setup Guide | Opens instructions about how to install the Help files and configure EDM to use the Help files. |

Expand a folder by clicking it. Some folders have subfolders such as the Edit folder, which has the Port, Diagnostics, and other subfolders.

Within each folder and subfolder menu, there are numerous options, which provide access to tabs. To open an option, select it. The selected tab displays in the menu bar and opens in the content pane. The following table describes the main folders in the navigation pane.

**Table 44: Navigation Pane Folders**

| Menu             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Device           | Use the Device menu to refresh and update device information or enable polling. <ul style="list-style-type: none"> <li>Preference Setting — Enable polling or hot swap detection. Configure the frequency to poll the device.</li> <li>Refresh Status — Use this option to refresh the device view.</li> <li>Rediscover Device — Use this to trigger a rediscovery to update all of the device information.</li> </ul>                                                                                                                                                                                                                                                                         |
| VRF Context view | Use the VRF Context view to switch to another VRF context when you use the embedded EDM. GlobalRouter is the default view at log in. You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open only five tabs for each EDM session.                                                                                                                                                                                                                                                                                                                                                                       |
| Edit             | Use the Edit menu to view and configure parameters for the chassis hardware or for the currently selected object. The selected object can be one or more ports. You can also use the Edit menu to perform the following tasks: <ul style="list-style-type: none"> <li>check and configure ports, including the internal Extreme Integrated Application Hosting ports, on the device</li> <li>run diagnostic tests</li> <li>change the configuration of many features, including but not limited to, the file system, NTP, OVSDDB, SMTP, Link-state tracking, service delivery, Fabric Attach, VTEP, DvR, Management Instance, Endpoint Tracking, and SNMPv3 settings for the device</li> </ul> |
| Graph            | Use the Graph menu to view and configure EDM statistics and to produce graphs of the chassis or port statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Power Management | Use the Power Management menu to view and configure Energy Saver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| VLAN             | Use the VLAN menu to view and configure VLANs, spanning tree groups (STG), MultiLink Trunks/LACP, SMLT, and SLPP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IS-IS            | Use the IS-IS menu to view and configure IS-IS, Shortest Path Bridging MAC (SPBM), statistics, and I-SIDs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| VRF              | Use the VRF menu to view and create VRFs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 44: Navigation Pane Folders (continued)**

| Menu | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP   | <p>Use the IP menu to view and configure IP routing functions for the system, including the following:</p> <ul style="list-style-type: none"> <li>• IP-VPN</li> <li>• IP-MVPN</li> <li>• IP</li> <li>• TCP/UDP</li> <li>• OSPF</li> <li>• RIP</li> <li>• VRRP</li> <li>• RSMLT</li> <li>• BGP</li> <li>• Multicast</li> <li>• MSDP</li> <li>• IGMP</li> <li>• IPFIX</li> <li>• PIM</li> <li>• SPB-PIM-GW</li> <li>• DHCP Relay</li> <li>• DHCP Snooping</li> <li>• ARP Inspection</li> <li>• Source Guard</li> <li>• UDP Forwarding</li> <li>• IS-IS</li> <li>• Policies</li> <li>• BFD</li> </ul> |

**Table 44: Navigation Pane Folders (continued)**

| Menu           | Description                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Security       | Use the Security menu to view and configure access policies, ACL filters, certificates, and features such as RADIUS, RADIUS CoA, SSH, IPSec, TACACS+, and EAPoL.                                                                                                              |
| QOS            | Use the QOS menu to view and configure mapping tables, QoS port states, CoS Queue Stats, and Queue Profiles.                                                                                                                                                                  |
| Serviceability | Use the Serviceability menu to enable, configure, or view: <ul style="list-style-type: none"> <li>• RMON</li> <li>• sFlow</li> <li>• Application Telemetry</li> <li>• SLA Monitor</li> <li>• RESTCONF</li> <li>• Virtual services</li> <li>• ExtremeCloud IQ Agent</li> </ul> |

## Menu Bar

The menu bar is above the content pane and consists of two rows of tabs.

- The top row displays the tabs you can open through the navigation pane. These primary tabs appear in the sequence in which you open them.
- After you click a primary tab, the secondary tabs associated with it appear in the bottom row. Click a secondary tab to display it in the content pane.

In both the top and bottom rows of the menu bar, if the number of tabs exceeds the viewable space, the system displays left- and right-pointing arrows. Click an arrow to scroll to the required tab.

To reduce the number of tabs on the top row, you can click the X on the right corner of a tab to remove it from the row. The following figure shows a sample menu bar.

**Figure 4: Menu bar**

## Toolbar

The toolbar buttons provide quick access to commonly used operational commands. The buttons that appear vary depending on the tab you select. However, the Apply, Refresh, and Help buttons are on

almost every screen. Other common buttons are Insert and Delete. The following list detail the common toolbar buttons.

- Apply—Use this button to execute all edits that you make.
- Refresh—Use this button to refresh all data on the screen.
- Help—Use this button to display online help that is context sensitive to the current dialog box.
- Insert—Use this button to display a secondary dialog box related to the selected tab. After you edit the configurable parameters, click the Insert button in the dialog box. This causes a new entry to appear in the dialog box of the selected tab.
- Delete—Use this button to delete a selected entry.

The following figure shows a sample toolbar.

**Figure 5: Toolbar**

## Content Pane

The content pane is the main area on the right side of the window that displays the configuration tabs and dialog boxes. Use the content pane to view or configure parameters on the switch.

### Note

You can view valid ranges for all configurable parameters on EDM tabs.

The following figure is a sample that shows the content pane for the Port 1/3 General, Interface tab. If you want to compare the information in two tabs, you can undock one, then open another tab. For more information about undocking a tab, see [Undocking and docking tabs](#) on page 272.

**Figure 6: Content pane**

## EDM user session extension

If the EDM user session remains unused for a duration of ten minutes, the system displays the following message:

Your session will expire in about 5 minute(s). Would you like to extend the session?

If you do not respond, EDM automatically ends the session with the following message: `Your session has expired.`

You can log on again if you want to continue to use EDM.

## EDM interface procedures

---

This section contains procedures for starting and using Enterprise Device Manager (EDM). The software is built-in to the switch, and you do not need to install additional software.

### Connect to EDM

#### Before You Begin

- Ensure that the switch is running.
- Note the IP address of the switch.
- Ensure that you use a supported browser version.
- Ensure that you enable the web server using CLI.

#### About This Task

Perform this procedure to connect to EDM to configure and maintain your network through a graphical user interface.

#### Procedure

1. In the address field, enter the IP address of the system using the following formats: **https://<IP\_address>** (default) or **http://<IP\_address>**.

#### Note

By default the Web server is configured with the secure-only option, which requires you to use HTTPS to access EDM. To access EDM using HTTP, you must disable the secure-only option.

2. In the **User Name** field, type the user name.  
The default is admin.
3. In the **Password** field, type a password.  
The default is password.
4. Select **Log On**.

### Configure the Web Management Interface

#### Note

DEMO FEATURE - Read Only User for EDM is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

### Before You Begin

- Enable the web server.
- For VSP 8600 Series, enable the web server RO user in CLI.

### About This Task

Configure the web management interface to change the user names and passwords for management access to the switch using a web browser.

HTTP, FTP, and TFTP server supports both IPv4 and IPv6 addresses, with no difference in functionality or configuration.

You can also use the CLI interface for creating users.

### Procedure

1. In the navigation pane, open the **Configuration > Security > Control Path** folders.
2. Select **General**.
3. Select the **Web** tab.
4. Complete the **WebRWAUserName** and **WebRWAUserPassword** fields to specify the user name and password for access to the web interface.  
This user will have full permission.
5. To enable the RO user for the web server, select **WebROEnable**.

#### Note

This step does not apply to VSP 8600 Series.

6. Complete the **WebROUserName** and **WebROUserPassword** fields to specify the user name and password for access to the web interface.  
This user will have read only permission.
7. Select **Apply**.

### Web Field Descriptions

Use the data in the following table to use the **Web** tab.

| Name                                                                               | Description                                                                                        |
|------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>WebRWAUserName</b>                                                              | Specifies the RWA username from 1-20 characters. The default is admin.                             |
| <b>WebRWAUserPassword</b>                                                          | Specifies the password from 1-32 characters. The default is 12345678.                              |
| <b>WebROEnable</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Enables the web server read-only (RO) user, which is disabled by default after a software upgrade. |

| Name                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WebROUserName</b>                                                                     | Specifies the RO username from 1–20 characters. The default is user.<br><br><b>Note:</b><br>Product Notice: For VSP 8600 Series the web server RO username must be enabled in CLI.                                                                                                                                                                                                                                  |
| <b>WebROUserPassword</b>                                                                 | Specifies the password from 1–32 characters. The default is password.                                                                                                                                                                                                                                                                                                                                               |
| <b>MinimumPasswordLength</b>                                                             | Configures the minimum password length. By default, the minimum password length is 8 characters.                                                                                                                                                                                                                                                                                                                    |
| <b>HttpPort</b>                                                                          | Specifies the HTTP port for web access. The default value is 80.                                                                                                                                                                                                                                                                                                                                                    |
| <b>HttpsPort</b>                                                                         | Specifies the HTTPS port for web access. The default value is 443.                                                                                                                                                                                                                                                                                                                                                  |
| <b>SecureOnly</b>                                                                        | Controls whether the secure-only option is enabled. The default is enabled.                                                                                                                                                                                                                                                                                                                                         |
| <b>InactivityTimeout</b>                                                                 | Specifies the idle time (in seconds) to wait before the EDM login session expires. The default value is 900 seconds (15 minutes).                                                                                                                                                                                                                                                                                   |
| <b>TlsMinimumVersion</b>                                                                 | Configures the minimum version of the TLS protocol supported by the web-server. You can select from the following options: <ul style="list-style-type: none"> <li>• <code>tlsv10</code> – Configures the version to TLS 1.0.</li> <li>• <code>tlsv11</code> – Configures the version to TLS 1.1.</li> <li>• <code>tlsv12</code> – Configures the version to TLS 1.2</li> </ul> The default is <code>tlsv12</code> . |
| <b>InUseCertType</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series. | Shows if the certificate is self-signed or user-installed.<br><br><b>Note:</b><br>Product Notice: For VSP 8600 Series use the <b>show web-server</b> command in CLI to view this information.                                                                                                                                                                                                                       |
| <b>HelpTftp/Ftp_SourceDir</b>                                                            | Configures the TFTP or FTP directory for Help files, in one of the following formats: <code>a.b.c.d:/peer:/ [&lt;dir&gt;]</code> . The path can use 0–256 characters. The following example paths illustrate the correct format: <ul style="list-style-type: none"> <li>• <code>192.0.2.1:/Help</code></li> <li>• <code>192.0.2.1/</code></li> </ul>                                                                |
| <b>DefaultDisplayRows</b>                                                                | Configures the web server display row width between 10–100. The default is 30.                                                                                                                                                                                                                                                                                                                                      |
| <b>LastChange</b>                                                                        | Shows the last web-browser initiated configuration change.                                                                                                                                                                                                                                                                                                                                                          |

| Name                                    | Description                                                                                     |
|-----------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>NumHits</b>                          | Shows the number of hits to the web server.                                                     |
| <b>NumAccessChecks</b>                  | Shows the number of access checks performed by the web server.                                  |
| <b>NumAccessBlocks</b>                  | Shows the number of access attempts blocked by the web server.                                  |
| <b>LastHostAccessBlockedAddressType</b> | Shows the address type, either IPv4 or IPv6, of the last host access blocked by the web server. |
| <b>LastHostAccessBlockedAddress</b>     | Shows the IP address of the last host access blocked by the web server.                         |
| <b>NumRxErrors</b>                      | Shows the number of receive errors the web server encounters.                                   |
| <b>NumTxErrors</b>                      | Shows the number of transmit errors the web server encounters.                                  |
| <b>NumSetRequest</b>                    | Shows the number of set-requests sent to the web server.                                        |

## Using the chassis shortcut menu

### About This Task

Perform the following procedure to display the chassis shortcut menu.

### Procedure

1. In the Device Physical View, select the chassis.
2. Right-click the chassis.

### **Chassis shortcut menu** field descriptions

Use the data in the following table to use the **Chassis** shortcut menu.

| Name                         | Description                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Edit</b>                  | Edits chassis parameters.                                                                                                                      |
| <b>Graph</b>                 | Graphs chassis statistics.                                                                                                                     |
| <b>Refresh Status</b>        | Refreshes the status of the chassis and MDAs.                                                                                                  |
| <b>Refresh Port Tooltips</b> | Refreshes the port tooltip data of the system. The port tooltip data contains the following variables: Slot/Port, PortName, and PortOperSpeed. |

## Using the port shortcut menu

### About This Task

Perform this procedure to display the port shortcut menu.

### Procedure

1. In the Device Physical View, select a port.
2. Right-click the selected port.

### **Port shortcut menu** field descriptions

Use the data in the following table to use the port shortcut menu.

| Name                          | Description                                  |
|-------------------------------|----------------------------------------------|
| <b>Edit General</b>           | Configures the general options for the port. |
| <b>Edit IP</b>                | Configures the IP options for the port.      |
| <b>Edit IPv6</b>              | Configures the IPv6 options for the port.    |
| <b>Channelization Enable</b>  | Enables channelization for the port.         |
| <b>Channelization Disable</b> | Disables channelization for the port.        |
| <b>Graph</b>                  | Displays the statistics for the port.        |
| <b>Enable</b>                 | Enables the port.                            |
| <b>Disable</b>                | Disables the port.                           |

## Using a table-based tab

### About This Task

Change an existing configuration using a table-based tab. You cannot edit grey-shaded fields in the table. The following procedure is an illustration on how to use a table-based tab.

#### Note

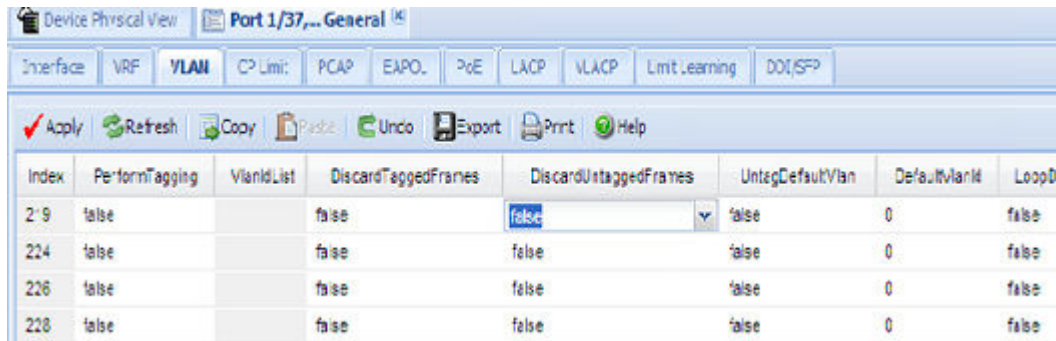

You can expand the appropriate folders for any feature you configure and select a table-based tab.

### Procedure

1. In the Device Physical View, select multiple ports.
2. In the navigation pane, expand the **Configuration > Edit > Port > General** folders.
3. Click the **VLAN** tab.
 

The system displays a table-based tab with the VLAN information.
4. Select a table-based tab.
5. Double-click a white-shaded field to edit the value.

- Click the arrow in the list field to view the options, and then select the appropriate value.

- In a text-entry field, double-click, and then edit the value.

- Click **Apply** to save the configuration changes.

## Monitor Multiple Ports and Configuration Support

### About This Task

You can monitor or apply the same configuration changes to more than one port by using the multiple port selection function. You can use the standard menu or the shortcut menu to edit the configuration settings for multiple ports.

#### Tip

A selected port shows a yellow outline around the port.

### Procedure

- Click the **Device Physical View** tab.
- To select multiple ports, press the **Control** key, and then click the required ports.

#### Note

When you use the Enterprise Device Manager (EDM) embedded in the software, you can select a maximum of 24 ports.

No port limitation exists for COM users.

## Open Folders and Tabs

### About This Task

Perform this procedure to navigate in EDM.

### Procedure

1. In the navigation pane, expand the **Configuration** folder.
2. Click a subfolder to expand the subfolder and see the list of menu options, for example, the **VLAN** folder.
3. In a folder or subfolder menu, click an option to open the related tabs.

## Undocking and docking tabs

### About This Task

Perform this procedure to undock a tab. You can undock tabs to have more than one tab visible at a time.

### Procedure

1. In the navigation pane, click a tab.
2. In the menu bar, click and drag a tab to undock it.
3. In the top right corner of the tab, click **pages** to dock the tab.

*Example of undocking and docking tabs*

### Procedure

1. Click the **Device Physical View** tab.
2. In the Device Physical View, select a port. In this example, right-click port 3.
3. In the **Port** shortcut menu, click **Edit General**.
4. Click and drag the **Port 1/3 General** tab wherever you want on the screen as shown in the following figure.

5. To reposition the tab anywhere on the screen, click and drag the title bar.
6. To manipulate the tab, click on the buttons in the top-right of the dialog box.

- Click the up arrowhead to minimize the tab as shown in the following figure.

- Click the down arrowhead to restore the tab to its original size.
- Click the pages to dock the tab back into the menu bar.
- Click the X to close the tab.

## Installing EDM help files

While the EDM GUI is bundled with the switch software, the associated EDM help files are not. To access the help files from the EDM GUI, you must install the EDM help files on a TFTP or FTP server in your network.

Use the following procedure to install the EDM help files on a TFTP or FTP server, and configure EDM to use the help files

### Before You Begin

If you use an FTP server to store the help files, ensure that you configure the switch with the host user name and password.

### Procedure

- Download the EDM help file.
- On a TFTP or FTP server reachable from the switch, create a directory called **Help**.

#### Tip

You can name the directory anything that will help you remember its purpose.

- Unzip the EDM help zip file into the directory created in the preceding step.
- In the EDM navigation pane, expand the **Configuration > Security > Control Path** folders.
- Click **General**.
- Click **Web**.
- In the **HelpTftp/Ftp\_SourceDir** field, enter the IP address of the file server and the path to the help files, for example, 192.0.2.15:/home/Help/.

## File Management in EDM

This section contains procedures for managing files with Enterprise Device Manager (EDM).

Use the File System tab to perform the following tasks:

- Copy a file.
- Check the amount of memory used and the number of files stored in the internal flash memory.
- Verify the name, size, and storage date of each file present in the internal flash memory.
- Display USB file information.

## Copy a File

### About This Task

Copy files on the internal flash.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Copy File** tab.
4. Edit the fields as required.
5. Click **Apply**.

### **Copy File** Field Descriptions

Use the data in the following table to use the **Copy File** tab.

| Name               | Description                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Source</b>      | Identifies the device and file name to copy. You must specify the full path and filename, for example, <deviceip-ftp server>: /<filename>                                                                                                                                               |
| <b>Destination</b> | Identifies the location to which to copy the source file with the filename, for example, /intflash/<filename>                                                                                                                                                                           |
| <b>Action</b>      | Starts or stops the copy process.                                                                                                                                                                                                                                                       |
| <b>Result</b>      | Specifies the result of the copy process: <ul style="list-style-type: none"> <li>• none</li> <li>• inProgress</li> <li>• success</li> <li>• fail</li> <li>• invalidSource</li> <li>• invalidDestination</li> <li>• outOfMemory</li> <li>• outOfSpace</li> <li>• fileNotFound</li> </ul> |

## Display Storage Use

### About This Task

Display the amount of memory used, memory available, and the number of files for internal flash memory.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Storage usage** tab

### **Storage Usage** Field Descriptions

Use the data in the following table to use the **Storage Usage** tab.

| Name                     | Description                                                               |
|--------------------------|---------------------------------------------------------------------------|
| <b>IntflashBytesUsed</b> | Specifies the number of bytes used in internal flash memory.              |
| <b>IntflashBytesFree</b> | Specifies the number of bytes available for use in internal flash memory. |
| <b>IntflashNumFiles</b>  | Specifies the number of files in internal flash memory.                   |
| <b>UsbBytesUsed</b>      | Specifies the number of bytes used in USB device.                         |
| <b>UsbBytesFree</b>      | Specifies the number of bytes available for use in USB device.            |
| <b>UsbNumFiles</b>       | Specifies the number of files in USB device.                              |

## Display Internal Flash File Information

### About This Task

Display information about the files in internal flash memory on this device.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **Flash Files** tab.

### **Flash Files** field descriptions

Use the data in the following table to use the **Flash Files** tab.

| Name        | Description                                              |
|-------------|----------------------------------------------------------|
| <b>Slot</b> | Specifies the slot number.                               |
| <b>Name</b> | Specifies the directory name of the file.                |
| <b>Date</b> | Specifies the creation or modification date of the file. |
| <b>Size</b> | Specifies the size of the file.                          |

## Display USB File Information

### About This Task

Display information about the files on a USB device to view general file information.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **File System**.
3. Click the **USB Files** tab.

### *USB Files* field descriptions

Use the data in the following table to use the **USB Files** tab.

| Name        | Description                                              |
|-------------|----------------------------------------------------------|
| <b>Slot</b> | Specifies the slot number of the device.                 |
| <b>Name</b> | Specifies the directory name of the file.                |
| <b>Date</b> | Specifies the creation or modification date of the file. |
| <b>Size</b> | Specifies the size of the file.                          |

# Image Upgrade

---

[Image Naming Conventions](#) on page 278

[Interfaces](#) on page 278

[File Storage Options](#) on page 278

[Boot Loader Image on Universal Hardware](#) on page 279

[Before You Upgrade](#) on page 279

[Saving the Configuration](#) on page 283

[Upgrade the Software](#) on page 284

[Verifying the upgrade](#) on page 287

[Committing an upgrade](#) on page 288

[Downgrade the Software](#) on page 288

[Deleting a software release](#) on page 290

[Update the Complex Programmable Logic Device \(CPLD\) Image](#) on page 291

[Upgrade the Boot Loader Image](#) on page 293

This section details what you must know to upgrade the switch.

## Upgrades

---

Install new software upgrades to add functionality to the switch. Major and minor upgrades are released depending on how many features the upgrade adds or modifies.

## Upgrade time requirements

---

Image upgrades take less than 30 minutes to complete. The switch continues to operate during the image download process. A service interruption occurs during the installation and subsequent reset of the device. The system returns to an operational state after a successful installation of the new software and device reset.

## Before you upgrade the software image

---

Before you upgrade the switch, ensure that you read the entire upgrading procedure.

You must keep a copy of the previous configuration file (config.cfg), in case you need to return to the previous version. The upgrade process automatically converts, but does not save, the existing configuration file to a format that is compatible with the new software release. The new configuration file may not be backward compatible.

## Image Naming Conventions

---

The switch software use a standardized dot notation format.

### Software Images

Software image names use one of the following number formats to identify release and maintenance values:

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance
Release Update.tgz
```

```
Product Name.Major Release.Minor Release.Maintenance Release.Maintenance
Release Update.voss
```

For example, the image file name `voss4k.4.2.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 4, a minor release version of 2, a maintenance release version of 1 and a maintenance release update version of 0. Similarly, the image file name `vsp4k.3.0.1.0.tgz` denotes a software image for the VSP 4450 Series product with a major release version of 3, a minor release version of 0, a maintenance release version of 1 and a maintenance release update version of 0. TGZ is the file extension.

#### Note

Product Notice: 5520 Series image files use a `.voss` extension rather than a `.tgz` extension.

## Interfaces

---

You can apply upgrades to the switch using the Command Line Interface (CLI).

For more information about CLI, see [Command Line Interface](#) on page 238.

## File Storage Options

---

This section details what you must know about the internal boot and system flash memory and Universal Serial Bus (USB) mass-storage device, which you can use to store the files that start and operate the switch.

The switch file system uses long file names.

### Internal flash

The switch has two internal flash memory devices: the boot flash memory and the system flash memory. The system flash memory size is 2 gigabytes (GB).

Boot flash memory is split into two banks that each contain a different copy of the boot image files. Only the Image Management feature can make changes to the boot flash.

The system flash memory stores configuration files, runtime images, the system log, and other files. You can access files on the internal flash through the `/intflash/` folder.

## USB device

The switch can use a USB device for additional storage or configuration files, release images, and other files. The USB device provides a convenient, removable mechanical to copy files between a computer and a switch, or between switches. In cases where network connectivity has not yet been established, or network file transfer is not feasible, you can use a USB device to upgrade the configuration and image files on the switch.

## File Transfer Protocol

You can use File Transfer Protocol (FTP) to load the software directly to the switch, or to download the software to the internal flash memory or to an installed USB device.

The switch can act as an FTP server or client. If you enable the FTP daemon (ftpd), you can use a standards-based FTP client to connect to the switch by using the CLI log on parameters. Copy the files from the client to either the internal flash memory or USB device.

## Boot Loader Image on Universal Hardware

On universal hardware products, new VOSS software activations automatically detect the uboot image, check if it is valid, and then compare the version of the uboot image with the version currently on the system. If the system started with the default uboot image, indicated by `Boot Version Used` in the **show sys-info uboot** command output, and the uboot image in the activated software release is newer, image synchronization performs a default uboot upgrade. After the default uboot upgrade is complete, the **show sys-info uboot** command output displays the uboot version from the system boot time, so it still shows the previous version, but it also indicates that the default uboot was upgraded and that a system reboot is required.

After you reboot the system for a default uboot upgrade, if a temporary default uboot upgrade file is present on the system, if the system started with the default uboot image, and if the default and alternate uboot versions are not the same, the alternate uboot is upgraded. You must restart the system for the alternate uboot upgrade to take effect.

## Before You Upgrade

This section provides important feature impacts you need to understand before you upgrade the switch software.

### Important Upgrade Note for Systems using IPv6 Static Neighbors

Due to an issue in VOSS 4.2.1 and later releases, the port number for an IPv6 static neighbor is saved with the wrong value in the configuration file if the port is part of an MLT or SMLT. You can view the incorrect port number by using the **show running-config** command.

If performing a named boot (e.g. **boot config.cfg**), the configuration loading fails and the switch remains in a default configuration. You can manually source the configuration file (e.g. **source config.cfg**) to retrieve/reapply the configuration (minus the IPv6 neighbor configuration with the invalid port value).

If you boot the switch without a specified configuration (e.g. `reset -y`), the primary configuration fails to load and the backup configuration file is loaded instead.

#### Caution

You should never configure an IPv6 static neighbor on a port belonging to an MLT or SMLT.

## Pre-upgrade Instructions for IS-IS Metric Type

The command used to redistribute routes into IS-IS supports a parameter called `metric-type`, which can take one of two values: **internal** or **external**. In releases that do not support the external metric type, the routes are always advertised into IS-IS as internal, irrespective of whether you configure the metric-type to internal or external. The saved configuration itself correctly shows the value that you selected.

If the configuration file has redistribution commands that set the metric-type to external, after you upgrade to a release that supports the external metric type, the routes will be advertised into IS-IS as external routes. This constitutes a change in how the routes are advertised into IS-IS after the upgrade as compared to before the upgrade. This configuration can cause unintended traffic issues if the other switches in the network are not yet upgraded to a release that recognizes external routes in IS-IS.

To know which release supports the external metric type on your platform, see [Release Notes for VOSS](#) for interoperability considerations.

To avoid unintentionally impacting traffic immediately following an upgrade, as a best practice, check the existing IS-IS redistribution configuration of a switch to determine if the metric-type is set to external in the redistribution commands. If metric-type external is not used in the redistribution, the switch can be upgraded using the normal upgrade procedures. If the metric-type external is used with any redistribution command, change it to internal, and then save the configuration. After this the switch can be upgraded using the normal upgrade procedures.

*Commands to check metric-type in redistribution configuration:*

```
Switch:1(config-isis)#show ip isis redistribute [vrf WORD<1-16>]
=====
 ISIS Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE SUBNET ENABLE LEVEL RPOLICY

RIP 0 internal allow TRUE 11
OSPF 0 external allow TRUE 11
LOC 0 external allow TRUE 11
```

*Commands to change metric-type to internal for GRT:*

```
router isis
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

*Commands to change metric-type to internal for VRF:*

```
router vrf WORD<1-16>
isis redistribute <protocol> metric-type internal
save config
```

The protocol above could be one of the following: direct, ospf, static, rip or bgp.

## Important upgrade consideration regarding MACsec

The switch software does not support the replay-protect option when MACsec is configured with static security keys. In some early releases, the replay-protect option is still visible and configurable, even though it is not supported. If you configured the replay-protect option in an early release and you are upgrading to switch software configured with MACsec using static security keys, follow the steps below to disable replay-protect before you upgrade the switch software to a release where the option is not available.

Beginning in Release 8.1, replay protection is available as part of the MACsec Key Agreement (MKA) feature on the VSP 8404 and VSP 8404C platforms. For platforms that do not support MKA, disable replay protection.

### Note

Replay-protect must be disabled on both ends of the MACsec enabled link.

### About This Task

If replay-protect is not disabled on the remote end of the MACsec link prior to the upgrade of the local node, traffic on the MACsec-enabled links will be dropped until replay-protect is also disabled on the remote node. As a best practice, complete the following procedure before initiating the upgrade.

### Procedure

1. To check if replay-protect has been enabled on any of the interfaces, use the **show macsec status** command.
2. For each interface where MACsec replay protect is enabled, perform the following tasks:
  - a. Disable MACsec replay-protect on the remote end of the MACsec enabled the link.
  - b. Disable MACsec replay-protect on the local end of the MACsec enabled link.
  - c. Save the configuration on both nodes.
  - d. Start the software upgrade.

## VLAN and MLT Upgrade Considerations

*VLAN or MLT Name Uses all Numbers*

Representational State Transfer Configuration Protocol (RESTCONF) does not allow VLAN or MLT names that contain all numbers. Beginning with VOSS 8.0, the VLAN or MLT name cannot use all

numbers. If, in a release prior to 8.0, you configured a name that was all numbers, see the following table to understand the impact of upgrading to a newer release.

**Table 45: Upgrade impact on interface names with all numbers**

| Target upgrade release            | Impact after upgrade                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VOSS 8.0.5.x, 8.0.6.x, or 8.0.7.x | The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.                                                                                                                                                                                               |
| VOSS 8.0.8 and later              | If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in <a href="#">Representational State Transfer Configuration Protocol (RESTCONF)</a> on page 2645. |
| VOSS 8.1 or 8.1.1.x               | The system prepends VLAN- or MLT- , and appends -01, to the name during the upgrade. For example, the VLAN name 222 becomes VLAN-222-01.                                                                                                                                                                                               |
| VOSS 8.1.2 and later              | If you plan to enable RESTCONF, you must check interface names for invalid special characters or conflicts, and make necessary modifications manually. For information about how to check interface names, see the RESTCONF content in <a href="#">Representational State Transfer Configuration Protocol (RESTCONF)</a> on page 2645. |

## Extreme Integrated Application Hosting Virtual Service Upgrade Considerations

### *Virtual Service and vport Name Length Change*

In VOSS 8.0.5, the length of the virtual service name and vport name changed to 80 and 32 characters respectively. If, in a release prior to 8.0.5, you configured a name with length that exceeds the new value, you must change the name before you upgrade to 8.0.5 or later.

If you do not change the name prior to upgrade, the virtual service configuration will not pass a consistency check in VOSS 8.0.5 and later, and the configuration will not be loaded. You will need to modify your configuration to comply with the new name lengths and reload it for the virtual service to load.

## IPFIX Upgrade Considerations

In VOSS 8.0.5, the range for the IPFIX aging interval changed from <1-1800> to <1-60>. If, in a release prior to 8.0.5, you configured the aging interval to be greater than 60 seconds and you upgrade to 8.0.5 or later, your configuration will be updated to 60 seconds.

## Digital Certificate Upgrade Considerations

### *Public Key Length*

To support SNMP walk for rcDigitalCertTable where the public key length exceeds 2,048 characters, VOSS 8.1 and later configures MAX\_KEY\_LEN to 2,048 to extend PublicKey to hold a maximum of 4,096-bit key. After this key length is updated, the format for `/intflash/.cert/cert_info.cfg` changes based on the new public key maximum length and you will be unable to restore the CertInfoTable from this file.

If you upgrade to VOSS 8.1 or later from an earlier release, you must reconfigure the certificates because you cannot restore the old certificate configuration after reboot.

The switch displays the following log message after you upgrade to VOSS 8.1, or later, and reboot:

```
GlobalRouter DIGITALCERT ERROR Unable to restore info from /
intflash/.cert/cert_info.cfg due to different/wrong format
```

## Fast PoE and Perpetual PoE Upgrade Considerations

When you upgrade from VOSS 8.1.X to VOSS 8.1.5, the POE Controller undergoes a firmware update, which reverts previously configured Fast PoE and Perpetual PoE settings back to the default values. The system displays a message to inform you about this change.

## Saving the Configuration

Save the configuration

- When you make a change to the configuration.
- To create a backup configuration file before you upgrade the software on the switch.

After you change the configuration, you must save the changes on the device. Save the configuration to a file to retain the configuration settings.

Note that not all CLI commands are included in configuration files. Typical examples include, but are not limited to some operational and security-related commands.

### **Note**

When loading large configuration files or large sections of a configuration file, avoid copying and pasting of the files into the console or terminal window as it can lead to the loss of configuration. You must either source the file or boot to the intended configuration file. Sourcing and booting allow for the debug and verification of the configuration file using the boot config flags. For more information about booting, sourcing, and debugging or verification using boot flags, see [Command Line Interface Commands Reference for VOSS](#).

### **About This Task**

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support IPv4 and IPv6 addresses.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. Save the running configuration:  

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

**Example**

```
Switch:1> enable
```

Save the configuration to the default location:

```
Switch:1# save config
```

Identify the file as a backup file and designate a location to save the file:

```
Switch:1# save config backup /usb/PreUpgradeBackup.cfg
```

**Variable Definitions**

The following table defines parameters for the **save config** command.

| Variable                 | Value                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>backup</i> WORD<1-99> | Saves the specified file name and identifies the file as a backup file.<br>WORD<1-99> uses one of the following format: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters. |
| <i>file</i> WORD<1-99>   | Specifies the file name in one of the following format: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> </ul> The file name, including the directory structure, can include up to 99 characters.                                                                 |
| <i>verbose</i>           | Saves the default and current configuration. If you omit this parameter, the command saves only parameters you change.                                                                                                                                                                                                                             |

**Upgrade the Software****Important**

Upgrades from some releases require release-specific steps. For more information, see [Release Notes for VOSS](#).

Perform this procedure to upgrade the software on the switch. This procedure shows how to upgrade the software using the internal flash memory as the file storage location.

Use one of the following options to upload the file with the new software to the switch:

- Use FTP or SFTP to transfer the file.
- Download the image file to your computer. Copy the file to a USB device and insert the USB device into the USB port on the switch.

You can store up to six software releases on the switch. If you have six releases already stored on the switch, then you will be prompted to remove one release before you can proceed to add and activate a new software release.

For information about how to remove a software release, see [Deleting a software release](#) on page 290.

### Before You Begin

- To obtain the new software, go to the Extreme Networks support site: <http://www.extremenetworks.com/support>. You need a valid user or site ID and password.
- Back up the configuration files.
- Use an FTP or SFTP application or USB device to transfer the file with the new software release to the switch.
- Ensure that you have not configured a VLAN above 4059. If you have, you must port all configuration on this VLAN to another VLAN, before you begin the upgrade.

#### Caution

Only VLAN range 2 to 4059 is supported. All configuration on a higher numbered VLAN from earlier releases will be lost after the upgrade.

- Check the MACsec configuration on the device prior to upgrading. For more information, see [Important upgrade consideration regarding MACsec](#) on page 281.

#### Note

Software upgrade configurations are case-sensitive.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. If you are using the USB port to transfer files, go to the next step. If you are using FTP or SFTP to download the files, start the FTP daemon on the switch and enable the `ftpd` flag for FTP or `sshd` flag for SFTP:

#### Note

Start an FTP session from your computer to the switch using the same username and password used to Telnet or SSH to the switch. Upload or copy the image to the switch.

```
boot config flag <ftpd | sshd>
```

```
end
```

3. Download the files to the switch through FTP or SFTP, or transfer them to the switch through the USB port.
4. Enter Privileged EXEC configuration mode by exiting the Global Configuration mode.  
`exit`
5. Extract the release distribution files to the `/intflash/release/` directory:  
`software add WORD<1-99>`
6. Install the image:  
`software activate WORD<1-99>`
7. Restart the switch:  
`reset`

### Important

After you restart the system, you have the amount of time configured for the commit timer to verify the upgrade and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer has expired. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

8. After you restart the switch, enter Privileged EXEC configuration mode:  
`rwa`  
  
`enable`
9. Confirm the software is upgraded:  
`show software`
10. Commit the software:  
`software commit`

### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

## Example

### Note

The image file name is switch dependent. See [Release Notes for VOSS](#) for information about file names.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags ftpd
Switch:1(config)#end
Switch:1(config)#copy /usb/VOSS8K.6.0.0.0.tgz /intflash/VOSS8K.6.0.0.0.tgz
Switch:1(config)#exit
Switch:1#software add VOSS8K.6.0.0.0.tgz
Switch:1#software activate VOSS8K.6.0.0.0.GA
Switch:1#reset
```

```

Switch:1#show software
=====
 software releases in /intflash/release/
=====
VOSS8K.5.0.0.0.GA (Primary Release)
VOSS8K.4.2.1.0.GA (Backup Release)

Auto Commit : enabled
Commit Timeout : 10 minutes

Remaining time until software auto-commit is 8 minutes 59 seconds

Switch:1#show software detail

=====
 software releases in /intflash/release/
=====
VOSS8K.4.2.1.0.GA (Backup Release)
 KERNEL 2.6.32_int38
 ROOTFS 2.6.32_int38
 APPFS VOSS8K.4.2.1.0.int012
AVAILABLE ENCRYPTION MODULES
 3DES
 AES/DES

VOSS8K.5.0.0.0.GA (Primary Release)
 KERNEL 2.6.32_int38
 ROOTFS 2.6.32_int38
 APPFS VOSS8K.5.0.0.0.GA
AVAILABLE ENCRYPTION MODULES
 3DES
 AES/DES

Auto Commit : enabled
Commit Timeout : 10 minutes

Remaining time until software auto-commit is 8 minutes 41 seconds

Switch:1#software commit
Executing software commit for version VOSS8K.5.0.0.0.GA.
Software commit successful

```

## Verifying the upgrade

Verify your upgrade to ensure proper switch operation.

### Procedure

1. Check for alarms or unexpected errors:  

```
show logging file tail
```
2. Verify all modules and slots are online:  

```
show sys-info
```

## Committing an upgrade

---

Perform the following procedure to commit an upgrade.

### About This Task

The software commit functionality for software upgrades allows maximum time set by the commit timer (the default is 10 minutes) to ensure that the upgrade is successful. If you enable the auto-commit option, the system automatically commits to the new software version after the commit timer expires.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. (Optional) Configure the timer to activate the software:  

```
sys software commit-time <10-60>
```

The default is 10 minutes.

#### Note

VSP 8600 Series default is 15 minutes.

3. **(Optional)** Extend or reduce the time to commit the software:  

```
software reset-commit-time [<1-60>]
```
4. Commit the upgrade:  

```
software commit
```

#### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

## Downgrade the Software

---

Perform this procedure to downgrade the switch from the current trusted version to a previous release.

#### Important

In VOSS 4.2 and later, the encryption modules are included in the image file. Therefore, the **load-encryption** command and the **software add-module** command is present but no longer applicable to the current release. You do not require a CLI command to add or load the encryption module. Use the **software add-module** command only if you downgrade to a release earlier than VOSS 4.2.

**Important**

MACsec connectivity association (CA) configurations fail during downgrade. If you plan to downgrade MACsec to an earlier version, delete the MACsec CA entries, perform the downgrade, and then reconfigure the MACsec CA entries. This applies to both 2AN and 4AN modes.

**Before You Begin**

Ensure that you have a previous version installed.

**About This Task****Note**

The image file name is switch dependent. See [Release Notes for VOSS](#) for information about file names.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. Extract the release distribution files to the /intflash/release/ directory:

```
software add WORD<1-99>
```

3. Extract the module files to the /intflash/release directory:

```
Software add-module [software version] [modules file name]
```

**Note**

This step applies to downgrades to a software version earlier than VOSS 4.2.

4. Activate a prior version of the software:

```
software activate WORD<1-99>
```

5. Restart the switch:

```
reset
```

**Important**

After you restart the system, you have the amount of time configured for the commit timer to verify the software change and commit the software to gold. If you do not commit the software to gold and auto-commit is not enabled, the system restarts with the last known working version after the commit timer expires. This feature ensures you can regain control of the system if an upgrade fails. By default, auto-commit is enabled.

6. Commit the software change:

```
software commit
```

### Important

If you disable the auto-commit feature, you must run the **software commit** command manually before the commit timer expires to commit the new software version, otherwise the system restarts automatically to the previous (committed) version. By default, auto-commit is enabled.

7. Verify the downgrade:

- Check for alarms or unexpected errors using the `show logging file tail` command.
- Verify all modules and slots are online using the `show sys-info` command.

8. (Optional) Remove unused software:

```
software remove WORD<1-99>
```

## Variable Definitions

The following table defines parameters for the `software` command.

| Variable            | Value                                                                           |
|---------------------|---------------------------------------------------------------------------------|
| activate WORD<1-99> | Specifies the name of the software release image.                               |
| add WORD<1-99>      | Specifies the path and version of the compressed software release archive file. |
| remove WORD<1-99>   | Specifies the path and version of the compressed software release archive file. |

## Deleting a software release

Perform this procedure to remove a software release from the switch.

### Note

There is a limit of six software releases that can be stored on the switch. If you have six releases already stored on the switch, then you will be prompted to remove one release before you can proceed with adding and activating a new software release.

### Procedure

1. Enter Privileged EXEC configuration mode:

```
enable
```

2. Remove software:

```
software remove WORD<1-99>
```

### Example

The following steps are just an example. The same steps apply to other switches.

```
Switch:1>enable
```

```
Switch:1#software remove VSP4K.4.1.0.0
```

## Update the Complex Programmable Logic Device (CPLD) Image

### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

During the device bootup, if an older version of a CPLD module is detected, the system displays a log message to upgrade the CPLD module image.

The following is an example of the log message:

```
1 2020-01-17T13:08:16.630Z VSP-4900-12MXU-12XE CP1 - 0x0026050d -
00000000 GlobalRouter SW INFO cpu CPLD/FPGA module is running older
version. Recommended to upgrade using command cpld-install.
```

You can also use **show sys-info cpld** command to check the current version of the CPLD module on the device.

### Before You Begin

Upgrade the software on the switch to the latest build.

### About This Task

The **cpld-install** command compares the image version of the modules with the current version on the device:

- If the versions are the same, the command exits.
- If the current version is an earlier version, you must update the image version of the specific module.

The device automatically restarts after successful installation of the specific module.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Update one of the following CPLDs:

- APP:

```
cpld-install app [WORD<1-99>]
```

- BOOT:

```
cpld-install boot [WORD<1-99>]
```

- CPU:

```
cpld-install cpu [WORD<1-99>]
```

- Field-Programmable Gate Array (FPGA):

```
cpld-install fgpa [WORD<1-99>]
```

- Main CPLD module:

```
cpld-install main [WORD<1-99>]
```

- Port:  

```
cpld-install port [WORD<1-99>]
```
- VIM (Versatile Interface Module):  

```
cpld-install vim [WORD<1-99>]
```

3. When prompted, type *y* to continue with the CPLD update.

### Example

Update CPLD for port module.

```
Switch:1>cpld-install port /intflash/1.1.8_sd_portpld.tgz
image file md5 checksum passed
Current port CPLD version is 0x1108, 1.1.08

Do you want to continue with cpld update? (y/n) ? y

WARNING: Upgrading FPGA requires writing to a device

WARNING: It will take about a minute or so to complete.

WARNING: DO NOT TURN POWER OFF OR MAKE ANY HARDWARE CHANGES ONCE YOU START THIS OPERATION.

## Variable Definitions

The following table defines parameters for the **cpld-install** command .

The following table applies to 5520 Series.

| Variable                | Value                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>app</i>              | Updates the APP module.                                                                                                                                                                            |
| <i>boot</i>             | Updates the BOOT module.                                                                                                                                                                           |
| <i>main</i>             | Updates the main CPLD module.                                                                                                                                                                      |
| <i>port</i>             | Updates the Port module.                                                                                                                                                                           |
| <i>WORD&lt;1-99&gt;</i> | Specifies the image filename.<br><br><b>Note:</b> This parameter is optional. If you do not specify the filename, the command checks the .tgz file for the image from the running VOSS filesystem. |

The following table applies to VSP 4900 Series.

| Variable                | Value                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cpu</i>              | Updates the CPU module.                                                                                                                                                                            |
| <i>fpga</i>             | Updates the FPGA module.                                                                                                                                                                           |
| <i>port</i>             | Updates the Port module.                                                                                                                                                                           |
| <i>vim</i>              | Updates the VIM module.                                                                                                                                                                            |
| <i>WORD&lt;1-99&gt;</i> | Specifies the image filename.<br><br><b>Note:</b> This parameter is optional. If you do not specify the filename, the command checks the .tgz file for the image from the running VOSS filesystem. |

## Upgrade the Boot Loader Image

### Note

This procedure does not apply to 5520 Series, VSP 4900 Series, VSP 7400 Series, or XA1400 Series.

### Warning

This command is an advanced-level command that upgrades the device uboot image. Only use this command if specifically advised to do so by Technical Support. Improper use of this command can result in permanent damage to the device and render it unusable.

If the need to use this command arises, instructions on usage will be provided by technical support.

### Before You Begin

- Transfer the image to the `/intflash/` directory on the switch.

### About This Task

For information about the boot loader image on universal hardware, see [Boot Loader Image on Universal Hardware](#) on page 279.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View the current uboot version:  
`show sys-info uboot`
3. Upgrade the boot loader image:  
`uboot-install WORD<1-99>`
4. Restart the system.

### Example

```
Switch:1#>show sys-info uboot

U-Boot Info :

Default Version : 2.2.1.2
Alternate Version : 2.2.1.2
Boot Version Used : Default
Trusted Delivery Status : Boot Image Verified
```

## Variable Definitions

The following table defines parameters for the `uboot-install` command.

| Variable                      | Value                                                               |
|-------------------------------|---------------------------------------------------------------------|
| <code>WORD&lt;1-99&gt;</code> | Specifies the full path and filename that contains the uboot image. |

## Address Resolution Protocol

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station uses

Address Resolution Protocol (ARP) to determine the physical address for a network host by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts.

The network station uses ARP to determine the host physical address as follows:

- The network station broadcasts a special packet, called an ARP request, that asks the host at the specified IP address to respond with its physical address.
- All network hosts receive the broadcast request.
- Only the specified host responds with its hardware address.
- The network station then maps the host IP address to its physical address and saves the results in an address-resolution cache for future use.
- The network station ARP table displays the associations of the known MAC address to IP address.

You can create ARP entries, and you can delete individual ARP entries.

## Enable ARP traffic

The switch accepts and processes ARP traffic, spanning tree bridge packet data units (BPDU), and Topology Discovery Protocol packets on port-based VLANs with the default port action of drop. If a filter port action is drop for a packet, ARP packets are also dropped. As a result, ARP entries on that port are cleared and are not relearned when the ARP aging timer expires.

To prevent dropped ARP packets, configure the following options:

- A user-defined protocol-based VLAN for ARP EtherType (byprotocol usrDefined 0x0806).
- Ports as static members to this VLAN with the default port action of drop.
- The port default VLAN ID to the correct port-based VLAN where the ARPs are processed.

You do not need to make configuration changes for the BPDU and Topology Discovery Protocol packets.

Only one user-defined protocol-based VLAN for ARP is allowed for each Spanning Tree Group (STG). If the ports with the default port action of drop are in different STGs, you must create additional user-defined protocol-based VLANs.

## Proxy ARP

A network station uses proxy ARP to respond to an ARP request from a locally attached host or end station for a remote destination. The network station sends an ARP response back to the local host with its own MAC address of the network station interface for the subnet on which the ARP request was received. The reply is generated only if the device has an active route to the destination network.

The following figure shows an example of proxy ARP operation. In this example, host C with mask 24 appears to be locally attached to host B with mask 16, so host B sends an ARP request for host C. However, the switch is between the two hosts. To enable communication between the two hosts, the switch responds to the ARP request with the IP address of host C but with its own MAC address.

**Figure 7: Proxy ARP operation**

## Loop detection

To prevent cases of ARP looping, configure the ARP loop detection flag to detect this situation. When a loop is detected, the port is shut down.

## Flushing router tables

For administrative or troubleshooting purposes, sometimes you must flush the routing tables. Flush routing tables either by VLAN or by port. In a VLAN context, all entries associated with the VLAN are flushed. In a port context, all entries associated with the port are flushed.

## Reverse Address Resolution Protocol

Certain devices use the Reverse Address Resolution Protocol (RARP) to obtain an IP address from a RARP server. MAC address information for the port is broadcast on all ports associated with an IP protocol-based or port-based VLAN. To enable a device to request an IP address from a RARP server outside its IP VLAN, you must create a RARP protocol-based VLAN.

RARP has the format of an ARP frame but its own Ethernet type (8035). You can remove RARP from the IP protocol-based VLAN definition and treat it as a separate protocol, thus creating a RARP protocol-based VLAN.

A typical network topology provides desktop switches in wiring closets with one or more trunk ports that extend to one or more data center switches where attached servers provide file, print, and other services. Use RARP functionality to define all ports in a network that require access to a RARP server as potential members of a RARP protocol-based VLAN. You must define all tagged ports and data center RARP servers as static or permanent members of the RARP VLAN. Therefore, a desktop host broadcasts an RARP request to all other members of the RARP VLAN. In normal operation, these members include only the requesting port, tagged ports, and data center RARP server ports. Because all other ports are potential members of this VLAN and RARP is only transmitted at startup, all other

port VLAN memberships expire. With this feature, one or more centrally located RARP servers extend RARP services across traditional VLAN boundaries to reach desktops globally.

## ARP configuration using the CLI

Network stations that use IP protocol require both a physical address and an IP address to transmit packets. In situations where the station knows only the network host IP address, the Address Resolution Protocol (ARP) lets you use the network station to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address.

A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

ARP response is enabled by default.

### Enabling ARP on a port or a VLAN

Enable ARP on the device so that it answers local ARP requests.

#### About This Task

You can enable or disable ARP responses on the device. You can also enable ARP proxy, which lets a router answer a local ARP request for a remote destination.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP on the device:

```
ip arp-response
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-response
```

## Enabling ARP proxy

### About This Task

Configure an ARP proxy to allow the platform to answer a local ARP request for a remote destination. ARP proxy is disabled by default.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable ARP proxy on the device:

```
ip arp-proxy enable
```

Use the no operator to disable ARP proxy: `no ip arp-proxy [enable]`

### Example

Enable ARP proxy on VLAN 200:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 200
Switch:1(config-if)#ip arp-proxy enable
```

## View ARP Information

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display ARP information for a specified port or for all ports:

```
show ip arp interface gigabitethernet [slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```
3. Display ARP information for a VLAN:

```
show ip arp interface vlan <1-4059>
```

### Example

```
Switch:1>show ip arp interface
```

```
=====
```

```

### Variable definitions

Use the data in the following table to use the **show ip arp** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A.B.C.D</i>                                               | Specifies the IP address of a network.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                             |
| <i>interface</i>                                             | Displays ARP interface configuration information.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>spbm-tunnel-as-mac</i>                                    | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>-s</i>                                                    | Specifies a subnet.<br>You must indicate the IP address followed by the subnet mask expressed as <A.B.C.D> <A.B.C.D>.                                                                                                                                                                                                                                                                                                                                                     |
| <i>vlan &lt;1-4059&gt;</i>                                   | Displays ARP entries for a particular VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable                              | Value                                                                                                                                                                                                                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF name expressed as text from 1 to 16 characters in length.<br>The total number of ARPs listed in the summary line of the <b>show ip arp</b> output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF). |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFIDs as text from 0 to 512 characters in length.<br>The total number of ARPs listed in the summary line of the <b>show ip arp</b> output represents the total number of ARPs on the chassis, including all VRFs (which includes the Management Router VRF).   |

Use the data in the following table to help you understand the **show ip arp interface** command output.

| Variable | Value                                                                                        |
|----------|----------------------------------------------------------------------------------------------|
| PORT_NUM | Indicates the port number.                                                                   |
| DOPROXY  | Indicates if ARP proxy responses are enabled or disabled on the specified interface.         |
| DORESP   | Indicates if the sending of ARP responses is enabled or disabled on the specified interface. |

Use the data in the following table to help you understand the **show ip arp interface vlan** command output.

| Variable | Value                                                                                        |
|----------|----------------------------------------------------------------------------------------------|
| VLAN_ID  | Indicates the VLAN ID.                                                                       |
| DOPROXY  | Indicates if ARP proxy responses are enabled or disabled on the specified interface.         |
| DORESP   | Indicates if the sending of ARP responses is enabled or disabled on the specified interface. |

## Configuring IP ARP static entries

### About This Task

Configure ARP static entries to modify the ARP parameters on the device. The only way to change a static ARP is to delete the static ARP entry and create a new entry with new information.

#### Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure ARP static entries on the device:

```
ip arp <A.B.C.D> 0x00:0x00:0x00:0x00:0x00:0x00 {slot/port [-slot/port]
[, ...]}
```

## Example

Configure ARP static entries:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip arp 192.0.2.10 00-16-76-7D-80-C2 2/1
```

### Variable definitions

Use the data in the following table to use the `ip arp` command.

**Table 47: Variable definitions**

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>request-threshold</code><br><50-1000> | Configures the maximum number of outstanding ARP requests that a device can generate. The range is 50-1000. The default value is 500.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>timeout</code> <1-32767>              | Configures the length of time in seconds an entry remains in the ARP table before timeout. The range is 1-32767.<br>To configure this option to the default value, use the <b>default</b> operator with this command.<br><br><b>Note:</b><br>The aging of ARP records is tied to the aging of MAC records. The ARP record for a given IP address is not removed unless the associated MAC record ages out and the router stops receiving a response to ARP requests for that IP address. In cases where the ARP aging time is set to less than the MAC aging time, the switch waits until the MAC ages out before deleting the ARP for an inactive host. |
| <A.B.C.D>                                   | Adds ARP entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Clearing ARP entries

Use this procedure to clear dynamic ARP table entries associated with the interface or VLAN.

## Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Clear ARP entries:
 

```
clear ip arp interface <gigabitethernet|vlan> <slot/port[/sub-port] [-slot/port[/sub-port]][, ...] | <1-4059>>
```

## Example

Clear ARP entries:

```
Switch:1> enable
Switch:1# clear ip arp interface gigabitethernet 1/16
```

### Variable definitions

Use the data in the following table to use the **clear ip arp interface** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                       | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>gigabitethernet vlan</i>                                    | Specifies the interface type.                                                                                                                                                                                                                                                                                                                                                                                              |
| { <i>slot/port[/sub-port] [-slot/port[/sub-port]][, ...]</i> } | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Showing ARP table information

Show ARP information to view the configuration information in the ARP table.

### About This Task

When you use the *interface* parameter with the **show ip arp** command you can display ARP configuration information only for a specific switch.

The **show ip arp** command displays all of the configured and dynamically learned ARP entries in the ARP table.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the ARP table:  
show ip arp [<A.B.C.D>] [-s <A.B.C.D>] [gigabitEthernet <slot/port[/sub-port]>] [interface <gigabitEthernet|vlan>] [nlb] [spbm-tunnel-as-mac] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]

## Example

```
Switch:1#show ip arp

### Variable definitions

Use the data in the following table to help you use the **show ip arp** command.

| Variable               | Value                                               |
|------------------------|-----------------------------------------------------|
| -s                     | Specifies the subnet for the table.                 |
| <i>gigabitEthernet</i> | Displays the entries for a particular brouter port. |

| Variable                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>interface</i>                 | Displays ARP interface configuration information. Use the following parameters to display ARP table information specifically for: <ul style="list-style-type: none"> <li>gigabitethernet {slot/port[-slot/port][,...]} displays IP ARP gigabitethernet interface information</li> <li>VLAN &lt;1-4059&gt; displays IP ARP VLAN interface information</li> </ul> Example: <code>show ip arp interface vlan 1</code>                                                                                                                                                                                                                                                                                                                                       |
| <i>nlb</i>                       | Displays the Network Load Balancing (NLB) ARP entries on the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>spbm-tunnel-as-mac</i>        | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>vlan</i>                      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Use these parameters to display ARP table information specifically for: <ul style="list-style-type: none"> <li>vrf WORD&lt;1-16&gt;—the VLAN VRF name in a range from 1 to 16 characters</li> <li>vrfids WORD&lt;0-512&gt;—the VLAN VRF ID in a range from 0 to 512</li> </ul> Example: <code>show ip arp vlan 1 vrf 1</code> |
| <i>vrf WORD &lt;1-16&gt;</i>     | Specifies the name of the VRF. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>vrfids WORD &lt;0-512&gt;</i> | Specifies the VRF ID. The total number of ARPs listed in the summary line of the "show ip arp" display represents the total number of ARPs on the chassis including all VRFs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <A.B.C.D>                        | Specifies the network IP address for the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use the data in the following table to help you understand the output of the **show ip arp** command.

| Parameter   | Description                                        |
|-------------|----------------------------------------------------|
| IP_ADDRESS  | Indicates the IP address where ARP is configured.  |
| MAC_ADDRESS | Indicates the MAC address where ARP is configured. |

| Parameter              | Description                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN                   | Indicates the VLAN address where ARP is configured.                                                                                                                                                         |
| PORT                   | Indicates the port where ARP is configured.                                                                                                                                                                 |
| TYPE                   | Indicates the type of learning (dynamic or local) where ARP is configured.                                                                                                                                  |
| TTL<10 secs>           | Indicates the time to live as tenths of a second where ARP is configured.                                                                                                                                   |
| TUNNEL                 | Displays the remote host name in the TUNNEL column for the SPBM ARP entry.                                                                                                                                  |
| MULTICAST-MAC-FLOODING | Displays whether IP ARP multicast MAC flooding is enabled or disabled. When enabled, the ARP entries for multicast MAC addresses are associated with the VLAN or port interface on which they were learned. |
| AGING (Minutes)        | Displays when the ARP aging timer expires.                                                                                                                                                                  |
| ARP-THRESHOLD          | Displays the maximum number of outstanding ARP requests that a device can generate.                                                                                                                         |

## Configuring Gratuitous ARP

Use the following procedure to configure Gratuitous Address Resolution Protocol (ARP). When Gratuitous ARP is enabled the switch allows all Gratuitous ARP request packets. The default is enabled.

If you disable Gratuitous ARP, the switch only allows Gratuitous ARP packets associated with Routed Split Multi-Link Trunking (RSMLT) or Virtual Router Redundancy Protocol (VRRP), and the switch discards all other Gratuitous ARP request packets.

### About This Task

ARP translates network layer (layer 3) IP addresses into link layer (layer 2) MAC addresses. A host sends a Gratuitous ARP request packet to inform other hosts of the existence of an interface on the network, so other local hosts can update their ARP tables. If the IP or MAC address changes, or in the event of a failover, a host sends a Gratuitous ARP request packet to inform other hosts to update their ARP tables.

VRRP and RSMLT use gratuitous ARP to update the MAC address tables on switches.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable Gratuitous ARP:
 

```
ip gratuitous-arp
```
3. (Optional) Disable Gratuitous ARP:
 

```
no ip gratuitous-arp
```
4. (Optional) Configure Gratuitous ARP to the default value:
 

```
default ip gratuitous-arp
```
5. Save the changed configuration.
 

```
save config [backup WORD<1-99>] [file WORD<1-99>] [verbose]
```

## ARP configuration using Enterprise Device Manager

Network stations using the IP protocol need both a physical address and an IP address to transmit a packet. In situations where the station knows only the network host IP address, the network station can use Address Resolution Protocol (ARP) to determine a network host physical address by binding a 32-bit IP address to a 48-bit MAC address. A network station can use ARP across a single network only, and the network hardware must support physical broadcasts. If a network station wants to send a packet to a host but knows only the host IP address, the network station uses ARP to determine the host physical address.

### Enabling or disabling ARP on the router port or a VRF instance

#### About This Task

After you assign the IP address, you can configure ARP. By default, ARP Response is enabled and Proxy ARP is disabled.

#### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **ARP** tab.
5. In the **DoProxy** check box, select **enable** to enable the Proxy ARP function.
6. In the **DoResp** check box, select **enable** to configure the system to respond to an ARP. The default is enable.
7. Click **Apply**.

The ARP function is available only when the port or VLAN is routed; that is, it is assigned an IP address.

#### *ARP field descriptions*

Use the data in the following table to use the **ARP** tab fields.

| Name           | Description                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DoProxy</b> | Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable. |
| <b>DoResp</b>  | Configures the system to send ARP responses for this IP interface address. The default value is enable.                                                |

### Enabling or disabling ARP on a VLAN or a VRF instance

#### About This Task

Use the following procedure to enable ARP on VLAN level.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **ARP** tab.
6. In the **DoProxy** field, click **enable** to enable the Proxy ARP function.
7. In the **DoResp** field, click **enable** to configure the system to respond to an ARP. The default is enable.
8. Click **Apply**.

The ARP dialog box is available only if the port or VLAN is routed; that is, it is assigned an IP address.

### **ARP** field descriptions

Use the data in the following table to use the **ARP** tab.

| Name           | Description                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DoProxy</b> | Configures the system to respond to an ARP request from a locally attached host or end station for a remote destination. The default value is disable. |
| <b>DoResp</b>  | Configures the system to send ARP responses for this IP interface address. The default value is enable.                                                |

## Viewing and managing ARP

### About This Task

You can view and manage known MAC address to IP address associations. In addition, you can create or delete individual ARP entries.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.

### **ARP** field descriptions

Use the data in the following table to use the **ARP** tab.

| Name               | Description                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetAddress</b>  | Specifies the IP address corresponding to the media-dependent physical address.                                                                                                                                                                    |
| <b>IfIndex</b>     | Identifies the router interface for this ARP entry: <ul style="list-style-type: none"> <li>• Brouter interfaces are identified by the slot/port number of the brouter port.</li> <li>• VLAN interfaces are identified by the vlan name.</li> </ul> |
| <b>PhysAddress</b> | Specifies the media-dependent physical address (that is, the Ethernet address).                                                                                                                                                                    |
| <b>Type</b>        | Specifies the type of ARP entry: <ul style="list-style-type: none"> <li>• local—a locally configured ARP entry</li> <li>• static—a statically configured ARP entry</li> <li>• dynamic—a learned ARP entry</li> </ul>                               |

| Name               | Description                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TimeToLive</b>  | Indicates the time to live where the ARP is configured.                                                                                                                                                                    |
| <b>DestIfIndex</b> | Indicates the slot/port on which the ARP entry was learned. For brouter interfaces this is the same value as IfIndex, but for VLAN interfaces, it designates the particular port in the VLAN on which the ARP was learned. |
| <b>DestVlanId</b>  | VLAN ID where the ARP is configured.                                                                                                                                                                                       |
| <b>BMac</b>        | Identifies the backbone MAC address if the entry is learned from an SPBM network.                                                                                                                                          |
| <b>DestCvid</b>    | Identifies the customer VLAN ID for a Switched UNI port.                                                                                                                                                                   |

## Creating static ARP entries

### About This Task

Use the following procedure to create a static ARP entry.

#### Note

Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast operations.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **ARP** tab.
4. Click **Insert**.
5. In the **NetAddress** field, type the IP address.
6. Click **Port**.  
OR  
Click **Port in VLAN**
7. In the dialog box, select the interface.
8. Click **OK**.
9. In the **PhysAddress** field, type the MAC address.
10. Click **Insert**.

## Configuring ARP proxy

### About This Task

With an ARP proxy, the switch can respond to an ARP request from a locally attached host or end station for a remote destination. Proxy ARP does so by sending an ARP response back to the local host with its own MAC address of the router interface for the subnet on which the ARP request was received. The reply is generated only if the system has an active route to the destination network.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs > Basic**.
3. Choose a VLAN.
4. Click **IP**.
5. Click **ARP** tab.
6. Select **DoProxy enable**.
7. Click **Apply**.

**Table 48: Alternative routes product support**

| Feature                                                          | Product         | Release introduced |
|------------------------------------------------------------------|-----------------|--------------------|
| For configuration details, see <a href="#">VOSS User Guide</a> . |                 |                    |
| Alternative routes for IPv4                                      | 5520 Series     | VOSS 8.2.5         |
|                                                                  | VSP 4450 Series | VSP 4000 4.0       |
|                                                                  | VSP 4900 Series | VOSS 8.1           |
|                                                                  | VSP 7200 Series | VOSS 4.2.1         |
|                                                                  | VSP 7400 Series | VOSS 8.0           |
|                                                                  | VSP 8200 Series | VSP 8200 4.0       |
|                                                                  | VSP 8400 Series | VOSS 4.2           |
|                                                                  | VSP 8600 Series | VSP 8600 4.5       |
|                                                                  | XA1400 Series   | VOSS 8.0.50        |
| Alternative routes for IPv6                                      | 5520 Series     | VOSS 8.2.5         |
|                                                                  | VSP 4450 Series | VOSS 5.1           |
|                                                                  | VSP 4900 Series | VOSS 8.1           |
|                                                                  | VSP 7200 Series | VOSS 5.1           |
|                                                                  | VSP 7400 Series | VOSS 8.0           |
|                                                                  | VSP 8200 Series | VOSS 5.1           |
|                                                                  | VSP 8400 Series | VOSS 5.1           |
|                                                                  | VSP 8600 Series | VSP 8600 6.2       |
|                                                                  | XA1400 Series   | Not Supported      |

To avoid traffic interruption, you can globally enable the alternative routes feature so the router can use the next-best route, also known as an alternative route, if the best route becomes unavailable.

Routers learn routes to a destination through routing protocols. Routers maintain a routing table of the learned alternative routes sorted in order by route preference, route costs, and route sources. The first route on the list is the best route and the route that the router prefers to use.

The alternative route concept also applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route without waiting for the update interval to expire.

## Route Preference

---

On the switch, all standard routing protocols have default preference values that determine the routing priority of the protocol. The router uses default preferences to select the best route when a clash exists in preference between the protocols.

You can modify the global preference for a protocol to give the protocol a higher or lower priority than other protocols. If you change the global preference for a static route and all best routes remain best routes, only the local route tables change. However, if the protocol preference change causes best routes to no longer be best routes, the change affects neighboring route tables.

### Important

Changing route preferences is a process-intensive operation that can affect system performance and network reach while you perform route preference procedures. As a best practice, if you want to change preferences for static routes or routing protocols, do so when you configure routes or during a maintenance window.

If a router learns a route with the same network mask and cost values from multiple sources, the router uses the route preferences to select the best route to add to the forwarding database.

### Note

To modify the preference for a route, you do *not* need to disable a route before you edit the configuration.

## Preferences for Static Routes

---

When you configure a static route on the switch, you can specify a global preference for the route. You can also specify an individual route preference that overrides the global static route preference. The preference value can be between 0 and 255, with 0 reserved for local routes and 255 representing an unreachable route.

## Preferences for Dynamic Routes

---

You can modify the preference value for dynamic routes through route filtering and IP policies, and this value overrides the global preference for the protocol.

The following table shows the default preferences for routing protocols and route types. Use this table to help you modify the global preference value.

**Table 49: Routing protocol default preferences**

| Protocol               | Default preference |
|------------------------|--------------------|
| Local                  | 0                  |
| Static                 | 5                  |
| SPBM_L1                | 7                  |
| OSPF intra-area        | 20                 |
| OSPF inter-area        | 25                 |

## Alternative Route Configuration using CLI

### Enable IPv4 Alternative Routes

#### About This Task

The default value is enabled. If you disable the alternative-route parameter, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readed.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Activate the alternative route feature globally:
 

```
ip alternative-route
```

## Enable IPv6 Alternative Routes

Use this procedure to enable IPv6 alternative routes and view the configuration on the switch.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable IPv6 alternative routes:

```
ipv6 alternative-route
```

#### Note

IPv6 alternative routes are enabled by default.

3. Verify the configuration of the IPv6 alternative route:

```
show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]
```

```
show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<0-512>]
```

*Example:*

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf globalRouter
Switch:1(router-vrf)#ipv6 alternative-route

Switch:1#show ipv6 global

## Alternative Route Configuration using EDM

### Enable IPv4 Alternative Routes Globally

#### Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3909.

#### About This Task

Globally enable alternative routes so that you can subsequently enable it on interfaces.

#### Procedure

- In the navigation tree, expand **Configuration > IP**.
- Select **IP**.
- Select the **Globals** tab.
- Select **AlternativeEnable**.

If the **AlternativeEnable** parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are re-added.

- Select **Apply**.

### Enable IPv6 Alternative Routes Globally

Global configuration includes the following:

- IPv6 alternative routes: To avoid traffic interruption, enable alternative routes globally on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

## Before You Begin

Change the VRF instance as required to configure IPv6 globally on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

## Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. To enable IPv6 alternative routes, click **AlternativeRouteEnable**.
5. Select **Apply**.

## IPv6 alternative routes configuration example

To avoid traffic interruption, you can enable alternative routes globally to replace the best route with the next-best route, if the best route becomes unavailable.

The concept of alternative route applies between routing protocols. For example, if an OSPFv3 route becomes unavailable and an alternative RIPng route is available, the system activates the RIPng route immediately without waiting for an update interval to expire.

By default, the alternative routes feature is globally enabled on the switch.

The following example demonstrates this behavior.

In this example, you configure OSPFv3 and RIPng routes on two switches Switch-1 and Switch-2, as shown in the following figure.

## Configuration on Switch-1

### VLAN configuration:

On Switch-1, configure VLAN 2 and the IPv6 interface address 2000:0:0:0:0:0:0:1/64.

```
Switch1:1:1>enable
Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch1:1(config)#vlan create 2 type port-mstprstp 0
Switch1:1(config)#vlan members 2 4/5
Switch1:1(config)#interface vlan 2
Switch1:1(config-if)#ipv6 interface address 2000:0:0:0:0:0:0:1/64
```

```
Switch1:1(config-if)#ipv6 interface enable
Switch1:1(config-if)#exit
Switch1:1(config)#show vlan basic
```

```

**Viewing route and alternative route configuration on the switches**

On Switch-1 and Switch-2, the route 3000:0:0:0:0:0:2/64 is learned using the protocols RIPng and OSPFv3. The OSPFv3 route is learned as the best route because of its route preference value of 20. The RIPng route is added as alternative route as it has the route preference 100, which is greater than the OSPFv3 route preference of 20. On Switch-2, the route 3000:0:0:0:0:0:2/64 is a local route.

**Viewing route and alternative route configuration on Switch-1:**

**Changing the route preference on Switch-1**

On the switch, default preferences are assigned to all standard routing protocols. You can modify the global preference for a protocol to give it a higher or lower priority than other protocols. When you change the preference for a static route, if all best routes remain best routes, only the local route tables change. However, if changing the protocol preference causes best routes to no longer be best routes, neighboring route tables can be affected.

In the following example scenario, you configure a different routing preference for the RIPng protocol on Switch-1 and observe the learning of best and alternative routes. The existing route preference for RIPng is 100.

```
Switch1:1#show ipv6 route alternative

```

Configure a different route preference for the RIPng protocol, for example, 19:

```

Switch1:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch1:1(config)#ipv6 route preference protocol ripng 19
Switch1:1(config)#exit

```

Verify the route preference configuration:

```

Switch1:1#show ipv6 route preference

=====
 IPv6 Route Preference - GlobalRouter
=====
PROTOCOL DEFAULT CONFIG

LOCAL 0 0
STATIC 5 5
SPBM_L1 7 7

Extreme Networks offers two Analytics solutions that monitor traffic on your network:

- sFlow
- Application Telemetry

**Important**

You can use either sFlow, or sFlow with Application Telemetry or both at the same time as they can coexist on a switch. Note that to enable Application Telemetry, you must enable sFlow first.

In both solutions, the switch collects flow information and sends it to a central server that processes the information and provides statistical data in the form of reports. Then you can use Extreme Management Center to analyze the reports to give you a full understanding of the applications on your network and learn who is using those applications. Extreme Management Center also provides information such as DoS tracking, security monitoring, and statistics for protocols, ports, and applications.

This section describes how Application Telemetry works and how to configure it. Because there is some commonality between the two features, this chapter also describes some sFlow features.

For further information about sFlow, see [sFlow Fundamentals](#) on page 2952.

For more information about Extreme Management Center, see the documentation on the Extreme Networks Documentation portal ([www.extremenetworks.com/documentation/](http://www.extremenetworks.com/documentation/)) with special attention to the *Application Analytics User Guide*.

## How Application Telemetry Works

---

Both sFlow and Application Telemetry mirror packets to a server for deep packet inspection, but they collect streams in very different ways:

- sFlow samples 1 out of  $n$  packets to create flow streams. This methodology achieves scalability and applies to high speed networks, but it provides limited application visibility.
- Application Telemetry does not sample some packets like sFlow; it monitors all traffic and uses policy rules to filter packets for analysis. This pattern matching methodology enables Application Telemetry to monitor all application-level traffic flows at wire speed on all interfaces simultaneously.

The policy rules that Application Telemetry uses are ACL and ACE filters that are pre-configured in a policy configuration file called `sflow.pol`. This policy file is not user configurable. These rules enable the switch to recognize several signatures that represent a combination of the following:

- IP protocol type (TCP/UDP)
- TCP flags
- Layer 4 port numbers
- data patterns (defined as offset/data/mask triplets)

Pattern matching enables Application Telemetry to target very specific, well-defined packets in each flow and not full streams of traffic. Thus, the switch mirrors only a relatively few packets to the Analytics

Engine. It is the Analytics Engine that performs deep packet inspection to create reports of statistical data.

### Important

When you enable Application Telemetry, the switch loads the filter rules based on the logic below:

- Application Telemetry uses the `apptelemetry.pol` or the `sflow.pol` file because the filter rules can exist in either file. The `sflow.pol` file is the default file and is included with the image that is loaded on the switch. This file contains the default filter rules. The `apptelemetry.pol` file is the user-defined file, which can be updated by the Extreme Management Center. To use this file, configure Application Telemetry using the Extreme Management Center. When you run the Application Telemetry LiveUpdate VOSS script from Extreme Management Center, the updated `apptelemetry.pol` file is placed in `/intflash/`.
- When you enable Application Telemetry, the feature uses the files in the following order:
  - If the user-defined file (`apptelemetry.pol`) exists, then the switch loads the rules from this file.
  - If the `apptelemetry.pol` file does not exist or if there is a problem reading this file, then the switch uses the default `sflow.pol` file.

## Common Elements Between sFlow and Application Telemetry

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

The tunnel source is the switch that you want to monitor:

- sFlow sends sampled flows.
- Application Telemetry sends packets that match its policy rules.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the `sflow agent-ip` command.

### Note

The switch sends only one mirrored copy, even if the packet matches two or more policies. For information on which mirrored copies take precedence, see [Configuration considerations](#).

The tunnel destination for the mirrored traffic is a server where software performs a deep packet inspection of the mirrored traffic.

- sFlow sends flow and counter samples as datagrams to the sFlow Collector.
- Application Telemetry sends packets that match the policy rules over a GRE tunnel to the Analytics Engine.

To configure the tunnel destination, they both use the **sflow collector <1-2>** command.

### Important

You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.

## Operational Considerations and Restrictions

The following section describes operational considerations for deploying Application Telemetry, including general considerations that apply to all platforms, followed by a summary of platform-specific considerations.

### General Considerations

The following section describes general Application Telemetry operational considerations for all platforms.

- When you enable Application Telemetry, it is globally enabled on all ports. You cannot disable the feature on a per-port basis.
- Application Telemetry supports IPv4 and IPv6 packets, although host monitoring is available for IPv4 hosts only.
- Application Telemetry filter rules are not user configurable. However, an updated `app-telemetry.pol` file can be installed through the Extreme Management Center.
- If a user-created filter rule (ACL) conflicts with an Application Telemetry defined filter, the user-created rule always takes precedence.
- There are two configurable sFlow collectors (Collector 1 and Collector 2). However, Application Telemetry uses Collector 1 only and you must configure it before enabling Application Telemetry.
- In a Fabric Extend deployment on VSP 4450 Series, VSP 7200 Series, VSP 8000 Series, or VSP 8400 Series, Application Telemetry does not mirror ingressing NNI to UNI IP Shortcut traffic.

### Platform-Specific Considerations

The following tables provide a summary of operational considerations for different VOSS switches.

**Table 51: Supported flow types**

| Attribute                                                       | 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series | VSP 8600 Series |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|-----------------|
| Flows that ingress standard VLAN ports                          | Supported                                                                                                         | Supported       |
| Flows that ingress UNI ports                                    | Supported                                                                                                         | Supported       |
| Flows that ingress NNI ports and egress UNI ports (Layer 2 VSN) | Supported                                                                                                         | Not supported   |

**Table 51: Supported flow types (continued)**

| Attribute                                                       | 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series | VSP 8600 Series |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|-----------------|
| Flows that ingress NNI ports and egress UNI ports (Layer 3 VSN) | Supported                                                                                                         | Not supported   |
| Flows that ingress NNI ports and terminate locally              | Supported                                                                                                         | Not supported   |
| Flow that ingress NNI ports and egress NNI ports                | Not supported                                                                                                     | Not supported   |
| Flows on DvR Controllers or DvR Leafs                           | Supported                                                                                                         | Supported       |

**Table 52: Application Telemetry collector/server reachability**

| Attribute                     | 5520 Series, VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series                                                                                                                                                                                                                                                                                                                                                                                                            | VSP 8600 Series                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Fabric Connect – Layer 2 VSNs | Yes<br>When the Analytics Engine is reachable over a Layer 2 VSN, the GRE packets are encapsulated with MAC-in-MAC (IEEE 802.1ah) at the originating BEB. The MAC-in-MAC header is removed at the terminating BEB and the original GRE packet is sent to the collector. Note also that the MAC-in-MAC encapsulation plus the GRE encapsulation adds 60 bytes to the original packet. Therefore, if the original packet is close to the maximum transmission unit (MTU), the mirrored copy can exceed the MTU and be dropped. | Yes<br>When the Analytics Engine is reachable over a Layer 2 VSN, the GRE packets are encapsulated with MAC-in-MAC (IEEE 802.1ah) at the originating BEB. | Supported using Extreme Management Center | Yes                                                                                                               | Yes             |

## Configuration Overview

After the optional step of uploading the `apptelemetry.pol` file to flash memory using Extreme Management Center, activate Application Telemetry by configuring the following:

1. Configure the IP address of the egress interface for the GRE tunnel with the `sFlow agent-ip` command.
2. Enable sFlow with the `sflow enable` command.
3. Configure the IP address of the Analytics Engine with the `sFlow collector 1` command.
4. Enable Application Telemetry with the `app-telemetry enable` command.

The following figure shows the Application Telemetry agent on various routers and switches with packets being sent to the Analytics Engine.

**Figure 8: Application Telemetry Overview**

**Table 61: Application Telemetry Legend**

| Number | Description                  |
|--------|------------------------------|
| 1      | Analytics Engine             |
| 2      | GRE tunnels                  |
| 3      | Application Telemetry agents |

## Host Monitoring

You can use Application Telemetry to get better visibility for a selected host by performing a timed packet capture for both incoming and outgoing traffic specific to that host. Initiate the packet capture (PCAP) from Extreme Management Center and specify a source or destination IP address to match. Extreme Management Center pushes an additional rule to the Application Telemetry agent on the switch, which captures packets that match this rule and uses the existing ERSPAN GRE session to mirror these packets to Analytics Engine for analysis.

To use this feature, all configuration occurs in Extreme Management Center. The following prerequisites for configuration must be met:

- Application Telemetry is active.
- The Analytics Engine records application flows.

- You can see the flows in Extreme Management Center.

In Extreme Management Center, select a flow and configure packet capture. You can specify the host, either the originating or destination host for the flow, and a monitoring interval. For more information about how to configure packet capture in Extreme Management Center, see the Extreme Management Center documentation.

The following list identifies restrictions specific to host monitoring:

- You cannot configure monitoring of the same host twice.
- Host monitoring shares resources with the filter ACL application. The maximum number of hosts that can be monitored depends on the number of ACEs you configure. If no resources are available, the Resource Manager generates an error for both applications.
- You cannot configure monitoring of the sFlow agent IP address or collector IP address.

Although you use Extreme Management Center to configure the packet capture, the switch logs a message when this feature is activated or deactivated. Configuration of host monitoring is not saved; the monitoring is time-based.

**Note**

Host monitoring is supported beginning with Extreme Management Center version 8.2.4.

## Application Telemetry Configuration Using CLI

---

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using CLI.

### Configuring the Agent IP Address

Use this procedure to configure the source of the Application Telemetry packets.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the agent IPv4 address:  
`sflow agent-ip {A.B.C.D}`

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
```

### Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

| Variable    | Definition                             |
|-------------|----------------------------------------|
| {A.B.C.D. } | Specifies the agent-ip address (IPv4). |

## Configuring an Analytics Engine and Enabling Application Telemetry Globally

Use this procedure to enable Application Telemetry and configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

### Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

### Before You Begin

- You must configure the sFlow agent IP address.
- You must enable sFlow before you can enable Application Telemetry.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the Analytics Engine information using Collector 1:

```
sflow collector 1 address {A.B.C.D} [owner WORD<1-20>] [vrf
WORD<1-16>]
```

3. Verify the Analytics Engine configuration:

```
show sflow collector 1
```

4. Enable Application Telemetry:

```
app-telemetry enable
```

5. Verify the global configuration:

```
show app-telemetry status
```

### Note

The output of this command shows whether Application Telemetry is enabled or not and if the collector is reachable.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#show sflow collector 1

=====
 sFlow Collector Configuration Info
=====
Id Owner Collector-IP Port Timeout (secs) Reachable via

1 sflow1 192.0.2.26 6343 497 192.0.2.15

All 1 out of 1 Total Num of sflow collector entries displayed
Switch:1(config)#app-telemetry enable
Switch:1(config)#show app-telemetry status
Application Telemetry is enabled
Collector is reachable via 192.0.2.26
```

### Variable Definitions

Use the data in the following table to use the **sflow collector** command.

| Variable                          | Value                                                                                                                                                                                                                                                  |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-2>                             | Specifies the ID of the collector where you want to send packets for analysis. Application Telemetry uses Collector 1 only.                                                                                                                            |
| <i>owner</i> WORD<1-20>           | Specifies the name of the collector.                                                                                                                                                                                                                   |
| <i>Collector-IP</i><br>{A.B.C.D.} | Specifies the IP address of the collector.                                                                                                                                                                                                             |
| <i>port</i> <1-65535>             | Specifies the destination port. The default port is 6343.<br><br><b>Note:</b><br>Application Telemetry does not use this parameter.                                                                                                                    |
| <i>timeout</i> <1-65535>          | Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the switch sends data forever.<br><br><b>Note:</b><br>Application Telemetry does not use this parameter. |
| <i>vrf</i> WORD<1-16>             | Specifies the name of the VRF used to reach the collector.<br><br><b>Note:</b><br>This parameter is not supported on all hardware platforms.                                                                                                           |

## Viewing Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View Application Telemetry counters:

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

### Example

```
Switch:1>show app-telemetry counter

=====
Application Telemetry Counters
=====
EntryId Name Packets Bytes

1 ssh 1258 72145
2 sslclient 457 27000

All 2 out of 2 Total Num of Application Telemetry counters entries displayed
```

## Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Clear Application Telemetry counters:

```
clear app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

3. Verify that the counters were cleared:

```
show app-telemetry counter [name <WORD<1-32> | id <1-2000>]
```

### Example

Clear the counters.

```
Switch:1>enable
Switch:1#clear app-telemetry counter
Switch:1>show app-telemetry counter

=====
Application Telemetry Counters
=====
EntryId Name Packets Bytes

1 ssh 0 0
2 sslclient 0 0

```

All 2 out of 2 Total Num of Application Telemetry counters entries displayed

## Application Telemetry Configuration Using EDM

Use Application Telemetry to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure this feature using EDM.

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination.

Both sFlow and Application Telemetry use an agent to package either the sFlow streams or the Application Telemetry packets. To configure the agent, they both use the **Serviceability > Sflow > Globals** and **Serviceability > Sflow > Collector** tabs. For more information, see [sFlow Configuration Using EDM](#) on page 2963.

### Enabling Application Telemetry Globally

Use this procedure to globally enable Application Telemetry so it can send packets to an Analytics Engine. By default, Application Telemetry is globally disabled.

#### Before You Begin

You must complete the following:

- Configure an agent IP address.
- Enable sFlow.
- Configure Collector 1.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Globals** tab.
4. Select the **AdminEnable** check box.
5. Click **Apply**.

#### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                     | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>       | Shows whether Application Telemetry is enabled. By default, the check box is not enabled. |
| <b>ClearCounterStats</b> | Clears the Application Telemetry status counters.                                         |

## Viewing Application Telemetry Counters

Use the following procedure to view the Application Telemetry status counters. The switch assigns an ID to each counter and displays information about each filter rule by name. The information includes how many packets were transmitted to the Analytics Engine that matched the specified pattern in the rule and the total number of bytes in the packets.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Click the **Counter** tab.

### Counter field descriptions

Use the data in the following table to use the **Counter** tab.

| Name                | Description                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>CounterId</b>    | Shows the Application Telemetry rule ID.                                                                        |
| <b>CounterName</b>  | Shows the rule name.                                                                                            |
| <b>CounterPkts</b>  | Shows the number of packets transmitted to the Analytics Engine that matched the specified pattern in the rule. |
| <b>CounterBytes</b> | Shows the total number of bytes in the packets.                                                                 |

## Clearing Application Telemetry Counters

Use this procedure to clear the Application Telemetry status counters. You can clear all of the counters or specify just the counters you want to clear by name or ID.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Application Telemetry**.
3. Perform one of the following actions:
  - To clear all the counters, click the **Globals** tab, and then select **ClearCounterStats**.
  - To clear specific counters, click the **Counter** tab, select the counter ID you want to clear, and then click **ClearStats**.
4. Click **Apply**.

## Viewing Application Telemetry Status

### About This Task

Use this procedure to view the status of the Application Telemetry collector.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.

2. Click **Application Telemetry**.
3. Click the **Status** tab.

#### *Status field descriptions*

Use the data in the following table to use the **Status** tab.

| Name                        | Description                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Collector IP Address</b> | Shows the address of the Application Telemetry collector.                                                          |
| <b>IsReachable</b>          | Shows whether the Application Telemetry collector is reachable.                                                    |
| <b>NextHop</b>              | If the collector is reachable, shows the name or address of the next hop through which the collector is reachable. |

Use Bidirectional Forwarding Detection (BFD) to provide a failure detection mechanism between two systems.

The following sections provide information and procedures for BFD.

## BFD Fundamentals

The following sections provide fundamentals information about Bidirectional Forwarding Detection (BFD).

### BFD Overview

Bidirectional Forwarding Detection (BFD) is a simple Hello protocol used between two peers. In BFD, peer systems periodically transmit BFD packets to each other. If one of the systems does not receive a BFD packet after a certain period of time, the system assumes that the link or other system is not operating.

A path is considered operational when bidirectional communication is established between systems. However, this does not preclude the use of unidirectional links.

BFD provides low-overhead, short-duration failure detection between two systems. BFD also provides a single mechanism for connectivity detection over any media, at any protocol layer.

Because BFD sends rapid failure-detection notifications to the routing protocols that run on the local system, which initiates routing table recalculations, BFD helps reduce network convergence time.

BFD supports IPv4/IPv6 single hop detection for static routes, OSPFv2, OSPFv3, iBGP, iBGPv6. Forwarding path failure detection for Fabric Extend tunnels is supported over an IPv4 network only.

#### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**Note**

iBGPv6 is not supported in VRF.

## BFD Operation

VOSS uses one BFD session for all protocols with the same destination. For example, if a network runs OSPFv2 and BGP across the same link with the same peer, only one BFD session is established, and BFD shares session information with both routing protocols.

You can enable BFD over data paths with specified OSPFv2 and OSPFv3 neighbors, BGP neighbors, static routing next-hop addresses, and Fabric Extend tunnels.

VOSS supports BFD asynchronous mode, which sends BFD control packets between two systems to activate and maintain BFD neighbor sessions. To reach an agreement with its neighbor about how rapidly failure detection occurs, each system estimates how quickly it can send and receive BFD packets.

A session begins with the periodic, slow transmission of BFD control packets. When bidirectional communication is achieved, the BFD session comes up.

After the session is up, the transmission rate of Control packets can increase to achieve detection time requirements. If Control packets are not received within the calculated detection time, the session is declared down. After a session is down, Control packet transmission returns to the slow rate.

If a session is declared down, it cannot come back up until the remote end signals that it is down (three-way handshake). A session can be kept administratively down by configuring the state of AdminDown.

In asynchronous mode, detection time is equal to the value of DetectMult received from the remote system multiplied by the agreed transmit interval of the remote system (the greater of RequiredMinRxInterval and DesiredMinTxInterval.) DetectMult is approximately equal to the number of sequential packets that must be missed to declare a session down.

## BFD States

A session normally proceeds through three states; two states are used to establish a session (Init and Up) and one state is used to tear down a session (Down). This allows a three-way handshake for both session establishment and session teardown, assuring that both systems are aware of all session state changes. There is a fourth state (AdminDown) that you can use to administratively put a session down indefinitely.

- Down state: Indicates the session is down or has just been created. The session will remain in Down state until the remote system sends a BFD control packet indicating anything other than Up state. If the control packet signals Down state, the session advances to Init state. If the control packet signals Init state, the session advances to Up state.
- Init state: In this state, the host system establishes communications with the remote system and sends a request to move the session to the Up state, but the remote system has not yet recognized the request. A session remains in Init state until it receives a BFD control packet signaling Init or Up state, or until the connectivity timer expires, indicating communication with the remote system is lost.

- Up state: Indicates the BFD session is established and connectivity is working. A session remains in Up state until connectivity fails or until the session is taken down administratively.
- AdminDown state: Indicates the BFD session is being held down administratively. This causes the remote system to enter Down state and remain there until the local system exits AdminDown state.

## BFD Configuration

The following sections provide conceptual information about BFD configuration. For detailed procedural information about BFD configuration, see [BFD Configuration using CLI](#) on page 349 and [BFD Configuration using EDM](#) on page 363.

### *Enable BFD*

To enable Bidirectional Forwarding Detection (BFD) between 2 peers:

- Configure BFD globally.
- Configure BFD on the required interfaces of both peer systems.
- Enable BFD on the required routing protocols.
- Specify the next-hop device with which the switch initiates the BFD session.

### *Delete a BFD Session*

To delete a BFD session, disassociate all applications with the BFD session, then administratively bring down the BFD session.

#### **Note**

To successfully delete a BFD session, you must execute the commands in the following order:

1. Disassociate all applications from the BFD session.
2. Disable BFD at the global level or interface level, which transitions the BFD session to AdminDown state.

If you change the above order of operations, the BFD session is not deleted.

## BFD Considerations

The following considerations apply to Bidirectional Forwarding Detection (BFD):

- BFD is supported only in asynchronous mode. Demand mode and echo functionalities are not supported.
- You configure BFD parameters on a per session basis, not on a per next-hop basis.
- BFD creates multiple sessions even though a neighbor shares an IP address.
- The granularity of the fault detection interval in BFD is 100 ms, and the minimum multiplier is 2.

The minimum value for the transmit interval or the receive interval is 100 ms. If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

You can configure a total of 16 BFD sessions. Of the 16 possible BFD sessions, you can configure a maximum of 4 BFD sessions with the minimum value for transmit interval or receive interval. You

can configure the remaining BFD sessions with a transmit interval or a receive interval that is greater than or equal to the 200 ms default value.

- BFD is not supported over RSMLT links. This applies to BFD sessions over IPv4 interfaces and IPv6 interfaces.
- Inter-tunnel routing with 6in4 tunnels is not supported. This means that incoming IPv6 packets over a tunnel cannot be forwarded over another tunnel configured on the same VOSS switch.
- BFD for Interior Border Gateway Protocol (iBGP) and BGPv6 in VRF is not supported.
- Session dampening is not supported for BFD.
- BFD for eBGPv6 in VRF is not supported.
- VOSS supports BFD multihop only at the eBGP application level. For other applications, VOSS does not support BFD multihop, as defined by RFC 5883. However, there is no requirement for source and destination IP addresses to be in the same subnet.
- BFD over IPv6 Fabric Extend (FE) tunnels is not supported.
- The minimum value for the transmit interval or the receive interval is 1 second with a fault detection time of 3 seconds for BFD over IPv4 FE tunnels.
- BFD does not support a static route flag.
- BFD is not supported on a Virtual Router Redundancy Protocol (VRRP) interface.
- High Availability for BFD is not supported.
- You can configure a total of 256 BFD and Virtual Link Aggregation Control Protocol (VLACP) sessions.
- BFD packets cannot be mirrored when BFD is configured on the switch.

## BFD Configuration using CLI

---

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using CLI. BFD provides low-overhead, short-duration failure-detection between two systems.

### Enable BFD Globally

#### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

#### Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must also configure BFD at the interface level and at the application level.

### Procedure

1. Enter BFD Router Configuration mode:

```
enable

configure terminal

router bfd
```

2. Enable BFD:

```
router bfd enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bfd
Switch:1(router-bfd)#router bfd enable
```

## Configure BFD on an IPv4 Interface

### About This Task

Use the following procedure to enable and to configure Bidirectional Forwarding Detection (BFD) on an IPv4 interface. All interface configuration is performed at the VLAN, GigabitEthernet, or Loopback level.

#### Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

### Procedure

1. Enter Interface Configuration mode:

```
enable

configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
- `interface loopback <1-256>`
- `interface vlan <1-4059>`

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ip bfd enable
```

3. (Optional) Configure the transmit interval:  

```
ip bfd interval <100-65335>
```
4. (Optional) Configure the minimum receive interval:  

```
ip bfd min-rx <100-65335>
```
5. (Optional) Configure the multiplier:  

```
ip bfd multiplier <1-20>
```
6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:  

```
ip bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:  

```
ip bfd vlan <1-4094>
```
8. (Optional) In Loopback Interface Configuration mode, you can configure a value for loopback:  

```
ip bfd loopback <1-256>
```

### Variable Definitions

The following table defines parameters for the **ip bfd** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                              |
| enable                                                             | Enable BFD on a port, VLAN, or loopback.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| interval <100-65335>                                               | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value. |
| min-rx <100-65335>                                                 | Specifies the receive interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.     |

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| multiplier <1-20>                                          | Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                 |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| vlan <1-4094>                                              | Specifies the VLAN ID in the range of 1 to 4094.                                                                                                                                                                                                                                                                                                              |
| loopback <1-256>                                           | Specifies the Loopback ID in the range of 1 to 256.                                                                                                                                                                                                                                                                                                           |

## Configure BFD on an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to enable and to configure BFD on an IPv6 interface. All interface configuration is performed at the VLAN or GigabitEthernet level.

#### Note

Enabling BFD on an interface does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the application level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BFD on an interface:

```
ipv6 bfd enable
```
3. (Optional) Configure the transmit interval:

```
ipv6 bfd interval <100-65335>
```

4. (Optional) Configure the minimum receive interval:

```
ipv6 bfd min-rx <100-65335>
```

5. (Optional) Configure the multiplier:

```
ipv6 bfd multiplier <1-20>
```

6. (Optional) In GigabitEthernet Interface Configuration mode, you can configure a value for port:

```
ipv6 bfd port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) In VLAN Interface Configuration mode, you can configure a value for VLAN:

```
ipv6 bfd vlan <1-4094>
```

### Variable Definitions

The following table defines parameters for the **ip bfd** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                              |
| enable                                                | Enable BFD on a port, VLAN, or loopback.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| interval <100-65335>                                  | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value. |
| min-rx <100-65535>                                    | Specifies the receive interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>For XA1400 Series, the default is 1000 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.     |

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| multiplier <1-20>                                          | Specifies the multiplier used to calculate the amount of time BFD waits before declaring a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                 |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| vlan <1-4094>                                              | Specifies the VLAN ID in the range of 1 to 4094.                                                                                                                                                                                                                                                                                                              |
| loopback <1-256>                                           | Specifies the Loopback ID in the range of 1 to 256.                                                                                                                                                                                                                                                                                                           |

## Enable BFD at the BGP Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD supports internal Border Gateway Protocol (iBGP) and external Border Gateway Protocol (eBGP) on IPv4 interfaces. You configure BFD on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. BFD does not support BGPv6 for VRF on IPv6 interfaces.

#### Note

Enabling BFD at the BGP application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Enable BFD for the BGP protocol:
 

```
neighbor WORD<0-1536> fall-over bfd
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch:1(router-bgp)#neighbor 192.0.2.15 fall-over bfd
```

### Variable Definitions

The following table defines parameters for the **neighbor** command.

| Variable     | Value                                                 |
|--------------|-------------------------------------------------------|
| WORD<0-1536> | Specifies the peer IP address or the peer group name. |

## Enable BFD at the OSPF Application Level

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD supports Open Shortest Path First (OSPF) for IPv4 interfaces and OSPFv3 for IPv6 interfaces.

Use the following procedure to enable BFD at the OSPF application level.

#### Note

Enabling BFD at the OSPF application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Enable BFD on an IPv4 interface under the OSPF protocol:

```
ip ospf bfd
```

3. Enable BFD on an IPv6 interface under the OSPF protocol:

```
ipv6 ospf bfd
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#ip ospf bfd
```

### Variable Definitions

The following table defines parameters for the **ip ospf bfd** command.

**Table 63:**

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]<br/>[-slot/port[/sub-<br/>port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>&lt;1-4059&gt;</code>                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Configure BFD on an IPv4 Static Route

### About This Task

Use the following procedure to configure BFD on an IPv4 static route.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure BFD on an IPv4 static route:  

```
ip route bfd {A.B.C.D}
```

### Variable Definitions

The following table defines parameters for the **ip route bfd** command.

**Table 64:**

| Variable               | Value                                        |
|------------------------|----------------------------------------------|
| <code>{A.B.C.D}</code> | Specifies the BFD static route IPv4 address. |

## Configure BFD on an IPv6 Static Route

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to configure BFD on an IPv6 static route.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure BFD on an IPv6 static route:  

```
ipv6 route bfd WORD<0-128>
```
3. (Optional) Configure an IPv6 static route for a port:  

```
ipv6 route bfd WORD<0-128> port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. (Optional) Configure an IPv6 static route for a VLAN:  

```
ipv6 route bfd WORD<0-128> vlan <1-4094>
```

*Variable Definitions*

The following table defines parameters for the **ipv6 route bfd** command.

| Variable                                                   | Value                                                    |
|------------------------------------------------------------|----------------------------------------------------------|
| WORD<0-128>                                                | Specifies the BFD static route IPv6 address.             |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Specifies the port number for the BFD IPv6 static route. |
| vlan <1-4094>                                              | Specifies the VLAN ID for the BFD IPv6 static route.     |

**Clear BFD Session Statistics**

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**About This Task**

Use the following procedure to clear local and remote Bidirectional Forwarding Detection (BFD) session statistics for IPv4 or IPv6 interfaces.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. (Optional) Clear BFD session statistics for an IPv4 interface:  

```
clear ip bfd stats
```
3. Clear BFD session statistics for an IPv6 interface:  

```
clear ipv6 bfd stats
```

*Variable Definitions*

The following table defines parameters for the **clear ip bfd stats** command.

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Global Configuration

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use this procedure to display global configuration information for BFD.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global BFD configuration information:  

```
show ip bfd [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

The following example displays global configuration information for BFD on an IPv4 interface.

```
Switch:1>show ip bfd
=====
 BFD information - GlobalRouter
=====
 BFD Version : 1
 Admin Status : TRUE
 Trap Enable : FALSE
=====
Total session number : 1

UP: 1, DOWN: 0, AdminDown: 0, Init: 0
=====
```

*Variable Definitions*

The following table defines parameters for the **show ip bfd** command.

**Table 65:**

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Configuration for an IPv4 Interface

## About This Task

Use the following procedure to display BFD configuration on an interface.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

```
show ip bfd interfaces GigabitEthernet [{slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

3. Display BFD on a VLAN interface:

```
show ip bfd interfaces vlan [<1-4059>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

## Examples

The following example displays VLAN interface configuration information for BFD.

```
Switch:1>show ip bfd interfaces vlan 11
=====
 Vlan Bfd
=====
VLAN STATUS MIN_RX INTERVAL MULTIPLIER VRF-ID

11 enable 200 200 3 0
```

The following example displays Loopback interface configuration information for BFD:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
=====
 Circuitless IP Interface Bfd
=====
INTF ID STATUS MIN_RX INTERVAL MULTIPLIER VRF-ID

1 enable 200 200 3 0
2 enable 200 200 3 2
```

## Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <1-4059>                                                   | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD Configuration for an IPv6 Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use the following procedure to display BFD configuration on an IPv6 interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD on a Gigabit Ethernet interface:

```
show ipv6 bfd interfaces GigabitEthernet [{slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]]
```

3. Display BFD on a VLAN interface:

```
show ipv6 bfd interfaces vlan <1-4059>
```

### Example

The following example displays port configuration information for BFD.

```
Switch:1>show ipv6 bfd interfaces gigabitEthernet 1/3

=====
Port Bfd
=====
PORT STATUS MIN_RX INTERVAL MULTIPLIER VRF-ID

1/3 enable 200 200 3 0
```

### Variable Definitions

The following table defines parameters for the **show ip bfd interfaces** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <1-4059>                                                   | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

| Variable           | Value                                   |
|--------------------|-----------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name.   |
| vrfids WORD<0-512> | Specifies a VRF or range of VRFs by ID. |

## Display BFD IPv4 Neighbor Information

### About This Task

Use this procedure to display BFD session information for IPv4 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:  

```
show ip bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:  

```
show ip bfd neighbors next-hop {A.B.C.D}
```
4. (Optional) Display BFD neighbor information for a particular VRF:  

```
show ip bfd neighbors vrf WORD<1-16>
```
5. (Optional) Display BFD neighbor information for a VRF ID or a range of VRF IDs:  

```
show ip bfd neighbors vrfids WORD<0-512>
```

### Example

The following example displays BFD session information for an IPv4 neighbor.

```
Switch:1>show ip bfd neighbors
=====
 BFD Session - GlobalRouter
=====
MY_DISC YOUR_DISC NEXT_HOP STATE MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME REMOTE_STATE APP RUN

1 0 192.0.2.11 Down 3 200 200 1000 600 Down O

1 out of 1 BFD session displayed
=====
APP and RUN Legend:
 B=BGP, O=OSPF, S=Static Route
=====
```

### Variable Definitions

The following table defines parameters for the **show ip bfd neighbors** command.

| Variable           | Value                                                                             |
|--------------------|-----------------------------------------------------------------------------------|
| {A.B.C.D}          | Specifies the next-hop IP address in the format a.b.c.d.                          |
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Display BFD IPv6 Neighbor Information

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

Use this procedure to display information about BFD IPv6 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD neighbor information:  

```
show ipv6 bfd neighbors
```
3. (Optional) Display BFD neighbor next-hop information:  

```
show ipv6 bfd neighbors next-hop WORD<0-128>
```
4. (Optional) Display BFD neighbor information for a particular VRF:  

```
show ipv6 bfd neighbors vrf WORD<1-16>
```
5. (Optional) Display BFD neighbor information for a range of VRFs:  

```
show ipv6 bfd neighbors vrfids WORD<0-512>
```

### Example

The following example displays BFD session information for an IPv6 neighbor.

```
Switch:1>show ipv6 bfd neighbors
=====
BFD Session - GlobalRouter
=====
MY_DISC YOUR_DISC NEXT_HOP STATE MULTI MIN_TX MIN_RX ACT_TX DETECT_TIME REMOTE_STATE APP RUN
1 0 2001:DB8:0:0:25AB:0:0:1 Down 3 200 200 1000 0 Down 0

1 out of 1 BFD session displayed

APP and RUN Legend:
 B=BGP_IPv6, O=OSPFv3, S=IPv6 Static Route

```

### Variable Definitions

The following table defines parameters for the **show ipv6 bfd neighbors** command.

| Variable           | Value                                                                             |
|--------------------|-----------------------------------------------------------------------------------|
| WORD<0-128>        | Specifies the next-hop IPv6 address in the format a:b:c:d:e:f:g:h.                |
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Display BFD Statistics

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

## About This Task

Use the following procedure to display BFD statistics for IPv4 or IPv6 interfaces.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display BFD IPv4 statistics:  

```
show ip bfd stats [vrf] [vrfids]
```
3. Display BFD IPv6 statistics:  

```
show ipv6 bfd stats [vrf] [vrfids]
```

### Example

The following example displays BFD statistics for IPv4 interfaces.

```
Switch:1>show ip bfd stats
=====
 BFD staticstics - GlobalRouter
=====
MY_DISC YOUR_DISC NEXT_HOP PACKET_IN PACKET_OUT LAST_UP LAST_DOWN

1 0 192.0.2.10 4661750 4620630 16007202 84431796
=====
```

The following example displays BFD statistics for IPv6 interfaces.

```
Switch:1>show ipv6 bfd stats
=====
 BFD staticstics - GlobalRouter
=====
MY_DISC YOUR_DISC NEXT_HOP PACKET_IN PACKET_OUT LAST_UP LAST_DOWN

1 0 2001:DB8:0:0:0:0:ffff 4661750 4620630 16007202 84431796
=====
```

### Variable Definitions

The following table defines parameters for the **show ip bfd stats** command.

| Variable | Value                                   |
|----------|-----------------------------------------|
| vrf      | Specifies a VRF instance by VRF name.   |
| vrfids   | Specifies a VRF or range of VRFs by ID. |

## BFD Configuration using EDM

Use the following procedures to configure Bidirectional Forwarding Detection (BFD) using EDM. BFD provides low-overhead, short-duration failure-detection between two systems.

## Enable BFD Globally

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD globally.

#### Note

Enabling BFD globally does not establish a BFD session. To establish a BFD session, you must enable BFD at the interface level and at the application level.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Globals** tab.
4. In the **AdminStatus** field, select **enabled**.
5. (Optional) Select **TrapEnabled** to send BFD traps.

### BFD Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                 | Description                                               |
|----------------------|-----------------------------------------------------------|
| <b>AdminStatus</b>   | Specifies whether BFD is enabled.                         |
| <b>VersionNumber</b> | Specifies the current version number of the BFD protocol. |
| <b>TrapEnabled</b>   | Specifies whether BFD traps are sent.                     |

## Display BFD Sessions

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to display information about BFD sessions. You can optionally display BFD session information for IPv4 or IPv6 interfaces.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Sessions** tab.
4. (Optional) Select **Filter**.
5. (Optional) Select **AddrType**.
6. (Optional) In the **AddrType** field, specify a value for address type.

*BFD Sessions Field Descriptions*

Use the data in the following table to use the **Sessions** tab.

| Name                        | Description                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Discriminator</b>        | Specifies the local discriminator that uniquely identifies the BFD session.                                                                                              |
| <b>RemoteDiscr</b>          | Specifies the discriminator of the remote system in the BFD session.                                                                                                     |
| <b>UdpPort</b>              | Specifies the UDP Port for the BFD session. The default value is the well-known value for the port.                                                                      |
| <b>State</b>                | Specifies the state of the BFD session. Possible values are Down, Up, Init, and AdminDown.                                                                               |
| <b>Addr</b>                 | Specifies the IP address of the interface associated with the BFD session. A value of unknown (0) indicates the BFD session is not associated with a specific interface. |
| <b>DesiredMinTxInterval</b> | Specifies the preferred minimum interval for transmitting BFD control packets by the local system.                                                                       |
| <b>ReqMinTxInterval</b>     | Specifies the minimum interval for transmitting BFD control packets that the local system can support.                                                                   |
| <b>DestAddr</b>             | Specifies the destination IP address of the interface associated with the BFD session.                                                                                   |
| <b>OldState</b>             | Specifies the old state of the BFD session.                                                                                                                              |
| <b>App</b>                  | Specifies the applications configured on the BFD session.                                                                                                                |
| <b>AppRun</b>               | Specifies the applications running on the BFD session.                                                                                                                   |
| <b>AddrType</b>             | Specifies the IP address type of the interface associated with this BFD session. Possible values are ipv4 and ipv6.                                                      |

## Configure BFD for an IPv4 Interface on a Port

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IP**.
3. Select the **BFD** tab.
4. Select **Enable**.
5. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
6. (Optional) In the **TxInterval** field, specify the transmit interval.
7. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

*BFD Field Descriptions*

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enable BFD on the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>MinRxInterval</b> | Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value. |
| <b>TxInterval</b>    | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.                                                                                   |
| <b>Multiplier</b>    | Specifies a value for the multiplier used to calculate a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                                                                                                                                                                                |

## Configure BFD for an IPv6 Interface on a Port

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **IPv6 BFD Interface** tab.
4. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
5. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
6. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

*BFD Field Descriptions*

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the BFD interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MinRxInterval</b> | Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                                                                                                                                                                                |

## Configure BFD for an IPv4 Interface on a VLAN

### About This Task

BFD provides a failure detection-mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv4 interface on a VLAN.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IP**.
6. Select **BFD**.
7. Select **Enable**.
8. (Optional) In the **MinRxInterval** field, specify the minimum receive interval..
9. (Optional) In the **TxInterval** field, specify the transmit interval.

10. (Optional) In the **Multiplier** field, specify a value for the multiplier used to calculate a receive timeout.

#### IP BFD field descriptions

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enable BFD on the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>MinRxInterval</b> | Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value. |
| <b>TxInterval</b>    | Specifies the transmit interval in milliseconds. The default is 200 ms.<br><br><b>Note:</b><br>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.                                                                                   |
| <b>Multiplier</b>    | Specifies a value for the multiplier used to calculate a receive timeout. The default is 3.<br><br><b>Note:</b><br>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.                                                                                                                                                                                                                                |

## Configure BFD for an IPv6 Interface on a VLAN

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable and configure BFD for an IPv6 interface on a VLAN.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to configure BFD.
5. Select **IPv6**.
6. Select **IPv6 BFD Interface**.

7. (Optional) In the **MinRxInterval** column, double-click the field and type a value for **MinRxInterval**.
8. (Optional) In the **TxInterval** column, double-click the field and type a value for **TxInterval**.
9. (Optional) In the **Multiplier** column, double-click the field and type a value for **Multiplier**.

### IPv6 BFD Interface field descriptions

Use the data in the following table to use the **IPv6 BFD Interface** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies an index value that uniquely identifies the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Enable</b>        | Enable BFD on the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>MinRxInterval</b> | <p>Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.</p> <p><b>Note:</b><br/>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.</p> |
| <b>TxInterval</b>    | <p>Specifies the transmit interval in milliseconds. The default is 200 ms.</p> <p><b>Note:</b><br/>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.</p>                                                                                   |
| <b>Multiplier</b>    | <p>Specifies a value for the multiplier used to calculate a receive timeout. The default is 3.</p> <p><b>Note:</b><br/>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.</p>                                                                                                                                                                                                                                |

## Enable BFD for BGP Peers

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peers.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.

3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

### **Peers** Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>              | Specifies the BGP peer instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>LocalAddrType</b>         | Specifies the local IP address type of the entered BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>LocalAddr</b>             | Specifies the local IP address of the entered BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>RemoteAddrType</b>        | Specifies the remote IP address type of the entered BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>RemoteAddr</b>            | Specifies the remote IP address of the entered BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>AdminStatus</b>           | Specifies the administrative status of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>PeerState</b>             | Specifies the BGP peer connection state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0–65535.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535. |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                    |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginate</b>      | When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DefaultOriginateIpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Name                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>RouteRefresh</b>                                                                            | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AsOverride</b><br><br><b>Note:</b><br>This field does not appear on all hardware platforms. | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                                                                                      | Description                                                                                                      |
|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>AllowAsIn</b><br><b>Note:</b><br>This field does not appear on all hardware platforms. | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                       |
| <b>Ipv6RoutePolicyIn</b>                                                                  | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b>                                                                 | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>                                                                      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>                                                                          | Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.                                              |

## Enable BFD for BGP Peer Groups

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for Border Gateway Protocol (BGP) peer groups.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

### *Peer Groups* field descriptions

Use the data in the following table to use the **Peer Groups** tab.

| Name             | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <b>Index</b>     | Specifies the index of this peer group.                             |
| <b>GroupName</b> | Specifies the peer group to which this neighbor belongs (optional). |
| <b>Enable</b>    | Enables or disables the peer group.                                 |

| Name                         | Description                                                                                                                                                                                                                                                                                                  |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteAs</b>              | Configures a remote AS number for the peer-group in the range 0-65535.                                                                                                                                                                                                                                       |
| <b>DefaultOriginate</b>      | When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.                                                                                                                                                |
| <b>DefaultOriginateIpv6</b>  | When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.                                                                                                                                                        |
| <b>EbgpMultiHop</b>          | When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled.                                                                                                                                               |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.                                                                                                                                                                                          |
| <b>KeepAlive</b>             | Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.                                                                                                                                                                                      |
| <b>HoldTime</b>              | Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.                                                                                                                                                       |
| <b>Weight</b>                | Assigns an absolute weight to a BGP network. The default value is 100.                                                                                                                                                                                                                                       |
| <b>MaxPrefix</b>             | Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.                                                                                                                                                                   |
| <b>NextHopSelf</b>           | Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.                                                                                                                                                                                 |
| <b>RoutePolicyIn</b>         | Specifies the route policy that applies to all networks learned from this group of peers.                                                                                                                                                                                                                    |
| <b>RoutePolicyOut</b>        | Specifies the route policy that applies to all outgoing updates to this group of peers.                                                                                                                                                                                                                      |
| <b>RouteReflectorClient</b>  | Specifies that this peer group is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                     |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes). |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication. The default is disable.                                                                                                                                                                                                                                             |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                             |
| <b>SendCommunity</b>         | Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.                                                                                                                                                                         |

| Name                               | Description                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AfUpdateSourceInterfaceType</b> | Specifies the interface type.                                                                                                                                                                                                                                 |
| <b>AfUpdateSourceInterface</b>     | Specifies the IP address used for circuitless IP (CLIP) for this peer group.                                                                                                                                                                                  |
| <b>Vpvn4Address</b>                | Enables BGP address families for IPv4 (BGP) and L3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.                                                                                                                                       |
| <b>IppvnLiteCap</b>                | Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.                                                                                                                             |
| <b>RouteRefresh</b>                | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0. |
| <b>AsOverride</b>                  | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.                                                                                                                                           |
| <b>AllowedAsIn</b>                 | Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.                                                                                                                                                                              |
| <b>IPv6Cap</b>                     | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                 |
| <b>Ipv6RoutePolicyIn</b>           | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                                                                                                                                                                |
| <b>Ipv6RoutePolicyOut</b>          | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                                                                                                                                                               |
| <b>Ipv6MaxPrefix</b>               | Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.                                                                                                                                                 |
| <b>BfdEnable</b>                   | Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.                                                                                                                                                                                      |

## Enable BFD for BGPv6 Peers

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for BGPv6 peers.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

#### Note

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

## Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Select **BfdEnable**.

### *Peers* Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteAddr</b>            | Specifies the remote IPv6 address of the entered BGP+ peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>PeerState</b>             | Specifies the BGPv6 peer connection state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535. |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                         |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginatelpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable. Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Name                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RouteRefresh</b>                                                                                    | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <p><b>AsOverride</b></p> <p><b>Note:</b><br/>This field does not appear on all hardware platforms.</p> | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <p><b>AllowAsIn</b></p> <p><b>Note:</b><br/>This field does not appear on all hardware platforms.</p>  | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Ipv6RoutePolicyIn</b>                                                                               | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Ipv6RoutePolicyOut</b>                                                                              | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Ipv6MaxPrefix</b>                                                                                   | Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>                                                                                       | Enables Bidirectional Forwarding Detection (BFD) for this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Enable BFD for OSPF on an IPv4 Port Interface

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv4 port interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **OSPF** tab.
5. Select **BfdEnable**.

### OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>           | Enables or disables OSPF routing on the specified port. The default is false.                                                                                                                                                                                                                                                                                                                                      |
| <b>HelloInterval</b>    | Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.                             |
| <b>RtrDeadInterval</b>  | Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet, and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds. |
| <b>DesigRtrPriority</b> | Specifies the priority of this port in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.                                                                                                      |
| <b>Metric</b>           | Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is $(10^9 / \text{interface speed})$ . The default is 1. <ul style="list-style-type: none"> <li>• FFFF—No route exists for this TOS.</li> <li>• IPCP links—Defaults to 0.</li> <li>• 0—Use the interface speed as the metric value when the state of the interface is up.</li> </ul>                                  |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthType</b>          | <p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha1—Specifies secure hash algorithm (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <b>AuthKey</b>           | Specifies the key (up to 8 characters) when you specify simple password authentication in the port AuthType variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>AreaId</b>            | Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AdvertiseWhenDown</b> | <p>Advertises the network on this port as up, even if the port is down. The default is false.</p> <p>After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>IfType</b>            | <p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>PollInterval</b>      | Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must have the same poll interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>IfMtuIgnore</b>       | Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>BfdEnable</b>         | Enable Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Enable BFD for OSPF on an IPv4 VLAN Interface

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv4 VLAN interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IP**.
6. Select **OSPF**.
7. Select **BfdEnable**.

### *OSPF* Field Descriptions

Use the data in the following table to use the **OSPF** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>           | Enables or disables OSPF routing on the specified VLAN. The default is false.                                                                                                                                                                                                                                                                                                                                     |
| <b>HelloInterval</b>    | Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.                            |
| <b>RtrDeadInterval</b>  | Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds. |
| <b>DesigRtrPriority</b> | Specifies the priority of this VLAN in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.                                                                                                     |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b>            | <p>Specifies the metric for this TOS on this VLAN. The value of the TOS metric is <math>(10^9 / \text{interface speed})</math>. The default is 1.</p> <ul style="list-style-type: none"> <li>• FFFF—No route exists for this TOS.</li> <li>• IPCP links—Defaults to 0.</li> <li>• 0—Use the interface speed as the metric value when the state of the interface is up.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>AuthType</b>          | <p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <b>AuthKey</b>           | <p>Specifies the key (up to eight characters) when you specify simple password authentication in the VLAN AuthType variable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>AreaId</b>            | <p>Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>AdvertiseWhenDown</b> | <p>Advertises the network even if the port is down. If true, OSPF advertises the network on this VLAN as up, even if the port is down. The default is false.</p> <p>After you configure a port without a link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even when the link is down. To disable advertising based on link states, disable AdvertiseWhenDown.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>IfType</b>            | <p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PollInterval</b>      | <p>Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must use the same poll interval.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name               | Description                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfMtuIgnore</b> | Specifies whether the VLAN ignores the MTU configuration. To allow the switch to accept OSPF DD packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes. |
| <b>BfdEnable</b>   | Enables Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                 |

## Enable BFD for OSPF on an IPv6 Port Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable BFD for the OSPF protocol on an IPv6 port interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IPv6**.
4. Select the **IPv6 OSPF Interface** tab.
5. Select **Insert**.
6. Select **BfdEnable**.

### *IPv6 OSPF Interface* field descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

| Name          | Description                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>  | Shows the interface index for the IPv6 interface on which OSPFv3 is configured.                                                                                                                                        |
| <b>Areald</b> | Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                       |
| <b>Type</b>   | Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul> |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminStat</b>              | Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.                                                                                                                                                                                                  |
| <b>RtrPriority</b>            | Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router.<br>The default is 1. |
| <b>TransitDelay</b>           | Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.                                                                                                                                                                                                                                                                                                               |
| <b>RetransInterval</b>        | Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.                                                                                                                                                                                                                 |
| <b>HelloInterval</b>          | Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.                                                                                                                                                                                                                   |
| <b>RtrDeadInterval</b>        | Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.                                                                                                                                                                                                               |
| <b>PollInterval</b>           | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.                                                                                                                                                                                                                                                                                                                          |
| <b>State</b>                  | Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>                                                                                                                                               |
| <b>DesignatedRouter</b>       | Shows the router ID for the designated router.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>BackupDesignatedRouter</b> | Shows the router ID for the backup designated router.                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MetricValue</b>        | Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.<br><br><b>Note:</b><br>If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface. |
| <b>LinkLsaSuppression</b> | Specifies whether Link LSA suppression is enabled.                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>          | Enable Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                  |

## Enable BFD for OSPF on an IPv6 VLAN Interface

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

### About This Task

BFD provides a failure-detection mechanism between two systems. Use the following procedure to enable OSPF BFD on an IPv6 VLAN interface.

#### Note

Enabling BFD at the application level does not establish a BFD session. To establish a BFD session, you must enable BFD globally and at the interface level.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Select **VLANS**.
3. Select the **Basic** tab.
4. Select the VLAN on which you want to enable BFD for OSPF.
5. Select **IPv6**.
6. Select **IPv6 OSPF Interface**.
7. Select **Insert**.
8. Select **BfdEnable**.

### **IPv6 OSPF Interface** field descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>           | Shows the interface index for the IPv6 interface on which OSPFv3 is configured.                                                                                                                                                                                                                                                                                                                                                       |
| <b>Areaid</b>          | Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                                                                                                                                                                                                                      |
| <b>Type</b>            | Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>                                                                                                                                                                                                                |
| <b>AdminStat</b>       | Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.                                                                                                                                                                                                  |
| <b>RtrPriority</b>     | Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router.<br>The default is 1. |
| <b>TransitDelay</b>    | Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.                                                                                                                                                                                                                                                                                                               |
| <b>RetransInterval</b> | Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.                                                                                                                                                                                                                 |
| <b>HelloInterval</b>   | Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.                                                                                                                                                                                                                   |
| <b>RtrDeadInterval</b> | Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.                                                                                                                                                                                                               |
| <b>PollInterval</b>    | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.                                                                                                                                                                                                                                                                                                                          |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>                  | Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesginatedRouter</li> <li>• otherDesignatedRouter</li> </ul>                                                                                    |
| <b>DesignatedRouter</b>       | Shows the router ID for the designated router.                                                                                                                                                                                                                                                                                                                             |
| <b>BackupDesignatedRouter</b> | Shows the router ID for the backup designated router.                                                                                                                                                                                                                                                                                                                      |
| <b>MetricValue</b>            | Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.<br><br><b>Note:</b><br>If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface. |
| <b>LinkLsaSuppression</b>     | Specifies whether Link LSA suppression is enabled.                                                                                                                                                                                                                                                                                                                         |
| <b>BfdEnable</b>              | Enables Bidirectional Forwarding Detection (BFD) for OSPF.                                                                                                                                                                                                                                                                                                                 |

## Configure BFD on an IPv4 Static Route

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BFD**.
3. Select **Insert**.
4. In the **NextHop** field, type the IPv4 address of the next hop of the BFD session.
5. (Optional) In the **Vrflid** field, type the ID of the VRF associated with the BFD session.

*BFD Static Route Field Descriptions*

Use the data in the following table to use the **Static Route** tab.

| Name           | Description                                                    |
|----------------|----------------------------------------------------------------|
| <b>NextHop</b> | Specifies the IPv4 address of the next hop of the BFD session. |
| <b>Vrflid</b>  | Specifies the ID of the VRF associated with the BFD session.   |
| <b>VrfName</b> | Specifies the name of the VRF associated with the BFD session. |

**Configure BFD on an IPv6 Static Route**

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IPv6 BFD**.
3. Select **Insert**.
4. In the **Interface** field, select either **Port** or **Vlan** and select an interface.
5. In the **NextHop** field, type the IPv6 address of the next hop of the BFD session.
6. (Optional) In the **Vrflid** field, type the ID of the VRF associated with the BFD session.

*IPv6 BFD Static Route Field Descriptions*

Use the data in the following table to use the **Static Route** tab.

| Name             | Description                                                    |
|------------------|----------------------------------------------------------------|
| <b>Interface</b> | Specifies either a port or VLAN interface.                     |
| <b>NextHop</b>   | Specifies the IPv4 address of the next hop of the BFD session. |
| <b>Vrflid</b>    | Specifies the ID of the VRF associated with the BFD session.   |
| <b>VrfName</b>   | Specifies the name of the VRF associated with the BFD session. |

**Display BFD Performance Counters**

BFD for IPv6 interfaces is a demonstration feature on some products. For more information about feature support, see [VOSS Feature Support Matrix](#).

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **BFD**.
3. Select the **Performance counters** tab.

*BFDPerformance Counters Field Descriptions*

Use the data in the following table to use the **Performance counters** tab.

| Name          | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <b>PktIn</b>  | Specifies the total number of BFD messages received for this BFD session. |
| <b>PktOut</b> | Specifies the total number of BFD messages sent for this BFD session.     |

# BGP

**BGP fundamentals on page 390**

**BGP configuration using CLI on page 427**

**BGP Verification Using CLI on page 455**

**BGP configuration using EDM on page 473**

**BGP Configuration Examples on page 497**

The following sections provide conceptual information and procedures that you can use to configure Border Gateway Protocol (BGP) services. The following operations are supported by BGP:

- IPv4
- 4-byte AS
- Peer groups
- Redistribution

Examples and network illustrations in these sections illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

## BGP fundamentals

Border Gateway Protocol (BGP) is an inter-domain routing protocol that provides loop-free routing between autonomous systems (AS) or within an AS. This section describes the major BGP features.

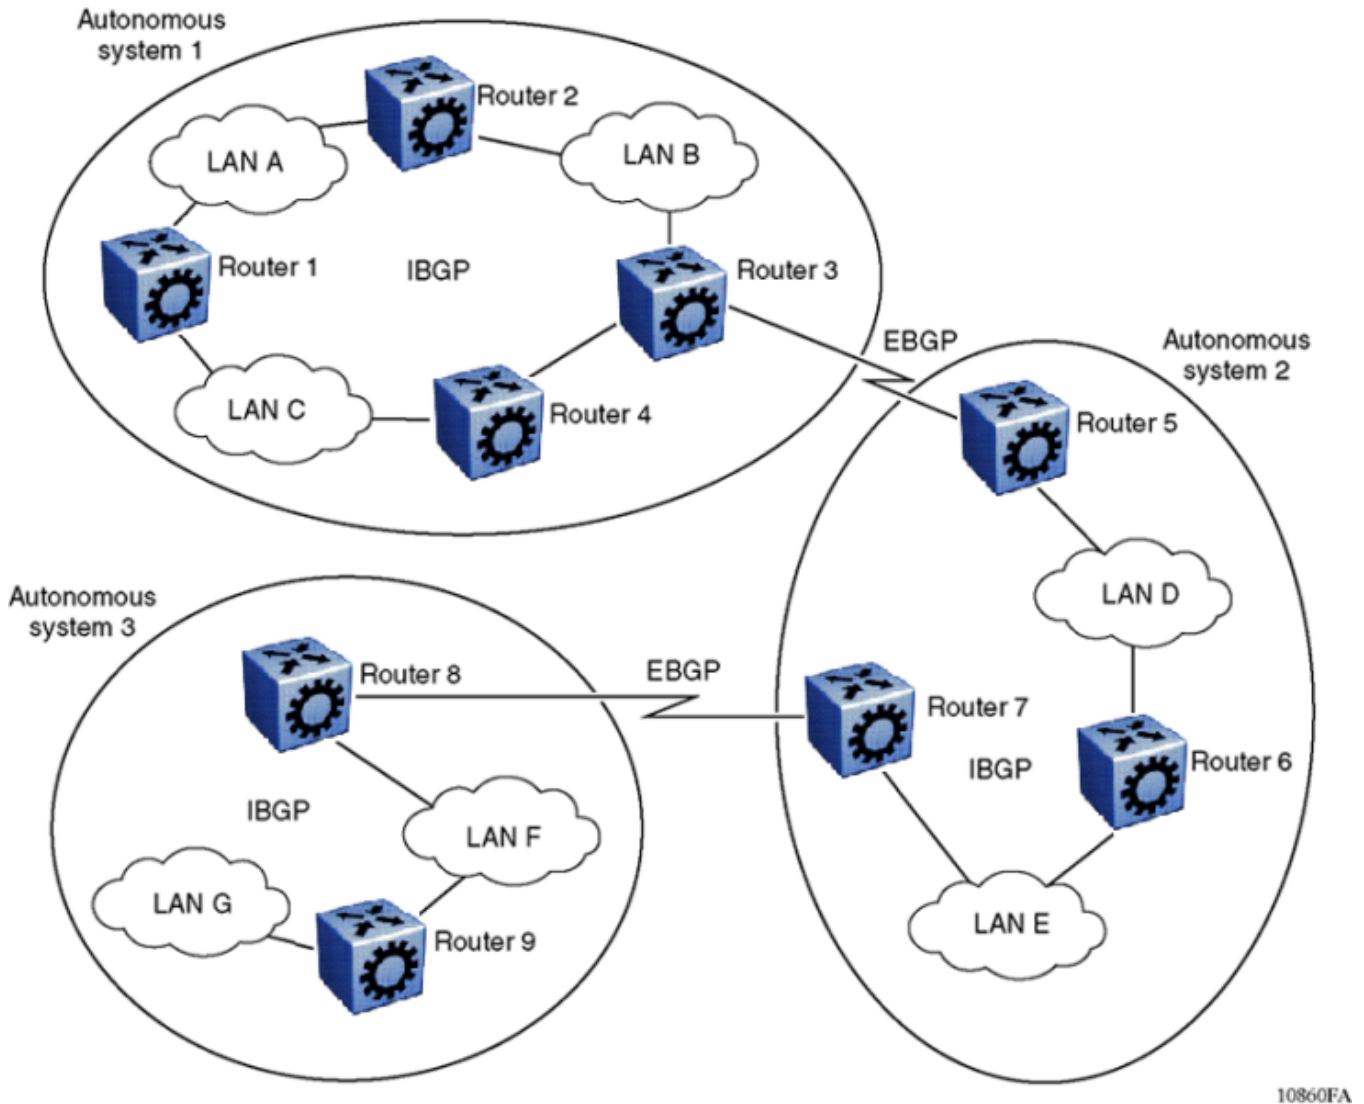

## Autonomous Systems

An Autonomous system (AS) is a group of routers and hosts run by a single technical administrator that has a single, clearly defined routing policy. Each AS uses a unique AS number assigned by the appropriate Internet Registry entity. LANs and WANs that interconnect by IP routers form a group of

networks called an internetwork. For administrative purposes, internetworks divide into boundaries known as autonomous systems.

The following figure shows a sample internetwork segmented into three autonomous systems.

**Figure 9: Internetwork segmented into three autonomous systems**

BGP exchanges information between autonomous systems as well as between routers within the same AS. As shown in the preceding figure, routers that are members of the same AS and exchange BGP updates run internal BGP (iBGP), and routers that are members of different autonomous systems and exchange BGP updates run external BGP (eBGP).

#### *Internal and external BGP routing*

The switch supports both iBGP intra-AS routing and eBGP external-AS routing. With iBGP, each router within an AS runs an interior gateway protocol (IGP), such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). The iBGP information, along with the IGP route to the originating BGP border router, determines the next hop to use to exchange information with an external AS. Each router uses iBGP exclusively to determine reachability to external autonomous systems. After a router receives

an iBGP update destined for an external AS, it passes the update to IP for inclusion in the routing table only if a viable IGP route to the correct border gateway is available.

BGP speakers in different autonomous systems use eBGP to communicate routing information.

#### *BGP speaker*

BGP routers employ an entity within the router, referred to as a BGP speaker, which transmits and receives BGP messages and acts upon them. BGP speakers establish a peer-to-peer session with other BGP speakers to communicate.

All BGP speakers within an AS must be fully meshed. The following figure shows a BGP network with fully-meshed BGP speakers.

10861FA

**Figure 10: BGP networks**

#### *Transit AS*

An AS with more than one BGP speaker can use iBGP to provide a transit service for networks located outside the AS. An AS that provides this service is a transit AS. As shown in the preceding figure, [BGP networks](#), AS 40 is the transit AS. AS 40 provides information about the internal networks, as well as transit networks, to the remaining autonomous systems. The iBGP connections between routers D, E, and F provide consistent routing information to the autonomous systems.

### *Stub and multihomed autonomous systems*

As shown in the preceding figure, [BGP networks](#), an AS can include one or more BGP speakers that establish peer-to-peer sessions with BGP speakers in other autonomous systems to provide external route information for the networks within the AS.

A stub AS has a single BGP speaker that establishes a peer-to-peer session with one external BGP speaker. In this case, the BGP speaker provides external route information only for the networks within its own AS.

A multihomed AS has multiple BGP speakers.

### *Peers*

BGP uses Transmission Control Protocol (TCP) as a transport protocol. When two routers open a TCP connection to each other for the purpose of exchanging routing information, they form a peer-to-peer relationship. In the preceding figure, [BGP networks](#), Routers A and D are BGP peers, as are Routers B and E, C and E, F and G, and Routers D, E, and F.

Although Routers A and D run eBGP, Routers D, E, and F within AS 40 run iBGP. The eBGP peers directly connect to each other, while the iBGP peers do not. As long as an IGP operates and allows two neighbors to logically communicate, the iBGP peers do not require a direct connection.

#### **Note**

You cannot create the same iBGP peers on two different VRFs, or the same eBGP peers on two different chassis. Only one local autonomous system (AS) can exist for each chassis or VRF.

Because all BGP speakers within an AS must be fully meshed logically, the iBGP mesh can grow to large proportions and become difficult to manage. You can reduce the number of peers within an AS by creating confederations and route reflectors.

BGP peers exchange complete routing information only after the peers establish a connection. Thereafter, BGP peers exchange routing updates. An update message consists of a network number, a list of autonomous systems that the routing information passed through (the AS path), and other path attributes that describe the route to a set of destination networks. When multiple paths exist, BGP compares the path attributes to choose the preferred path. Even if you disable BGP, the system logs all BGP peer connection requests. For more information about update messages, see [BGP Updates](#) on page 411.

### *Supernet advertisements*

BGP has no concept of address classes. Each network listed in the network layer reachability information (NLRI) portion of an update message contains a prefix length field, which describes the length of the mask associated with the network. The prefix length field allows for both supernet and subnet advertisement. The supernet advertisement is what makes classless interdomain routing (CIDR) possible (see [CIDR and aggregate addresses](#) on page 400).

### *Bandwidth and maintenance reduction*

BGP provides two features that reduce the high bandwidth and maintenance costs associated with a large full-mesh topology:

- confederations
- route reflectors

#### **Note**

Confederations and route reflectors are not supported on iBGP for non-default VRFs.

For information on confederations and route reflectors, see [Routing information consolidation](#) on page 400.

### *BGP 4 Byte AS Support*

Each Autonomous System (AS) must have its own unique number. Because the 2-byte AS numbering scheme is unable to meet the increasing demand, the switch supports 4-byte AS numbers. This feature is enabled by supporting RFC 4893, BGP Support for 4-octet AS Number Space.

The switch supports the following three types of peer relationships as a result of 4 byte AS support:

- Old peer to old peer
- Old peer to new peer
- New peer to new peer

An old peer is the one that supports 2-byte AS numbers only and new peer is the one that supports both 2-byte AS numbers and 4-byte AS numbers.

RFC4893 supports two new path attributes:

- AS4\_PATH contains the AS path encoded with a 4-octet AS number.
- AS4-AGGR is a new aggregator attribute that carries a 4-octet AS number.

**Figure 11: 2-byte and 4-byte Mixed Environment**

The preceding figure shows an example of how the switch uses the AS4\_PATH attribute in a mixed environment. The figure illustrates how a 2-byte BGP speaker interoperates with a 4-byte BGP speaker.

Router B is a 2-byte BGP speaker. Router A substitutes AS\_PATH with the AS\_TRANS, a 2-octet AS number defined by RFC4893 for backward compatibility, and encodes the 4-byte AS into AS4\_PATH in BGP updates it sends to router B.

Router B does not understand the AS4\_PATH but does preserve the information and sends it to router C.

Router C is a 4-byte BGP speaker. Router C merges the information received in AS\_PATH and AS4\_PATH, and encodes the 4-byte AS when it sends the AS\_PATH information to router D.

#### Old Peer to Old Peer

When the peer relationship between an old peer and another old peer is established, 4 byte AS numbers contained in the AS4\_PATH and AS4\_AGGREGATOR are transited to other peers.

#### Important

Do not assign 23456 as an AS number. The Internet Assigned Numbers Authority (IANA) reserved this number for the AS\_TRANS attribute and BGP uses it to facilitate communication between peer modes. AS\_TRANS uses a 2-byte AS format to represent a 4-byte AS number. The switch interprets the AS\_TRANS attribute and propagates it to other peers.

#### New Peer to New Peer

The new BGP speaker establishes its 4 byte AS support through BGP capability advertisement. A BGP speaker that announces such capability and receives it from its peer, uses 4 byte AS numbers in

AS\_PATH and AGGREGATOR attributes and assumes these attributes received from its peer are encoded in 4 byte AS numbers.

The new BGP attributes AS4\_PATH and AS4\_AGGREGATOR received from the new BGP speaker between the new BGP peers in the update message is discarded.

### Old Peer to New Peer

An old BGP speaker and a new BGP speaker can form peering relationship only if the new BGP speaker is assigned a 2 byte AS number. This 2 byte number can be any global unique AS number or AS\_TRANS.

New BGP speaker sends AS path information to the old BGP speaker in AS\_PATH attribute as well as AS4\_PATH attribute. If the entire AS\_PATH consists of only 2 byte AS numbers then the new BGP speaker does not send AS4\_PATH information.

The 4-byte AS number feature does not in any way restrict the use or change the way you configure 2-byte AS numbers. You can also configure 2-byte AS or 4 byte AS numbers in AS path lists, community lists, and route policies.

### BGP 4-byte AS Number Notation

BGP 4-byte AS numbers are represented in two ways: AS Plain and AS dot. The default form of representing the AS numbers is AS Plain while you have an option to configure AS dot. AS Plain form of representation is preferred over AS dot representation as a large amount of network providers find the AS dot notation incompatible with the regular expressions used by them. In case of any issues, troubleshooting and analyzing also gets difficult with AS dot notation.

### BGP AS Number Format - AS Plain

**Table 67: Default Asplain 4-Byte Autonomous System Number Format**

| Format  | Configuration Format                              | Show Command Output and Regular Expression Match Format |
|---------|---------------------------------------------------|---------------------------------------------------------|
| asplain | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295 | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295       |
| asdot   | 2-byte: 1 to 65535<br>4-byte: 1.0 to 65535.65535  | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295       |

### BGP AS Number Format - ASdot

**Table 68: Asdot 4-Byte Autonomous System Number Format**

| Format  | Configuration Format                              | Show command output and Regular Expression Match Format |
|---------|---------------------------------------------------|---------------------------------------------------------|
| asplain | 2-byte: 1 to 65535<br>4-byte: 65536 to 4294967295 | 2-byte: 1 to 65535<br>4-byte: 1.0 to 65535.65535        |
| asdot   | 2-byte: 1 to 65535<br>4-byte: 1.0 to 65535.65535  | 2-byte: 1 to 65535<br>4-byte: 1.0 to 65535.65535        |

For more information on configuring 4 byte AS numbers, see [Configure 4-byte AS numbers](#) on page 432.

## Routing information consolidation

Use the information in this section to understand how to reduce the size of routing tables.

### *CIDR and aggregate addresses*

Classless interdomain routing (CIDR) is an addressing scheme (also known as supernetting) that eliminates the concept of classifying networks into class types. Earlier addressing schemes identified five classes of networks: Class A, Class B, Class C, Class D, and Class E. This document does not discuss Classes D (used for multicast) and E (reserved and currently not used).

Network 195.215.0.0, an illegal Class C network number, becomes a legal supernet when represented in CIDR notation as 195.215.0.0/16. The /16 is the prefix length and expresses the explicit mask that CIDR requires. In this case, the addition of the prefix /16 indicates that the subnet mask consists of 16 bits (counting from the left).

Using this method, supernet 195.215.0.0/16 represents 195.215.0.0 255.255.0.0. The following table shows the conversion of prefix length to subnet mask.

**Table 69: CIDR conversion**

| Prefix | Dotted-decimal | Binary                                  | Network class            |
|--------|----------------|-----------------------------------------|--------------------------|
| /1     | 128.0.0.0      | 1000 0000 0000 0000 0000 0000 0000 0000 | 128 Class A              |
| /2     | 192.0.0.0      | 1100 0000 0000 0000 0000 0000 0000 0000 | 64 Class A               |
| /3     | 224.0.0.0      | 1110 0000 0000 0000 0000 0000 0000 0000 | 32 Class A               |

**Table 69: CIDR conversion (continued)**

| Prefix | Dotted-decimal | Binary                                  | Network class |
|--------|----------------|-----------------------------------------|---------------|
| /18    | 255.255.192.0  | 1111 1111 1111 1111 1100 0000 0000 0000 | 64 Class C    |
| /19    | 255.255.224.0  | 1111 1111 1111 1111 1110 0000 0000 0000 | 32 Class C    |
| /20    | 255.255.240.0  | 1111 1111 1111 1111 1111 0000 0000 0000 | 16 Class C    |
| /21    | 255.255.248.0  | 1111 1111 1111 1111 1111 1000 0000 0000 | 8 Class C     |
| /22    | 255.255.252.0  | 1111 1111 1111 1111 1111 1100 0000 0000 | 4 Class C     |
| /23    | 255.255.254.0  | 1111 1111 1111 1111 1111 1110 0000 0000 | 2 Class C     |
| /24    | 255.255.255.0  | 1111 1111 1111 1111 1111 1111 0000 0000 | 1 Class C     |

Use CIDR to assign network prefixes of arbitrary lengths, as opposed to the obsolete class system, which assigned prefixes as even multiples of an octet.

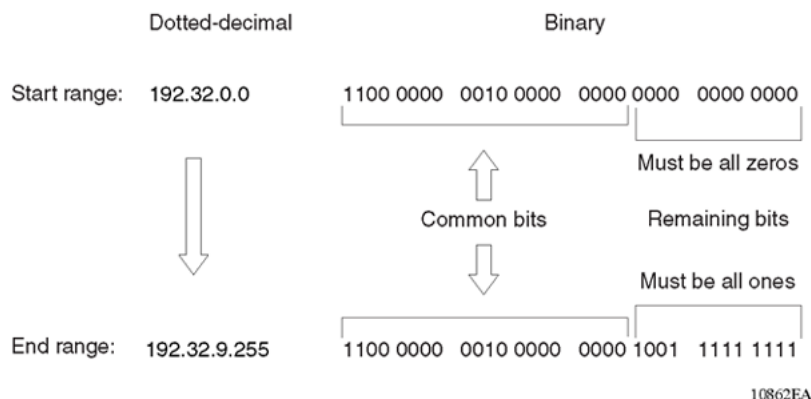

For example, you can assign a single routing table supernet entry of 195.215.16/21 to represent 8 separate Class C network numbers: 195.215.16.0 through 195.215.23.0.

*Supernet addressing*

You can create a supernet address that covers an address range.

For example, to create a supernet address that covers an address range of 192.32.0.0 to 192.32.9.255, perform the following steps:

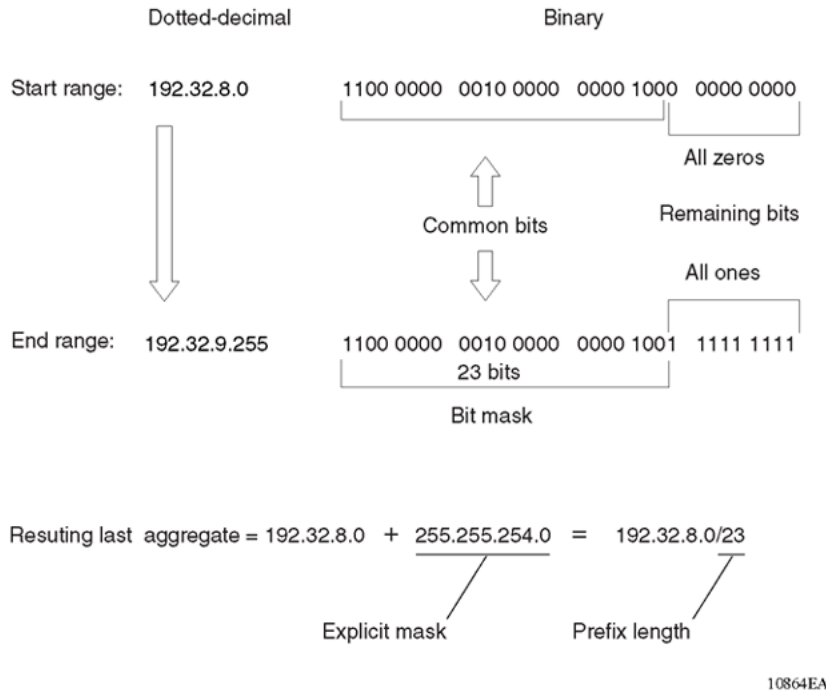

1. Convert the starting and ending address range from dotted-decimal notation to binary notation (see the following figure).

**Figure 12: Binary notation conversion**

2. Locate the common bits in both ranges. Ensure that the remaining bits in the start range are zeros, and the remaining bits in the end range are all ones. In this example, the remaining bits in the end range are not all ones.
3. If the remaining bits in the end range are not all ones, you must recalculate to find the IP prefix that has only ones in the remaining bits in the end range.
4. Recalculate to find a network prefix that has all ones in the remaining end range bits (see the following figure). In this example, 192.32.7.255 is the closest IP prefix that matches the common bits for the start range.

**Figure 14: Last aggregate and prefix length**

The final result of calculating the supernet address that ranges from 192.32.0.0 to 192.32.9.255 is as follows:

192.32.0.0 (with mask) 255.255.248.0 = 192.32.0.0/21

192.32.8.0 (with mask) 255.255.254.0 = 192.32.8.0/23

#### *Aggregate routes*

Eliminating the idea of network classes provides an easy method to aggregate routes. Rather than advertise a separate route for each destination network in a supernet, BGP uses a supernet address to advertise a single route (called an aggregate route) that represents all the destinations. CIDR also reduces the size of the routing tables used to store advertised IP routes.

The following figure shows an example of route aggregation using CIDR. In this example, a single supernet address 195.215.0.0/16 advertises 256 separate Class C network numbers 195.215.0.0 through 195.215.255.0.

**Figure 15: Aggregating routes with CIDR**

### *Confederations*

A BGP router configured for iBGP establishes a peer-to-peer session with every other iBGP speaker in the AS. In an AS with a large number of iBGP speakers, this full-mesh topology can result in high bandwidth and maintenance costs.

### **Note**

Confederations are not supported on iBGP for non-default VRFs.

As shown in the following example, a full-mesh topology for an AS with 50 iBGP speakers requires 1225 internal peer-to-peer connections:

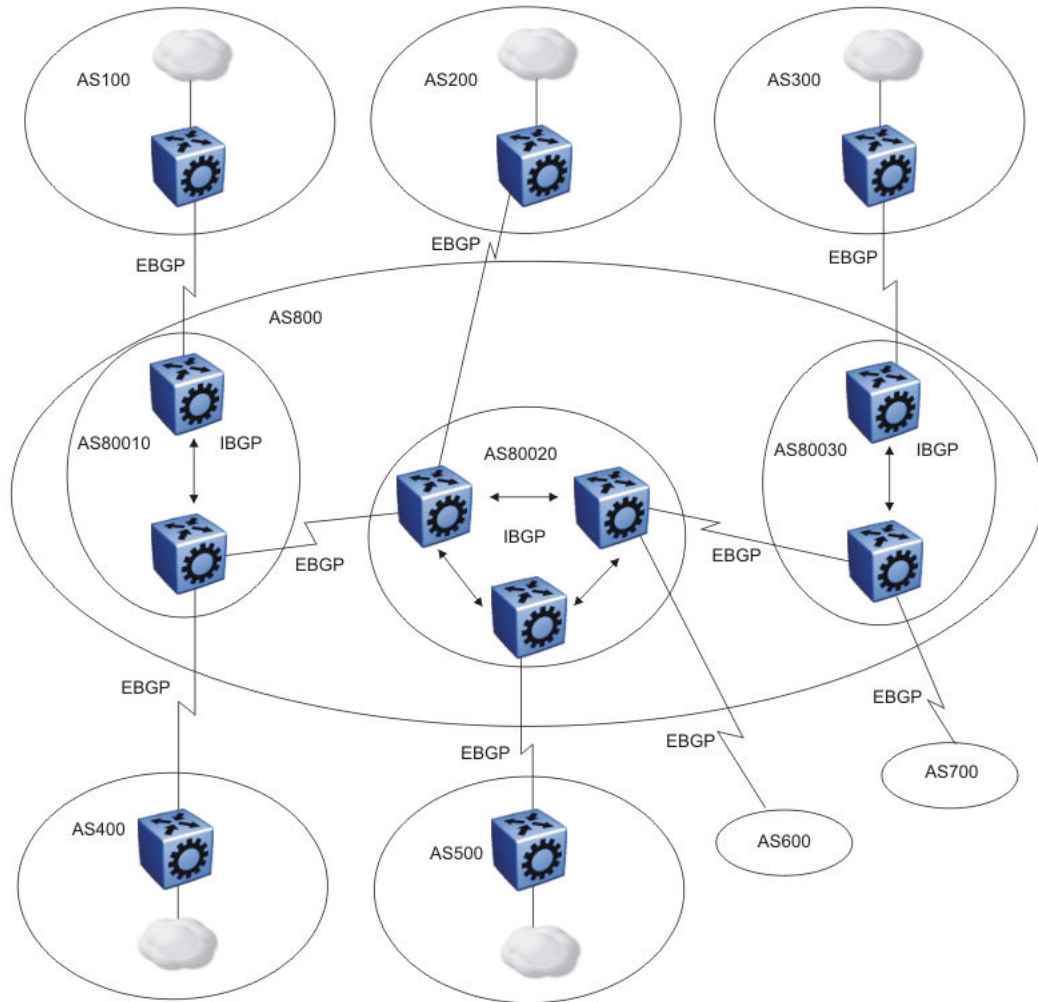

Example:

$$n \times (n-1)/2 = n \text{ iBGP sessions}$$

where:

$$50 \times (50-1)/2 = 1225 \text{ number of unique iBGP sessions}$$

You can reduce the high bandwidth and maintenance costs associated with a large full-mesh topology by dividing the AS into multiple smaller autonomous systems (sub-autonomous systems), and then group them into a single confederation (see the following figure).

**Figure 16: Confederations**

As shown in the preceding figure, each sub-AS is fully meshed within itself and has eBGP sessions with other sub-autonomous systems in the same confederation.

Although the peers in different autonomous systems have eBGP sessions with the various sub-AS peers, they preserve the next-hop, Multi-Exit Discriminator (MED), and local preference information and exchange routing updates as if they were iBGP peers. All of the autonomous systems retain a single interior gateway protocol (IGP). When the confederation uses its own confederation identifier, the group of sub-autonomous systems appear as a single AS (with the confederation identifier as the AS number).

#### *Route reflectors*

Another way to reduce the iBGP mesh inherent in an AS with a large number of iBGP speakers is to configure a route reflector. Using this method, when an iBGP speaker needs to communicate with other

BGP speakers in the AS, the speaker establishes a single peer-to-peer route reflector client session with the iBGP route reflector.

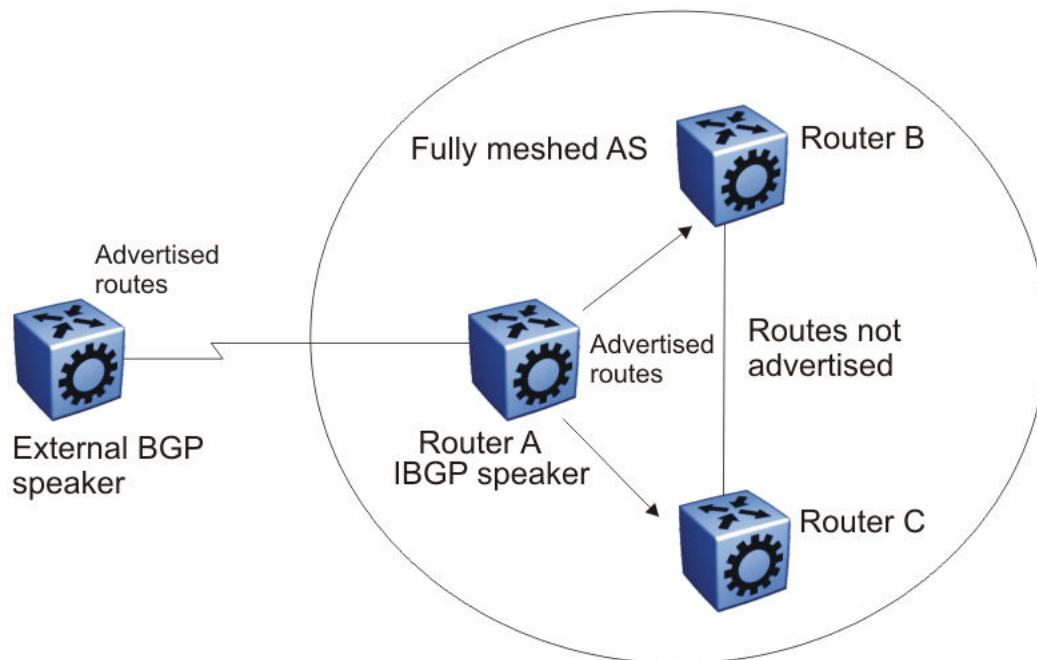

#### Note

Route reflectors are not supported on iBGP for non-default VRFs.

In an AS, more than one route reflector cluster can exist and more than one route reflector in a cluster. When more than one reflector exists in a cluster, take care to prevent route loops.

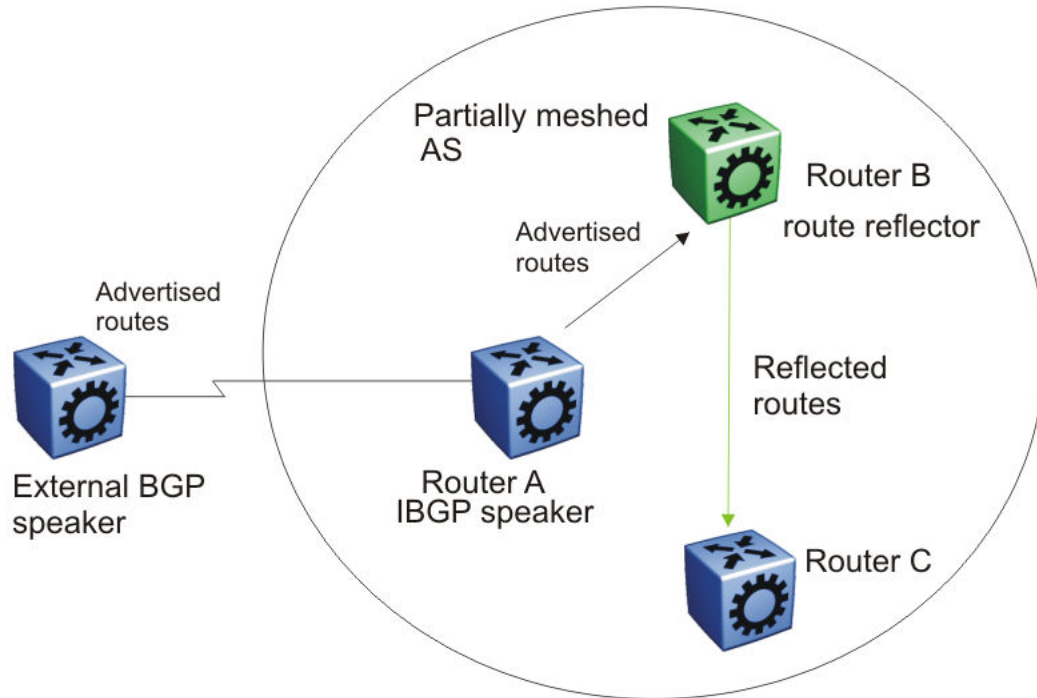

The following figure shows a simple iBGP configuration with three iBGP speakers (routers A, B, and C). Without route reflectors, after Router A receives an advertised route from an external neighbor, it must advertise the route to Routers B and C.

**Figure 17: Fully meshed AS with iBGP speakers**

Routers B and C do not readvertise the iBGP learned routes to other iBGP speakers. BGP does not allow routers to pass routes learned from internal neighbors on to other internal neighbors, which avoids routing information loops.

As shown in the following figure, when you configure an internal BGP peer (Router B) as a route reflector, all of the iBGP speakers do not need to be fully meshed. In this case, the assigned route reflector passes iBGP learned routes to a set of iBGP neighbors.

**Figure 18: AS with route reflector**

After Router B, the route reflector, receives routes from Router A (the iBGP speaker), it advertises them to router C. Conversely, after the route reflector receives routes from internal peers, it advertises those routes to Router A. Routers A and C do not need an iBGP session.

Route reflectors separate internal peers into two groups: client peers and nonclient peers. The route reflector and its clients form a cluster. The client peers in the cluster do not need to be fully meshed, and do not communicate with iBGP speakers outside their cluster. Nonclient peers must be fully meshed with each other.

The following figure shows a cluster, where Router A is the route reflector in a cluster with client routers B, C, and D. Routers E, F, and G are fully meshed, nonclient routers.

**Figure 19: Route reflector with client and nonclient peers**

## BGP Communities

You can group destinations into communities to simplify policy administration. A community is a group of destinations that share a common administrative property.

Use community control routing policies with respect to destinations. Create communities when you have more than one destination and want to share a common attribute.

The following list identifies specific community types:

- Internet—advertise this route to the Internet community
- no advertise—do not advertise to BGP peers including iBGP peers

You can use a community to control which routing information to accept, prefer, or distribute to other BGP neighbors. If you specify the append option in the route policy, the router adds the specified community value to the existing value of the community attribute. Otherwise, the specified community value replaces a previous community value.

## BGP path attributes

You can create policies that control routes, work with default routing, control specific and aggregated routes, and manipulate BGP path attributes.

Four categories of BGP path attributes exist:

- Well-known mandatory attributes must be in every BGP update message.
- Well-known discretionary attributes can be in a BGP update message.
- Optional transitive attributes are accepted and passed to other BGP peers.
- Optional non-transitive attributes can be either accepted or ignored, but must not pass along to other BGP peers.

Border routers that utilize built-in algorithms or manually configured policies to select paths use path attributes. BGP uses the following path attributes to control the path a BGP router chooses:

- origin (well-known mandatory)
- AS\_path (well-known mandatory)
- next hop (well-known mandatory)
- MED attribute (optional non-transitive)
- local preference (well-known discretionary)
- atomic aggregate (well-known discretionary)
- aggregator (optional transitive)
- community (optional transitive)

For more information about path attributes in BGP updates, see [Path Attributes](#) on page 412.

## BGP Route Selection

A BGP router determines the best path to a destination network. This path is then eligible for use in the IP forwarding table and the router also advertises the path to its eBGP peers. To choose the best of multiple BGP routes to a destination, the router executes a best path algorithm.

The algorithm chooses a route in the following order:

- highest weight

Weight is a locally significant parameter associated with each BGP peer. You can use the weight to influence which peer paths the router uses.

- highest local preference

The local preference has global significance within an AS. You can manipulate the preference using route policies to influence path selection.

- prefer locally originated paths

The router prefers a path locally originated using the network, redistribution, or aggregate command over a path learned through a BGP update. The router prefers local paths sourced by network or redistribute commands over local aggregates sourced by the aggregate address command.

- shortest AS path

The AS path parameter specifies the autonomous systems that the network prefix traversed. The AS path commonly determines the best path. For example, a router can choose a path based on whether the network passed through a specific AS. You can configure a route policy to match the AS, and then modify the local preference. Also, you can pad the AS path before the AS advertises it to a peer AS, so that downstream routers are less likely to prefer the advertised network path.

The AS\_CONFED\_SEQUENCE length will also be considered while picking the best path inside the confederation.

- lowest origin type

The order of preference is IGP, EGP, INC (incomplete).

- lowest MED

The MED parameter influences the preferred path from a remote AS to the advertising AS. This parameter applies when there are multiple exit points from the remote AS to the advertising AS. A lower MED value indicates a stronger path preference than a higher MED value. By default, the MED attribute is ignored as specified by the BGP global parameter Always Compare MED except when the routes come from the same AS. This parameter must be enabled for MEDs to be compared (and for this step of the best path algorithm to execute).

The router compares MEDs regardless of what the first (neighboring) AS specified in the AS\_PATH. Deterministic MED, when enabled, means that the first AS of the multiple paths must be the same. Paths received with no MED are assigned a MED of 0, unless the global BGP parameter Missing Is Worst is enabled. If so, received paths are assigned a MED of 4 294 967 294. Missing is Worst is enabled by default. The "no-med-path-is-worst" flag has an impact only when the "First AS" or the "Most Left AS" is the same for multiple routes received. The router changes paths received with a MED of 4 294 967 295 to 4 294 967 294 before insertion into the BGP table.

#### Note

You cannot enable or disable the MED selection process. BGP aggregation does not occur when routes have different MEDs or next hops.

When MED value is set in route-map configuration, the configured MED value is not applicable if it is already set in the associated Path Attribute.

1. When router A sets MED value of 100 by route-map, it will send Path Attribute with MED=100 to EBGP peer B.
2. Router B sends Path Attribute with MED=100 to IBGP peer C.
3. If the route-map is configured with "set MED 200", then router C does not apply MED=200 to the Path Attribute as it is already set to 100 when it is received from router B.
4. Router D will get Path Attribute with MED=100 so that router C does not influence router D when it selects the best route.

Example: If Prefix: X is set as MED=100 from router A, it will be received at B with MED=100, and will carry same MED=100 value to router C, as it is an IBGP peer. Router C will not propagate MED=100 value to D as MED is a non-transitive attribute, so MED can travel maximum of 1 AS.

- lowest IGP metric to the BGP next-hop

If multiple paths exist whose BGP next-hop is reachable through an IGP, the path with the lowest IGP metric to the BGP next-hop is chosen.

- prefer external paths (learned by eBGP) over internal paths (iBGP)

The system prefers external paths over internal paths.

- if Equal Cost Multipath (ECMP) is enabled, insert up to four paths in the routing table

If you enable ECMP, multiple BGP learned routes that use the same metric to different IP next-hops are installed in the IP forwarding table for traffic load-balancing purposes.

- lowest router ID

The lowest router ID, or Circuitless IP (CLIP) address, is preferred.

## BGP and dampened routes

The switch supports route dampening (route suppression). When you use route dampening, a route accumulates penalties each time the route fails. After the accumulated penalties exceed a threshold, the router no longer advertises the route. The router enters the suppressed routes into the routing table only after the accumulated penalty falls below the reuse threshold.

Route flap dampening suppresses the advertisement of the unstable route until the route becomes stable. For information about how to enable flap-dampening, see [Configure BGP](#) on page 427. For information about viewing flap dampening configurations, see [Viewing global flap-dampening configurations](#) on page 460.

Dampening applies only to routes that are learned through an eBGP. Route flap dampening prevents routing loops and protects iBGP peers from having higher penalties for routes external to the AS.

The following paragraph describes the algorithm that controls route flaps.

After the route flaps the first time

- the router creates a route history entry
- a timer starts (180 seconds)

If the route does not flap again, the router uses this timer to delete the history entry after the 180 seconds expires.

After the route flaps a second time

- The penalty is recalculated based on the decay function.

If the penalty is greater than the cut-off value (1536), the route is suppressed and the reuse time is calculated based on the reuse time function.

- The reuse timer starts.

After the reuse time expires, the suppressed route is announced again (the reuse time is recalculated if the route flaps again). The penalty decays slower for withdrawn routes than for update routes. The route history entry is kept longer if the route is withdrawn. For update history, the delete time is 90 seconds and the withdrawn history delete time is 180 seconds.

## BGP Updates

BGP uses update messages to communicate information between two BGP speakers. The update message can advertise a single feasible route to a peer, or withdraw multiple unfeasible routes from service.

The following figure shows the format of an update message.

### Figure 20: Update Message Format

This section describes how BGP uses the update message fields to communicate information between BGP speakers.

#### *Withdrawn Routes Length*

The withdrawn routes length parameter (referred to in RFC1771 as the Unfeasible Routes Length field) indicates the total length of the withdrawn routes field in octets. The withdrawn routes length field calculates the length of the NLRI field. For example, a value of 0 indicates that no routes are withdrawn from service, and that the withdrawn routes field is not present in this update message.

#### *Withdrawn Routes*

The withdrawn routes parameter is a variable-length parameter that contains a list of IP prefixes for routes that are withdrawn from service. The following figure shows the format of an IP prefix.

### Figure 21: IP Prefix Format

The length indicates the number of bits in the prefix (also called the network mask).

For example, 192.0.2.0/24 is equivalent to 192.0.2.0 255.255.255.0 (the /24 indicates the number of bits in the length parameter to represent the network mask 255.255.255.0).

The prefix parameter contains the IP address prefix itself, followed by enough trailing bits to make the length of the whole field an integer multiple of 8 bits (1 octet).

#### *Total Path Attributes Length*

The total path attributes length parameter indicates the total length of the path attributes parameter in octets.

The total path attributes length calculates the length of the NLRI parameter. For example, a value of 0 indicates that no NLRI field is present in this update message.

#### *Path Attributes*

The path attributes parameter is a variable-length sequence of path attributes that exists in every BGP update. The path attributes contain BGP attributes associated with the prefixes in the NLRI parameter.

For example, the attribute values allow you to specify the prefixes that the BGP session can exchange, or which of the multiple paths of a specified prefix to use.

The attributes carry the following information about the associated prefixes:

- the path origin
- the AS paths through which the prefix is advertised
- the metrics that display degrees of preference for this prefix

The following figure shows the encoding used with the path attribute parameter.

**Figure 22: Path Attribute Encoding**

#### *Attribute Type*

As shown in the following figure, the attribute type is a two-octet field that comprises two sub-fields: attribute flags and attribute type code.

**Figure 23: Attribute Type Fields**

The attribute flags parameter is a bit string that contains four binary values that describe the attribute, and four unused bits. The following list provides bit descriptions (from the high-order bit to the low-order bit):

- The high-order bit (bit 0) is the optional bit. When this bit is set (the value is 1), the attribute is optional. When this bit is clear (the value is 0), the attribute is well-known. Well-known attributes must be recognized by all BGP implementations and, when appropriate, passed on to BGP peers. Optional attributes are not required in all BGP implementations.
- The second high-order bit (bit 1) is the transitive bit. For well-known attributes, this bit must be set to 1. For optional attributes, it defines whether the attribute is transitive (when set to 1) or non-transitive (when set to 0).
- The third high-order bit (bit 2) is the partial bit. The partial bit defines whether the information in the optional transitive attribute is partial (when set to 1) or complete (when set to 0). For well-known attributes and for optional non-transitive attributes the partial bit must be set to 0.
- The fourth high-order bit (bit 3) is the extended length bit. The extended length bit defines whether the attribute length is one octet (when set to 0) or two octets (when set to 1). The attribute flag can use the extended length only if the length of the attribute value is greater than 255 octets.
  - If the extended length bit of the attribute flags octet is set to 0, the third octet of the path attribute contains the length of the attribute data in octets.
  - If the extended length bit of the attribute flags octet is set to 1, then the third and the fourth octets of the path attribute contain the length of the attribute data in octets.
- The lower-order four bits of the attribute flags octet are unused. The lower-order four bits must be zero (and must be ignored when received).

The attribute type code parameter contains the attribute type code, as defined by the Internet Assigned Numbers Authority (IANA). The attribute type code uniquely identifies the attribute from all others. The remaining octets of the path attribute represent the attribute value and are interpreted according to the attribute flags and the attribute type code parameters.

The following table shows the supported attribute type codes.

**Table 70: BGP Mandatory Path Attributes**

| Attribute              | Type code | Description                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Origin                 | 1         | Defines the origin of the path information: <ul style="list-style-type: none"> <li>• Value = 0 --- IGP (the path is valid all the way to the IGP of the originating AS)</li> <li>• Value = 1--- EGP (the last AS in the AS path uses an EGP to advertise the path)</li> <li>• Value = 2--- Incomplete (the path is valid only to the last AS in the AS path)</li> </ul> |
| AS path                | 2         | Contains a list of the autonomous systems that packets must traverse to reach the destinations. This code represents each AS path segment as follows: <ul style="list-style-type: none"> <li>• path segment type</li> <li>• path segment length</li> <li>• path segment value</li> </ul>                                                                                |
| Next hop               | 3         | Specifies the IP address of the border router to use as a next hop for the advertised destinations (destinations listed in the NLRI field of the update message).                                                                                                                                                                                                       |
| Multixit discriminator | 4         | Discriminates among multiple exit or entry points to the same neighboring AS on external (internal-AS) links.                                                                                                                                                                                                                                                           |
| Local preference       | 5         | Indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers                                                                                                                                                                                                                                                           |
| Atomic aggregate       | 6         | Ensures that certain NLRI is not deaggregated                                                                                                                                                                                                                                                                                                                           |
| Aggregator             | 7         | Identifies which AS performed the most recent route aggregation. This attribute contains the last AS number that formed the aggregate route followed by the IP address of the BGP speaker that formed the aggregate route.                                                                                                                                              |

#### *Attribute Length*

The attribute length can be one or two octets in length, depending on the value of the extended length parameter in the attributes flag field.

This parameter indicates the length of the attribute value field.

#### *Attribute Value*

The attribute value contains the actual value of the specific attribute. The system implements the attribute value according to the values in the attribute flags and the attribute type code parameters.

#### *NLRI*

The NLRI parameter is a variable length field that contains a list of prefixes. The packet size that BGP speakers can exchange limits the number of prefixes in the list.

## Equal Cost Multipath

Equal Cost Multipath (ECMP) support allows a BGP speaker to perform route or traffic balancing within an AS by using multiple equal-cost routes submitted to the routing table by OSPF, RIP, or static routes.

For more information about ECMP, see [Equal Cost Multipath](#) on page 1750.

## MD5 message authentication

Authenticate BGP messages by using Message Digest 5 (MD5) signatures. After you enable BGP authentication, the BGP speaker verifies that the BGP messages it receives from its peers are actually from a peer and not from a third party masquerading as a peer.

BGPv4 TCP MD5 message authentication provides the following features:

- A TCP MD5 signature can exist for BGP peers. You can configure authentication and secret keys for each peer. Peers configured with common secret keys can authenticate each other and exchange routing information.
- The switch can concurrently have BGP peers with authentication enabled and other BGP peers with authentication disabled.
- The switch always encrypts the secret keys.

After you enable BGPv4 TCP MD5 authentication, the router computes an MD5 signature for each TCP packet based on the TCP packet and an individual peer secret key. The router adds this MD5 signature to the TCP packet that contains a BGP message and sends it with the packet, but it does not send the secret key.

The receiver of the TCP packet also knows the secret key and can verify the MD5 signature. A third party that tries to masquerade as the sender, however, cannot generate an authentic signature because it does not know the secret key.

In commands, the term *password* refers to the secret key. The secret keys provide security. If the keys are compromised, then the authentication itself is compromised. To prevent this, the switch stores the secret keys in encrypted form.

### *MD5 signature generation*

BGP peers calculate MD5 signatures in BGP messages based on the following elements:

- TCP pseudo-header
- TCP header, excluding options
- TCP segment data
- TCP MD5 authentication key

If TCP receives an MD5 authentication key, it reduces its maximum segment size by 18 octets, which is the length of the TCP MD5 option. TCP adds an MD5 signature to each transmitted packet. The peer inserts the resulting 16-byte MD5 signature into the following TCP options: *kind*=19, *length*=18.

*MD5 signature verification*

After the switch receives a packet, it performs three tests. The following table lists the tests and the event message that TCP logs if a test fails.

**Table 71: MD5 signature verification rules on BGP TCP packets**

| Condition tested                                                  | Action on success                                 | Failure event message           |
|-------------------------------------------------------------------|---------------------------------------------------|---------------------------------|
| Is the connection configured for MD5 authentication?              | Verify that the packet contains a kind=19 option. | TCP MD5 No Signature            |
| Is MD5 authentication enabled for this TCP connection?            | TCP computes the expected MD5 signature.          | TCP MD5 Authentication Disabled |
| Does the computed MD5 signature match the received MD5 signature? | TCP sends the packet to BGP.                      | TCP MD5 Invalid Signature       |

If a packet passes a test, it proceeds to the next test. After a packet passes all three tests, TCP accepts the packet and sends it to BGP.

If a packet fails a test, the switch logs an event, increments the count of TCP connection errors (wfTcpConnMd5Errors), and discards the packet. The TCP connection remains open.

## BGP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPF routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPF routes through BGP. This sends OSPF routes to a router that uses BGP.

The switch can redistribute routes:

- on an interface basis.
- on a global basis between protocols on a single VRF instance (intraVRF).
- between the same or different protocols on different VRF instances (interVRF).

Configure interface-based redistribution by configuring a route policy and apply it to the interface. Configure the match parameter to the protocol from which to learn the routes.

You can redistribute routes on a global basis, rather than on an interface basis. Use the **ip bgp redistribute** command to accomplish the (intraVRF) redistribution of routes through BGP, so that BGP redistribution occurs globally on all BGP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to BGP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

Use caution when you configure redistribution. An improperly configured parameter can cause the router to advertise learned eBGP routes out of your local AS. If this happens, the local AS can route other networks.

Do not use redistribution if you peer to an Internet Service Provider (ISP) and do not want traffic to transit your local AS.

When you redistribute OSPF routes into BGP, route priorities can create routing loops. Because BGP has a higher route preference than OSPF external type 1 and 2 routes, if you redistribute OSPF external type 1 and 2 routes into BGP, the router uses the BGP routes, which can cause a routing loop.

#### *Route-maps and BGP neighbors*

BGP Routing Information Base (BGP RIB) stores routing information received from different peers. BGP RIB has two types of BGP routes, External and Internal (Local). The routes learned from BGP neighbors are External routes and all imported routes are considered as Internal (Local) routes.

In BGP RIB, the OSPF routes redistributed into BGP are considered as Internal (Local) and are matched by route-type only when the keyword is set to **local**. When match route-type is set to **external**, the route-maps applied on BGP neighbors are ignored and the set operation is not performed.

#### **Note**

This is applied only on the route-maps applied to BGP neighbors in BGP RIB, and not considered when applying a route-map to the redistribute command.

#### *BGP route redistribution and DvR*

DvR Controllers redistribute routes (direct routes, static routes and the default route) into the DvR domain. You can configure redistribution of DvR host routes into BGP.

For information on DvR, see [Distributed Virtual Routing](#) on page 660.

## BGP+

The switch extends the BGPv4 process to support the exchange of IPv6 routes using BGPv4 peering. BGP+ is an extension of BGPv4 for IPv6, which is indicated using the Address Family Identifier (AFI) in the BGP header.

The switch supports capabilities for AFI with the following values: 1 (IPv4) and 2 (IPv6). If the switch receives an OPEN message advertising an AFI with a different value, the connection is closed and a BGP notification message is sent to the peer mentioning unsupported capability.

BGP+ is only supported on the global VRF instance.

#### **Note**

Ensure you configure IPv6 forwarding for BGP+ to work.

Note that the BGP+ support on the switch is not an implementation of BGPv6. Native BGPv6 peering uses the IPv6 Transport layer (TCPv6) for establishing the BGPv6 peering, route exchanges, and data traffic.

The switch supports the exchange of IPv6 reachability information over IPv4 transport. To support BGP+, the switch supports two BGP protocol extensions, standards RFC 4760 (multi-protocol extensions to BGP) and RFC 2545 (MP-BGP for IPv6). These extensions allow BGPv4 peering to be enabled with IPv6 address family capabilities.

The implementation of BGP+ on the switch uses an existing TCPv4 stack to establish a BGPv4 connection. Optionally, nontransitive BGP properties are used to transfer IPv6 routes over the BGPv4 connection. Any BGP+ speaker has to maintain at least one IPv4 address to establish a BGPv4 connection.

Different from IPv4, IPv6 introduces scoped unicast addresses, identifying whether the address is global or link-local. When BGP+ is used to convey IPv6 reachability information for interdomain routing, it is sometimes necessary to announce a next hop attribute that consists of a global address and a link-local address. For BGP+, no distinction is made between global and site-local addresses.

The BGP+ implementation includes support for BGPv6 policies, including redistributing BGPv6 into OSPFv3, ISIS, RIPng, and advertising OSPFv3, ISIS, RIPng, IPv6 static and local routes into BGPv6 (through BGP+). It also supports the aggregation of global unicast IPv6 addresses.

When configuring BGP+ on the router that is enabled only for IPv6 (the router does not have an IPv4 address), then BGP router ID must be manually configured for the router.

BGP+ does not support confederations. You can configure confederations for IPv4 routes only.

The basic configuration of BGP+ is the same as BGPv4 with one additional parameter added and some existing commands altered to support IPv6 capabilities. You can enable and disable IPv6 route exchange by specifying the address family attribute as IPv6. Note that an IPv6 tunnel is required for the flow of IPv6 data traffic.

### *BGP+ tunnel*

When you use BGP+ you must configure an IPv6 tunnel and static routes at BGP+ peers.

When BGP+ peers advertise route information, they use Update messages to advertise route information.

These RTM routes contain next-hop addresses from the BGP peer that the route was learned from.

The static routes correlate the next-hop addresses represented by the IPv4-mapped IPv6 address to a specific outgoing interface.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 2001:DB8:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10 where
2001:DB8:0:0:0:ffff:192.0.2.0 is the IPv4-mapped IPv6 address of the BGP peer at 192.0.2.0
```

## ECMP with BGP+

The ECMP feature supports and complements BGP+ protocol.

The number of equal-cost-paths supported can differ by hardware platform. For more information, see [Release Notes for VOSS](#).

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

#### Note

To add BGP+ equal cost paths in the routing table, you must enable the following:

- IPv6 ECMP feature globally
- BGP multiple-paths attribute

## BGPv6

BGP peering over IPv6 transport uses a BGPv6 peer to exchange IPv6 routes over an IPv6 transport layer. This is different than BGP+, which enables exchange of IPv6 routes over a BGPv4 peer. Also with BGP+, you must use an IPv6 tunnel to install and configure IPv6 routes in an IPv6 Routing Table Manager (RTM). BGP+ uses an IPv4 mapped IPv6 address for the next hop address and requires you to configure IPv6 static routes and install IPv6 routes in an IPv6 RTM where the next hop for the static route is an IPv6 tunnel interface.

BGPv6 supports the following:

- Input/Output policies.
- Redistribution of OSPFv3, IS-IS, IPv6 static route, and IPv6 direct routes into BGPv6.
- Aggregation of global unicast IPv6 addresses.

#### Note

BGP+ also supports the preceding features.

#### RFC

The switch supports the BGP multiprotocol extension, as described in RFC 4760. Also supports RFC 2545 (MP-BGP for IPv6).

The BGP protocol extensions ensure peering can be enabled with IPv6 address family capabilities.

#### Route exchange

BGPv6 does not exchange any IPv4 routes. BGPv6 advertises or learns only IPv6 routes.

The following table shows the differences between BGPv4 and BGPv6 for route exchange.

|       | GRT/VRF | IPv4 Routes Exchange | IPv6 Routes Exchange                                                                |
|-------|---------|----------------------|-------------------------------------------------------------------------------------|
| BGPv4 | GRT     | Supported            | Supported (BGP+)                                                                    |
|       | VRF     | Supported            | Not supported<br><br><b>Note:</b><br>IPv6 over IPv4 tunnels is not yet virtualized. |

|       | GRT/VRF | IPv4 Routes Exchange | IPv6 Routes Exchange |
|-------|---------|----------------------|----------------------|
| BGPv6 | GRT     | Not supported        | Supported            |
|       | VRF     | Not supported        | Supported            |

Specify the address family attribute as IPv6 to enable IPv6 route exchange.

You can enable IPv6 route exchange by specifying the address family attribute as IPv6. Optionally, you can use non-transitive BGP properties to exchange IPv6 routes between the BGPv6 peering. Any BGPv6 speaker must maintain at least one IPv6 address to establish a BGPv6 connection. The IPv6 scoped unicast addresses can identify the address as global or link-local. If you use BGPv6 to convey IPv6 reachability information for interdomain routing, you can also announce a next hop attribute that consists of a global address and a link-local address.

#### Note

BGPv6 does not support adjacency on link-local.

### Authentication

BGPv6 uses IPsec for security. MD-5 authentication is supported for BGPv4 and is not supported for BGPv6.

The following table shows the differences between BGPv4 and BGPv6 for authentication.

|       | MD5           | IPsec         | SHA1/SHA2     |
|-------|---------------|---------------|---------------|
| BGPv4 | Supported     | Not supported | Not supported |
| BGPv6 | Not supported | Supported     | Not supported |

**Note:**  
IP Sec is not virtualized, hence BGPv6 is supported only in Global Router mode, and not supported in VRF mode.

### MD5 authentication

MD5 authentication is not supported in BGPv6 so it is not necessary to enable MD5 authentication.

### IPsec

Only IPsec is supported. Therefore, MD5 authentication cannot be configured.

### Consistency checking

Includes consistency checking for MD5 authentication. BGP peer and BGP peer group configuration for IPv6 addresses include a rule to block MD5 authentication. If you attempt to configure MD5 authentication, you will receive an error message.

### IPv6 tunneling

With BGPv6, IPv6 tunneling is not required for IPv6 data traffic flow. An IPv6 tunnel is required for BGP +.

## Circuitless IP

Circuitless IP (CLIP) is a virtual (or loopback) interface that you do not associate with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Note also that an iBGP session exists between two additional addresses 195.39.128.1/32 (CLIP 1) and 195.39.128.2/32 (CLIP 2).

**Figure 24: Routers with iBGP connections**

The system treats the CLIP interface like an IP interface and treats the network associated with the CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

The router advertises routes to other routers in the domain either as external routes using the route-redistribution process or after you enable OSPF in a passive mode to advertise an OSPF internal route. You can configure only the OSPF protocol on the CLIP interface. After you create a CLIP interface, the system software programs a local route with the CPU as the destination ID. The CPU processes all packets destined to the CLIP interface address. The system treats other packets with destination addresses associated with this network (but not to the interface address) as if they are from an unknown host.

A circuitless IP or CLIP address is a logical IP address for network management, as well as other purposes. The CLIP is typically a host address (with a 32 bit subnet mask). Configure the OSPF router ID to the configured CLIP address. By default, the BGP router ID is automatically equivalent to the OSPF router ID.

For information about how to configure CLIP interfaces, see [Configuring a CLIP Interface](#) on page 1776 and [Configure a Circuitless IPv4 Interface](#) on page 1799.

## BGP Configuration Considerations and Limitations

Use the information in this section to help you configure BGP on your switch, which supports BGPv4 as described in RFC 1771.

### *BGP Implementation Guidelines*

The following list provides guidelines to successfully implement BGP:

- BGP does not operate with an IP router in nonforwarding (host-only) mode. Make sure that the routers you want BGP to operate with are in forwarding mode.
- If you use BGP for a multihomed AS (one that contains more than a single exit point), use OSPF for your IGP and BGP for your sole exterior gateway protocol, or use intra-AS iBGP routing.
- If OSPF is the IGP, use the default OSPF tag construction. Using EGP or modifying the OSPF tags makes network administration and proper configuration of BGP path attributes difficult.
- For routers that support both BGP and OSPF, the OSPF router ID and the BGP identifier must be the same IP address. The BGP router ID automatically uses the OSPF router ID.
- In configurations where BGP speakers reside on routers that have multiple network connections over multiple IP interfaces (the typical case for iBGP speakers), consider using the address of the circuitless (virtual) IP interface as the local peer address. In this configuration, you ensure that BGP is reachable as long as an active circuit exists on the router.
- By default, BGP speakers do not advertise or inject routes into the IGP. You must configure route policies to enable route advertisement.
- Coordinate routing policies among all BGP speakers within an AS so that every BGP border router within an AS constructs the same path attributes for an external path.
- Configure accept and announce policies on all iBGP connections to accept and propagate all routes. Make consistent routing policy decisions on external BGP connections.

### *Minimum Requirements*

You must configure the following minimum parameters:

- router ID
- local AS number
- enable BGP globally
- BGP neighbor peer session: remote IP addresses
- enable BGP peers
- When you use both BGP and OSPF, the OSPF and BGP router ID must be the same.

The router ID must be a valid IP address of an IP interface on the router or a CLIP address. BGP update messages use this IP address. By default, the BGP router ID automatically uses the OSPF router ID.

You cannot configure the BGP router ID if you configure BGP before you configured the OSPF router ID. You must first disable BGP, configure the OSPF route ID, and then enable BGP globally.

You can add BGP policies to the BGP peer configuration to influence route decisions. BGP policies apply to the peer through the soft-reconfiguration commands.

After you configure the switch for BGP, some parameter changes can require you to enable or disable the BGP global state or the neighbor admin-state.

You can dynamically modify BGP policies. On the global level, the BGP redistribution command has an apply parameter that causes the policy to take effect after you issue the command.

### *BGP Neighbor Maximum Prefix Configuration*

By default, the maximum prefix parameter limits 12 000 NLRI messages for each neighbor. The maximum prefix parameter limits the number of routes that the switch can accept.

The maximum prefix parameter prevents large numbers of BGP routes from flooding the network if you implement an incorrect configuration. You can assign a value to the maximum prefix limit, including 0 (0 means unlimited routes). When you configure the maximum prefix value, consider the maximum number of active routes that your equipment configuration can support.

### *BGP and OSPF Interaction*

RFC1745 defines the interaction between BGP and OSPF when OSPF is the IGP within an autonomous system. For routers that use both protocols, the OSPF router ID and the BGP ID must be the same IP address. You must configure a BGP route policy to allow BGP advertisement of OSPF routes.

Interaction between BGPv4 and OSPF can advertise supernets to support CIDR. BGPv4 supports interdomain supernet advertisements; OSPF can carry supernet advertisements within a routing domain.

### *BGP and Internet Peering*

By using BGP, you can perform Internet peering directly between the switch and another edge router. In such a scenario, you can use each switch for aggregation and link it with a Layer 3 edge router, as shown in the following figure.

**Figure 25: BGP and Internet peering**

In cases where the Internet connection is single-homed, to reduce the size of the routing table, as a best practice, advertise Internet routes as the default route to the IGP.

For route scaling information, see [Release Notes for VOSS](#).

### *Routing Domain Interconnection with BGP*

You can implement BGP so that autonomous routing domains, such as OSPF routing domains, connect. This connection allows the two different networks to begin communicating quickly over a common

infrastructure, thus providing additional time to plan the IGP merger. Such a scenario is particularly effective when you need to merge two OSPF area 0.0.0.0s, as shown in the following figure.

**Figure 26: Routing Domain Interconnection with BGP**

*BGP and Edge Aggregation*

You can perform edge aggregation with multiple point of presence or edge concentrations. The switch supports 12 pairs (peering services). You can use BGP to inject dynamic routes rather than using static routes or RIP (see the following figure).

**Figure 27: BGP and Edge Aggregation**

*BGP and ISP Segmentation*

You can use the platform as a peering point between different regions or autonomous systems (AS) that belong to the same ISP. In such cases, you can define a region as an OSPF area, an AS, or a part of an AS.

You can divide the AS into multiple regions that each run different IGPs. Interconnect regions logically by using a full iBGP mesh. Each region then injects its IGP routes into iBGP and also injects a default route inside the region. For destinations that do not belong to the region, each region defaults to the BGP border router.

Use the community parameter to differentiate between regions. To provide Internet connectivity, this scenario requires you to make your Internet connections part of the central iBGP mesh (see the following figure).

**Figure 28: Multiple Regions Separated by iBGP**

In the preceding figure, consider the following:

- The AS is divided into three regions that each run different and independent IGPs.
- Regions logically interconnect by using a full-mesh iBGP, which also provides Internet connectivity.
- Internal non-BGP routers in each region default to the BGP border router, which contains all routes.
- If the destination belongs to another region, the traffic is directed to that region; otherwise, the traffic is sent to the Internet connections according to BGP policies.

To configure multiple policies between regions, represent each region as a separate AS. Implement eBGP between autonomous systems, and implement iBGP within each AS. In such instances, each AS injects its IGP routes into BGP, where they are propagated to all other regions and the Internet.

The following figure shows the use of eBGP to join several autonomous systems.

**Figure 29: Multiple regions Separated by eBGP**

You can obtain AS numbers from the Inter-Network Information Center (NIC) or use private AS numbers. If you use private AS numbers, be sure to design your Internet connectivity carefully. For example, you can introduce a central, well-known AS to provide interconnections between all private autonomous systems and the Internet. Before it propagates the BGP updates, this central AS strips the private AS numbers to prevent them from leaking to providers.

The following figure illustrates a design scenario in which you use multiple OSPF regions to enable peering with the Internet.

**Figure 30: Multiple OSPF Regions Peering with the Internet**

*BGP Peers*

The following list provides rules related to BGP peers:

- Only metric (=MED) attribute is applied to the output policy if its BGP peer is IBGP
- metric (=MED) and community attributes are applied to output policy if its BGP peer is EBGP

- To influence EBGP and IBGP peers with all applicable BGP attributes, configure **route-map** as an option to **neighbor** command, for example, `neighbor 192.0.2.2 out-route-map policy1`

### *BGP and Route Aggregation*

When you configure the attribute-map with the aggregate command, community, metric, AS Path, and next-hop attributes are set, while the origin attribute is not set.

### *BGP Session Flapping when IPv6 Forwarding is Enabled or Disabled*

In a BGP session that is established with IPv4 and IPv6 capability, disabling or enabling IPv6 forwarding results in BGP session flapping due to capability negotiation. The flapping session in turn affects the IPv4 routing through BGP and the BGP session gets terminated. Ultimately, a capability negotiation takes place to re-establish the IPv4 and IPv6 capable session.

## BGP configuration using CLI

Configure the Border Gateway Protocol (BGP) to create and maintain an interdomain routing system that guarantees loop-free routing information between autonomous systems (AS).

For information about how to configure route policies for BGP, see [Configure IP Route Policies](#) on page 2764.

## Configure BGP

Configure BGP globally to enable BGP on the switch and determine how BGP operates.

### Before You Begin

- To configure the suppress-map, advertise-map, or attribute-map options, the route policy for those options must exist.
- For initial BGP configuration, you must know the AS number.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Specify the AS number and enable BGP:

```
router bgp [WORD <0-11>] [enable]
```

#### Note

- This command applies only on VRF 0. To enable BGP globally on other VRFs, use the **ip bgp enable** command. You must configure BGP locally before you configure it globally.
- You can also configure AS number on non-default VRFs. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 454.

- Access Router BGP Configuration mode:

```
router bgp
```

- Configure BGP variables or accept the default values.

### Example

Specify the AS number and enable BGP:

```
Switch(config)#router bgp 3 enable
```

Access Router BGP Configuration mode:

```
Switch(config)#router bgp
```

```
Switch(router-bgp)#
```

### Variable Definitions

The following table defines parameters for the **router bgp** command.

| Variable           | Value                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-11> | Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0. |
| <i>enable</i>      | Enables BGP on the router.                                                                            |

Use the data in the following table to use the BGP variables in BGP and VRF Router Configuration mode.

| Variable                                        | Value                                                                                                                              |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>aggregate-address</i><br><i>WORD</i> <1-256> | Specifies an IP address and its length in the form {a.b.c.d/len}, or an IPv6 address and its length in the form {ipv6addr/len}.    |
| <i>auto-peer-restart enable</i>                 | Enables the process that automatically restarts a connection to a BGP neighbor. The default value is enable.                       |
| <i>auto-summary</i>                             | When enabled, BGP summarizes networks based on class limits, for example, Class A, B, and C networks. The default value is enable. |

| Variable                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bgp always-compare-med</code>                                                      | Enables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default value is disable.                                                                                                                                                                                                                                                                                                                |
| <code>bgp aggregation</code>                                                             | Enables the aggregation feature on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>bgp client-to-client reflection</code>                                             | Enables or disables route reflection between two route reflector clients. This variable applies only if the route reflection value is enable. The default value is disable. You can enable route reflection even when clients are fully meshed.<br>This variable only applies to VRF 0.<br>Example: <code>Switch(router-bgp) # bgp client-to-client reflection</code><br>System Response: Restart or soft-restart BGP for the change to take effect.                                                                                                    |
| <code>bgp cluster-id {A.B.C.D}</code>                                                    | Configures a cluster ID. This variable applies only if the route reflection value is enable, and if multiple route reflectors are in a cluster. {A.B.C.D} is the IP address of the reflector router.<br>This variable only applies to VRF 0.<br>Example: <code>Switch(router-bgp) # bgp cluster-id 0.0.0.0</code>                                                                                                                                                                                                                                       |
| <code>bgp confederation identifier &lt;0-4294967295&gt; [peers WORD&lt;0-255&gt;]</code> | Configures a BGP confederation.<br><code>identifier&lt;0-4294967295&gt;</code> specifies the confederation identifier. Use 0-65535 for 2-byte AS and <0-4294967295> for 4-byte AS.<br><code>peers WORD&lt;0-255&gt;</code> lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,.....). Use quotation marks (") around the list of autonomous systems.<br><b>Note:</b><br>Use this command only on VRF 0.<br>Example: <code>Switch(router-bgp) # bgp confederation identifier 1 peers "20 30 40"</code> |
| <code>bgp default local-preference &lt;0-2147483647&gt;</code>                           | Specifies the default value of the local preference attribute. The default value is 0. You must disable BGP before you can change the default value.<br>Example: <code>Switch(router-bgp) # bgp default local-preference 2-12</code>                                                                                                                                                                                                                                                                                                                    |
| <code>bgp deterministic-med enable</code>                                                | Enables deterministic MED.<br>Example: <code>Switch(router-bgp) # bgp deterministic-med enable</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Variable                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bgp multiple-paths &lt;1-8&gt;</code>       | <p>Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1.</p> <p>Example: <code>Switch(router-bgp) # bgp multiple-paths 4</code></p> <p><b>Note:</b><br/>Configuring the <code>bgp multiple-paths</code> variable does not affect existing routes. The routing table does not show ECMP routes; instead only one route is shown in the routing table.</p> <p>To view Equal-Cost Multipath (ECMP) routes, receive the routes after executing the <code>bgp multiple-paths</code> variable, or toggle the BGP state.</p> <p>The number of equal-cost-paths supported can differ by hardware platform. For more information, see <a href="#">Release Notes for VOSS</a>.</p> |
| <code>comp-bestpath-med-confed enable</code>      | <p>When enabled, compares MED attributes within a confederation. The default value is disable.</p> <p>This variable only applies to VRF 0.</p> <p>Example: <code>Switch(router-bgp) # comp-bestpath-med-confed enable Restart or soft-restart BGP for the change to take effect</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>debug-screen &lt;off on&gt;</code>          | <p>Displays debug messages on the console, or saves them in a log file. Disable BGP screen logging (off) or enable BGP screen logging (on).</p> <p>Example: <code>Switch(router-bgp) # debug-screen on</code><br/>System Response: BGP Screen Logging is On</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>default-information originate</code>        | <p>Enables the advertisement of a default route to peers, if the route exists in the routing table. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>default-information ipv6-originate</code>   | <p>Enables the advertisement of an IPv6 default route to peers, if the route exists in the routing table. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>default-metric &lt;-1-2147483647&gt;</code> | <p>Configures a value to send to a BGP neighbor to determine the cost of a route a neighbor uses. A default metric value solves the problems associated with redistributing routes that use incompatible metrics. For example, whenever metrics do not convert, using a default metric provides a reasonable substitute and redistribution proceeds. Use this option in conjunction with the redistribute commands so the current routing protocol uses the same metric for all redistributed routes. The default value is 0.</p>                                                                                                                                                                                                                                                                       |
| <code>flap-dampening enable</code>                | <p>Enables route suppression for routes that flap on and off. The default value is disable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <code>global-debug mask</code><br><code>WORD&lt;1-100&gt;</code>       | Displays specified debug information for BGP global configurations. The default value is none. <ul style="list-style-type: none"> <li>• <code>&lt;WORD 1-100&gt;</code> is a list of mask choices separated by commas with no space between choices.</li> </ul> Mask choices are: <ul style="list-style-type: none"> <li>• <code>none</code> disables all debug messages.</li> <li>• <code>all</code> enables all debug messages.</li> <li>• <code>error</code> enables display of debug error messages.</li> <li>• <code>packet</code> enables display of debug packet messages.</li> <li>• <code>event</code> enables display of debug event messages.</li> <li>• <code>trace</code> enables display of debug trace messages.</li> <li>• <code>warning</code> enables display of debug warning messages.</li> <li>• <code>state</code> enables display of debug state transition messages.</li> <li>• <code>init</code> enables display of debug initialization messages.</li> <li>• <code>filter</code> enables display of debug messages related to filtering.</li> <li>• <code>update</code> enables display of debug messages related to sending and receiving updates.</li> </ul> Example: <code>Switch(router-bgp)# global-debug mask event, trace, warning, state</code> |
| <code>ibgp-report-import-rt enable</code>                              | Configures BGP to advertise imported routes to an interior BGP (iBGP) peer. This variable enables or disables advertisement of nonBGP imported routes to other iBGP neighbors. The default value is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>ignore-illegal-rtrid enable</code>                               | When enabled, BGP overlooks an illegal router ID. For example, you can configure this variable to enable or disable the acceptance of a connection from a peer that sends an open message using a router ID of 0 (zero). The default value is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>neighbor-debug-all mask</code><br><code>WORD&lt;1-100&gt;</code> | Displays specified debug information for BGP neighbors. The default value is none. For mask options, see the <code>global-debug mask WORD&lt;1-100&gt;</code> variable.<br>Example: <code>Switch(router-bgp)# neighbor-debug-all mask error, packet, event.trace, state, filter</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>no-med-path-is-worst enable</code>                               | Enables BGP to treat an update without a MED attribute as the worst path. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>quick-start enable</code>                                        | Enables the quick-start flag for exponential backoff.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>route-reflector enable</code>                                    | Enables the reflection of routes from iBGP neighbors. The default value is disable.<br>This variable only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>route-refresh</code>                                             | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.<br>This variable only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>router-id {A.B.C.D}</code>     | Specifies the BGP router ID in IP address format. This variable only applies to VRF 0.                                                                                                                                                                                                                                                                  |
| <code>synchronization</code>         | Enables the router to accept routes from BGP peers without waiting for an update from the IGP. The default value is enable.                                                                                                                                                                                                                             |
| <code>traps enable</code>            | Enables BGP traps.                                                                                                                                                                                                                                                                                                                                      |
| <code>vrf-as WORD&lt;0-11&gt;</code> | Configures an AS number on a specific VRF instance. Use 0-65535 for a 2-byte AS and <0-4294967295> for a 4-byte AS.<br>The default value of 0, or configuring the local-as in the VRF to 0, is equivalent to deleting the local-as configured on user-defined VRFs, and in both cases the local-as on the VRF becomes the local-as on the GlobalRouter. |

### Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group.

#### Tip

The following tips can help you use the debug commands:

- Display debug commands for multiple mask choices by entering the mask choices separated by commas, with no space between choices.
- To end (disable) the display of debug messages, use the mask choice of none.
- You can save debug messages in a log file, or you can display the messages on your console using the debug-screen command.

For more information about the logged debug messages, see [Alarms and Logs Reference for VOSS](#).

## Configure 4-byte AS numbers

Configure Autonomous System (AS) numbers using the 4-byte format and represent the numbers in octets.

### Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Configure the local AS number at Global Router (VRF0) only.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The AS list for the route policies accepts AS number only in the **asplain** format. If you create policies using **asplain** and configure the switch with **asdot**, the match will not occur.

### About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2-byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Disable BGP to change the AS number format.  
`no router bgp enable`
3. Enable the 4-byte AS numbering format.  
`router bgp as-4-byte enable`
4. To use the dotted octet notation, enable as-dot.  
`router bgp as-dot enable`
5. Configure the 4-byte AS number and enable BGP. If you have enabled as-dot, enter the AS number in octet.  
`router bgp WORD<0-11> enable`
6. Access Router BGP Configuration mode:  
`router bgp`
7. (Optional) Configure BGP confederation identifier.  
`bgp confederation identifier <0-4294967295>`
8. (Optional) Configure BGP confederation peers.  
`bgp confederation peers WORD<0-255>`

### Example

Disable BGP to change the AS number format.

```
Switch(config)# no router bgp enable
```

Enable the 4-byte AS numbering format.

```
Switch(config)# router bgp as-4-byte enable
```

To use the dotted octet notation, enable as-dot.

```
Switch(config)# router bgp as-dot enable
```

Configure the 4-byte AS number and enable BGP.

```
Switch(config)# router bgp 65536 enable
```

### Variable Definitions

The following table defines parameters for the **router bgp** command.

| Variable                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-4-byte</i><br><i>&lt;enable&gt;</i>        | Enables the switch for using 4 byte numbers for an autonomous system (AS). The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>as-dot</i> <i>&lt;enable&gt;</i>              | Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable the 4-byte-as and as-dot parameters, enter numbers in the range of 1.0 to 65535.65535. The default value is disable.<br><br><b>Note:</b><br>This parameter is not supported with BGP+.                                                                                                                                                                                                                                                                                                                                                     |
| <i>WORD</i> <i>&lt;0-11&gt;</i><br><i>enable</i> | Sets the local autonomous system (AS) number. You cannot change local-as when BGP is set to enable. <ul style="list-style-type: none"> <li>To set a 2-byte local AS number, enter a local-as number in the range of 0 to 65535.</li> <li>To set a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295.</li> </ul> <b>Note:</b><br>If as-4-byte is set to false, the range for AS number is 0-65535 and if as-4-byte is set to true, the range is 0-4294967295.<br><br>If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535.<br><br><b>Note:</b><br>This parameter is not supported with BGP+. |

## Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

### Before You Begin

- Disable BGP before you enable aggregation.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

## Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Enable BGP aggregation:
 

```
bgp aggregation enable
```
3. Add an aggregate route to the routing table:
 

```
aggregate-address WORD<1-256> {advertise-map WORD<0-1536>} [as-set]
[attribute-map WORD<0-1536>] [summary-only] [suppress-map WORD<0-1536>]
```
4. Exit to Global Configuration mode:
 

```
exit
```
5. Enable BGP:
 

```
router bgp [<0-65535>] [enable]
```

## Example

Add an aggregate route to the routing table:

```
Switch(router-bgp)# aggregate-address 2001:DB8::/32 advertise-map map1
attribute-map map2
```

Enable BGP:

```
Switch(router-bgp)# router bgp 4 enable
```

### Variable Definitions

The following table defines parameters for the **aggregate-address** command.

| Variable                          | Value                                                                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <i>advertise-map</i> WORD<0-1536> | Specifies the route map name for route advertisements.                                                                               |
| <i>as-set</i>                     | Enables autonomous system information. The default value is disable.                                                                 |
| <i>attribute-map</i> WORD<0-1536> | Specifies the route map name.                                                                                                        |
| WORD <1-256>                      | Specifies an IP address and its length in the appropriate form. The value must be entered in the format a.b.c.d/len or ipv6addr/len. |

| Variable                               | Value                                                                                                                                                                                                                |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>summary-only</i>                    | Enables the summarization of routes not included in routing updates. This variable creates the aggregate route and suppresses advertisements of more specific routes to all neighbors. The default value is disable. |
| <i>suppress-map WORD&lt;0-1536&gt;</i> | Specifies the route map name for the suppressed route list.                                                                                                                                                          |

The following table defines parameters for the **router bgp** command.

| Variable               | Value                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------|
| <i>&lt;0-65535&gt;</i> | Specifies the AS number. You cannot enable BGP until you change the local AS to a value other than 0. |
| <i>enable</i>          | Enables BGP on the router.                                                                            |

## Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

### Procedure

- Enter BGP Router Configuration mode:
 

```
enable
configure terminal
router bgp
```
- Specify IGP network prefixes for BGP to advertise:
 

```
network <WORD 1-256> [metric <0-65535>]
```

### Example

Specify IGP network prefixes for BGP to advertise:

```
Switch(router-bgp)# network 2001:DB8::/32 metric 32
```

### Variable Definitions

The following table defines parameters for the **network** command.

| Variable                | Value                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-256>     | Specifies an IP address and its length in the appropriate form.                                                                                                                               |
| <i>metric</i> <0-65535> | Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0-65535. |

## Configure BGP Peers or Peer Groups

Configure peers and peer groups to simplify BGP configuration and make updates more efficient.

BGP speakers can have many neighbors configured with similar update policies. For example, many neighbors use the same distribute lists, filter lists, outbound route maps, and update source. Group the neighbors that use the same update policies into peer groups and peer associations.

### Note

- If required, route policies exist.
- You configure BGPv4 on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.
- Route refresh is not currently supported on non-default VRFs.
- Not all parameters are supported on non-default VRFs.

### About This Task

Many of the command variables in this procedure use default values. You can accept the default values or change them to customize the configuration.

### Procedure

1. Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
2. Create a peer or peer group:
 

```
neighbor WORD<0-1536>
```
3. Apply a route policy to all incoming routes:
 

```
For BGPv4: neighbor WORD<0-1536> in-route-map WORD<0-256>

For BGPv6: neighbor WORD<0-1536> ipv6-in-route-map WORD<0-256>
```

4. Apply a route policy to all outgoing routes:  
For BGPv4: `neighbor WORD<0-1536> out-route-map WORD<0-256>`  
For BGPv6: `neighbor WORD<0-1536> ipv6-out-route-map WORD<0-256>`
5. (Optional) Configure the source IP address:  
`neighbor WORD<0-1536> update-source WORD<1-256>`
6. Enable MD5 authentication (for BGPv4):  
`neighbor WORD<0-1536> MD5-authentication enable`
7. Specify an MD5 authentication password (for BGPv4):  
`neighbor password <nbr_ipaddr|peer-group-name> WORD<0-1536>`
8. Change the default values for other command variables as required.
9. Enable the configuration:  
`neighbor WORD<0-1536> enable`

### Example

Create a peer or a peer group:

```
Switch(router-bgp) # neighbor peergroupa
```

Apply a route policy (in-route-map or out-route-map) to all incoming or outgoing routes:

```
Switch(router-bgp) # neighbor peergroupa in-route-map map1 out-route-map
map2
```

Configure the source IP address:

```
Switch(router-bgp) # neighbor peergroupa update-source 192.0.2.1
```

Enable MD5 authentication:

```
Switch(router-bgp) # neighbor peergroupa MD5-authentication enable
```

Specify an MD5 authentication password:

```
Switch(router-bgp) # neighbor password peergroupa password
```

Enable the configuration:

```
Switch(router-bgp) # neighbor peergroupa enable
```

### Variable Definitions

The following table defines parameters for the **neighbor** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address-family</i> <ipv6>          | Enables the IPv6 address family on BGP neighbor.<br>Switch(router-bgp)# neighbor peergroupa<br>address-family ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>advertisement-interval</i> <5-120> | Specifies the time interval, in seconds, that transpires between each transmission of an advertisement from a BGP neighbor. The default value is 5 seconds.<br>Switch(router-bgp)# neighbor peergroupa<br>advertisement-interval 26 enable<br>The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or it should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <i>allow-as-in</i>                    | Allows BGP to inject updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>default-ipv6-originate</i>         | Enables IPv6 BGP neighbor default originate.<br>Switch(router-bgp)# neighbor peergroupa<br>default-ipv6-originate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>default-originate</i>              | Enables the switch to send a default route advertisement to the specified neighbor. A default route does not need to be in the routing table. The default value is disable.<br>Do not use this command if <b>default-information originate</b> is globally enabled.<br>Switch(router-bgp)# neighbor peergroupa<br>default-originate enable peer-group test                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>ebgp-multihop</i>                  | Enables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable.<br>Switch(router-bgp)# neighbor peergroupa<br>ebgp-multihop retry-interval 3 timers 4 5                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>enable</i>                         | Enables the BGP neighbor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>fall-over bfd</i>                  | Enable fall-over Bidirectional Forwarding Detection (BFD).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>in-route-map</i> WORD<0-256>       | Applies a route policy rule to all incoming routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates.<br>WORD<0-256> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy.<br>Switch(router-bgp)# neighbor peergroupa<br>in-route-map map1 address-family ipv6                                                                                                                                                                                                                                                                                                                                                                      |

| Variable                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>out-route-map WORD&lt;0-256&gt;</code> | Applies a route policy rule to all outgoing routes that are learned from, or sent to, the peers or peer groups of the local router. The local BGP router is the BGP router that allows or disallows routes and configures attributes in incoming or outgoing updates.<br><code>WORD&lt;0-256&gt;</code> is an alphanumeric string length (0-256 characters) that indicates the name of the route map or policy. |
| <code>peer-group &lt;WORD 0-1536&gt;</code>  | Adds a BGP peer to the specified subscriber group. You must create the specified subscriber group before you use this command.                                                                                                                                                                                                                                                                                  |
| <code>remote-as &lt;WORD 0-11&gt;</code>     | Configures the remote AS number of a BGP peer or a peer-group. You must disable the admin-state before you can configure this variable.<br><code>Switch(router-bgp) # neighbor peergroupa remote-as As-number &lt;WORD 0-11&gt;</code> is an alphanumeric string length (0-11 characters) that indicates the AS number.                                                                                         |
| <code>remove-private-as enable</code>        | Strips private AS numbers when an update is sent. The default value is enable.                                                                                                                                                                                                                                                                                                                                  |
| <code>retry-interval &lt;1-65535&gt;</code>  | Configures the time interval, in seconds, for the ConnectRetry timer. The default value is 120 seconds.<br><code>Switch(router-bgp) # neighbor 198.51.100.2 retry-interval 34</code><br>You can configure the retry interval for BGP neighbors only; you cannot configure the retry interval for BGP peer groups.                                                                                               |
| <code>route-reflector-client</code>          | Configures the specified neighbor or group of neighbors as a route reflector client. The default value is disable. All configured neighbors become members of the client group and the remaining iBGP peers become members of the nonclient group for the local route reflector.<br><br><b>Note:</b><br>This variable only applies to VRF 0.<br><br><code>Switch(router-bgp) # neighbor</code>                  |
| <code>route-refresh</code>                   | Enables route refresh for the BGP peer. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.<br><br><b>Note:</b><br>This variable only applies to VRF 0.                                                                                                            |
| <code>send-community</code>                  | Enables the switch to send the update message community attribute to the specified peer. The default value is disable.                                                                                                                                                                                                                                                                                          |
| <code>site-of-origin</code>                  | Specifies a site of origin that is added to the extended communities list in each route from a specific peer.                                                                                                                                                                                                                                                                                                   |

| Variable                                            | Value                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>soft-reconfiguration-in enable</code>         | Enables the router to relearn routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.                                                                                                |
| <code>timers &lt;0-21845&gt; &lt;0-65535&gt;</code> | Configures timers, in seconds, for the BGP speaker for this peer.<br><0-21845> is the keepalive time. The default is 60. As a best practice, configure a value of 30 seconds.<br><0-65535> is the hold time. The default is 180.<br>Switch(router-bgp)# neighbor peergroupa<br>timers 4 6                |
| <code>update-source WORD&lt;1-256&gt;</code>        | Specifies the source IPv4 address {A.B.C.D.} or IPv6 address to use when the system sends BGP packets to this peer or peer group. You must disable the admin-state before you can configure this variable.<br>Switch(router-bgp)# neighbor peergroupa<br>update-source 192.0.2.2 weight 560              |
| <code>weight &lt;0-65535&gt;</code>                 | Specifies the weight of a BGP peer or peer group, or the priority of updates the router can receive from that BGP peer. The default value is 0. If you have particular neighbors that you want to use for most of your traffic, you can assign a higher weight to all routes learned from that neighbor. |
| <code>WORD&lt;0-1536&gt;</code>                     | Specifies the peer IP address or the peer group name.                                                                                                                                                                                                                                                    |

## Configure a BGP Peer or Peer Group Password

Use this procedure to configure a BGP peer or peer group password for Transmission Control Protocol (TCP) MD5 authentication between two peers.

### Note

You configure BGP peer on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix `ip bgp`. The VRF must have an RP Trigger of BGP. Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:
 

```
enable

configure terminal

router bgp
```
- Assign a BGP peer or peer group password:
 

```
neighbor password <nbr_ipaddr|peer-group=name> WORD <0-1536>
```

### Example

Assign a BGP peer or peer group password:

```
Switch(router-bgp)# neighbor password peergroupa password1
```

### Variable Definitions

The following table defines parameters for the **neighbor password <nbr\_ipaddr|peer-group-name>** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>password &lt;nbr_ipaddr peer-group-name&gt; WORD &lt;0-1536&gt;</code> | Specifies a password for TCP MD5 authentication between two peers.<br>WORD <0-1536> is an alphanumeric string length from 0 to 1536 characters.<br>To disable this option, use <b>no</b> operator with the command.<br>To configure this option to the default value, use <b>default</b> operator with the command. |

## Configure Redistribution to BGP

Configure a redistribution entry to announce routes of a certain source protocol type into the BGP domain such as: DvR routes, static routes, Routing Information Protocol (RIP) routes, or direct routes. Use a route policy to control the redistribution of routes.

### Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

### Before You Begin

- If required, a route policy exists.
- You can configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

### Note

Route refresh is not currently supported on non-default VRFs.

- Before you redistribute DvR host routes to BGP, you must disable BGP aggregation and BGP auto-summarization of networks, using the commands **no ip bgp aggregation enable** and **no ip bgp auto-summary** respectively.

Disabling these settings ensures that all the DvR host routes are correctly advertised into BGP and are not summarized.

### Note

When applying a route map to an inter-vrf redistribution, the route map and any associated IP prefix lists must be configured first on the source VRF before configuring the redistribute policy on the destination VRF.

Inter-vrf redistribution is not supported on IPv6 routes.

## Procedure

1. Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static>
```

### Note

Redistribution of ripng routes into BGP is supported only on VRF 0.

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> route-map WORD<0-64> [vrf-src WORD<1-16>]
```

4. If required, configure the route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric <0-65535> [vrf-src WORD<1-16>]
```

5. If required, configure the route metric-type:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric-type live-metric [vrf-src WORD<1-16>]
```

6. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> enable [vrf-src WORD<1-16>]
```

7. Exit BGP Router Configuration mode:

```
exit
```

8. Apply the redistribution instance configuration:

```
For IPv4: ip bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf WORD<1-16>] [vrf-src <WORD 1-16>]
```

```
For IPv6: ipv6 bgp apply redistribute <direct|dvr|isis|ospf|rip|static> [vrf <WORD 1-16>]
```

9. Apply BGP redistribution to a specific VRF:

```
ip bgp apply redistribute vrf WORD<1-16>
```

Changes do not take effect until you apply them.

10. View all routes (including DvR host routes) that are redistributed into BGP:

View routes redistributed from GRT to BGP:

For IPv4: `show ip bgp imported-routes`

For IPv6: `show bgp ipv6 imported-routes`

View routes redistributed to BGP for a specific VRF instance:

For IPv4: `show ip bgp imported-routes [vrf WORD<1-64>] [vrfids WORD<0-512>]`

For IPv6: `show bgp ipv6 imported-routes [WORD<1-256>] [vrf WORD<1-16>] [vrfids WORD<0-255>]`

## Example

### Example 1:

Redistribute direct routes from the VRF instance `source1` into BGP, in the GRT context.

Create a redistribution instance:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgp
Switch(router-bgp)#redistribute direct vrf-src source1
```

If required, specify a route policy to govern redistribution:

```
Switch(router-bgp)# redistribute direct route-map policy1 vrf-src source1
```

If required, configure the route metric:

```
Switch:1(router-bgp)# redistribute direct metric 4 vrf-src source1
```

Enable the instance:

```
Switch:1(router-bgp)# redistribute direct enable vrf-src source1
```

Exit BGP Router Configuration mode:

```
Switch:1(router-bgp)# exit
```

Apply the redistribution instance configuration:

```
Switch:1(config)# ip bgp apply redistribute direct vrf-src source1
```

### Example 2:

Redistribute DvR routes from the GRT to BGP:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router bgpSwitch:1(router-bgp)#redistribute dvr
Switch:1(router-bgp)#redistribute dvr enable
```

```
Switch:1(router-bgp)#exit
Switch:1(config)#ip bgp apply redistribute dvr
```

View the host routes (including DvR host routes) that are redistributed from the GRT to BGP:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

```

### Example 3:

Redistribute DvR routes to BGP for the specific VRF instance `vrf1`:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#ip bgp redistribute dvr
Switch:1(router-vrf)#ip bgp redistribute dvr enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip bgp apply redistribute dvr vrf vrf1
```

View the DvR host routes that are redistributed to BGP for vrf `vrf1`:

```
Switch:1(config)#show ip bgp imported-routes vrf vrf1

```

### Example 4:

This example demonstrates redistribution of inter-VRF routes (both direct and DvR routes) to BGP, with a route policy configured.

Redistribute inter-VRF DvR routes between VRFs (with VRF IDs 10 and 30), to BGP.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf 10
```

```

Switch:1(router-vrf)#ip prefix-list "test10" 192.0.2.0/24 ge 25 le 32
Switch:1(router-vrf)#route-map "test10" 1
Switch:1(router-vrf)#permit
Switch:1(router-vrf)#enable
Switch:1(router-vrf)#match network "test10"
Switch:1(router-vrf)#set metric 99
Switch:1(router-vrf)#exit

Switch:1(config)#router vrf 30
Switch:1(router-vrf)#ip bgp redistribute direct vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute direct enable vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr route-map "test10" vrf-src 10
Switch:1(router-vrf)#ip bgp redistribute dvr enable vrf-src 10
Switch:1(router-vrf)#exit

Switch:1(config)#ip bgp apply redistribute direct vrf 30 vrf-src 10
Switch:1(config)#ip bgp apply redistribute dvr vrf 30 vrf-src 10

```

### Variable Definitions

The following table defines parameters for the **redistribute** and **ip bgp apply redistribute** commands.

| Variable                                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;direct   dvr   ipv6-direct   ipv6-isis   ipv6-static   isis   ospf   ospfv3   rip   ripng  static &gt;</code> | Specifies the type of routes to redistribute (the protocol source).                                                                                                                                                                                                                                                                                                                             |
| <code>enable</code>                                                                                                     | Enables the BGP route redistribution instance.                                                                                                                                                                                                                                                                                                                                                  |
| <code>metric &lt;0-65535&gt;</code>                                                                                     | Configures the metric to apply to redistributed routes.                                                                                                                                                                                                                                                                                                                                         |
| <code>metric-type live-metric</code>                                                                                    | Configures the metric type to apply to redistributed routes. When you enable the live-metric option, when BGP redistributes static, RIP, OSPF, IS-IS, or DvR routes, the metric value is taken from the routing table and is set to the Path attributes as a MED value. By default, this option is disabled, which means the BGP MED value is not derived from the metric in the routing table. |
| <code>route-map WORD&lt;0-64&gt;</code>                                                                                 | Configures the route policy to apply to redistributed routes.                                                                                                                                                                                                                                                                                                                                   |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                       | Specifies the name of a VRF instance.                                                                                                                                                                                                                                                                                                                                                           |
| <code>vrf-src WORD&lt;1-16&gt;</code>                                                                                   | Specifies the source VRF instance by name for route redistribution.                                                                                                                                                                                                                                                                                                                             |

## Configure redistribution to BGP+ for VRF 0

Configure an IPv6 redistribute entry to announce IPv6 routes of a certain source protocol type into the BGP domain, for example, static, OSPF, IS-IS, RIPng, or direct routes. Use a route policy to control the redistribution of routes.

### Note

When a route map with attributes set to `origin` and `local-pref` is applied to the BGP redistribute command, the attributes are not applied to the redistributed routes.

### Before You Begin

- If required, a route policy exists.

### Procedure

1. Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

2. Create a redistribution instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static>
```

3. If required, specify a route policy to govern redistribution:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> route-map WORD <0-64>
```

4. If required, configure a route metric:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> metric <0-65535>
```

5. Enable the instance:

```
redistribute <direct|dvr|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|ripng|static> enable
```

Unlike IPv4 redistribution, you do not need to manually apply the IPv6 redistribution instance. Once you enable the IPv6 redistribution instance, it is automatically applied.

### Example

Specify a route policy to govern redistribution by using the following command:

```
Switch:1(router-bgp)#redistribute ipv6-direct route-map policy2
```

### Variable Definitions

The following table defines parameters for the **redistribute <ipv6-direct|ipv6-static|ospfv3|ipv6-isis|ripng>** command.

**Table 72: Variable definitions**

| Variable                           | Value                                                                                                                                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                      | Enables the BGP route redistribution instance. The default value is none.<br>To configure this option to the default value, use <b>default</b> operator with the command.<br>To disable this option, use <b>no</b> operator with the command. |
| <i>metric&lt;0-65535&gt;</i>       | Configures the metric to apply to redistributed routes. The default value is 0.<br>To configure this option to the default value, use <b>default</b> operator with the command.                                                               |
| <i>route-map &lt;Word 0-64&gt;</i> | Configures the route policy to apply to redistributed routes. The default value is none.<br>To configure this option to the default value, use <b>default</b> operator with the command.                                                      |

### Job Aid

Use the data in the following table to know how route policies are used for BGP from IPv6 perspective.

**Table 73: BGP for IPv6 Route Policy Support**

|                  | REDISTRIBUTE |             |        |            |       | ACCEPT | ANNOUNCE |
|------------------|--------------|-------------|--------|------------|-------|--------|----------|
|                  | IPv6 Direct  | IPv6 Static | OSPFv3 | IPv6 IS-IS | RIPng | BGP    | BGP      |
| MATCH            |              |             |        |            |       |        |          |
| as-path          |              |             |        |            |       | Yes    | Yes      |

## Configure AS Path Lists

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create the path list:

```
ip as-list <1-1024> memberid <0-65535> <permit|deny> as-path WORD<0-1536>
```

Use this command for each member by specifying different member IDs.

### Example

Create the path list:

```
Switch(config)# ip as-list 234 memberid 3456 permit as-path "5"
```

#### Variable Definitions

The following table defines parameters for the **ip as-list** command.

| Variable      | Value                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| <0-65535>     | Specifies an integer value between 0-65535 that represents the regular expression entry in the AS path list.      |
| <1-1024>      | Specifies an integer value from 1-1024 that represents the AS-path list ID you want to create or modify.          |
| <permit deny> | Permits or denies access for matching conditions.                                                                 |
| WORD<0-1536>  | Specifies the AS number as an integer value between 0-1536. Place multiple AS numbers within quotation marks ("). |

## Configure Community Lists

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

### Before You Begin

- You configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```

- Create a community list:

```
ip community-list <1-1024> memberid <0-65535> <permit|deny> community-
string WORD<0-256>
```

### Example

Create a community list:

```
Switch(config)# ip community-list 1 memberid 4551 permit community-
string internet
```

#### Variable Definitions

The following table defines parameters for the **ip community-list** command.

| Variable      | Value                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-65535>     | Specifies an integer value from 0-65535 that represents the member ID in the community list.                                                                                                                                                                                                                                                                                        |
| <1-1024>      | Specifies an integer value from 1-1024 that represents the community list ID.                                                                                                                                                                                                                                                                                                       |
| <permit deny> | Configures the access mode, which permits or denies access for matching conditions.                                                                                                                                                                                                                                                                                                 |
| WORD<0-256>   | Specifies the community as an alphanumeric string value with a string length from 0-256 characters. Enter this value in one of the following formats: <ul style="list-style-type: none"> <li>(AS num:community-value)</li> <li>(well-known community string)</li> </ul> Well known communities include: internet, no-export, no-advertise, local-as (known as NO_EXPORT_SUBCONFED). |

## Configure Extended Community Lists

Configure community lists to specify permitted routes by BGP extended community attributes, including route targets and sites of origin (SOO). This list acts as a filter that matches route targets and SOO.

### Before You Begin

- Configure BGP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip bgp**. The VRF must have an RP Trigger of BGP.

#### Note

Route refresh is not currently supported on non-default VRFs.

### Procedure

- Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```

- Create an extended community list based on the route target attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> rt {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>} [soo {<0-65535> <0-2147483647>|
<A.B.C.D> <0-65535>}]
```

You can optionally configure the SOO attributes at the end of the same command or you can configure the SOO separately using the syntax in the following step.

- Create an extended community list based on the SOO attribute:

```
ip extcommunity-list <1-1024> memberId <0-65535> soo {<0-65535>
<0-2147483647>|<A.B.C.D> <0-65535>}
```

### Example

Create an extended community list based on the route target attribute:

```
Switch(config)# ip extcommunity-list 1 memberid 234 rt 192.0.2.1 5 soo
32 45
```

#### Variable Definitions

The following table defines parameters for the **ip extcommunity-list** command.

| Variable           | Value                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <1-1024>           | Specifies an integer value from 1-1024 that represents the community list ID you want to create or modify. |
| memberId <0-65535> | Specifies an integer value from 0-65535 that represents the member ID in the community list.               |

| Variable                                                                                                  | Value                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rt &lt;0-65536&gt; &lt;0-2147483647&gt;</code><br><code>rt &lt;A.B.C.D&gt; &lt;0-65535&gt;</code>   | Specifies the route target in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}).   |
| <code>soo &lt;0-65535&gt; &lt;0-2147483647&gt;</code><br><code>soo &lt;A.B.C.D&gt; &lt;0-65535&gt;</code> | Specifies the site of origin in the format {AS number:assigned number} (that is, {0-65535}:{0-2147483647}) or {ipaddress:assigned number} (that is, {a.b.c.d}:{0-65535}). |

## Configure an AS Number for a Non-default VRF

The Autonomous System (AS) number configured on the global Virtual Routing Forwarding (VRF) instance, called the GlobalRouter (GRT), is inherited by all user-created VRFs by default, however, you can override the AS number for the specific VRF instance using the following procedure.

### Before You Begin

- Disable BGP synchronization.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Set the AS number:

```
ip bgp vrf-as WORD<0-11>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ip bgp vrf-as 3
```

### Variable Definitions

The following table defines parameters for the **ip bgp vrf-as** command.

| Variable           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-11> | <p>Configures the local autonomous system (AS) number for the specific VRF instance. You cannot change local-as when BGP is set to enable.</p> <ul style="list-style-type: none"> <li>To configure a 2-byte local AS number, enter a local-as number in the range of 0 to 65535.</li> <li>To configure a 4-byte local-as number, enable the 4-byte as variable and enter a number in the range of 0 to 4294967295.</li> </ul> <p><b>Note:</b><br/>If as-4-byte is configured to false, the range for AS number is 0-65535 and if as-4-byte is configured to true, the range is 0-4294967295.</p> <p>If you enable as-dot, enter the AS number in octets in the range of 1.0 to 65535.65535.<br/>The AS number in a specific VRF instance inherits the AS number in the GlobalRouter in the following instances:</p> <ul style="list-style-type: none"> <li>Configuring the AS number in a specific VRF instance to 0 (<b>ip bgp vrf-as 0</b>).</li> <li>Deleting the AS number in a specific VRF instance (<b>no ip bgp vrf-as</b> or <b>default ip bgp vrf-as</b>).</li> </ul> |

## BGP Verification Using CLI

Use **show** commands to verify Border Gateway Protocol (BGP) configuration and to monitor or troubleshoot BGP operation.

### Note

If the next hop of a BGP route is resolved using an IS-IS route, show commands can display the IS-IS internal next hop from the 127.1.x.y class rather than the IS-IS sys name.

### Viewing BGP aggregate information

Display information about current aggregate addresses.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about current aggregates:

```
show ip bgp aggregates [<prefix/len>] [vrf WORD <1-16>] [vrfids WORD<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp aggregates** command.

| Variable                              | Value                                         |
|---------------------------------------|-----------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Specifies the IP address and the mask length. |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name.             |
| <code>vrfids WORD&lt;0-255&gt;</code> | Specifies a range of VRFs by ID number.       |

## Viewing IPv6 BGP+ aggregate information

Display information about current IPv6 aggregate addresses.

### About This Task

Use BGP 4 byte AS numbers to ensure the continuity of loop-free inter-domain routing information between ASs and to control the flow of BGP updates as 2 byte AS numbers will deplete soon.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current IPv6 aggregates:

```
show bgp ipv6 aggregates [<WORD 1-256>] [vrf <WORD 1-16>] [vrfids
<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 aggregates** command.

| Variable                           | Value                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------|
| <code>WORD &lt;1-256&gt;</code>    | Specifies the IPv6 prefix and the prefix length (the length can be 0 to 128).     |
| <code>vrf WORD &lt;1-16&gt;</code> | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| <code>vrfids &lt;0-255&gt;</code>  | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                |

## Viewing CIDR routes

Display information about classless interdomain routing (CIDR) routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about CIDR routes:

```
show ip bgp cidr-only [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp cidr-only** command.

| Variable                              | Value                                                                                                                           |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Specifies an exact match of the prefix. This variable is an IP address and an integer value from 0-32 in the format a.b.c.d/xx. |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                               |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                              |

### Job Aid

Use the data in the following table to understand the **show ip bgp cidr-only** command output.

**Table 74: show ip bgp cidr-only field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NETWORK/MASK    | Specifies the network IP address and exact mask length (must be an integer value from 0-32).                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PEER REM ADDR   | Specifies the IP address of the remote peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| NEXTHOP ADDRESS | Specifies the IP address of the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ORG             | Specifies the source of a route: <ul style="list-style-type: none"> <li>IGP — the route is interior to the originating AS that inserts this route into the BGP table (0 = IGP).</li> <li>EGP — the route is learned through an Exterior Gateway Protocol (EGP) before it is inserted into the BGP table (1 = BGP).</li> <li>Incomplete — the origin of the route is unknown or learned by some other means. For example, the router learns these routes through RIP, OSPF, or static routes (2 = Incomplete).</li> </ul> |
| LOC PREF        | Specifies the local preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Viewing BGP configuration

View information about the BGP configuration.

### Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about the current BGP configuration:

```
show ip bgp conf [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

```
=====
BGP Configuration - VRF vrfl
=====
```

```

BGP version - 4
 local-as - 22610
 Identifier - 27.82.217.1
 BGP on/off - ON
 as-4-byte - disable
 as-dot - disable
 aggregation - enable
 always-cmp-med - disable
 auto-peer-restart - enable
 auto-summary - enable
 comp-bestpath-med-confed - disable
 default-local-preference - 100
 default-metric - -1
 deterministic-med - disable
 flap-dampening - disable
 debug-screen - Off
 global-debug - none
 ibgp-report-import-rt - enable
 ignore-illegal-rtrid - enable
 max-equalcost-routes - 1
 no-med-path-is-worst - enable
 route-refresh - disable
 orig-def-route - disable
 orig-v6-def-route - disable
 quick-start - disable
 synchronization - enable

--More-- (q = quit)

```

### Variable Definitions

The following table defines parameters for the **show ip bgp conf** command.

| Variable                              | Value                                                                             |
|---------------------------------------|-----------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                |

## Viewing BGP confederation

Display information about BGP confederations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about current BGP confederations:

```
show ip bgp confederation
```

### Example

```

Switch(config)#show ip bgp confederation
confederation identifier 0
confederation peer as

```

## Viewing flap-dampened routes

Display information about flap-dampened routes to determine unreliable routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about flap-dampened routes:

```
show ip bgp dampened-paths {A.B.C.D} [<prefix/len>] [longer-prefixes]
[vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp dampened-paths** command.

| Variable                        | Value                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>                | Specifies the source IP address in the format a.b.c.d.                                                                                                    |
| <i>longer-prefixes</i>          | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                         |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                                                        |

### Job Aid

Use the data in the following table to understand the **show ip bgp dampened-paths** command output.

**Table 75: show ip bgp dampened-paths field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NETWORK/MASK    | Specifies the network IP address and exact mask length (must be an integer value from 0-32).                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PEER REM ADDR   | Specifies the IP address of the remote peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| NEXTHOP ADDRESS | Specifies the IP address of the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ORG             | Specifies the source of a route: <ul style="list-style-type: none"> <li>• IGP — the route is interior to the originating AS that inserts this route into the BGP table (0 = IGP).</li> <li>• EGP — the route is learned through an Exterior Gateway Protocol (EGP) before it is inserted into the BGP table (1 = BGP).</li> <li>• Incomplete — the origin of the route is unknown or learned by some other means. For example, the router learns these routes through RIP, OSPF, or static routes (2 = Incomplete).</li> </ul> |
| LOC PREF        | Specifies the local preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Viewing global flap-dampening configurations

Display global information about flap-dampening.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display global information about flap-dampening:

```
show ip bgp flap-damp-config [prefix/len] [vrf WORD<1-16>] [vrfrids
WORD<0-512>]
```

### Example

```
Switch(config)# show ip bgp flap-damp-config vrf vrf1
```

```
=====
 BGP Flap Dampening - VRF vrf1
=====
 Status - enable
 PolicyName - N/A
 CutoffThreshold - 1536
 ReuseThreshold - 512
 Decay - 2
 MaxHoldDown - 180
```

### Variable Definitions

The following table defines parameters for the **show ip bgp flap-damp-config** command.

| Variable            | Value                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------|
| <prefix/len>        | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32). |
| vrf WORD<1-16>      | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                      |
| vrfrids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                     |

### Job aid

Use the data in the following table to understand the **show ip bgp flap-damp-config** command output.

**Table 76: show ip bgp flap-damp-config field descriptions**

| Field           | Description                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------|
| Status          | Indicates the global state of the route flap dampening feature. Valid values are enable or disable. |
| PolicyName      | This field does not apply to the switch.                                                            |
| CutoffThreshold | Indicates the penalty level that causes route suppression.                                          |
| ReuseThreshold  | Specifies the system-configured time for route reuse.                                               |

**Table 76: show ip bgp flap-damp-config field descriptions (continued)**

| Field       | Description                                                              |
|-------------|--------------------------------------------------------------------------|
| Decay       | Indicates the decay rate based on the decay algorithm.                   |
| MaxHoldDown | Indicates the maximum length of time, in seconds, to suppress the route. |

## Viewing imported routes

Display information about BGP imported routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP imported routes:

```
show ip bgp imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp imported-routes** command.

| Variable                        | Value                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>          | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                         |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                                                        |

### Job Aid

Use the data in the following table to understand the **show ip bgp imported-routes** command output.

**Table 77: show ip bgp imported-routes field descriptions**

| Field     | Description                            |
|-----------|----------------------------------------|
| ROUTE     | Specifies the IP address of the route. |
| METRIC    | Specifies the route metric.            |
| COMMUNITY | Specifies the BGP community.           |
| LOCALPREF | Specifies the local preference.        |

**Table 77: show ip bgp imported-routes field descriptions (continued)**

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NEXTHOP | Specifies the IP address of the next hop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ORIGIN  | Specifies the source of a route: <ul style="list-style-type: none"> <li>IGP — the route is interior to the originating AS that inserts this route into the BGP table (0 = IGP).</li> <li>EGP — the route is learned through an Exterior Gateway Protocol (EGP) before it is inserted into the BGP table (1 = BGP).</li> <li>Incomplete — the origin of the route is unknown or learned by some other means. For example, the router learns these routes through RIP, OSPF, or static routes (2 = Incomplete).</li> </ul> |

## Viewing BGPv6 imported routes

Display information about BGPv6 imported routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 imported routes:

```
show bgp ipv6 imported-routes [<prefix/len>] [longer-prefixes] [vrf
WORD<1-16>] [vrfids WORD<0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 imported-routes** command.

| Variable                        | Value                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>          | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1–16 characters).                                                                         |
| <i>vrfids WORD&lt;0-255&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0–255).                                                                                        |

## Viewing BGP neighbors information

Display information about BGP neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display information about BGP neighbors:

```
show ip bgp neighbors [{A.B.C.D}] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

3. Display information about BGP peer advertised routes:

```
show ip bgp neighbors {A.B.C.D} advertised-routes [<prefix/len>]
[longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

4. Display information about BGP peer routes:

```
show ip bgp neighbors {A.B.C.D} routes [<prefix/len>] [community
<enable|disable>] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

5. Display statistics for BGP peers:

```
show ip bgp neighbors {A.B.C.D} stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

```
Switch:#show ip bgp neighbors vrf vrf1
```

```

### Variable Definitions

The following table defines parameters for the **show ip bgp neighbors** command.

| Variable                                | Value                                                                                                                                                     |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>                        | Specifies the IP address.                                                                                                                                 |
| <i>community &lt;enable disable&gt;</i> | Enables or disables the display of community attributes.                                                                                                  |
| <i>longer-prefixes</i>                  | Shows long prefixes. The longer-prefixes indicate the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>prefix/len</i>                       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                    |
| <i>vrf WORD&lt;1-16&gt;</i>             | Specifies a VRF instance by name.                                                                                                                         |
| <i>vrfids WORD&lt;0-512&gt;</i>         | Specifies a range of VRFs by ID number.                                                                                                                   |

## Viewing BGPv6 neighbors information

View information about BGPv6 neighbors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View information about BGPv6 neighbors:  

```
show bgp ipv6 neighbors [WORD<1-256>] [vrf <WORD 1-16>] [vrfids <0-255>]
```
3. View information about BGPv6 peer advertised routes:  

```
show bgp ipv6 neighbors WORD<1-256> advertised-routes [WORD<1-256>] [longer-prefixes] [vrf <WORD 1-16>] [vrfids <0-255>]
```
4. View information about BGPv6 peer routes:  

```
show bgp ipv6 neighbors WORD<1-256> routes [WORD<1-256>] [community <enable|disable>] [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Example

The following examples shows the summary output for **show bgp ipv6 neighbors** command, and the *advertised-routes* and *routes* variable options.

```
Switch:1>show bgp ipv6 neighbors vrf vrf1

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 neighbors** command.

| Variable                 | Value                                          |
|--------------------------|------------------------------------------------|
| <i>WORD</i> <1-256>      | Specifies the IPv6 address.                    |
| <i>advertised-routes</i> | Specifies an IPv6 neighbors advertised routes. |
| <i>routes</i>            | Specifies an IPv6 neighbors routes.            |
| <i>WORD</i> <1-256>      | Specifies an IPv6 address/length.              |

| Variable                                | Value                                                                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>longer-prefixes</i>                  | Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128. For example, show from prefix :X::X:X/len to X:X::X/X/ 128. |
| <i>community &lt;enable disable&gt;</i> | Enables or disables the display of community attributes.                                                                                                        |
| <i>vrf</i>                              | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                               |
| <i>vrfids</i>                           | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                                                                                              |

## Viewing BGP network configurations

Display information about BGP network configurations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP network configurations:

```
show ip bgp networks [<prefix/len>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp networks** command.

| Variable                        | Value                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;prefix/len&gt;</i>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32). |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                                                     |

## Viewing IPv6 BGP+ network configurations

Display information about BGP+ network configurations.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP+ network configurations:

```
show bgp ipv6 networks <WORD 1-256> [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 networks** command.

| Variable     | Value                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------|
| <WORD 1-256> | Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128). |
| vrf          | Specifies a VRF instance by name (the string length ranges from 1-16 characters).             |
| vrfids       | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                            |

## Viewing BGP peer group information

Display information about BGP peer groups.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP peer groups:

```
show ip bgp peer-group [WORD<0-1536>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp peer-group** command.

| Variable           | Value                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by name (the string length ranges from 1-16 characters).       |
| vrfids WORD<0-512> | Specifies a range of VRFs by ID number (the ID ranges from 0-512).                      |
| WORD<0-1536>       | Specifies the name of the peer group (the string length ranges from 0-1536 characters). |

## Viewing BGP redistributed routes

Display information about BGP redistributed routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP redistributed routes:

```
show ip bgp redistributed-routes [<prefix/len>] [vrf WORD<1-16>]
[vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp redistributed-routes** command.

| Variable                              | Value                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;prefix/len&gt;</code>       | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0–32). |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name (the string length ranges from 1–16 characters).                                      |
| <code>vrfids WORD&lt;0-255&gt;</code> | Specifies a range of VRFs by ID number (the ID ranges from 0–255).                                                     |

### Job aid

Use the data in the following table to understand the **show ip bgp redistributed-routes** command output.

**Table 78: show ip bgp redistributed-routes field descriptions**

| Field    | Description                                                                            |
|----------|----------------------------------------------------------------------------------------|
| SRC-VRF  | Indicates the redistribution source VRF instance.                                      |
| SRC      | Indicates the redistribution source: RIP, Local, Static, or OSPF.                      |
| MET      | Indicates the metric value.                                                            |
| MET-TYPE | Indicates the redistribution metric type.                                              |
| ENABLE   | Indicates whether the redistribution policy is enabled (T) true or disabled (F) false. |
| RPOLICY  | The route policy currently assigned to the redistribution.                             |

## Viewing BGPv6 redistributed routes

Display information about BGPv6 redistributed routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGPv6 redistributed routes:

```
show bgp ipv6 redistributed-routes [vrf <WORD 1-16>] [vrfids <0-255>]
```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 redistributed-routes** command.

| Variable | Value                                                                             |
|----------|-----------------------------------------------------------------------------------|
| vrf      | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids   | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                |

## Viewing a summary of BGP configurations

Display summarized information about BGP.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display summarized information about BGP:

```
show ip bgp summary [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

The following example shows partial output for the **show ip bgp summary** command.

```
Switch:1>show ip bgp summary vrf vrf1

*Variable Definitions*

The following table defines parameters for the **show ip bgp summary** command.

| Variable                              | Value                                   |
|---------------------------------------|-----------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by name.       |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRFs by ID number. |

*Job aid*

Use the data in the following table to understand the **show ip bgp summary** command output.

**Table 79: Variable definitions**

| Field          | Description                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP version    | Specifies the version of BGP that runs on the router.                                                                                                                                                                                                                                              |
| local-as       | Specifies the local autonomous system number.                                                                                                                                                                                                                                                      |
| Identifier     | Specifies the BGP identifier.                                                                                                                                                                                                                                                                      |
| Decision state | Specifies the BGP process state.                                                                                                                                                                                                                                                                   |
| NEIGHBOR       | Specifies the IP address of the remote peer.                                                                                                                                                                                                                                                       |
| RMTAS          | Specifies the AS number of the remote peer.                                                                                                                                                                                                                                                        |
| STATE          | Specifies the peer operating state: Idle, Accept, Connect, Open, Open-sent, and Established.                                                                                                                                                                                                       |
| HLDTM          | Specifies the negotiated hold time timer.                                                                                                                                                                                                                                                          |
| KPALV          | Specifies the keep alive timer.                                                                                                                                                                                                                                                                    |
| HLDCFG         | Specifies the configured hold time timer.                                                                                                                                                                                                                                                          |
| KPCFG          | Specifies the configured keep alive timer.                                                                                                                                                                                                                                                         |
| WGHT           | Specifies the weight value assigned to the peer.                                                                                                                                                                                                                                                   |
| CONRTY         | Specifies the retry timer.                                                                                                                                                                                                                                                                         |
| ADVINT         | Specifies the advertisement interval.                                                                                                                                                                                                                                                              |
| UPTime         | Specifies how long (in seconds) this peer has been in the established state, or how long since this peer was last in the established state. It is set to zero when a new peer is configured or when the router is booted. If the peer never reaches the established state, the value remains zero. |

## Viewing a summary of BGPv6 configurations

View a summary of BGP peering over IPv6 transport.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View BGPv6 summary:

```
show bgp ipv6 summary [vrf <WORD 1-16>] [vrfids <0-255>]
```

## Example

The following example shows partial output for the **show bgp ipv6 summary** command.

```
Switch:1>show bgp ipv6 summary vrf vrf1

=====
 BGP ipv6 Summary - VRF vrf1
=====

 BGP version - 4
 local-as - 200
 Identifier - 0.0.0.6
 Decision state - Idle
 The total number of routes is 1

BGPv6 NEIGHBOR INFO :

NEIGHBOR RMTAS STATE HLDTM KPALV HLDCFG KPCFG WGHT CONRTY ADVINT

```

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 summary** command.

| Variable | Value                                                                             |
|----------|-----------------------------------------------------------------------------------|
| vrf      | Specifies a VRF instance by name (the string length ranges from 1-16 characters). |
| vrfids   | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                |

## Viewing BGP routes

Display information about BGP routes.

### Note

BGP stores route information on the AVL tree and this command retrieves that information. Information in the AVL tree is not sorted. The information returned by this command will not be displayed in any particular order.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about BGP routes:

```
show ip bgp route [<prefix/len>] [community <enable|disable>] [ip
{A.B.C.D}] [longer-prefixes] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

The following table defines parameters for the **show ip bgp route** command.

| Variable                                | Value                                                                                                                                                  |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>community &lt;enable disable&gt;</i> | Enables or disables the display of community attributes.                                                                                               |
| <i>ip {A.B.C.D}</i>                     | Specifies an IP address.                                                                                                                               |
| <i>longer-prefixes</i>                  | Shows long prefixes. Longer-prefixes indicates the mask length from a specified prefix to 32 (for example, show from prefix a.b.c.d/len to a.b.c./32). |
| <i>&lt;prefix/len&gt;</i>               | Shows paths with this prefix. The prefix is the IP address and exact mask length (must be an integer value from 0-32).                                 |
| <i>vrf WORD&lt;1-16&gt;</i>             | Specifies a VRF instance by name.                                                                                                                      |
| <i>vrfids WORD&lt;0-512&gt;</i>         | Specifies a range of VRFs by ID number.                                                                                                                |

### Job Aid

Use the data in the following table to understand the **show ip bgp route** command output.

**Table 80: show ip bgp route**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NETWORK/MASK    | Specifies the path prefix address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PEER REM ADDR   | Specifies the remote peer address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| NEXTHOP ADDRESS | Specifies the BGP next hop address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ORG             | Specifies the source of a route: <ul style="list-style-type: none"> <li>• IGP – the route is interior to the originating AS that inserts this route into the BGP table (0 = IGP).</li> <li>• EGP – the route is learned through an Exterior Gateway Protocol (EGP) before it is inserted into the BGP table (1 = BGP).</li> <li>• Incomplete – the origin of the route is unknown or learned by some other means. For example, the router learns these routes through RIP, OSPF, or static routes (2 = Incomplete).</li> </ul> |
| LOCAL PREF      | Specifies the local preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Viewing BGPv6 routes

Display information about BGPv6 routes.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Privileged EXEC mode:  
enable
3. Display information about BGP routes:  
show bgp ipv6 route [<WORD 1-256> [longer-prefixes]] [community <enable|disable>] [ipv6 <WORD 1-256>] [vrf <WORD 1-16>] [vrfids <0-255>]

### Variable Definitions

The following table defines parameters for the **show bgp ipv6 route** command.

| Variable                   | Value                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [<WORD 1-256>]             | Specifies the IPv6 prefix and the prefix length (must be an integer value between 0 and 128).                                                                     |
| community <enable disable> | Enables or disables the display of community attributes.                                                                                                          |
| ipv6 <WORD 1-256>]         | Specifies an IPv6 address.                                                                                                                                        |
| longer-prefixes            | Shows long prefixes. The longer-prefixes indicate the mask length from any specified prefix to 128 (for example, show from prefix X::X:X/X/len to X::X:X/X/ 128). |
| vrf                        | Specifies a VRF instance by name (the string length ranges from 1-16 characters).                                                                                 |
| vrfids                     | Specifies a range of VRFs by ID number (the ID ranges from 0-255).                                                                                                |

## BGP configuration using EDM

Configure Border Gateway Protocol (BGP) to create an inter-domain routing system that guarantees loop-free routing information between autonomous systems.

For information about how to configure route policies, see [Configure a Route Policy](#) on page 2777.

### Configure BGP

Enable BGP so that BGP runs on the router. Configure general BGP parameters to define how BGP operates on the system.

#### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Generals** tab.

4. In AdminStatus, select **enable**.
5. Configure the local autonomous system (AS) ID.
6. In the **Aggregate** area, enable or disable route aggregation as required.
7. Configure the BGP options as required.
8. In the **DebugMask** area, select the check box for the type of information to show for BGP debugging purposes.
9. Configure BGP confederations as required.
10. Configure BGP route reflectors as required.
11. Click **Apply**.

### Generals Field Descriptions

Use the data in the following table to use the **Generals** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bgpVersion</b>  | Specifies the version of BGP that operates on the router.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                             |
| <b>Identifier</b>  | Specifies the BGP router ID number.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>AdminStatus</b> | Enables or disables BGP on the router. The default is disable. You cannot enable AdminStatus until you change the LocalAS value to a nonzero value.                                                                                                                                                                                                                                                                |
| <b>4ByteAs</b>     | Enables or disables 4-byte AS numbers. The default is disable.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                        |
| <b>LocalAs</b>     | Configures the local AS number in the range of 0–65535. You cannot change the LocalAs value if AdminStatus is enable.<br><br><b>Note:</b><br>If the inserted LocalAs is 0, then the LocalAs in that VRFcontext loses its significance and it becomes the LocalAs configured in GlobalRouter (the equivalence to CLI commands <b>ip bgp vrf-as 0</b> and <b>no ip bgp vrf-as</b> or <b>default ip bgp vrf-as</b> ). |
| <b>AsDot</b>       | Enables or disable the AS dot notation format for the 4-byte AS number. The default is disable.<br>The AS dot notation is easier to read and remember than the AS plain notation, but it can be difficult to convert from AS plain to AS dot. The IETF prefers the AS plain notation.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                 |
| <b>Aggregate</b>   | Enables or disables aggregation. The default is enable.                                                                                                                                                                                                                                                                                                                                                            |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultMetric</b>          | Configures the metric sent to BGP neighbors. The default metric determines the cost of a route a neighbor uses. Use this parameter in conjunction with the redistribute parameters so that BGP uses the same metric for all redistributed routes. The default is -1. The range is -1-2147483647.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DefaultLocalPreference</b> | Specifies the default local preference. The local preference indicates the preference that AS border routers assign to a chosen route when they advertise it to iBGP peers. The default is 100. The range is 0-2147483647.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>AlwaysCompareMed</b>       | Enables or disables the comparison of the multi-exit discriminator (MED) parameter for paths from neighbors in different autonomous systems. The system prefers a path with a lower MED over a path with a higher MED. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DeterministicMed</b>       | Enables or disables deterministic MED. Deterministic MED compares the MEDs after routes advertised by different peers in the same AS are chosen. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AutoPeerRestart</b>        | Enables or disables the process that automatically restarts a connection to a BGP neighbor. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AutoSummary</b>            | Enables or disables automatic summarization. If you enable this variable, BGP summarizes networks based on class limits (for example, Class A, B, or C networks). The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>NoMedPathIsWorst</b>       | Enables or disables NoMedPathIsWorst. If you enable this variable, BGP treats an update without a MED attribute as the worst path. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>BestPathMedConfed</b>      | Enables or disables the comparison of MED attributes within a confederation. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DebugMask</b>              | Displays the specified debug information for BGP global configurations. The default value is none. Other options are <ul style="list-style-type: none"> <li>• none disables all debug messages.</li> <li>• event enables the display of debug event messages.</li> <li>• state enables display of debug state transition messages.</li> <li>• update enables display of debug messages related to updates transmission and reception.</li> <li>• error enables the display of debug error messages.</li> <li>• trace enables the display of debug trace messages.</li> <li>• init enables the display of debug initialization messages.</li> <li>• all enables all debug messages.</li> <li>• packet enables the display of debug packet messages.</li> <li>• warning enables the display of debug warning messages.</li> <li>• filter enables the display of debug messages related to filtering.</li> </ul> |
| <b>IgnoreIllegalRouterId</b>  | Enables BGP to overlook an illegal router ID. For example, this variable enables the acceptance of a connection from a peer that sends an open message using a router ID of 0. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Name                             | Description                                                                                                                                                                                                                   |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Synchronization</b>           | Enables or disables the router to accept routes from BGP peers without waiting for an update from the IGP. The default is enable.                                                                                             |
| <b>MaxEqualcostRoutes</b>        | Configures the maximum number of equal-cost-paths that are available to a BGP router by limiting the number of equal-cost-paths the routing table can store. The default value is 1; the range is 1-8.                        |
| <b>IbgpReportImportRoute</b>     | Configures BGP to report imported routes to an interior BGP (iBGP) peer. This variable also enables or disables reporting of non-BGP imported routes to other iBGP neighbors. The default is enable.                          |
| <b>FlapDampEnable</b>            | Enables or disables route suppression for routes that go up and down (flap). The default is disable.                                                                                                                          |
| <b>QuickStart</b>                | Enables or disables the Quick Start feature, which forces the BGP speaker to begin establishing peers immediately, instead of waiting for the auto-restart timer to expire. The default is disable.                           |
| <b>TrapEnable</b>                | Enables or disables the BGP traps. The default is disable.                                                                                                                                                                    |
| <b>ConfederationASIdentifier</b> | Specifies a BGP confederation identifier in the range of 0-65535.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                                                |
| <b>ConfederationPeers</b>        | Lists adjoining autonomous systems that are part of the confederation in the format (5500,65535,0,10,.....).. This value can use 0-255 characters.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.               |
| <b>RouteReflectionEnable</b>     | Enables or disables the reflection of routes from iBGP neighbors. The default is enable.<br><br><b>Note:</b><br>This parameter applies only to VRF 0.                                                                         |
| <b>RouteReflectorClusterId</b>   | Configures a reflector cluster ID IP address. This variable applies only if you enable RouteReflectionEnable, and if multiple route reflectors are in a cluster.<br><br><b>Note:</b><br>This parameter applies only to VRF 0. |

| Name                                     | Description                                                                                                                                                                                                                                                                                              |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReflectorClientToClientReflection</b> | <p>Enables or disables route reflection between two route reflector clients. This variable applies only if RouteReflectionEnable is enable. The default is enable.</p> <p><b>Note:</b><br/>This parameter applies only to VRF 0.</p>                                                                     |
| <b>RouteRefresh</b>                      | <p>Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates it contains in its database that are eligible for the peer that issues the request.</p> <p><b>Note:</b><br/>This parameter only applies to VRF 0.</p> |

## Configure 4-byte AS numbers

Configure AS numbers using the 4-byte format and represent the numbers in octets.

### Before You Begin

- You cannot modify the global BGP configuration unless BGP is disabled.
- Make sure that you define AS numbers in policies the same way that you configure them for the router. The choices are asplain (regular expression) or asdot (dot notation). If you create policies using asplain and configure the switch with asdot, the match will not occur.

### About This Task

Use BGP 4-byte AS numbers to ensure the continuity of loop-free inter-domain routing information between autonomous systems and to control the flow of BGP updates as 2 byte AS numbers will deplete soon. AS Plain notation format is the default and the preferred form of representing 4-byte AS numbers over the AS dot notation format.

You have an option to configure AS dot notation format as well. With AS dot notation, analyzing and troubleshooting any issues encountered becomes difficult as it is incompatible with the regular expressions used by most of the network providers.

If you enable 4-byte AS numbers, or the dotted octet notation, for the Global Router (VRF0), the configuration is inherited by user-defined VRFs. You cannot enable 4-byte AS numbers on individual user-defined VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Generals** tab.
4. To change the AS number format, select **disable** for **AdminStatus**.
5. Select **Apply**.
6. In **4-byteAs**, select **enable**.

7. In **AsDot**, select **enable**.
8. In **LocalAs**, type the 4-byte AS number in octets.
9. In **AdminStatus**, select **enable**.
10. Select **Apply**.

#### **4-byte AS** Field Descriptions

Use the data in the following table to use the 4-byte AS related fields on the **Generals** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalAs</b> | Configures the local autonomous system (AS) number. You cannot change this field when AdminStatus is set to enable. This field sets a 2-byte local AS number in the range from 0 to 65535. To set a 4-byte local AS number, click enable in the 4ByteAs field and enter a number in the LocalAs field.<br>Attention: The switch does not support this parameter with BGP +. |
| <b>4byteAs</b> | Enables or disables the switch from using 4 byte numbers for autonomous systems.                                                                                                                                                                                                                                                                                            |
| <b>AsDot</b>   | Enables or disables representing AS numbers in octets. The default is disable so the switch uses the plain notation format. If you enable this field and the 4ByteAs field, enter the AS number in the LocalAs field.<br>Attention: The switch does not support this parameter with BGP +.                                                                                  |

## Configure Aggregate Routes

Configure aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

### Before You Begin

- Enable aggregate routes globally.
- You need the appropriate aggregate address and mask.
- If required, policies exist.
- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Configure the aggregate **Address** and **PrefixLen**.
6. Select **AsSetGenerate** or **SummaryOnly** as required.

7. Configure policies for the aggregate route.
8. Click **Insert**.

### **Aggregates** field descriptions

Use the data in the following table to use the **Aggregates** tab.

| Name                   | Description                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>         | Specifies the aggregate IP address.                                                                                                                                                                                   |
| <b>PrefixLen</b>       | Specifies the aggregate PrefixLen.                                                                                                                                                                                    |
| <b>AsSetGenerate</b>   | Enables or disables AS-set path information generation. The default is disable.                                                                                                                                       |
| <b>SummaryOnly</b>     | Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable. |
| <b>SuppressPolicy</b>  | Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.                                     |
| <b>AdvertisePolicy</b> | Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.                                                                        |
| <b>AttributePolicy</b> | Specifies the route policy (by name) used to determine aggregate route attributes.                                                                                                                                    |

## Configuring Aggregate IPv6 Routes

Configure IPv6 aggregate routes so that the router advertises a single route (aggregate route) that represents all destinations. Aggregate routes also reduce the size of routing tables.

To configure aggregate routes for IPv4, see [Configure Aggregate Routes](#) on page 478.

### **Before You Begin**

- Aggregate routes are enabled.
- You have determined the appropriate aggregate prefix and length.
- If required, policies exist.

### **Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Aggregates** tab.
4. Click **Insert**.
5. Specify the **aggregate Address** and **PrefixLen**
6. Configure **AsSetGenerate** and **SummaryOnly** as required.
7. Configure policies for the aggregate route.
8. Click **Insert**.

**Aggregates** field descriptions

Use the data in the following table to use the **Aggregates** tab.

| Name                   | Description                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>         | Specifies the aggregate address. The default is none.                                                                                                                                                                 |
| <b>PrefixLen</b>       | Specifies the length of the prefix (in bits).                                                                                                                                                                         |
| <b>AsSetGenerate</b>   | Enables or disables AS-set path information generation. The default is disable.                                                                                                                                       |
| <b>SummaryOnly</b>     | Enables or disables the summarization of routes in routing updates. Enable this parameter to create the aggregate route and suppress advertisements of more-specific routes to all neighbors. The default is disable. |
| <b>SuppressPolicy</b>  | Specifies the route policy (by name) used for the suppressed route list. Enable this parameter to create the aggregate route and suppress advertisements of the specified routes.                                     |
| <b>AdvertisePolicy</b> | Specifies the route policy (by name) used for route advertisements. The route policy selects the routes that create AS-set origin communities.                                                                        |
| <b>AttributePolicy</b> | Specifies the route policy (by name) used to determine aggregate route attributes.                                                                                                                                    |

## Configure Allowed Networks

Configure network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the network address, mask, and metric.
6. Click **Insert**.

**Network** field descriptions

Use the data in the following table to use the **Network** tab.

| Name                      | Description                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetworkAfAddr</b>      | Specifies the network prefix that BGP advertises.                                                                                                                                             |
| <b>NetworkAfPrefixLen</b> | Specifies the prefix length of the network address.                                                                                                                                           |
| <b>NetworkAfMetric</b>    | Specifies the metric to use when the system sends an update for the routes in the network table. The metric configures the MED for the routes advertised to eBGP peers. The range is 0–65535. |

## Configuring Allowed IPv6 Networks

Configure IPv6 network addresses to determine the network addresses that BGP advertises. The allowed addresses determine the BGP networks that originate from the switch.

To configure allowed IPv4 networks, see [Configure Allowed Networks](#) on page 480.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Network** tab.
4. Click **Insert**.
5. Configure the **network address, prefix length** and **metric**.
6. Click **Insert**.

**Network** field descriptions

Use the data in the following table to use the **Network** tab.

| Name                      | Description                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetworkAfAddr</b>      | Specifies the network prefix that BGP advertises. The default is none.                                                                                                                                  |
| <b>NetworkAfPrefixLen</b> | Specifies the network prefix length. The default is none.                                                                                                                                               |
| <b>NetworkAfMetric</b>    | Specifies the metric used when an update is sent for the routes in the network table. The metric configures the MED for the routes advertised to EBGP peers. The range is 0 to 65535. The default is 0. |

## Configure BGP Peers

Configure BGP peers to connect two routers to each other for the purpose of exchanging routing information. BGP peers exchange complete routing information only after they establish the peer connection.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **true**.  
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

### Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>              | Specifies the BGP peer instance.                                                                                                   |
| <b>LocalAddrType</b>         | Specifies the local IP address type of the entered BGP peer.                                                                       |
| <b>LocalAddr</b>             | Specifies the local IP address of the entered BGP peer.                                                                            |
| <b>RemoteAddrType</b>        | Specifies the remote IP address type of the entered BGP peer.                                                                      |
| <b>RemoteAddr</b>            | Specifies the remote IP address of the entered BGP peer.                                                                           |
| <b>AdminStatus</b>           | Specifies the administrative status of the BGP peer.                                                                               |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                |
| <b>PeerState</b>             | Specifies the BGP peer connection state.                                                                                           |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0–65535.                                                     |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                              |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGP peer that is more than one hop away from the local router. The default value is disable. |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                          |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                         |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                   |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                              |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                                                                                                                                                                                                                                                            |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845.                                                                                                                                                                                                                                    |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGP neighbor. The default value is 30 seconds and the range is 5–120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginate</b>      | When enabled, specifies that the current route originated from the BGP peer. This parameter enables or disables sending the default route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DefaultOriginatelpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0–65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0–2147483647. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DebugMask</b>             | Displays the specified debug information for the BGP peer. The default value is none. <ul style="list-style-type: none"> <li>• None disables all debug messages.</li> <li>• Event enables the display of debug event messages.</li> <li>• State enables display of debug state transition messages.</li> <li>• Update enables display of debug messages related to updates transmission and reception.</li> <li>• Error enables the display of debug error messages.</li> <li>• Trace enables the display of debug trace messages.</li> <li>• Init enables the display of debug initialization messages.</li> <li>• All enables all debug messages.</li> <li>• Packet enables the display of debug packet messages.</li> <li>• Warning enables the display of debug warning messages.</li> <li>• Filter enables the display of debug messages related to filtering.</li> </ul> |
| <b>SendCommunity</b>         | Enables or disables sending the community attribute of the update message to the specified peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Vpnv4Address</b>          | Specifies the vpnv4 routes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>IpvpnLiteCap</b>          | Enable or disable IP VPN-lite capability on the BGP neighbor peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Ipv6Cap</b>               | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SooAddress</b>            | Specifies the site-of-origin (SoO) address of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SooAsNumber</b>           | Specifies the site-of-origin (SoO) Autonomous System (AS) number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SooAssignedNum</b>        | Specifies the site-of-origin (SoO) assigned number of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SooType</b>               | Specifies the site-of-origin (SoO) type of the BGP peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>RouteRefresh</b>          | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                                                                                       | Description                                                                                                      |
|--------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>AsOverride</b><br><b>Note:</b><br>This field does not appear on all hardware platforms. | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.    |
| <b>AllowAsIn</b><br><b>Note:</b><br>This field does not appear on all hardware platforms.  | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                       |
| <b>Ipv6RoutePolicyIn</b>                                                                   | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                   |
| <b>Ipv6RoutePolicyOut</b>                                                                  | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>                                                                       | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>                                                                           | Enables Bidirectional Forwarding Detection (BFD) for this BGP peer.                                              |

## Configure BGPv6 Peers

Configure BGPv6 peers to connect two routers to each other for the purpose of exchanging routing information. BGPv6 peers exchange complete routing information only after they establish the peer connection.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **BGP+**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. Configure the peer, as required.
6. Select **Insert**.
7. In the **Enable** column, double-click the value, and then select **enable**.  
By default, new peer configuration parameters are disabled.
8. Select **Apply**.
9. To modify a peer configuration, double-click the value, and then select a new value.

**Peers** Field Descriptions

Use the data in the following table to use the **Peers** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteAddr</b>            | Specifies the remote IPv6 address of the entered BGP+ peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>GroupName</b>             | Specifies the peer group name to which the peer belongs (optional).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>PeerState</b>             | Specifies the BGPv6 peer connection state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer or peer-group in the range 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Enable</b>                | Controls whether the peer connection is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>EbgpMultiHop</b>          | Enables or disables a connection to a BGPv6 peer that is more than one hop away from the local router. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>RoutePolicyIn</b>         | Specifies the policy (by name) that applies to all network routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>RoutePolicyOut</b>        | Specifies the policy (by name) that applies to all outgoing route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RemovePrivateAs</b>       | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>UpdateSourceInterface</b> | Specifies the source IP address to use when the switch sends eBGP packets to this peer or peer group.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ConnectRetryInterval</b>  | Specifies the time interval, in seconds, for the connect retry timer. The suggested value for this timer is 120 seconds. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>HoldTimeConfigured</b>    | Specifies the time interval, in seconds, for the hold time for this BGP speaker with this peer. This value is in an open message sent to this peer by this BGP speaker. To determine the hold time with the peer, the switch compares this value with the HoldTime value in an open message received from the peer. The HoldTime must be at least three seconds. If the value is zero, the hold time does not establish with the peer. The suggested value for this timer is 180 seconds. The range is 0 to 65535.                                         |
| <b>KeepAliveConfigured</b>   | Specifies the time interval, in seconds, for the KeepAlive timer configured for this BGP speaker with this peer. KeepAliveConfigured determines the keep alive message frequency relative to HoldTimeConfigured; KeepAlive indicates the actual time interval for the keep alive messages. The maximum value for this timer is one-third of HoldTimeConfigured. If KeepAliveConfigured is zero, no periodic keep alive messages are sent to the peer after the peers establish a BGP connection. Configure a value of 60 seconds. The range is 0 to 21845. |
| <b>MD5Authentication</b>     | Enables and disables MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between each transmission of an advertisement from a BGPv6 neighbor. The default value is 30 seconds and the range is 5 to 120 seconds. The route advertisement interval feature is implemented using the time stamp that indicates when each route is advertised. The time stamp is marked to each route so that the route advertisement interval is compared to the time stamp and BGP is then able to make a decision about whether the route advertisement can be sent or should be delayed when a better route is received. This feature does not work for a withdraw route because the route entry is already removed when the processing route advertisement is sent and the time stamp marked in the route entry cannot be obtained. |
| <b>DefaultOriginatelpv6</b>  | When enabled, specifies that the current IPv6 route originated from the BGP peer. This parameter enables or disables sending the default IPv6 route information to the specified neighbor or peer. The default value is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Weight</b>                | Specifies the peer or peer group weight, or the priority of updates the system can receive from this BGP peer. The default value is 100 and the range is 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MaxPrefix</b>             | Configures a limit on the number of routes accepted from a neighbor. The default value is 12000 routes and the range is 0 to 2147483647.<br>A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>NextHopSelf</b>           | Specifies that the next-hop attribute in an iBGP update is the address of the local router or the router that generates the iBGP update. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>RouteReflectorClient</b>  | Specifies that this peer is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SoftReconfigurationIn</b> | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is disable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>RouteRefresh</b>                                                                            | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AsOverride</b><br><br><b>Note:</b><br>This field does not appear on all hardware platforms. | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>AllowAsIn</b><br><br><b>Note:</b><br>This field does not appear on all hardware platforms.  | Specifies the number of AS-in allowed for the BGP peer. The range is 1-10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Ipv6RoutePolicyIn</b>                                                                       | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Ipv6RoutePolicyOut</b>                                                                      | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Ipv6MaxPrefix</b>                                                                           | Configures a limit on the number of IPv6 routes accepted from a neighbor. A value of 0 means no limit exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>BfdEnable</b>                                                                               | Enables Bidirectional Forwarding Detection (BFD) for this peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Configure Peer Groups

Configure or edit peer groups to create update policies for neighbors in the same group.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Peer Groups** tab.

You can modify an existing parameter by double-clicking the value.

4. Select **Insert**.
5. Configure the peer group as required.
6. Select **Insert**.

### *Peer Groups* field descriptions

Use the data in the following table to use the **Peer Groups** tab.

| Name                         | Description                                                                                                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | Specifies the index of this peer group.                                                                                                                        |
| <b>GroupName</b>             | Specifies the peer group to which this neighbor belongs (optional).                                                                                            |
| <b>Enable</b>                | Enables or disables the peer group.                                                                                                                            |
| <b>RemoteAs</b>              | Configures a remote AS number for the peer-group in the range 0-65535.                                                                                         |
| <b>DefaultOriginate</b>      | When enabled, the BGP speaker (the local router) sends the default route 0.0.0.0 to a group of neighbors for use as a default route. The default is disabled.  |
| <b>DefaultOriginateIpv6</b>  | When enabled, the BGP speaker (the local router) sends the default route to a group of neighbors for use as a default route. The default is disabled.          |
| <b>EbgpMultiHop</b>          | When enabled, the switch accepts and attempts BGP connections to external peers that reside on networks that do not directly connect. The default is disabled. |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, that elapses between BGP routing updates. The default value is 30 seconds.                                            |
| <b>KeepAlive</b>             | Specifies the time interval, in seconds, between sent BGP keep alive messages to remote peers. The default value is 60.                                        |
| <b>HoldTime</b>              | Configures the hold time for the group of peers in seconds. Use a value that is three times the value of the KeepAlive time. The default value is 180.         |
| <b>Weight</b>                | Assigns an absolute weight to a BGP network. The default value is 100.                                                                                         |

| Name                               | Description                                                                                                                                                                                                                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxPrefix</b>                   | Limits the number of routes accepted from this group of neighbors. A value of zero indicates no limit. The default value is 12,000 routes.                                                                                                                                                                   |
| <b>NextHopSelf</b>                 | Specifies that the switch must set the NextHop attribute to the local router address before sending updates to remote peers.                                                                                                                                                                                 |
| <b>RoutePolicyIn</b>               | Specifies the route policy that applies to all networks learned from this group of peers.                                                                                                                                                                                                                    |
| <b>RoutePolicyOut</b>              | Specifies the route policy that applies to all outgoing updates to this group of peers.                                                                                                                                                                                                                      |
| <b>RouteReflectorClient</b>        | Specifies that this peer group is a route reflector client.<br><br><b>Note:</b><br>This parameter only applies to VRF 0.                                                                                                                                                                                     |
| <b>SoftReconfigurationIn</b>       | When enabled, the router relearns routes from the specified neighbor or group of neighbors without restarting the connection after the policy changes in the inbound direction. The default value is enable.<br>Enabling SoftReconfigurationIn stores all BGP routes in local memory (even non-best routes). |
| <b>MD5Authentication</b>           | Enables and disables MD5 authentication. The default is disable.                                                                                                                                                                                                                                             |
| <b>RemovePrivateAs</b>             | Strips (when enabled) private AS numbers when the switch sends an update. The default is enable.                                                                                                                                                                                                             |
| <b>SendCommunity</b>               | Enables or disables sending the community attribute of the update message to the specified peer group. The default value is disable.                                                                                                                                                                         |
| <b>AfUpdateSourceInterfaceType</b> | Specifies the interface type.                                                                                                                                                                                                                                                                                |
| <b>AfUpdateSourceInterface</b>     | Specifies the IP address used for circuitless IP (CLIP) for this peer group.                                                                                                                                                                                                                                 |
| <b>Vpvn4Address</b>                | Enables BGP address families for IPv4 (BGP) and L3 VPN (MP-BGP) support. Enable this parameter for VPN/VRF Lite routes.                                                                                                                                                                                      |
| <b>IpvpnLiteCap</b>                | Specifies (when enabled) that IP VPN Lite capability can be enabled or disabled on the BGP neighbor peer. The default is disable.                                                                                                                                                                            |
| <b>RouteRefresh</b>                | Enables or disables route refresh. If enabled, a route refresh request received by a BGP speaker causes the speaker to resend all route updates in the database that are eligible for the peer that issues the request. This parameter only applies to VRF 0.                                                |
| <b>AsOverride</b>                  | Specifies that the AS Override parameter can be enabled or disabled for the BGP peer group. The default is disable.                                                                                                                                                                                          |
| <b>AllowedAsIn</b>                 | Specifies the number of AS-in allowed for the BGP peer group. The range is 1-10.                                                                                                                                                                                                                             |
| <b>IPv6Cap</b>                     | Enable or disable the IPv6 capability on the BGP neighbor peer. The default value is disable.                                                                                                                                                                                                                |
| <b>IPv6RoutePolicyIn</b>           | Specifies the policy (by name) that applies to all network IPv6 routes learned from this peer.                                                                                                                                                                                                               |

| Name                      | Description                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Ipv6RoutePolicyOut</b> | Specifies the policy (by name) that applies to all outgoing IPv6 route updates.                                  |
| <b>Ipv6MaxPrefix</b>      | Configures a limit on the number of IPv6 routes accepted from a neighbor.<br>A value of 0 means no limit exists. |
| <b>BfdEnable</b>          | Enables Bidirectional Forwarding Detection (BFD) for the BGP peer group.                                         |

## Viewing IPv6 Community Attributes

View IPv6 community attributes for specific routes to utilize the update message fields to communicate information between BGP speakers. The Path Attribute values allow you to specify the prefixes that the BGP session can exchanged, or which of the multiple paths of a specified prefix to use.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Bgp Route Summary** tab.
4. Select a route for which you want to view the route summary information.
5. Click the **Route Comm Attr** option on the menu.

The **BGP Path Attributes** tab opens with the BGP IPv6 community attribute information.

### **BGP Path Attributes** field descriptions

Use the data in the following table to use the **Community List** tab.

| Name                | Description                                                                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Origin</b>       | Specifies the ultimate origin of the path information.                                                                                                                                                             |
| <b>NextHopAddr</b>  | Specifies the address of the border router that is used to access the destination network. This address is the nexthop address received in the UPDATE packet associated with this prefix.                          |
| <b>Med</b>          | This metric is used to discriminate between multiple exit points to an adjacent autonomous system. When the MED value is absent but has a calculated default value, this object will contain the calculated value. |
| <b>LocalPref</b>    | Specifies the value used during route decision process in the BGP protocol. Applicable to BGP only.                                                                                                                |
| <b>AggregatorAS</b> | Specifies the AS number of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.                              |

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AggregatorAddr</b> | Specifies the IP address of the last BGP4 speaker that performed route aggregation. If the AGGREGATOR path attribute is absent, this object will not be present in the conceptual row.                                                                                                                                                                                                                            |
| <b>String</b>         | This is a string representing the autonomous system path to the network which was received from the peer which advertised it. The format of the string is implementation-dependent, and is designed for operator readability.<br><br><b>Note:</b><br>SnmpAdminString is only capable of representing a maximum of 255 characters. This may lead to the string being truncated in the presence of a large AS Path. |

## Display Dampened Routes Information

Display dampened path information to see which routes are suppressed.

### Before You Begin

- Change the VRF instance as required to view BGP information about a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Enable dampened routes.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **BGP**.
3. Select the **Dampened Routes** tab.

### *Dampened Routes* field descriptions

Use the data in the following table to use the **Dampened Routes** tab.

| Name                   | Description                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddrPrefix</b>    | Specifies the IP address prefix in the NLRI field. This variable is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Bits beyond the length specified by IpAddrPrefixLen are set to zero. |
| <b>IpAddrPrefixLen</b> | Specifies the length, in bits, of the IP address prefix in the NLRI field.                                                                                                                                                  |
| <b>Peer</b>            | Specifies the IP address of the peer from which the router learns the path information.                                                                                                                                     |
| <b>FlapPenalty</b>     | Specifies the penalty based on number of route flaps.                                                                                                                                                                       |
| <b>FlapCount</b>       | Specifies the number of times a route flapped (went down and up) since the last time the penalty was reset to zero.                                                                                                         |
| <b>RouteDampened</b>   | Indicates whether this route is suppressed or announced.                                                                                                                                                                    |
| <b>ReuseTime</b>       | Specifies the system-configured time for route reuse.                                                                                                                                                                       |

## Configure Redistribution to BGP

Configure redistribute entries for BGP to announce routes of a certain source type to BGP, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

### Before You Begin

- If required, configure a route policy.
- When you configure BGP on a specific VRF instance, the VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.
- Before you redistribute DvR host routes to BGP, ensure that you disable BGP aggregation and BGP auto-summarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGP correctly, and are not summarized.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

### **Redistribute** field descriptions

Use the data in the following table to use the **Redistribute** tab.

| Name               | Description                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>    | Specifies the destination VRF instance (read-only).                                                                                                                                |
| <b>Protocol</b>    | Specifies the protocols that receive the redistributed routes.                                                                                                                     |
| <b>SrcVrfId</b>    | Specifies the source VRF instance (read-only).                                                                                                                                     |
| <b>RouteSource</b> | Specifies the source protocol for the route redistribution entry.                                                                                                                  |
| <b>Enable</b>      | Enables (or disables) a BGP redistribute entry for a specified source type.                                                                                                        |
| <b>RoutePolicy</b> | Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGP domain.                                                 |
| <b>Metric</b>      | Configures the metric for the redistributed route. The value can be a range between 0–65535. The default value is 0. Use a value that is consistent with the destination protocol. |

## Configure Redistribution to BGPv6

Configure redistribute entries for BGPv6 to announce routes of a certain source type to BGPv6, for example, DvR, direct, static, Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). If

you do not configure a route policy, then the switch uses the default action based on metric, metric type, and subnet. Use a route policy to perform detailed redistribution.

### Before You Begin

- If required, configure a route policy.
- Before you redistribute DvR host routes to BGPv6, ensure that you disable BGPv6 aggregation and BGPv6 autosummarization of networks. Disabling these settings ensures that all the DvR host routes are advertised into BGPv6 correctly, and are not summarized.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **BGP+**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source protocol.
6. If required, choose a route policy.
7. Configure the metric to apply to redistributed routes.
8. Enable the redistribution instance.
9. Click **Insert**.

### **Redistribute** field descriptions

Use the data in the following table to use the **Redistribute** tab.

| Name                                                                                         | Description                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Protocol</b><br><br><b>Note:</b><br>This field does not appear on all hardware platforms. | Specifies the protocols that receive the redistributed routes.                                                                                                                                                                                                                                        |
| <b>SrcVrfId</b>                                                                              | Specifies the source VRF instance (read-only).                                                                                                                                                                                                                                                        |
| <b>RouteSource</b>                                                                           | Specifies the source protocol for the route redistribution entry.                                                                                                                                                                                                                                     |
| <b>Enable</b>                                                                                | Enables (or disables) a BGPv6 redistribute entry for a specified source type.                                                                                                                                                                                                                         |
| <b>RoutePolicy</b>                                                                           | Configures the route policy to use for the detailed redistribution of external routes from a specified source into the BGPv6 domain.                                                                                                                                                                  |
| <b>Metric</b>                                                                                | Configures the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.                                                                                                                                                              |
| <b>MetricType</b>                                                                            | Specifies the metric type.<br>Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone.<br>The default is type2. |

## View BGP+ or BGPv6 Route Summary Information

You can display current IPv6 BGP+ route information.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.  
Use the **IP** folder in the navigation pane to view the IPv4 route summary.
2. Click **BGP+**.
3. Click the **Bgp Route Summary** tab to view the BGP route summary information

### *Bgp Route Summary field descriptions*

Use the data in the following table to use the **Bgp Route Summary** tab.

| Name              | Description                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Prefix</b>     | Specifies the IP address prefix in the Network Layer Reachability Information (NLRI) field. This is an IP address that contains the prefix with a length specified by IpAddrPrefixLen. Any bits beyond the length specified by IpAddrPrefixLen are set to zero. |
| <b>PrefixLen</b>  | Specifies the length, in bits, of the IP address prefix in the NLRI field.                                                                                                                                                                                      |
| <b>LocalAddr</b>  | The local address of this entry's BGP connection.                                                                                                                                                                                                               |
| <b>RemoteAddr</b> | Specifies the IP address of the peer from which path information was learned.                                                                                                                                                                                   |

## Viewing BGP Route Summary

Display BGP route summary.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **BGP**.
3. Click the **Bgp Route Summary** tab.

### *Bgp Route Summary field descriptions*

Use the data in the following table to use the Bgp Route Summary tab.

| Name              | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>Prefix</b>     | Configures the IP address of the route.                                |
| <b>PrefixLen</b>  | Specifies the IP address and the mask length (the length can be 0–32). |
| <b>LocalAddr</b>  | Specifies the local IP address of the entered BGP route.               |
| <b>RemoteAddr</b> | Specifies the remote IP address of the entered BGP route.              |

## Configure an AS Path List

Configure an AS path list to restrict the routing information a router learns or advertises to and from a neighbor. The AS path list acts as a filter that matches AS paths.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **As Path List** tab.
4. Click **Insert**.
5. Enter the appropriate information for your configuration.
6. Click **Insert**.

### *As Path List* field descriptions

Use the data in the following table to use the **As Path List** tab.

| Name                       | Description                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                  | Specifies the AS path list.                                                                                                                   |
| <b>MemberId</b>            | Specifies the AS path access list member ID.                                                                                                  |
| <b>Mode</b>                | Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route). |
| <b>AsRegularExpression</b> | Specifies the expression to use for the AS path.                                                                                              |

## Configure a Community Access List

Configure community lists to specify permitted routes by using their BGP community. This list acts as a filter that matches communities or AS numbers.

### Before You Begin

- Change the VRF instance as required to configure BGP on a specific VRF instance. The VRF must have an RP trigger of BGP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Policy**.
3. Click the **Community List** tab.
4. Click **Insert**.
5. Configure the list as required.
6. Click **Insert**.

**Community List** field descriptions

Use the data in the following table to use the **Community List** tab.

| Name             | Description                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>        | Specifies the community list. The range is 0-1024.                                                                                            |
| <b>MemberId</b>  | Specifies the community list member ID. The range is 0-65535.                                                                                 |
| <b>Mode</b>      | Specifies the action to take if the system selects a policy for a specific route. Select permit (allow the route) or deny (ignore the route). |
| <b>Community</b> | Specifies the community access list community string.                                                                                         |

## BGP Configuration Examples

This chapter shows configuration examples for BGP deployment options.

### IPv6 Tunnel Configurations for BGP+

You must configure an IPv6 tunnel and static routes at BGP+ peers when you use BGP+.

When BGP+ peers advertise route information, they use Update messages to advertise route information. And, when route information is encapsulated in Update messages, BGP+ peers convert their own IPv4 peer addresses to IPv4-mapped IPv6 addresses and insert them into the next-hop field in the Update message.

When the BGP+ software module receives Update messages, it adds route information to the IPv6 Routing Manager (RTM). These RTM routes contain next-hop addresses from the BGP peer that the route was learned from. The next-hop addresses are represented as IPv4-mapped IPv6 addresses.

But, because the IPv6 RTM cannot correlate the IPv4-mapped IPv6 address to a specific outgoing interface, you must create a manually-configured static route to make the link between the BGP peer and the IPv6 tunnel interface so that traffic can reach networks advertised by the peer.

Following is one way to express a static route in an IPv6-configured tunnel for BGP+:

```
ipv6 route 0:0:0:0:0:ffff:192.0.2.0/24 cost 1 tunnel 10
```

Configure the IPv6 tunnel endpoint and the BGP peer to reside on the same switch.

If the IPv6 tunnel endpoint and the BGP peer must reside on different switches you can terminate the tunnel on a different switch, but you must consider the following:

- Because the IPv6 tunnel endpoint does not reside on the same switch as the BGP peer, the BGP device cannot use the tunnel as the outgoing interface. That is, to reach the IPv6-configured tunnel endpoint, if the BGP peer resides on a different switch from the IPv6 tunnel endpoint, the next-hop for the manually-configured IPv4-mapped IPv6 static route is the native IPv6 interface next-hop address.

- The node where the tunnel terminates must contain all of the information needed to route the packets between the remote IPv6 network clouds.

**Note**

In order for the tunnel endpoint switch to be aware of all of the necessary IPv6 routes, you may need to redistribute the BGP routes into OSPFv3.

*IPv4-mapped IPv6 address*

IPv4-mapped IPv6 addresses are IPv4 addresses that the system has mapped into the IPv6 address space.

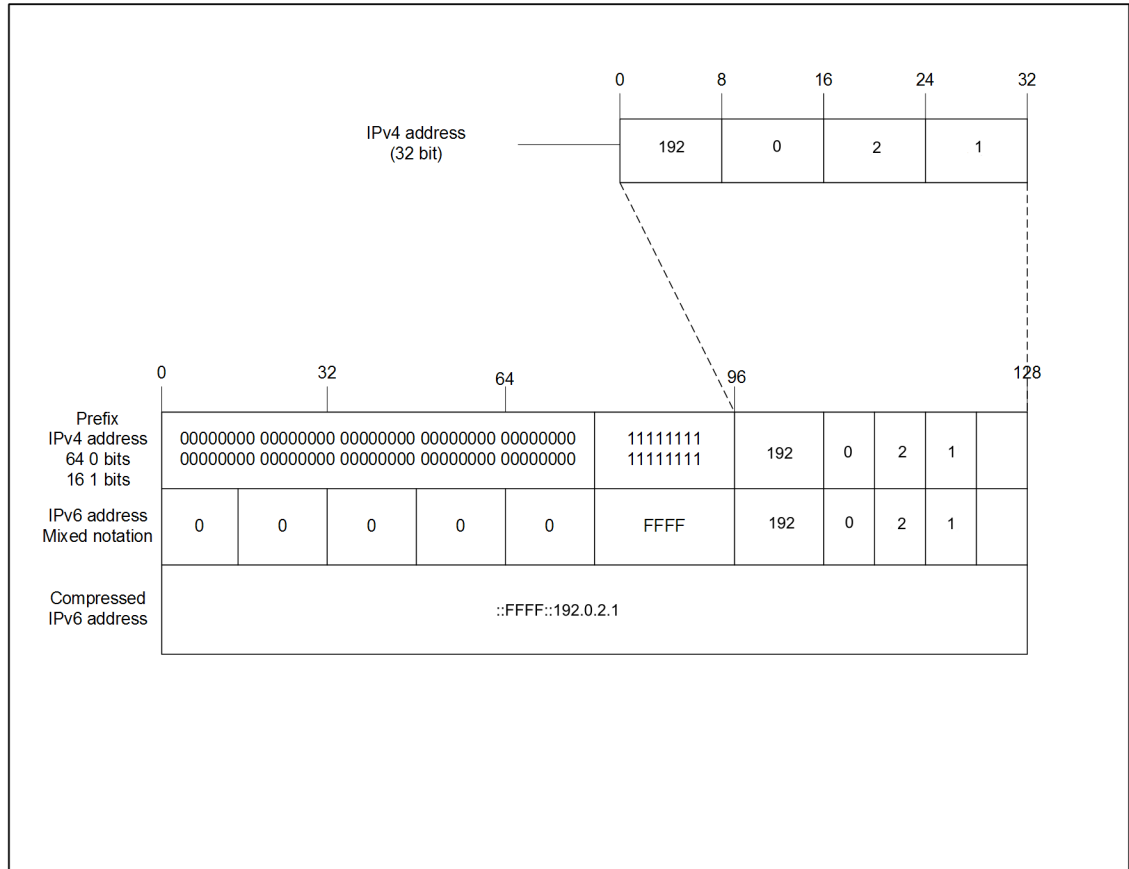

The system uses these IPv4-mapped IPv6 addresses for devices that are only IPv4-capable.

These IPv4-mapped address have the first 80 bits set to zeros, followed by the next 16 bits set to ones, and the last 32 bits have IPv4 addresses.

When converted to an IPv4-mapped IPv6 address, an IPv4 device address of 192.0.2.1 would be represented as one of the following:

- 0:0:0:0:FFFF:192.0.2.1
- ::FFFF:192.0.2.1

The following figure illustrates the components in an IPv4-mapped IPv6 address.

**Figure 31: IPv4-mapped IPv6 address components**

*eBGP+ peers between two switches with IPv6 Tunneling*

The following figure shows a sample network that contains eBGP+ peers using IPv6 tunneling.

**Figure 32: eBGP+ peers with IPv6 tunneling**

The configuration in the figure, *eBGP+ peers with IPv6 tunneling*, assumes that the BGP peer IP address is the next hop.

When you configure the static route for the BGP+ tunnel, you must designate the BGP peer IP address as the next hop in most cases.

You can configure multiple static routes, using the same tunnel, but you must ensure reachability when you create the static routes.

**R1 configuration**

```
interface GigabitEthernet 3/2
brouter port 3/2 vlan 2090 subnet 192.0.2.1/255.255.255.0 mac-offset 2
exit
BGP CONFIGURATION - GlobalRouter
#

router bgp as-dot enable
router bgp 65000 enable
router bgp
neighbor "192.0.2.2"
neighbor 192.0.2.2 remote-as 65001
neighbor 192.0.2.2 address-family ipv6
neighbor 192.0.2.2 enable
exit
IPV6 CONFIGURATION
#

ipv6 forwarding

IPV6 TUNNEL CONFIGURATION
#

ipv6 tunnel 10 source 192.0.2.1 address 2001:DB8::/32 destination 2001.
1.2

#
IPV6 STATIC ROUTE CONFIGURATION
#

ipv6 route 0:0:0:0:0:ffff:192.0.2.1 cost 1 tunnel 10
#
```

**R2 configuration**

```
interface GigabitEthernet 4/32
brouter port 4/32 vlan 2090 subnet 192.0.2.2/255.255.255.0 mac-offset
2
exit
BGP CONFIGURATION - GlobalRouter
#

router bgp as-dot enable
router bgp 65000 enable
router bgp
neighbor "192.0.2.1"
neighbor 192.0.2.1 remote-as 65000
neighbor 192.0.2.1 address-family ipv6
neighbor 192.0.2.1 enable
exit
IPV6 CONFIGURATION

192.0.2.1

#
IPV6 STATIC ROUTE CONFIGURATION
```

```
#
ipv6 route 0:0:0:0:0:ffff:192.0.2.1 cost 1 tunnel 10
#
```

### *iBGP+ peership on CLIP between two switches with IPv6 Tunneling*

The following figure shows a sample network that contains iBGP+ peers using IPv6 tunneling.

**Figure 33: iBGP+ peers on CLIP interfaces with IPv6 tunneling**

You must enable OSPF on the interface and globally as well.

If you cannot enable OSPF, you must configure static routes to provide reachability to the BGP+ peer.

The static route must point to the next hop for the routes to be installed in the IPv6 RTM.

The next hop must be the BGP peer IP address.

The IPv4 interfaces do not need to connect directly, but the routing table on each switch must include the IPv4 interface of the other switch.

iBGP between the CLIP interfaces needs to run OSPF as a routing protocol so that the BGP neighbor can remain reachable.

eBGP connections cannot use a CLIP interface as an end point.

#### **R1 configuration**

```
interface GigabitEthernet 3/2
brouter port 3/2 vlan 2090 subnet 192.0.2.1/255.255.255.0 mac-offset
2
exit
OSPF CONFIGURATION - GlobalRouter
#

router ospf enable

OSPF PORT CONFIGURATION
#

## Native IPv6 eBGP peership between two switches on VRF

The following figure shows a sample network that contains native IPv6 eBGP peers on VRFs.

**Figure 34: Native IPv6 eBGP peers on VRFs**

Configure the local AS first on GRT (and it is inherited by all VRFs), and then enable BGP on GRT/VRF.

You must configure the **address-family ipv6** option for IPv6 peers, otherwise, peer-ship is formed, but no routing updates between them will take place.

You must configure the **ebgp-multihop** option for the given eBGP peer that is not on one of local subnets (remote peers), otherwise, peer-ship will not be formed.

#### Note

The switch does not accept any configuration command for BGP in router-vrf configuration mode unless a BGP instance associated to the VRF context is created. You can use `ip bgp` command in router-vrf configuration mode to create a BGP instance on VRF.

## iBGP over User-created VRFs Configuration Example

This section shows examples of configured internal Border Gateway Protocol (iBGP) IPv4 and IPv6 peers over user-created Virtual Routing and Forwarding (VRF) instances.

### Note

The Autonomous System (AS) number configured on the global VRF is inherited by all user-created VRFs, however, you can override the AS number for a specific user-created VRF. For more information, see [Configure an AS Number for a Non-default VRF](#) on page 454.

### IPv4 iBGP Peers Configuration

# Chassis Operations

---

[Chassis operations fundamentals on page 515](#)

[Chassis operations configuration using the CLI on page 542](#)

[Chassis operations configuration using EDM on page 569](#)

The following sections provide information for chassis operations such as hardware and software compatibility.

## Chassis operations fundamentals

---

This section provides conceptual information for chassis operations such as hardware and software compatibility and power management. Read this section before you configure the chassis operations.

### Management Port

#### Note

The Management Router for management port configuration is only supported on VSP 8600 Series. For all other platforms, see [Segmented Management](#) on page 49.

The management port is a 10/100/1000 Mbps Ethernet port that you can use for an Out-of-Band (OOB) management connection to the switch. To remotely access the switch using the management port, you must configure an IP address for the OOB management port.

#### *Management Router VRF*

A separate VRF called Management Router (MgmtRouter) is reserved for the OAM (mgmt) port. The configured IP subnet must be globally unique because the management protocols, for example, SNMP, Telnet, and FTP, can go through in-band or out-of-band ports. The VRF ID for the Management Router is 512.

The switch never switches or routes transit packets between the Management Router VRF port and the Global Router VRF, or between the Management Router VRF and other VRF ports.

The switch honors the VRF of the ingress packet; however, in no circumstance does the switch enable routing between the Management VRF and Global Router VRF. The switch does not support the

configuration if you have an out-of-band management network with access to the same networks present in the GRT routing table.

**Note**

IPv6 is not supported on MgmtRouter.

*Non-virtualized client management applications*

Do not define a default route in the Management Router VRF. A route originating from the switch and used for non-virtualized client management applications, such as Telnet, Secure Shell (SSH), and FTP will always match a default route defined in the Management Router VRF.

If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides. When you specify a static route in the Management Router VRF, it enables the client management applications originating from the switch to perform out-of-band management without affecting in-band management. This enables in-band management applications to operate in the Global Router VRF.

Non-virtualized client management applications originating from the switch, such as Telnet, SSH, and FTP, follow the behavior listed below:

1. Look at the Management Router VRF route table
2. If no route is found, the applications will proceed to look in the Global Router VRF table

Non-virtualized client management applications include:

- DNS
- FTP client with the **copy** command
- NTP
- rlogin
- RADIUS authentication and accounting
- SSH
- SNMP clients in the form of traps
- SYSLOG
- TACACS+
- Telnet
- TFTP client

For management applications that originate outside the switch, the initial incoming packets establish a VRF context that limits the return path to the same VRF context.

*Virtualized management applications*

Virtualized management applications, such as ping and traceroute, operate using the specified VRF context. To operate ping or traceroute you must specify the desired VRF context. If not specified, ping

defaults to the Global Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF.

**Note**

IPv6 is not supported on MgmtRouter.

```
Switch:1(config)#ping 192.0.2.1 vrf MgmtRouter
192.0.2.1 is alive
```

Ping test for IPv6:

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

Traceroute test for IPv4:

```
Switch:1#traceroute 192.0.2.1 vrf MgmtRouter
```

Traceroute test for IPv6:

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

## Entity MIB - Physical Table

The Entity MIB - Physical Table assists in the discovery of functional components on the switch. The Entity MIB - Physical Table supports a physical interface table that includes information about the chassis, power supply, fan, I/O cards, console, and management port.

Some hardware platforms support removable interface modules while others offer a fixed configuration. The names used for these modules can vary depending on the hardware platform.

The following table identifies the entity index range for the switch components.

| Component                   | Entity index range |
|-----------------------------|--------------------|
| Chassis                     | 1                  |
| Power supply slot           | 3 to 8             |
| Fan tray and fan slot       | 9 to 16            |
| I/O slot                    | 17 to 30           |
| SF Slot                     | 31 to 36           |
| I/O card or module          | 37 to 50           |
| SF Card                     | 51 to 56           |
| Console port                | 57                 |
| Console port 2              | 58                 |
| Management port             | 64                 |
| Management port 2           | 65                 |
| Power supply                | 68 to 73           |
| Fan tray                    | 74 to 81           |
| Fan module                  | 82 to 105          |
| Port                        | 192 to 1023        |
| Pluggable Module and Sensor | 19201 to 102314    |

For more information about Entity MIB - Physical Table, see [View Physical Entities](#) on page 573.

## High Availability-CPU (HA-CPU)

|                                                                  | VSP 4450 Series | Not Applicable     |
|                                                                  | VSP 4900 Series | Not Applicable     |
|                                                                  | VSP 7200 Series | Not Applicable     |
|                                                                  | VSP 7400 Series | Not Applicable     |
|                                                                  | VSP 8200 Series | Not Applicable     |
|                                                                  | VSP 8400 Series | Not Applicable     |
|                                                                  | VSP 8600 Series | VSP 8600 6.3       |
|                                                                  | XA1400 Series   | Not Applicable     |

The High Availability-CPU (HA-CPU) framework supports redundancy at the hardware and application levels. The CP software runs on an Input/Output control (IOC) module in both slots 1 and 2, and the HA-CPU feature activates two CPUs simultaneously in master or standby role. These CPUs exchange topology data so that, if a failure occurs, one of the CPUs can take over the operations of the other. You can configure the CPUs to operate in either HA mode or non-HA mode. In HA mode, the two CPUs

synchronize configuration, protocol states, and tables. In non-HA mode, the two CPUs do not synchronize.

The default mode is HA disabled. To activate HA-CPU mode, use the **boot config flags ha-cpu** command. To deactivate HA-CPU mode, use the **no boot config flags ha-cpu** command.

If you switch from one mode to the other, the standby CP restarts in the specified HA mode (hot standby) or non-HA mode (warm standby). This does not impact the Input/Output process and there is no traffic loss on the physical slot of the card.

If a failure occurs and the chassis is configured for either HA mode (hot standby) or non-HA mode (warm standby), the CP software restarts and runs as standby. The system generates a trap to indicate the change from hot-standby mode to warm-standby mode.

#### Note

- The HA-CPU feature provides node-level redundancy. Hot standby mode is not supported with fabric functionality, which provides network-level redundancy.
- If your switch is in hot standby mode (ha-cpu boot flag is set to true), you must disable boot config flag to configure SPBM or vIST on the switch. When the switch is in warm standby mode (ha-cpu boot flag is set to false), you must disable SPBM and vIST to move to hot standby mode.
- When you try to switch-over from warm standby mode to hot standby mode using EDM, the system displays the following error message when you enable the boot config flag for ha-cpu:

```
Hot-standby mode cannot be enabled while SPB/VIST features are still
configured.
```

#### HA mode

In HA mode, also called hot standby, the platform synchronizes the master (primary) CPU information to the standby (secondary) CPU. The platform adds any configuration changes or application table changes to the master CPU by using bulk synchronization or incremental synchronization. Once synchronization is complete, both the CPUs contain the same configuration and application tables information. Application in HA mode support either full HA implementation or partial HA implementation. In full HA implementation, both the configuration and runtime application data tables exist on the master CPU and the standby CPU.

If the master CPU fails, the standby CPU takes over the master responsibility quickly and you do not see an impact on your network. Also, the IOC and SF modules as well as the full HA applications continue to operate and the full HA applications run consistency checks to verify the tables.

The following applications support full HA mode:

| Feature                                | Supported |
|----------------------------------------|-----------|
| Layer 1                                |           |
| Port configuration parameters          | Yes       |
| Layer 2                                |           |
| Media Access Control security (MACsec) | Yes       |

| Feature                                                         | Supported                    |
|-----------------------------------------------------------------|------------------------------|
| Multiple Spanning Tree Protocol parameters                      | Yes                          |
| Quality of Service (QoS) parameters                             | Yes                          |
| Rapid Spanning Tree Protocol parameters                         | Yes                          |
| VLAN parameters                                                 | Yes                          |
| Layer 3                                                         |                              |
| ARP entries                                                     | Yes                          |
| Border Gateway Protocol (BGP)                                   | Partial (configuration only) |
| Dynamic Host Configuration Protocol (DHCP) Relay                | Partial (configuration only) |
| Internet Group Management Protocol (IGMP)                       | Yes                          |
| IPv6                                                            | Partial (configuration only) |
| Access Control Lists                                            | Yes                          |
| Open Shortest Path First (OSPF)                                 | Yes                          |
| Protocol Independent Multicast (PIM)                            | Partial (configuration only) |
| Prefix lists and route policies                                 | Yes                          |
| Routing Information Protocol                                    | Yes                          |
| Router Discovery                                                | Yes                          |
| Static and default routes                                       | Yes                          |
| Virtual IP (VLANs)                                              | Yes                          |
| Virtual Router Redundancy Protocol                              | Yes                          |
| Transport Layer                                                 |                              |
| Network Load Balancing (NLB)                                    | Yes                          |
| Remote Access Dial-In User Services (RADIUS)                    | Yes                          |
| Terminal Access Controller Access-Control System plus (TACACS+) | Partial (configuration only) |
| UDP forwarding                                                  | Yes                          |

### *Partial HA*

A few applications in HA mode have partial HA implementation, where the system synchronizes user configuration data (including interfaces, IPv6 addresses and static routes) from the master CPU to the standby CPU. However, for partial HA implementation, the platform does not synchronize dynamic data learned by protocols. After failure, those applications restart and rebuild their tables, which causes an interruption to traffic that is dependent on a protocol or application with partial HA support.

The following applications support Partial HA:

- Layer 3
  - Border Gateway Protocol (BGP)
  - Dynamic Host Configuration Protocol (DHCP) Relay
  - IPv6

- Protocol Independent Multicast-Sparse Mode (PIM-SM)
- Protocol Independent Multicast-Source Specific Mode (PIM-SSM)
- Transport Layer
  - Terminal Access Controller Access Control System plus (TACACS+)

### *Non-HA mode*

In non-HA mode, also called warm standby, the platform does not synchronize the configuration between the master CPU and the standby CPU. When failover happens, the standby CPU switches to master role, and all the IOCs (except the new master CPU) are restarted. The new master CPU loads the configuration when all the cards are ready. These operations cause an interruption to traffic on all ports on the chassis.

#### Note

- When there is a switch-over to warm standby mode, only the RWA access level user can log in to the new master CPU console screen.

The remaining users can log in to the CPU console screen only after the master CP module reloads the configuration and displays the new login prompt.

- When the platform switches from standby CPU to master CPU in warm standby mode, the platform always uses the previously-saved primary configuration file to boot the chassis on the switch.
- The runtime config file must be present on the flash drive during the boot-up of both the master CPU and the standby CPU. If the config file that is used by the master CPU for booting is not available on the standby CPU, the standby CPU loads the default config file. You can run the **save config** command to synchronize the configuration settings or copy the boot config file from the master CPU to the standby CPU. The standby CPU must be rebooted to load the desired config file.

When the master CPU is physically removed in warm-standby mode, all cards are rebooted and the standby CPU switches to the master role and loads the saved configuration. If the old master CPU is physically not plugged in during this time, the respective slot configuration is not loaded to memory even though the configuration exists in the config file. When the old master CPU is re-inserted later, the system considers this as a first time insertion and loads the default configuration on the inserted CP card. This is expected behavior in warm-standby mode. To load the configuration for the re-inserted standby CPU, ensure that the **savetostandby** boot-flag is set to true after re-inserting the removed CPU, and run the CLI command **source <config-file>** on the active CPU.

### *HA-CPU support in Simplified vIST*

HA-CPU in Simplified vIST configurations enables synchronization of data for Layer 2 and Layer 3 applications between the master CPU and standby CPU, to provide hot standby capability.

## Power Manager

**Table 83: Power Manager product support**

| Feature                                                          | Product         | Release introduced |
|------------------------------------------------------------------|-----------------|--------------------|
| For configuration details, see <a href="#">VOSS User Guide</a> . |                 |                    |
| Power Management                                                 | 5520 Series     | VOSS 8.2.5         |
|                                                                  | VSP 4450 Series | Not Supported      |
|                                                                  | VSP 4900 Series | Not Supported      |
|                                                                  | VSP 7200 Series | Not Supported      |
|                                                                  | VSP 7400 Series | Not Supported      |
|                                                                  | VSP 8200 Series | Not Supported      |
|                                                                  | VSP 8400 Series | VOSS 4.2           |
|                                                                  | VSP 8600 Series | VSP 8600 4.5       |
|                                                                  | XA1400 Series   | Not Supported      |

Power Manager identifies the available power in the chassis (called the power budget), and determines if enough power is available to operate the installed components. Power Manager also gives you control over which module slots to supply power to and enables you to prioritize the slots that should shut down first if there isn't enough power available.

If the power usage exceeds the power budget, the system powers off the module with the lowest priority. After a power over-usage occurs, the system uses a Simple Network Management Protocol (SNMP) trap to send a message to the network administrator configured to receive the trap.

The system compares the total chassis power consumed against the total chassis power available, and verifies that if one power supply fails, enough power still remains to operate the chassis and components. If enough power is available to keep all modules powered on in the case of a single failed power supply, then the system is considered to have redundant power.

### Note

In a redundant power supply configuration, that is, a +1 configuration where the system has one or more power supplies above the actual requirement, the power management logic automatically employs load-sharing across all active power supplies. This load-sharing ensures that the switch draws power equally from all available power supplies to support the system requirements in a fully active model.

If the system does not have redundant power, then the system sends an SNMP trap to the receiver and a message to CLI to inform you that the device no longer operates in redundant power mode.

For information on configuring Power Manager, see the following:

- If using the CLI, see [Configuring power on module slots](#) on page 561 and [Configuring Slot Priority](#) on page 562.
- If using EDM, see [Configure Slot Priority](#) on page 607.

## Software Lock-up Detection

The software lock-up detect feature monitors processes on the CPU to limit situations where the device stops functioning because of a software process issue. Monitored issues include

- software that enters a dead-lock state
- a software process that enters an infinite loop

The software lock-up detect feature monitors processes to ensure that the software functions within expected time limit.

The CPU logs detail about suspended tasks in the log file.

## Jumbo frames

Jumbo packets and large packets are particularly useful in server and storage over Ethernet applications. If the payload to header relation increases in a packet, the bandwidth can be used more efficiently. For this reason, increasing Ethernet frame size is a logical option. The switch supports Ethernet frames as large as 9600 bytes, compared to the standard 1518 bytes, to transmit large amounts of data efficiently and minimize the task load on a server CPU.

### *Tagged VLAN support*

A port with VLAN tagging activated can send tagged frames. If you plan to use Jumbo frames in a VLAN, ensure that you configure the ports in the VLAN to accept Jumbo frames and that the server or hosts in the VLAN do not send frames that exceed 9600 bytes. For more information about how to configure VLANs, see [VLAN Configuration](#) on page 3805.

## Auto-Negotiation

**Table 84: Auto-Negotiation product support**

| Feature                                                          | Product         | Release introduced                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| For configuration details, see <a href="#">VOSS User Guide</a> . |                 |                                                                                                                                                                                                                                                                                                                                                                                                   |
| Auto-Negotiation                                                 | 5520 Series     | VOSS 8.2.5<br>Switch models: <ul style="list-style-type: none"> <li>5520-24T, 5520-24W, 5520-48T, 5520-48W, 5520-12MW-36W</li> <li>5520-48SE QSFP28/QSFP+ ports, and all fixed fiber ports, at 1 Gbps only</li> </ul> <p><b>Note:</b><br/>QSFP28 ports are only available if you disable Advanced Feature Bandwidth Reservation.</p> 5520-VIM-4XE at 1 Gbps only and 5520-VIM-4YE at 25 Gbps only |
|                                                                  | VSP 4450 Series | VSP 4000 4.0                                                                                                                                                                                                                                                                                                                                                                                      |

The Auto-Negotiation feature enables the devices to switch between the various operational modes in an ordered fashion and enables you to select a specific operational mode. The Auto-Negotiation feature also provides a parallel detection (called autosensing) function to recognize compatible devices, even if they do not support Auto-Negotiation and helps the device sense the link speed only; not the duplex mode.

You can use the **show interfaces gigabitEthernet 11-config** command to see the Auto-Negotiation operational state on a port. The operational state uses the configuration and transceiver type present in the port. If you enable Auto-Negotiation for the port but the transceiver type does not support Auto-Negotiation, the operational state is disabled (false).

#### Default Auto-Negotiation Behavior

The default Auto-Negotiation behavior depends on the switch model, port type, and transceiver type. The following table provides the default combinations.

**Table 85: 5520 Series default behavior**

| Model                                               | Port type                  | Transceiver type | Auto-Negotiation                                                                | FEC |
|-----------------------------------------------------|----------------------------|------------------|---------------------------------------------------------------------------------|-----|

*10/100/1000 Mbps Port Considerations*

Auto-Negotiation lets devices share a link, and automatically configures both devices so that they take maximum advantage of their abilities. Auto-Negotiation uses a modified 10BASE-T link integrity test pulse sequence to determine device ability.

**Important**

Product-specific considerations for Auto-Negotiation include:

- If Auto-Negotiation is disabled, the following hardware does not support half-duplex:
  - 8424GT ESM
  - 8424XT ESM
  - VSP 7254XTQ

Configure Auto-Negotiation as shown in the following table, where A and B are two Ethernet devices.

**Table 87: Recommended Auto-Negotiation Configuration on 10/100/1000BASE-TX ports**

| Port on A                | Port on B                | Remarks                                                  | Recommendations                                                                                             |
|--------------------------|--------------------------|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Auto-Negotiation enabled | Auto-Negotiation enabled | Ports negotiate on highest supported mode on both sides. | Use this configuration if both ports support Auto-Negotiation mode.                                         |
| Full-duplex              | Full-duplex              | Both sides require the same mode.                        | Use this configuration if you require full-duplex, but the configuration does not support Auto-Negotiation. |

Auto-Negotiation cannot detect the identities of neighbors and cannot shut down misconnected ports. Upper-layer protocols perform these functions.

#### Note

The 10 GigabitEthernet (GbE) fiber-based I/O module ports can operate at either 1 Gigabit per second (Gbps) or 10 Gbps, depending upon the capabilities of the optical transceiver that you install.

This presents an ambiguity with respect to the Auto-Negotiation settings of the port, while 1 GbE ports require Auto-Negotiation; Auto-Negotiation is not defined and is non-existent for 10 GbE ports.

For a 10-GbE fiber-based I/O module, you can swap between 1 GbE and 10 GbE operation by simply swapping transceivers. To help with the swap, you can configure Auto-Negotiation when you install a 10 GbE transceiver, even though Auto-Negotiation is not defined for 10 GbE.

You can do this in anticipation of a port changeover from 10 GbE to 1 GbE. In this manner, you can pre-configure a port in 1 GbE mode while the 10 GbE transceiver is still installed. The port is ready to go upon the changeover to the 1 GbE transceiver.

You can use a saved configuration file with Auto-Negotiation enabled, to boot a system with either 10 GbE or 1 GbE transceivers installed. If you install a 1 GbE transceiver, the system applies Auto-Negotiation. If you install a 10 GbE transceiver, the system does not remove the Auto-Negotiation settings from the configuration, but the system simply ignores the configuration because Auto-Negotiation settings are irrelevant to a 10 GbE transceiver. The system preserves the saved configuration for Auto-Negotiation when re-saved no matter which speed of transceiver you install.

### 25 GbE Port Considerations

The 25 GbE ports typically support 25 Gbps, 10 Gbps, and 1 Gbps operational speeds. Auto-Negotiation support varies depending on the pluggable type and speed.

The following table provides a summary of Auto-Negotiation support for 25 Gbps ports.

**Table 88: 25 Gbps Port Auto-Negotiation**

| Transceiver Type    | Auto-Negotiation                                                                                            |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| 25 Gbps DAC         | Supported<br><br><b>Note:</b><br>Exception: VIM5-2Y and VIM5-4Y do not support Auto-Negotiation at 25 Gbps. |
| 25 Gbps SR, LR, AOC | Not Supported                                                                                               |
| 10 Gbps             | Not Supported                                                                                               |
| 1 Gbps              | <b>Note:</b><br>Not Supported for VSP 7400-48Y.                                                             |

Forward Error Correction (FEC) is a negotiated port attribute for 25 GbE connections that support Auto-Negotiation. For more information, see [Forward Error Correction](#) on page 536.

### 40 GbE Port Considerations

Auto-Negotiation must be enabled in 40 GbE ports when using 40GbCR4 (copper Direct Attached Cables - DACs) pluggable modules as Clause 73 of the 40 GbE standard lists it as mandatory. Though the links may come up in 40 GbE ports even without Auto-Negotiation, the best practice is to always enable Auto-Negotiation. Otherwise, there might be link instability or FCS errors.

### 100 GbE Port Considerations

Ensure that you enable Auto-Negotiation for ports with 100GbCR4 modules plugged in.

Although Auto-Negotiation is mandatory as per the 100GbCR4 standard, and this is the default software configuration, you can disable Auto-Negotiation to connect with older systems that do not support it. The system does not support FEC on 100GbCR4 links with Auto-Negotiation disabled.

For more information about FEC, see [Forward Error Correction](#) on page 536.

## Auto-Negotiation Advertisements

Auto-Negotiation advertisements use Custom Auto-Negotiation Advertisement (CANA) to control the speed and duplex settings that the interface modules advertise during Auto-Negotiation sessions between Ethernet devices. Modules can only establish links using these advertised settings, rather than at the highest common supported operating mode and data rate.

Use CANA to provide smooth migration from 10 Mbps to 10000 Mbps on host and server connections. Using Auto-Negotiation only, the switch always uses the fastest possible data rates. In limited-uplink-bandwidth scenarios, CANA provides control over negotiated access speeds, and improves control over traffic load patterns.

Use the **auto-negotiation-advertisements** command to configure CANA.

To use CANA, you must enable Auto-Negotiation.

#### Important

If a port belongs to a MultiLink Trunking (MLT) group and you configure CANA on the port (that is, you configure an advertisement other than the default), you must apply the same configuration to all other ports of the MLT group if they support CANA.

The following platforms (switches and removable modules) support full duplex and half duplex modes for CANA:

| Platform        | Full duplex | Half duplex                                                                                     |
|-----------------|-------------|-------------------------------------------------------------------------------------------------|
| 5520 Series     | Yes         | Supported on 5520-24T, 5520-24W, 5520-48T, 5520-48W and ports 1/1/ - 1/36 on 5520-12MW-36Wonly. |
| VSP 4450 Series | Yes         | Yes                                                                                             |
| VSP 4900 Series | Yes         | Supported at 100Mbps on VSP4900-48P and first 12 ports of VSP4900-12MXU-12XEonly.               |

| Platform                                                          | Full duplex | Half duplex                             |
|-------------------------------------------------------------------|-------------|-----------------------------------------|
| VSP 7200 Series                                                   | Yes         | No                                      |
| VSP 7400 Series                                                   | yes         | No                                      |
| VSP 8200 Series                                                   | Yes         | No                                      |
| VSP 8400 Series<br>(includes 8424XT, 8418XTQ, and<br>8424GT ESMs) | Yes         | No                                      |
| VSP 8600 Series                                                   | Yes         | No                                      |
| XA1400 Series                                                     | Yes         | Yes<br>Supported on ports 1/1-1/4 only. |

|                                                                  | VSP 4450 Series | VSP 4000 4.0       |
|                                                                  | VSP 4900 Series | VOSS 8.1           |
|                                                                  | VSP 7200 Series | VOSS 4.2.1         |
|                                                                  | VSP 7400 Series | VOSS 8.0           |
|                                                                  | VSP 8200 Series | VSP 8200 4.0       |
|                                                                  | VSP 8400 Series | VOSS 4.2           |
|                                                                  | VSP 8600 Series | VSP 8600 4.5       |
|                                                                  | XA1400 Series   | VOSS 8.0.50        |

The switch supports an auto-discovery protocol known as the SynOptics Network Management Protocol (SONMP). SONMP allows a network management station (NMS) to formulate a map that shows the interconnections between Layer 2 devices in a network. SONMP is also called Topology Discovery Protocol (TDP).

All devices in a network that are SONMP-enabled send hello packets to their immediate neighbors, that is, to interconnecting Layer 2 devices. A hello packet advertises the existence of the sending device and provides basic information about the device, such as the IP address and MAC address. The hello packets allow each device to construct a topology table of its immediate neighbors. A network management station periodically polls devices in its network for these topology tables, and then uses the data to formulate a topology map.

If you disable SONMP, the system stops transmitting and acknowledging SONMP hello packets. In addition, the system removes all entries in the topology table except its own entry. If you enable SONMP, the system transmits a hello packet every 12 seconds. The default status is enabled.

### *SONMP for the Segmented Management Instance*

SONMP and LLDP both advertise the same topology IP address for the Segmented Management Instance management interface. SONMP supports IPv4 advertisement only. If all three management interfaces are configured, the advertised default topology IP priority is management CLIP, then management VLAN, then management OOB. You can change the default topology IP using CLI or EDM. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

## Channelization

**Table 90: Channelization product support**

| Feature                                                          | Product         | Release introduced          |
|------------------------------------------------------------------|-----------------|-----------------------------|
| For configuration details, see <a href="#">VOSS User Guide</a> . |                 |                             |
| Channelization of 40 Gbps ports                                  | 5520 Series     | VOSS 8.2.5                  |
|                                                                  | VSP 4450 Series | Not Applicable              |
|                                                                  | VSP 4900 Series | VOSS 8.1                    |
|                                                                  | VSP 7200 Series | VOSS 4.2.1                  |
|                                                                  | VSP 7400 Series | VOSS 8.0<br>VSP 7432CQ only |
|                                                                  | VSP 8200 Series | VOSS 4.2                    |
|                                                                  | VSP 8400 Series | VOSS 4.2                    |
|                                                                  | VSP 8600 Series | VSP 8600 6.1                |
|                                                                  | XA1400 Series   | Not Applicable              |
| Channelization of 100 Gbps ports                                 | 5520 Series     | Not Applicable              |
|                                                                  | VSP 4450 Series | Not Applicable              |
|                                                                  | VSP 4900 Series | Not Applicable              |
|                                                                  | VSP 7200 Series | Not Applicable              |
|                                                                  | VSP 7400 Series | VOSS 8.0<br>VSP 7432CQ only |
|                                                                  | VSP 8200 Series | Not Applicable              |
|                                                                  | VSP 8400 Series | Not Supported               |
|                                                                  | VSP 8600 Series | VSP 8600 6.2                |
|                                                                  | XA1400 Series   | Not Applicable              |

Use the channelization feature to configure a single port to operate as four individual ports. Channelization can apply to the following port speeds:

- 40 Gbps (Quad Small Form-factor Pluggable) (QSFP+) — when channelized, operates as four 10 Gbps ports

- 100 Gbps (QSFP28) — when channelized, operates as four 25 Gbps ports

**Note**

In cases where the hardware supports it, you can insert a 40 Gbps QSFP+ transceiver in a 100 Gbps port, and use the 100 Gbps port as a 40 Gbps port. If you enable channelization on a 100 Gbps port and the switch detects a 40 Gbps QSFP+ transceiver in the port, the port operates as four individual 10 Gbps ports.

If the switch detects a 100 Gbps QSFP28 transceiver and you enable channelization, the port operates as four 25 Gbps ports.

To know if you can use a 100 Gbps port as a 40 Gbps port and support the channelization of that port, see the applicable hardware documentation.

You can use breakout direct attach cables (DAC) or transceivers with fiber breakout cables to connect the channelized ports to other servers, storage, and switches.

By default, the ports are not channelized, which means that the ports operate as one single port at the fully supported speed. You can enable or disable channelization on a port.

For the number of ports on the switch that support channelization, see the applicable hardware documentation.

If the product supports channelization and you enable or disable channelization on a port, the port QoS configuration resets to default values. For information about configuring QoS values, see [Quality of Service](#) on page 2522.

**Note**

When you use channelized ports in an Split Multi-Link Trunking (SMLT) configuration, the channelized ports do not appear properly when you show MLT information for the remote port member if the remote switch runs a release that does not support channelization.

When a port is channelized, use only break out cables (copper or active optical DAC) in it. Using other cables in either a channelized port or a non-channelized port results in mismatched link status between link partners, which can lead to network issues.

### *Feature Interaction with Channelization*

Software features operate on channelized ports. When an interface is dechannelized, the interface cleans up all the channels.

If a feature operates on channel 1/1/1 and 1/1/2, and the circuit is dechannelized, the 1/1/1 configuration is saved and the commands are configured on 1/1. The configuration on 1/1/2 is deleted.

## Forward Error Correction

**Table 91: Forward Error Correction product support**

| Feature                                                          | Product         | Release introduced              |

|                                                                  | VSP 7400 Series | VOSS 8.0                        |
|                                                                  | VSP 8200 Series | Not Supported                   |
|                                                                  | VSP 8400 Series | VOSS 8.0                        |
|                                                                  | VSP 8600 Series | VSP 8600 6.2                    |
|                                                                  | XA1400 Series   | Not Applicable                  |

Forward Error Correction (FEC) is a method of obtaining error control in data transmission over an unreliable or noisy channel in which the source (transmitter) encodes the data in a redundant way by using an error correcting code (ECC). This redundancy enables a destination (receiver) to detect a limited number of errors and correct them without requiring a re-transmission.

FEC is useful where re-transmitting data is either expensive or impossible, for example, when transmitting to multiple receivers in multicast. However, although FEC provides more error control, it introduces a latency in data transmission.

### *FEC Configuration Options*

You typically configure FEC on a port. The supported options are:

- cl91 (Clause 91 RS-FEC)
- cl108 (Clause 108 RS-FEC):
- cl74 (Clause 74 Firecode R-FEC):
- auto:

FEC is not supported on:

- Out-of-band (OOB) management ports.

- 100 GbE ports that are changed to 40 GbE ports by dynamically swapping 100 Gb modules with 40 Gb modules. FEC does not support the 40 Gbps speed.

**Important**

- On ports that support FEC configuration, ensure that you configure the same option at both end-points. Otherwise, the link does not come up.
- You must enable FEC to achieve proper functionality when using interconnects such as the 25Gb SR, 25 Gb SR-lite, 25 Gb ESR optics or the 25 Gb AOC and 25 Gb DAC.
- FEC is not required on 100 Gb or 25 Gb long-range optics because these optics do error checking internally.

*Clause 91 RS-FEC*

This option supports both the 25 Gbps and 100 Gbps speeds. You can configure this option on ports with either the 100GbSR4 or 100GbCR4 modules plugged in, or on 100 GbE channelized ports operating at 25Gbps speed.

**Note**

Ensure that you enable Auto-Negotiation for ports with the 100GbCR4 modules plugged in; it is mandatory.

*Clause 108 RS-FEC*

This option also supports both the 25 Gbps and 100 Gbps speeds. It is similar to Clause 91 but provides extra latency.

*Clause 74 Firecode R-FEC*

This option supports only the 25 Gbps speed and is used in applications that require reduced latency.

*Auto*

This option automatically configures FEC based on port speed and pluggable module type.

- For 25 Gbps speeds, FEC CL108 is enabled for all transceiver types.
- For 100Gbps speeds:
  - FEC is disabled for 100GbE LR4 and ER4 transceivers.
  - FEC CL91 is enabled for all other transceiver types (for example, 100GbE SR4, CR4, AOC, CWDM4, SWDM4).

*FEC and Auto-Negotiation*

FEC is a negotiated port attribute for 25 Gb and 100 Gb connections that support Auto-Negotiation. If you enable Auto-Negotiation on a port for a supported transceiver type, the switch uses the configured FEC value in the negotiation advertisement. Peers can advertise different values, which means the resulting FEC operational state can be different than the one advertised.

The following table lists the 25 Gb end-point advertisements and the resulting FEC operational state:

**Table 92: 25 Gb end-point advertisements**

| Peer A | Peer B | Result |
|--------|--------|--------|
| CL108  | CL108  | CL108  |
| CL74   | CL74   | CL74   |
| No FEC | No FEC | No FEC |
| No FEC | CL108  | CL108  |
| No FEC | CL74   | CL74   |
| CL74   | CL108  | CL108  |

The following table lists the 100 Gb end-point advertisements and the resulting FEC operational state:

**Table 93: 100 Gb end-point advertisements**

| Peer A | Peer B | Result                                                                                                                                   |
|--------|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| CL91   | CL91   | CL91                                                                                                                                     |
| No FEC | No FEC | CL91<br><b>Note:</b><br>Even when both peers advertise no FEC, negotiation results in clause 91 FEC per IEEE standard mandatory setting. |
| No FEC | CL91   | CL91                                                                                                                                     |

You can use the **show interfaces gigabitEthernet config** command to see the FEC operational state for a port.

For additional details about support, see [Default Auto-Negotiation Behavior](#) on page 526.

## IEEE 802.3X Pause Frame Transmit

**Table 94: IEEE 802.3X Pause Frame Transmit product support**

| Feature                                                          | Product         | Release introduced |

|                                                                  | VSP 4450 Series | VOSS 6.0           |
|                                                                  | VSP 4900 Series | VOSS 8.1           |
|                                                                  | VSP 7200 Series | VOSS 6.0           |
|                                                                  | VSP 7400 Series | VOSS 8.0           |
|                                                                  | VSP 8200 Series | VOSS 6.0           |
|                                                                  | VSP 8400 Series | VOSS 6.0           |
|                                                                  | VSP 8600 Series | Not Supported      |
|                                                                  | XA1400 Series   | VOSS 8.1.50        |

The switch uses MAC pause frames to provide congestion relief on full-duplex interfaces.

### *Overview*

When congestion occurs on a port, the system can send or receive pause frames, also known as flow control, to temporarily pause the packet flow. The system uses flow control if the rate at which one or more ports receives or sends packets is greater than the rate the switch can process or accept the packets.

The switch can generate pause frames to tell the sending device to stop sending additional packets for a specified time period. After the time period expires, the sending device can resume sending packets. During the specified time period, if the switch determines the congestion is reduced, it can send pause frames to the sending device to instruct it to begin sending packets immediately.

### *Flow control mode and pause frames*

If you enable flow control mode, the switch drops packets on ingress when congestion occurs. If the switch is not in flow control mode, it drops packets at egress when congestion occurs.

Configure an interface to send pause frames when congestion occurs to alleviate packet drops due to flow control mode.

### *Auto-Negotiation*

Interfaces that support auto-negotiation advertise and exchange their flow control capability to agree on a pause frame configuration. IEEE 802.3 annex 28b defines the auto-negotiation ability fields and the

pause resolution. The switch advertises only two capabilities. The following table shows the software bit settings based on the flow control configuration.

**Note**

Not all interfaces support Auto-Negotiation. For more information, see your hardware documentation.

**Table 95: Advertised abilities**

| Interface configuration | Pause | ASM | Capability advertised                     |
|-------------------------|-------|-----|-------------------------------------------|
| Flow control enabled    | 1     | 0   | Symmetric pause                           |
| Flow control disabled   | 1     | 1   | Both Symmetric pause and asymmetric pause |

The following tables identifies the pause resolution.

**Table 96: Pause resolution**

| Local device pause | Local device ASM | Peer device pause | Peer device ASM | Local device resolution                       | Peer device resolution                        |
|--------------------|------------------|-------------------|-----------------|-----------------------------------------------|-----------------------------------------------|
| 0                  | 0                | Do not care       | Do not care     | Disable pause transmit and receive.           | Disable pause transmit and receive.           |
| 0                  | 1                | 0                 | Do not care     | Disable pause transmit and receive.           | Disable pause transmit and receive.           |

The following list identifies the type of interfaces that support auto-negotiated flow control:

- 10 Mbps/100 Mbps/1 Gbps copper
- 100 Mbps/1 Gbps/10 Gbps copper
- 1 Gbps fiber (in both SFP and SFP+ ports)

## Auto MDIX

Automatic medium-dependent interface crossover (Auto-MDIX) automatically detects the need for a straight-through or crossover cable connection and configures the connection appropriately. This removes the need for crossover cables to interconnect switches and ensures either type of cable can be used. The speed and duplex setting of an interface must be set to Auto for Auto-MDIX to operate correctly.

Auto MDIX is supported on all platforms with fixed copper ports. All fixed copper ports are supported.

## IOC Module Preconfiguration

**Table 97: IOC Module Preconfiguration**

| Feature                                                          | Product         | Release introduced |
|------------------------------------------------------------------|-----------------|--------------------|
| For configuration details, see <a href="#">VOSS User Guide</a> . |                 |                    |
| IOC Module Preconfiguration                                      | 5520 Series     | Not Applicable     |
|                                                                  | VSP 4450 Series | Not Applicable     |
|                                                                  | VSP 4900 Series | Not Applicable     |
|                                                                  | VSP 4900 Series | Not Applicable     |
|                                                                  | VSP 7200 Series | Not Applicable     |
|                                                                  | VSP 7400 Series | Not Applicable     |
|                                                                  | VSP 8200 Series | Not Applicable     |
|                                                                  | VSP 8600 Series | VSP 8600 8.0       |
|                                                                  | XA1400 Series   | Not Applicable     |

Using IOC Module Pre-Configuration, you can configure a slot for an IOC Module before you insert the module in the chassis. By specifying the slot and module type, all configuration at the slot or port level become available for that slot. You can issue configuration commands for a specific slot before you insert an IOC Module in that slot.

When you insert the IOC Module that matches the pre-configured module type in the specified slot, all configuration related to that slot is applied, and pre-configuration loads on the IOC Module automatically. However, if the module type of the inserted IOC Module does not match the module type of the IOC Module Pre-Configuration, then the IOC module functionality depends on the following card lock configurations:

- If the card lock option is enabled, the inserted IOC Module is rejected and does not boot up. Only modules that are of same type as the IOC Module Pre-Configuration type for the slot are able to boot up on that slot. The output of the **show-sys-info** command displays the operational status of the inserted module as `down-Mismatch`.
- If the card lock option is disabled, existing configuration is removed on that slot and a new IOC Module is accepted and boots up with default configuration.

When you remove an IOC Module from the chassis, all configuration on that slot is still available because the module was automatically pre-configured on that slot. You can view the configuration for the module by using the **show sys-info card** command. You can also change the configuration for an

IOC Module that has been removed from the chassis. When you save the configuration, the configuration for all slots is saved regardless of which modules are plugged into the chassis.

### Hotswapping IOC Modules

If a preconfigured IOC Module is replaced with a model that does not match the preconfigured IOC Module type and the card lock is enabled, then the IOC Module does not boot up. Either a module of the same type as the preconfigured IOC Module must be reinserted in the slot or the pre-configured IOC Module type must be removed from the configuration.

#### Important

Removing the preconfigured IOC Module type from the configuration also removes the configuration for the slot.

When a new IOC Module is inserted in the slot, the module boots with default configuration. If a module is inserted into a running system and the module type is not configured for the slot, the system automatically creates a preconfiguration with the module type of the IOC Module that was inserted. Then the module boots with default configuration.

## Chassis operations configuration using the CLI

---

This section provides the details to configure basic hardware and system settings.

### Enabling the High Availability-CPU (HA-CPU) mode

#### About This Task

Enable High Availability-CPU (HA-CPU) mode to enable devices with two CPUs to recover quickly from a failure of the master CPU.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the following boot flag:  
`boot config flags ha-cpu`

The configuration file is saved on both the CPUs. After you disable HA mode on the master CPU, the secondary CPU software automatically resets and loads the settings from the previously-saved configuration file.

3. Type `y` after the following prompt appears:

```
Do you want to continue (y/n) ?
```

Responding to the user prompt with a `y` causes the secondary CPU to reset itself automatically, and that secondary CPU restarts with HA mode enabled.

4. Save the configuration.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Enable HA mode:

```
Switch:1(config)#boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-Layer 2/3 features will be enabled in L2/L3 redundancy mode.
Do you want to continue (y/n)?y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Runtime configuration is being saved.
Resetting Slave CPU from Master CPU.
CP1 [01/07/17 15:21:50.605:UTC] 0x000045e3 00000000 GlobalRouter SNMP INFO Save config
successful.
CP2 [01/07/17 15:22:16.890:UTC] 0x000105e3 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync is complete (Standby CPU)
CP1 [01/07/17 15:22:17.407:UTC] 0x000105c8 00000000 GlobalRouter HW INFO HA-CPU: Table
Sync Completed on Secondary CPU
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Synchronized State.
Last Event : Table synchronization completed.
Mode : Warm Standby

Card Info :
 Slot# CardType Oper Admin Power
 Status Status State
 1 8624XS up-Master up on
 2 8624XS up-Warmstandby up on

Current Boot Config State: master 1
```

Save the configuration:

```
Switch:1(config)#save config
```

**What to Do Next****Note**

In HA-CPU mode, whenever there is a mismatch of boot config flags between the master CPU and the standby CPU, the standby CPU follows the master CPU. The mismatch could be due to different runtime config files or primary config files at standby CPU. Once the chassis boots up successfully on the switch, ensure that both the CPUs run the same primary config file and the running config file.

## Disabling the High Availability-CPU (HA-CPU) Mode

**About This Task**

Perform this procedure to disable HA mode.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following boot flag command:  

```
no boot config flags ha-cpu
```

The configuration file is saved on both the CPUs. After you enable HA mode on the master CPU, the secondary CPU software automatically synchronizes the configuration from the master CPU.

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Disable HA mode:

```
Switch:1(config)#no boot config flags ha-cpu
The config files on the Master and Slave will be overwritten with the current active
configuration.
-No longer Layer 2/3 features run in L2/L3 redundancy mode.
Do you want to continue (y/n) ? y
Boot configuration is being saved.
CP-1: Save config to file /intflash/config.cfg successful.
CP-2: Save /intflash/config.cfg to standby successful.
Resetting Slave CPU from Master CPU.
```

Verify the configuration:

```
Switch:1(config)#show ha-state
Current CPU State : Disabled State.
Last Event : No event.
Mode : Warm Standby

Card Info :
 Slot# CardType Oper Admin Power
 Status Status State
 1 8624XS up-Master up on
 2 8624XS up-Warmstandby up on

Current Boot Config State: master 1
```

## Removing an IOC Module with HA Mode Activated

**About This Task**

Perform this procedure to properly remove the IOC module that is in the master CP slot, when the system operates in HA mode.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Use the `sys action cpu-switch-over` command to fail over to another CP.
3. Remove the IOC module.

### Important

Do not reinsert an IOC module until at least 15 seconds has elapsed, which is long enough for another CP slot to become master.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys action cpu-switch-over
```

## Enabling jumbo frames

### About This Task

Enable jumbo frames to increase the size of Ethernet frames the chassis supports.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable jumbo frames:
 

```
sys mtu <1522-9600>
```

### Example

```
Switch:1> enable

Switch:1# configure terminal

Enable jumbo frames to 9600 bytes:

Switch:1#(config)# sys mtu 9600
```

### Variable Definitions

The following table defines parameters for the `sys mtu` command.

| Variable    | Value                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------|
| <1522-9600> | Configures the frame size support for the data path. Possible sizes are 1522, 1950 (default), or 9600 bytes. |

## Configuring port lock

### About This Task

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable port lock globally:  

```
portlock enable
```
3. Log on to GigabitEthernet Interface Configuration mode:  

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[, ...]}
```
4. Lock a port:  

```
lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} enable
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Unlock port 1/14:

```
Switch:1(config-if)# no lock port 1/14 enable
```

### Variable Definitions

The following table defines parameters for the **interface gigabitethernet** and **lock port** commands.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>For the <code>lock port</code> command, use the no form of this command to unlock a port: <code>no lock port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> |

## Configuring SONMP

### About This Task

Configure the SynOptics Network Management Protocol (SONMP) to allow a network management station (NMS) formulate a map that shows the interconnections between Layer 2 devices in a network. The default status is enabled.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Disable SONMP:  

```
no autotopology
```
3. Enable SONMP:  

```
autotopology
```

### Example

```
Switch:1> enable
```

```
Switch:1 configure terminal
```

Disable SONMP:

```
Switch:1 (config)# no autotopology
```

## Viewing the topology message status

### About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the contents of the topology table:  

```
show autotopology nmm-table
```

Unless the switch is physically connected to other devices in the network, this topology will be blank.

### Example

#### Note

In the following example, the column “ChassisType” uses a generic name. When you use the **show autotopology nmm-table**, your switch displays the actual chassis type.

```
Switch:1 (config)#show autotopology nmm-table
```

```
=====
```

```
Topology Table
```

```

=====

```

**Note**

When a peer switch is running an older software version that does not include support for SONMP hello messages with channelization information, it can only show the slot/port. It cannot show the sub-port.

*Job Aid*

The following table describes the column headings in the command output for `show autotopology nmm-table`.

**Table 98: Variable Definitions**

| Variable    | Value                                                                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Local Port  | Specifies the slot and port that received the topology message.                                                                                                                                                                                                                                       |
| IpAddress   | Specifies the IP address of the sender of the topology message.                                                                                                                                                                                                                                       |
| SegmentId   | Specifies the segment identifier of the segment from which the remote agent sent the topology message. This value is extracted from the message.                                                                                                                                                      |
| MacAddress  | Specifies the MAC address of the sender of the topology message.                                                                                                                                                                                                                                      |
| ChassisType | Specifies the chassis type of the device that sent the topology message.                                                                                                                                                                                                                              |
| BT          | Specifies the backplane type of the device that sent the topology message. The switch uses a backplane type of 12.                                                                                                                                                                                    |
| LS          | Indicates if the sender of the topology message is on the same Ethernet segment as the reporting agent.                                                                                                                                                                                               |
| CS          | Specifies the current state of the sender of the topology message. The choices are <ul style="list-style-type: none"> <li>topChanged—Topology information recently changed.</li> <li>HtBt (heartbeat)—Topology information is unchanged.</li> <li>new—The sending agent is in a new state.</li> </ul> |
| Rem Port    | Specifies the slot and port that sent the topology message.                                                                                                                                                                                                                                           |

**Associating a port to a VRF instance**

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

### Before You Begin

- The VRF instance must exist. For more information about the creation of VRFs, see [Create a VRF Instance](#) on page 3892.

### About This Task

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the Global Router, VRF 0, by default.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate a VRF instance with a port:

```
vrf <WORD 1-16>
```

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# interface gigabitethernet 1/12
```

```
Switch:1(config-if)# vrf red
```

## Configure an IP Address for the Management Port

#### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management](#) on page 49.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

**Before You Begin**

- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure an overlap between in-band and out-of-band networks.

**Procedure**

1. Enter mgmtEthernet Interface Configuration mode:
 

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the IP address and mask for the management port:
 

```
ip address {<A.B.C.D/X> | <A.B.C.D> <A.B.C.D>}
```
3. Configure an IPv6 address and prefix length for the management port:
 

```
ipv6 interface address WORD<0-255>
```
4. Show the complete network management information:
 

```
show interface mgmtEthernet
```
5. Show the management interface packet/link errors:
 

```
show interface mgmtEthernet error
```
6. Show the management interface statistics information:
 

```
show interface mgmtEthernet statistics
```

**Example**

Configure the IP address for the management port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtethernet mgmt
Switch:1(config-if)#ip address 192.0.2.24 255.255.255.0
```

*Variable Definitions*

The following table defines parameters for the **ip address** command.

| Variable                            | Value                                                 |
|-------------------------------------|-------------------------------------------------------|
| {<A.B.C.D/X>   <A.B.C.D> <A.B.C.D>} | Specifies the IP address followed by the subnet mask. |

The following table defines parameters for the **ipv6 interface address** command.

| Variable            | Value                                         |
|---------------------|-----------------------------------------------|
| <i>WORD</i> <0–255> | Specifies the IPv6 address and prefix length. |

## Configure Ethernet Ports with Auto-Negotiation

Configure Ethernet ports so they operate optimally for your network conditions.

### About This Task

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

All ports that belong to the same MLT or Link Aggregation Control Protocol (LACP) group must use the same port speed. In the case of MLTs, the software does not enforce this.

The software requires the same Auto-Negotiation settings on link partners to avoid incorrect declaration of link status. Mismatched settings can cause the links to stay down. Ensure the Auto-Negotiation settings between local ports and their remote link partners match before you upgrade the software.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Auto-Negotiation:

```
auto-negotiate [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] enable
```

3. Verify the configuration:

```
show interfaces gigabitEthernet l1-config [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]]
```

### Example

```
Switch:>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#auto-negotiate enable
Switch:1(config-if)#show interfaces gigabitEthernet l1-config 1/8
=====
Port Config l1
=====
```

| PORT<br>NUM | AUTO<br>NEG. | OPERATE<br>AUTO-NEG | CUSTOM AUTO<br>NEGOTIATION<br>ADVERTISEMENTS | ADMIN<br>DPLX SPD | OPERATE<br>DPLX SPD | ADMIN<br>TX-FLW-CTRL | OPERATE<br>TX-FLW-CTRL |
|-------------|--------------|---------------------|----------------------------------------------|-------------------|---------------------|----------------------|------------------------|
| 1/8         | true         | true                | Not Configured                               | full 10000        | 0                   | enable               | enable                 |

### Variable Definitions

The following table defines parameters for the **auto-negotiate** command.

| Variable                                                           | Value                                                                                                                                                          |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port or ports that you want to configure.                                                                                                        |
| <code>enable</code>                                                | Enables auto-negotiation for the port or other ports of the module.<br>The default Auto-Negotiation behavior depends on the switch model and transceiver type. |

## Configure Auto-Negotiation Advertisements

Configure local port Auto-Negotiation advertisements to specify the speed and duplex mode for traffic between local ports and remote link partners. Supported speeds and duplex modes vary, depending on your hardware.

### Before You Begin

You must enable Auto-Negotiation before you perform this procedure.

### About This Task

Configure local port Auto-Negotiation advertisements.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure Auto-Negotiation advertisements on one or more ports:

```
auto-negotiation-advertisements {10000-full|2500-full|5000-full|1000-
full|100-full|100-half|10-full|10-half}
```

or

```
auto-negotiation-advertisements port {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]} {10000-full|2500-full|5000-full|1000-full|
100-full|100-half|10-full|10-half}
```

- Verify the configuration:

```
show interfaces gigabitEthernet 11-config [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

### Variable Definitions

The following table defines parameters for the **auto-negotiation-advertisements** command.

| Variable                                                     | Value                                                   |
|--------------------------------------------------------------|---------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Specifies the port or ports that you want to configure. |
| <i>10000-full</i>                                            | Advertises 10000 Mbps full duplex.                      |
| <i>5000-full</i>                                             | Advertises 5000 Mbps full duplex.                       |
| <i>2500-full</i>                                             | Advertises 2500 Mbps full duplex.                       |
| <i>1000-full</i>                                             | Advertises 1000 Mbps full duplex.                       |
| <i>100-full</i>                                              | Advertises 10000 Mbps full duplex.                      |
| <i>100-half</i>                                              | Advertises 10000 Mbps half duplex.                      |
| <i>10-full</i>                                               | Advertises 10 Mbps full duplex.                         |
| <i>10-half</i>                                               | Advertises 10 Mbps half duplex.                         |
| <i>none</i>                                                  | Configures the Auto-Negotiate value to none.            |

## Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

### About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

#### Note

If you enable MACsec on an interface and you send small packet size traffic near line rate, the **In FlowCtrl** frame might increment in the output of the **show interface gigabitEthernet statistics** command because of the processing overhead caused by adding the MACsec header of 32 bytes. This is part of the expected over-subscription footprint.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable flow control mode:

```
boot config flags flow-control-mode
```

3. Save the configuration.

4. Exit Privileged EXEC mode:

```
exit
```

5. Reboot the chassis.

```
boot
```

6. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

7. Configure the interface to generate pause frames:

```
tx-flow-control [enable]
```

8. (Optional) Configure other interfaces to generate pause frames:

```
tx-flow-control port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} enable
```

9. Verify the boot flag configuration:

```
show boot config flags
```

10. Verify the interface configuration:

```
show interfaces gigabitEthernet ll-config {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

11. View the pause-frame packet count:

```
show interfaces gigabitEthernet statistics {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

## Example

Enable flow control on the system and configure slot 1, port 10 to send pause frames. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags flow-control-mode
Warning: Please save the configuration and reboot the switch
 for this configuration to take effect.
Switch:1<config>#save config
CP-1: Save config to file /intflash/config.cfg successful.
CP-1: Save license to file /intflash/license.xml successful.
Switch:1<config>#exit
Switch:1#boot
Are you sure you want to re-boot the switch (y/n) ?y
```

### Note

Flag support can vary across hardware models.

*Variable Definitions*

The following table defines parameters for the **tx-flow-control** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                                     | Configures the interface to send pause frames. By default, flow control is disabled.                                                                                                                                                                                                                                                                          |
| <i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show interfaces gigabitEthernet l1-config** and **show interfaces gigabitEthernet statistics** commands.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

**Enable Channelization**

Enable channelization on a port to configure it to operate as four channels, or ports.

**Important**

Enabling or disabling channelization resets the port QoS configuration to default values.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable channelization on a port:

```
channelize [port {slot/port[-slot/port] [,...]}] enable
```

3. Display the status of the ports:

```
show interfaces gigabitEthernet channelize [{slot/port[-slot/port]
[,...]}]
```

To display the details of the sub-ports, use:

```
show interfaces gigabitEthernet channelize detail [{slot/port/sub-
port[-slot/port/sub-port] [,...]}]
```

4. (Optional) To disable channelization on a port, enter:

```
no channelize [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}] enable
```

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitEthernet 2/1
Switch:1(config-if)# channelize enable
Enabling channelization on port 2/1. Subport 2/1/1 will inherit port 2/1 configuration.
Subports 2,3,4 will use default config. QSFP will be reset as removal and re-insert.
NOTE: Modify QOS configurations on all subports as required.
Do you wish to continue (y/n) ? y
```

Display the port status:

```
Switch:1(config)# show interfaces gigabitEthernet channelize 2/2-2/4
```

```
=====
 Port Channelization
=====
PORT ADMIN MODE CHANNEL TYPE

2/2 true 40G
2/3 false 40G
2/4 false 40G
```

The following is an example of how to disable channelization on a port:

```
Switch:1> enable
Switch:1# configure terminal
```

```
Switch:1(config)# interface gigabitethernet 2/2/1
Switch:1(config-if)# no channelize enable
```

### Variable Definitions

The following table defines parameters for the **channelization** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configure FEC on a Port

### About This Task

Use this procedure to configure Forward Error Correction (FEC) on supported ports.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. (Optional) Specify the port or ports to configure for FEC:

```
fec port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Configure FEC on a port:

```
fec {auto | c1108 | c174 | c191}
```

4. Verify the configuration:

```
show interfaces gigabitEthernet config {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

### Examples

Configure Clause 108 FEC on a 25 Gbps port 1/1:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#fec c1108
```

Verify the configuration when a 25 Gbps optic is present:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
 Port Config
=====
PORT DIFF-SERV QOS MLT VENDOR
NUM TYPE EN TYPE LVL ID NAME

1/1 25GbCX true core 1 0 Extreme
=====
 Port Config
=====
PORT ADMIN OPERATE AUTO ACCESS-SERV RMON FLEX-UNI ADMIN APPLICABLE OPERATE
NUM ROUTING ROUTING RECOVER EN FLEX-UNI FEC FEC FEC

1/1 Enable Disable Disable false Disable Disable Auto CL108 CL108
```

Verify the configuration when a 10 Gb optic is present in a 25 Gb port:

```
Switch:1(config-if)#show interfaces gigabitEthernet config 1/1
=====
 Port Config
=====
PORT DIFF-SERV QOS MLT VENDOR
NUM TYPE EN TYPE LVL ID NAME

1/1 10GbSR true core 1 0 Extreme
=====
PORT ADMIN OPERATE AUTO ACCESS-SERV RMON FLEX-UNI ADMIN APPLICABLE OPERATE
NUM ROUTING ROUTING RECOVER EN FLEX-UNI FEC FEC FEC

1/1 Enable Disable Disable false Disable Disable Auto Not Applicable Off
```

### Variable Definitions

The following table defines parameters for the **fec** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                  |
| <code>{auto   c1108   c174   c191}</code>                               | <p>Configures one of the following options for FEC on the port:</p> <ul style="list-style-type: none"> <li>• auto</li> <li>• Clause 91</li> <li>• Clause 108</li> <li>• Clause 74</li> </ul> <p><b>Note:</b><br/>On a 100 GbE port, only the Clause 91 and Clause 108 options are supported. On 100 GbE channelized ports (operating at 25 Gbps speed), you can configure Clause 108 for extra latency or Clause 74 for reduced latency.<br/>Configuration of FEC is not supported on a management port or on 100 GbE ports operating at 40 Gbps speed.</p> <p><b>Important:</b><br/>On ports that support FEC, always configure the same option on both end-points. Otherwise, the link does not come up.</p> |

## Configuring Serial Management Port Dropping

Configure the serial management ports to drop a connection that is interrupted for any reason. If you enable serial port dropping, the serial management ports drop the connection for the following reasons:

- modem power failure
- link disconnection
- loss of the carrier

Serial ports interrupted due to link disconnection, power failure, or other reasons force out the user and end the user session. Ending the user session ensures a maintenance port is not available with an active session that can allow unauthorized use by someone other than the authenticated user, and prevents the physical hijacking of an active session by unplugging the connected cable and plugging in another.

By default, the feature is disabled with enhanced secure mode disabled. If enhanced secure mode is enabled, the default is enabled.

For more information on enhanced secure mode, see [Enabling enhanced secure mode](#) on page 3329.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the serial port to drop if a connection is interrupted:  
`sys security-console`

### Example

Configure the serial port to drop if a connection is interrupted:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys security-console
```

## Configuring power on module slots

### About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configuring Slot Priority](#) on page 562.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable power to one or more slots:  
`sys power slot <1-4 | 1-8 | SF1-SF3>`
3. Disable power to one or more slots:  
`no sys power slot <1-4 | 1-8 | SF1-SF3>`

### Example

```
Switch:1>enable

Switch:1#configure terminal

Enable power to Slot 1:

Switch:1 (config)#sys power slot 1

Disable power to Slot 1:

Switch:1 (config)#no sys power slot 1
```

Enable power to Slots 3 and 5:

```
Switch:1(config)#sys power slot 3,5
```

Disable power to Slots 3 and 5:

```
Switch:1(config)#no sys power slot 3,5
```

### Variable Definitions

The following table defines parameters for the **sys power slot** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4   1-8   SF1-SF3> | Identifies the slot to provide power in one of the following formats: a single slot (1), a range of slots (1-3), or a series of slots (1,2,4). The default is to provide power to all slots.<br>Use the <b>no</b> operator to disable power to a slot.<br>Use the <b>default</b> operator to enable power to a slot.<br>Different hardware platforms support different slot ranges. Use the CLI Help to see the available range. |

## Configuring Slot Priority

### Note

This procedure only applies to VSP 8600 Series.

### About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.
- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

### Note

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a *low* priority and slots 4 and 5 have a *high* priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as *low* so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure slot priority:  

```
sys power slot-priority <3-8> {high|low}
```

**Example**

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Configure slot priority to determine that slot 3 has a low priority if insufficient power is available for all modules:

```
Switch:1(config)#sys power slot-priority 3 low
```

*Variable Definitions*

The following table defines parameters for the **sys power slot-priority** command.

| Variable                 | Value                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <3-8>                    | Identifies the module slot.                                                                                                                                    |
| <i>high</i>   <i>low</i> | Specifies whether the module should have a high or low priority setting if there is insufficient power available for all modules. The default is <i>high</i> . |

**Enable the Locator LED****Note**

This procedure only applies to 5520 Series and VSP 4900 Series.

**About This Task**

Perform this procedure to turn the system Locator LED on to provide a visual identification of a specific switch.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the system Locator LED:  

```
sys locator-led
```
3. Display the system Locator LED status:  

```
show sys locator-led
```

## Enable or Disable the USB Port

Perform this procedure to control USB access. For security reasons, you may want to disable this port to prevent individuals from using it. By default, the port is automatically mounted when a USB device is inserted.

### Before You Begin

- The switch must be in Enhanced Secure mode.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Disable the USB port:  

```
sys usb disable
```
3. Enable a previously disabled USB port:  

```
no sys usb disable
```

## Configure Port Speed

### About This Task

Manually configure the port speed.

#### Important

If Auto-Negotiation is disabled and you change the speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches may show an incorrect operational status of "up" for the mismatched ports.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the speed for one or more ports:

```
speed {10|100|1000|10000|2500|25000|5000}
```

or

```
speed port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} {10|100|1000|10000|2500|25000|5000}
```

### Variable Definitions

The following table defines parameters for the **speed** command.

| Variable                                                            | Value                                                   |
|---------------------------------------------------------------------|---------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Specifies the port or ports that you want to configure. |
| <code>10</code>                                                     | Configures the port speed to 10 Mbps.                   |
| <code>100</code>                                                    | Configures the port speed to 100 Mbps.                  |
| <code>1000</code>                                                   | Configures the port speed to 1 Gbps.                    |
| <code>10000</code>                                                  | Configures the port speed to 10 Gbps.                   |
| <code>2500</code>                                                   | Configures the port speed to 2.5 Gbps.                  |
| <code>25000</code>                                                  | Configures the port speed to 25 Gbps.                   |
| <code>5000</code>                                                   | Configures the port speed to 5 Gbps.                    |

## Configure Ports Speeds for All VIM Ports

### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [Release Notes for VOSS](#). The **sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command on an unsupported VIM.

### Before You Begin

Install the VIM before performing this procedure.

### About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the speed for all of the VIM ports:  

```
sys vim-speed {10000 | 25000}
```

*Variable Definitions*

The following table defines parameters for the **sys vim-speed** command.

| Variable                   | Value                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>10000   25000</code> | Configures all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps. The default is 25 Gbps. |

**Display Ports Speeds for All VIM Ports****Note**

This procedure only applies to 5520 Series and VSP 4900 Series.

Display the configured speed on all VIM ports.

**Note**

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [Release Notes for VOSS](#). The **show sys vim-speed** command is supported only on VIMs that must operate with all ports at the same speed. An error message displays if you run the command with an unsupported VIM installed.

**Before You Begin**

Install the VIM before performing this procedure.

**About This Task**

Use this procedure to display the configured speed of all ports in a multi-port VIM.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the speed for all of the VIM ports:  

```
show sys vim-speed
```

## Prepare a slot for IOC Module Preconfiguration using CLI

### About This Task

Use this procedure to designate a slot in the switch for IOC module preconfiguration. You can designate a slot for only one module type at a time.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
3. Designate a slot for IOC module preconfiguration:  
`preconfig slot <1-8> WORD<1-20> [lock]`
4. Verify IOC module preconfiguration:  
`show sys-info card`

### Example

The following examples prepare a slot for IOC module preconfiguration:

Prepare a slot for IOC module preconfiguration, with card lock enabled on the slot.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#preconfig slot 5 8624XT lock
```

Verify the configuration:

```
Switch:1(config)#show sys-info card

Card Info :
 Slot 5 :

 CardType : 8624XT
 CardDescription : 8624XT
 CardSerial# : SDNI86XSD282
 CardPart# : EC8604002-E6
 CardAssemblyDate : 20161125
 CardHWRevision : D2
 CardHWConfig : 0
 AdminStatus : up
 OperStatus : up
 PowerStatus : on
 Preconfigured : yes
 Preconfig CardType: 8624XT
 Preconfig Lock : yes
```

If card lock is enabled on the slot, and the module type of the inserted IOC module does not match the preconfigured IOC module type (for example, if the inserted module is type 8624XT but the

preconfigured module type is 8624XS), then the operational status of the inserted IOC module displays as down-Mismatch.

```
Switch:1(config)show sys-info card

Card Info :
 Slot 5 :

 CardType : 8624XS
 CardDescription : 8624XS
 CardSerial# : SDNI86XSD282
 CardPart# : EC8604002-E6
 CardAssemblyDate : 20161125
 CardHWRevision : D2
 CardHWConfig : 0
 AdminStatus : down
 OperStatus : down-Mismatch
 PowerStatus : down
 Preconfigured : yes
 Preconfig CardType: 8624XT
 Preconfig Lock : yes
```

Prepare another slot for IOC module preconfiguration, with no card lock enabled on the slot.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#preconfig slot 6 8624XS
```

Verify the configuration:

```
Switch:1(config)show sys-info card

Card Info :
 Slot 6 :

 CardType : 8624XS
 CardDescription : 8624XS
 CardSerial# : SDNI86XSD282
 CardPart# : EC8604002-E6
 CardAssemblyDate : 20161125
 CardHWRevision : D2
 CardHWConfig : 0
 AdminStatus : up
 OperStatus : up
 PowerStatus : on
 Preconfigured : yes
 Preconfig CardType: 8624XS
 Preconfig Lock : no
```

If card lock is disabled on the slot, and the IOC module type of the inserted card does not match the preconfigured module type, the existing configuration is deleted and the slot is automatically preconfigured with the module type of the inserted IOC module. The inserted module then boots up with default configuration.

In the following example, when the 8624XT module is inserted in a slot preconfigured for the 8624XS, the pre-configuration for the 8624XS is deleted because it is not locked. The slot is then automatically preconfigured for 8624XT when the IOC module is physically inserted in that slot.

```
Switch:1(config)#show sys-info card

Card Info :
 Slot 6 :

 CardType : 8624XT
 CardDescription : 8624XT
 CardSerial# : SDNI86XSD282
 CardPart# : EC8604002-E6
 CardAssemblyDate : 20161125
 CardHWRevision : D2
 CardHWConfig : 0
 AdminStatus : up
 OperStatus : up
 PowerStatus : on
 Preconfigured : yes
 Preconfig CardType: 8624XT
 Preconfig Lock : no
```

### Variable Definitions

The following table defines parameters for the **preconfig slot** command.

| Variable                 | Value                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;1-8&gt;</b>       | Specifies the slot number designated for pre-configuration.                                                                                                         |
| <b>WORD &lt;1-20&gt;</b> | Specifies the card type that can be assigned to the pre-configured slot.                                                                                            |
| <b>lock</b>              | Specifies that the IO card will be locked to the pre-configured slot. Only the IO card that matches the card type assigned to the pre-configured slot will operate. |

## Chassis operations configuration using EDM

This section provides the details to configure basic hardware and system settings using Enterprise Device Manager (EDM).

### Edit System Information

#### About This Task

Edit system identification information, configuration file information, and perform system actions.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **System** tab.
4. Enter or edit the information as required.
5. Click **Apply**.

**System** Field Descriptions

Use the data in the following table to use the **System** tab.

| Name                                                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Edit Chassis Information

### About This Task

Edit the chassis information to make changes to chassis-wide settings.

### Procedure

1. In the Device Physical View tab, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Chassis** tab.
5. Edit the necessary options.
6. Select **Apply**.

**Chassis** Field Descriptions

Use the data in the following table to use the **Chassis** tab.

| Name                                                                         | Description                                                                                                                                                                                                     |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>                                                                  | Specifies the chassis type.                                                                                                                                                                                     |
| <b>ModelName</b><br>This parameter does not appear on all platforms.         | Specifies the chassis model name.                                                                                                                                                                               |
| <b>BrandName</b><br>This parameter does not appear on all platforms.         | Specifies the chassis brand name.                                                                                                                                                                               |
| <b>PartNumber</b>                                                            | Specifies the device part number.                                                                                                                                                                               |
| <b>SerialNumber</b>                                                          | Specifies a unique chassis serial number.                                                                                                                                                                       |
| <b>HardwareRevision</b>                                                      | Specifies the current hardware revision of the device chassis.                                                                                                                                                  |
| <b>NumSlots</b>                                                              | Specifies the number of slots available in the chassis.                                                                                                                                                         |
| <b>NumPorts</b>                                                              | Specifies the number of ports currently installed in the chassis.                                                                                                                                               |
| <b>BaseMacAddr</b>                                                           | Specifies the starting point of the block of MAC addresses used by the switch for logical and physical interfaces.                                                                                              |
| <b>MacAddrCapacity</b>                                                       | Specifies the number of routable MAC addresses based on the BaseMacAddr.                                                                                                                                        |
| <b>Temperature</b><br>This parameter does not appear for all platforms.      | Specifies the temperature of the device.                                                                                                                                                                        |
| <b>MacFlapLimitTime</b><br>This parameter does not appear for all platforms. | Configures the time limit for the loop-detect feature, in milliseconds, for MAC flapping. The value ranges from 10–5000. The default value is 500.                                                              |
| <b>AutoRecoverDelay</b>                                                      | Specifies the time interval, in seconds, after which auto-recovery runs on ports to clear actions taken by CP Limit or link flap. The default is 30.                                                            |
| <b>MTUSize</b>                                                               | Configures the maximum transmission unit size. The default is 1950.                                                                                                                                             |
| <b>MgidUsageVlanCurrent</b>                                                  | Number of MGIDs for VLANs currently in use.                                                                                                                                                                     |
| <b>MgidUsageVlanRemaining</b>                                                | Number of remaining MGIDs for VLANs.                                                                                                                                                                            |
| <b>MgidUsageMulticastCurrent</b>                                             | Number of MGIDs for multicast currently in use.                                                                                                                                                                 |
| <b>MgidUsageMulticastRemaining</b>                                           | Number of remaining MGIDs for multicast.                                                                                                                                                                        |
| <b>DdmMonitor</b>                                                            | Enables or disables the monitoring of the DDM. When enabled, the user gets the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the SFP/XFP. The default is disable.       |
| <b>DdmMonitorInterval</b>                                                    | Configures the DDM monitor interval in the range of 5 to 60 in seconds. If any alarm occurs, the user gets the log message before the specific interval configured by the user. The default value is 5 seconds. |

| Name                                                                      | Description                                                                                                                                                       |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DdmTrapSend</b>                                                        | Enables or disables the sending of trap messages. When enabled, the trap message is sent to the Device manager, any time the alarm occurs. The default is enable. |
| <b>DdmAlarmPortdown</b>                                                   | Sets the port down when an alarm occurs. When enabled, the port goes down when any alarm occurs. The default is disable.                                          |
| <b>PowerUsage</b><br>This parameter does not appear on all platforms.     | Specifies the amount of power the CPU uses.                                                                                                                       |
| <b>PowerAvailable</b><br>This parameter does not appear on all platforms. | Specifies the amount of power available to the CPU.                                                                                                               |

## View Physical Entities

Perform this procedure to view information about the functional components of the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.

### *Physical Entities Field Descriptions*

The following table defines the use the Physical Entities tab.

| Name                | Description                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>        | Indicates the index of the entry.                                                                                                                                                         |
| <b>Descr</b>        | Indicates the name of the manufacturer for the physical entity.                                                                                                                           |
| <b>VendorType</b>   | Indicates the vendor-specific hardware type for the physical entity. Because there is no vendor-specifier registration for this device, the value is 0.                                   |
| <b>ContainedIn</b>  | Indicates the index value for the physical entity which contains this physical entity. A value of zero indicates that this physical entity is not contained in any other physical entity. |
| <b>Class</b>        | Indicates the general hardware type of the physical entity. The value is configured to the standard enumeration value that indicates the general class of the physical entity.            |
| <b>ParentRelPos</b> | Indicates the relative position of the child component among the sibling components.                                                                                                      |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>        | Indicates the name of the component, as assigned by the local device, and that is suitable to use in commands you enter on the console of the device. Depending on the physical component naming syntax of the device, the name can be a text name such as console, or a component number such as port or module number. If there is no local name, there is no value. |
| <b>HardwareRev</b> | Indicates the vendor-specific hardware revision string for the physical entity. If no specific hardware revision string is associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.                                   |
| <b>FirmwareRev</b> | Indicates the vendor-specific firmware revision string for the physical entity. If no specific firmware programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.                                         |
| <b>SoftwareRev</b> | Indicates the vendor-specific software revision string for the physical entity. If no specific software programs are associated with the physical component, or if this information is unknown, then this object contains a zero-length string, or there is no value. If there is no information available, there is no value.                                         |
| <b>SerialNum</b>   | Indicates the vendor-specific serial number string for the physical entity. The value is the serial number string printed on the component, if present. If there is no information available, there is no value.                                                                                                                                                       |
| <b>MfgName</b>     | Indicates the name of the manufacturer of the physical component. The value is the manufacturer name string printed on the component, if present. If the manufacturer name string associated with the physical component is unknown, then this object contains a zero-length string. If there is no information available, there is no value.                          |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ModelName</b> | Indicates the vendor-specific model name identifier string associated with the physical component. The value is the part number which is printed on the component.<br>If the model name string associated with the physical component is unknown, then this object contains a zero-length string.                                                               |
| <b>Alias</b>     | Indicates an alias name for the physical entity that is specified by a network manager, and provides a nonvolatile handle for the physical entity.<br>The software supports read-only and provides values for the port interface only.                                                                                                                          |
| <b>AssetID</b>   | Indicates a user-assigned asset tracking identifier for the physical entity. This value is specified by a network manager, and provides nonvolatile storage of this information.<br>Because this object is not supported, there is no value.                                                                                                                    |
| <b>IsFRU</b>     | Indicates whether or not the physical entity is considered a field replaceable unit. <ul style="list-style-type: none"> <li>• If the value is <code>true (1)</code>, then the component is a field replaceable unit.</li> <li>• If the value is <code>false (2)</code>, then the component is permanently contained within a field replaceable unit.</li> </ul> |
| <b>MfgDate</b>   | Indicates the manufacturing date of the managed entity. If the manufacturing date is unknown, then the value is <code>'0000000000000000'</code> .                                                                                                                                                                                                               |
| <b>Uris</b>      | Indicates additional identification information about the physical entity.<br><b>Uris</b> is not supported, therefore there is no value.                                                                                                                                                                                                                        |

## View Entity Aliases

### About This Task

Perform this procedure to view the entity aliases on the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.
3. Click the **Alias** tab.

*Alias Field Descriptions*

Use the following table to use the Alias tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>              | The index of the entry                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>LogicalIndexOrZero</b> | The index of the entry. The value of this object identifies the logical entity that defines the naming scope for the associated instance of the Mapping Identifier object. This is always 0.                                                                                                                                                                                                                     |
| <b>MappingIdentifier</b>  | The value of this object identifies a particular conceptual row associated with the indicated Physical Index and Logical Index pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. This is the OID of ifIndex.Port. |

## Viewing Entity Child Indexes

**About This Task****Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Entity**.
3. Click the **Child Index** tab.

*Child Index field descriptions*

Use the following table to use the **Child Index** tab.

| Name              | Description                                                                            |
|-------------------|----------------------------------------------------------------------------------------|
| <b>Index</b>      | Indicates the index of the entry.                                                      |
| <b>ChildIndex</b> | The index of the entry. The value of Physical Index for the contained physical entity. |

## Configure System Flags

**About This Task**

Configure the system flags to enable or disable flags for specific configuration settings.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **System Flags** tab.

4. Select the system flags you want to activate.
5. Clear the system flags you want to deactivate.
6. Click **Apply**.

#### Important

After you change certain configuration parameters, you must save the changes to the configuration file.

### **System Flags** Field Descriptions

Use the data in the following table to use the **System Flags** tab.

| Name                                                         | Description                                                                                                                                                                                                                  |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EnableAccessPolicy</b>                                    | Activates access policies. The default is disabled.                                                                                                                                                                          |
| <b>ForceTrapSender</b>                                       | Configures circuitless IP as a trap originator. The default is disabled.                                                                                                                                                     |
| <b>ForceIpHdrSender</b>                                      | If you enable Force IP Header Sender, the system matches the IP header source address with SNMP header sender networks. The default is disabled.                                                                             |
| <b>AuthSuccessTrapEnable</b>                                 | Enables the system to send the authentication success trap, rcnAuthenticationSuccess. The default is disabled.                                                                                                               |
| <b>MrouteStrLimit</b>                                        | Enable or disable Mroute stream limit in system. The default is disabled.                                                                                                                                                    |
| <b>DataPathFaultShutdownEnable</b>                           | Enable or disable data path fault shutdown. The default is enabled.                                                                                                                                                          |
| <b>PingTracerouteContextType</b>                             | Configures the default context for executing ping commands and traceroute commands. The default is grt.                                                                                                                      |
| <b>Note:</b><br>Exception: not supported on VSP 8600 Series. |                                                                                                                                                                                                                              |
| <b>UdpSrcByVirtualIpEnable</b>                               | Enables or disables virtual IP as the User Datagram Protocol (UDP) source. The default is disabled.                                                                                                                          |
| <b>ForceTopologyIpFlagEnable</b>                             | Activates or disables the flag that configures the CLIP ID as the topology IP. Values are true or false. The default is disabled.                                                                                            |
| <b>CircuitlessIpId</b>                                       | Uses the CLIP ID as the topology IP. Enter a value from 1–256.                                                                                                                                                               |
| <b>HaCpu</b>                                                 | Activates or disables the CPU High Availability feature. If you enable or disable High Availability mode, the secondary CPU resets automatically to load settings from the saved configuration file. The default is enabled. |
| <b>MasterCPUSlot</b>                                         | Specifies the slot number, either 1 or 2, for the master CPU. The default value is 1.                                                                                                                                        |
| <b>EnableSavetoStandby</b>                                   | Enables or disables automatic save of the configuration file to the standby CPU. The default value is enabled.                                                                                                               |

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HaCpuState</b> | Indicates the CPU High Availability state. <ul style="list-style-type: none"> <li>• initialization—Indicates the CPU is in this state.</li> <li>• oneWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU).</li> <li>• twoWayActive—Specifies modules that need to synchronize register with the framework (either locally or a message received from a remote CPU).</li> <li>• synchronized—Specifies table-based synchronization is complete on the current CPU.</li> <li>• remoteIncompatible—Specifies CPU framework version is incompatible with the remote CPU.</li> <li>• error—Specifies if an invalid event is generated in a specific state the CPU enters Error state.</li> <li>• disabled—Specifies High Availability is not activated.</li> <li>• peerNotConnected—Specifies no established peer connection.</li> <li>• peerConnected—Specifies peer connection is established.</li> <li>• lostPeerConnection—Specifies a lost connection to peer or standby CPU.</li> <li>• notSynchronized—Specifies table-based synchronization is not complete.</li> </ul> |
| <b>HaEvent</b>    | Indicates the High Availability event status. <ul style="list-style-type: none"> <li>• restart—Causes the state machine to restart.</li> <li>• systemRegistrationDone—Causes the CPU to transfer to One Way or Two Way Active state.</li> <li>• tableSynchronizationDone—Causes the CPU to transfer to synchronized state.</li> <li>• versionIncompatible—Causes the CPU to go to remote incompatible state</li> <li>• noEvent—Means no event occurred to date.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>StandbyCpu</b> | Indicates the state of the standby CPU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configure Channelization

Use this procedure to enable or disable channelization on a port. Channelization configures the port to operate as four channels, or ports.

### Important

Enabling or disabling channelization resets the port QoS configuration to default values.

### Procedure

1. In the Device Physical View tab, select a port that supports channelization.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Channelization** tab.

5. To enable channelization on the port, select **enable** .
6. Select **Apply** . Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Enable**.
7. To disable channelization on a port, select the first sub-port for the corresponding port, slot/port/1.
8. In the navigation pane, expand **Configuration > Edit > Port**.
9. Select **General**.
10. Select the **Channelization** tab.
11. To disable channelization on the port, select **disable**. This action will disable the four sub-ports.
12. Select **Apply** . Alternatively, you can right-click the port on the Device Physical View tab, and then select **Channelization Disable**.

### Channelization Field Descriptions

Use the data in the following table to use the **Channelization** tab.

| Name                  | Description                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Channelization</b> | This field determines whether channelization is enabled or disabled on the selected port. The two options are <b>enable</b> and <b>disable</b> . The default is <b>disable</b> . |

## Configure Basic Port Parameters

Configure options for port operations.

### About This Task

If you select more than one port, the format of the tab changes to a table-based tab.

When you use 1 Gigabit Ethernet SFP transceivers, the software disables Auto-Negotiation on the port. If you use 1 Gbps SFP transceivers, the remote end must also have Auto-Negotiation disabled.

### Procedure

1. In the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. Configure the fields as required.
 

10/100BASE-TX ports do not consistently auto-negotiate with older 10/100BASE-TX equipment. You can sometimes upgrade the older devices with new firmware or driver revisions. If an upgrade does not enable auto-negotiation to correctly identify the link speed and duplex settings, you can manually configure the settings for the link in question.

Check the Extreme Networks Web site for the latest compatibility information.
6. Select **Apply**.

**Interface** Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                                                                                             | Description                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                                                                                     | Displays the index of the port, written in the slot/port[/sub-port] format.                                                                                                                                                                                                                                           |
| <b>Name</b>                                                                                      | Configures the name of the port.                                                                                                                                                                                                                                                                                      |
| <b>Descr</b>                                                                                     | Displays the description of the port. A textual string containing information about the interface.                                                                                                                                                                                                                    |
| <b>Type</b>                                                                                      | Displays the type of connector plugged in the port.                                                                                                                                                                                                                                                                   |
| <b>Mtu</b>                                                                                       | Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. |
| <b>PhysAddress</b>                                                                               | Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address (e.g., a serial line), this object should contain an octet string of zero length.                         |
| <b>VendorDescr</b>                                                                               | Displays the vendor of the connector plugged in the port.                                                                                                                                                                                                                                                             |
| <b>DisplayFormat</b>                                                                             | Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port                                                                                                                                                                  |
| <b>AdminStatus</b>                                                                               | Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                                                             |
| <b>OperStatus</b>                                                                                | Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                       |
| <b>LicenseControlStatus</b><br><br><b>Note:</b><br>Exception: only supported on VSP 7200 Series. | Shows the port license status.                                                                                                                                                                                                                                                                                        |
| <b>ShutdownReason</b>                                                                            | Indicates the reason for a port state change.                                                                                                                                                                                                                                                                         |
| <b>LastChange</b>                                                                                | Displays the timestamp of the last change.                                                                                                                                                                                                                                                                            |
| <b>LinkTrap</b>                                                                                  | Enable or disable link trapping.                                                                                                                                                                                                                                                                                      |
| <b>AutoNegotiate</b>                                                                             | Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.                                                                                                                                                                           |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoNegAd</b>           | <p>Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware.</p> <p>The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability).</p> <p>Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port.</p> <p>If you select <b>default</b>, all capabilities supported by the hardware are advertised.</p> |
| <b>AdminDuplex</b>         | Configures the administrative duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OperDuplex</b>          | Indicates the operational duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AdminSpeed</b>          | <p>Configures the administrative speed for the port.</p> <p><b>Important:</b><br/>If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OperSpeed</b>           | Indicates the operational speed for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>QoSLevel</b>            | Selects the Quality of Service (QoS) level for this port. The default is level1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DiffServ</b>            | Enables the Differentiated Service feature for this port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Layer3Trust</b>         | Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Layer2Override8021p</b> | Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MltId</b>               | Shows the MLT ID associated with this port. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Locked</b>              | Shows if the port is locked. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>UnknownMacDiscard</b>   | Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. | <b>AutoSenseKeepAutoConfig</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the <b>show running-config</b> output. |
| <b>AutoSenseState</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series.          | Displays the Auto-sense port state.                                                                                                                                                           |

## Configure Basic Parameters on an Extreme Integrated Application Hosting Port

### About This Task

Perform this procedure to configure basic parameters on Extreme Integrated Application Hosting (IAH) ports, for example, auto negotiation, QoS level, and remote monitoring.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Interface** tab.
4. In the **Name** field, type a name for the IAH port.
5. Configure the fields as required.
6. Select **Apply**.

### Interface Field Descriptions

Use data in the following table to use the **Interface** tab.

| Name         | Description                                                                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b> | Specifies the index of the Extreme Integrated Application Hosting (IAH) port, written in the slot/port[/sub-port] format.                                                                                                                                                                                              |
| <b>Name</b>  | Specifies the name of the IAH port.                                                                                                                                                                                                                                                                                    |
| <b>Descr</b> | Specifies the information about the interface.                                                                                                                                                                                                                                                                         |
| <b>Type</b>  | Specifies the type of connector plugged in the IAH port.                                                                                                                                                                                                                                                               |
| <b>Mtu</b>   | Specifies the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. |

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PhysAddress</b>          | Specifies the physical address of the IAH port. The address of the interface at the protocol layer immediately below the network layer in the protocol stack. For interfaces which do not have such an address (like a serial line), this object should contain an octet string of zero length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>VendorDescr</b>          | Specifies the vendor of the connector plugged in the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DisplayFormat</b>        | Specifies the slot and port numbers (slot/port).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AdminStatus</b>          | Specifies the operational status of the IAH port. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OperStatus</b>           | Specifies the current status of the IAH port. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>LicenseControlStatus</b> | Specifies the IAH port license status.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ShutdownReason</b>       | Specifies the reason for the IAH port state change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>LastChange</b>           | Specifies the timestamp of the last change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>LinkTrap</b>             | Enables or disables link trapping. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AutoNegotiate</b>        | Enables or disables auto-negotiation for the IAH port. The default is true (enabled).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>AutoNegAd</b>            | Specifies the port speed and duplex abilities to be advertised during link negotiation. The abilities specified in this object are only used when auto-negotiation is enabled on the IAH port. If all bits in this object are disabled, and auto-negotiation is enabled on the IAH port, then the physical link process on the IAH port will be disabled (if hardware supports this ability). Any change in the value of this bit map will force the switch to restart the auto-negotiation process. The capabilities being advertised are either all the capabilities supported by the hardware or the user-configured capabilities, which is a subset of all the capability supported by hardware. By default, all capabilities supported by the hardware are enabled. |
| <b>AdminDuplex</b>          | Specifies the administrative duplex setting for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OperDuplex</b>           | Specifies the operational duplex setting for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AdminSpeed</b>           | Specifies the administrative speed for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OperSpeed</b>            | Specifies the operational speed for the IAH port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>QoSLevel</b>             | Specifies the Quality of Service (QoS) level for the IAH port. The default is level1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Name                          | Description                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DiffServ</b>               | Enables the Differentiated Service feature for the IAH port. The default is enabled.                                                                                                                                     |
| <b>Layer3Trust</b>            | Specifies if the system should trust Layer 3 packets coming from access links or core links only. The default is core.                                                                                                   |
| <b>Layer2Override8021p</b>    | Specifies whether Layer 2 802.1p override is enabled or disabled. The default is disabled.                                                                                                                               |
| <b>MltId</b>                  | Specifies the MLT ID associated with the IAH port. The default is 0.                                                                                                                                                     |
| <b>Locked</b>                 | Specifies if the IAH port is locked. The default is false.                                                                                                                                                               |
| <b>UnknownMacDiscard</b>      | Enables the functionality to discard packets with an unknown source MAC address, and prevents the other IAH port from sending packets with the same MAC address as the destination MAC address. The default is disabled. |
| <b>DirectBroadcastEnable</b>  | Specifies if the IAH port forwards direct broadcast traffic.                                                                                                                                                             |
| <b>OperRouting</b>            | Specifies the routing status of the IAH port. The default is disabled.                                                                                                                                                   |
| <b>HighSecureEnable</b>       | Enables or disables the high secure feature for the IAH port. The default is disabled.                                                                                                                                   |
| <b>RmonEnable</b>             | Enables or disables Remote Monitoring (RMON) on the IAH port. The default is disabled.                                                                                                                                   |
| <b>FlexUniEnable</b>          | Enables or disables Flex UNI on the IAH port. The default is disabled.                                                                                                                                                   |
| <b>EgressRateLimitState</b>   | Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the IAH port. The default is disabled.                                                                                    |
| <b>EgressRateLimit</b>        | Specifies the egress rate limit in Kbps. Different hardware platforms provide different port speeds. The default is 0.                                                                                                   |
| <b>TxFlowControl</b>          | <p>Specifies if the IAH port is sending pause frames. The default is disabled.</p> <p><b>Note:</b><br/>You must enable the flow control feature globally.</p>                                                            |
| <b>TxFlowControlOperState</b> | Specifies the operational state of flow control.                                                                                                                                                                         |
| <b>BpduGuardTimerCount</b>    | Specifies the duration since when the IAH port is disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the IAH port is enabled.                                                                    |

| Name                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BpduGuardTimeout</b>                    | Specifies the time (in seconds) for the IAH port-state recovery. After the IAH port is disabled by the BPDU guard, the IAH port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.                                                                                                                                                                                                            |
| <b>BpduGuardAdminEnabled</b>               | Enables or disables BPDU Guard on the IAH port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ForwardErrorCorrection</b>              | Configures one of the following options for Forward Error Correction (FEC) on the IAH port: <ul style="list-style-type: none"> <li>• CL 91</li> <li>• CL 108</li> <li>• CL 74</li> <li>• disable</li> <li>• auto</li> </ul> The disable option disables this configuration on the port.                                                                                                                                                                                                 |
| <b>ForwardErrorCorrectionApplicability</b> | Displays whether FEC is applicable on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OperAutoNegotiate</b>                   | Shows the operational state of Auto-Negotiation.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OperForwardErrorCorrection</b>          | Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.                                                                                                                                                                                                                                 |
| <b>Action</b>                              | Specifies the following actions on the IAH port: <ul style="list-style-type: none"> <li>• none - no action.</li> <li>• flushMacFdb - flush the MAC forwarding table.</li> <li>• flushArp - flush the ARP table.</li> <li>• flushIp - flush the IP route table.</li> <li>• flushAll - flush all tables.</li> <li>• triggerRipUpdate - manually triggers a RIP update.</li> <li>• clearLoopDetectAlarm - clears the loop detection alarm on the IAH port.</li> </ul> The default is none. |
| <b>Result</b>                              | Specifies the result of the selected action. The default is none.                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configure IEEE 802.3X Pause Frame Transmit

Configure IEEE 802.3X Pause frame transmit to eliminate or minimize packet loss.

### About This Task

By default, flow control mode is disabled. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.

By default, an interface does not send pause frames.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **Boot Config** tab.
4. For EnableFlowControlMode, select **enable**.
5. Click **Apply**.
6. Save the switch configuration.
7. Reboot the chassis, and log in again.
8. In the Device Physical View, select a port or ports.
9. In the navigation pane, expand **Configuration > Edit > Port**.
10. Click **General**.
11. Click the **Interface** tab.
12. For TxFlowControl, select **enable** to enable the interface to generate pause frames.
13. Click **Apply**.

## View the Boot Configuration

### About This Task

View the boot configuration to determine the software version, as well as view the source from which the switch last started.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **Boot Config** tab.

### **Boot Config** Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

| Name                           | Description                                                        |
|--------------------------------|--------------------------------------------------------------------|
| <b>SwVersion</b>               | Specifies the software version that currently runs on the chassis. |
| <b>LastRuntimeConfigSource</b> | Specifies the last source for the run-time image.                  |
| <b>PrimaryConfigSource</b>     | Specifies the primary configuration source.                        |

| Name                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrimaryBackupConfigSource</b>                                      | Specifies the backup configuration source to use if the primary does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFactoryDefaultsMode</b>                                      | <p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> <li>• <b>false</b>: The node does not use factory default settings at startup.</li> <li>• <b>fabric</b>: The node uses the factory default fabric mode settings at startup. Zero Touch Fabric Configuration is enabled.</li> <li>• <b>noFabric</b>: The node uses the factory default mode settings at startup.</li> </ul> <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> |
| <b>EnableDebugMode</b>                                                | <p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                     |
| <b>EnableRebootOnError</b>                                            | <p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EnableTelnetServer</b>                                             | Activates or disables the Telnet server service. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableRloginServer</b>                                             | Activates or disables the rlogin and rsh server. The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p><b>Note:</b><br/>Exception: only supported on VSP 8600 Series.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFtpServer</b>                                                | Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTP flag is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

The default value is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EnableSpbmConfigMode</b>                                           | Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Name                                                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EnableIpv6Mode</b><br><br><b>Note:</b><br>Exception: not supported on VSP 4450 Series or XA1400 Series .                                                          | Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.                                                                                                                                                                                                                                                                         |
| <b>EnableEnhancedsecureMode</b>                                                                                                                                      | Enables or disables the enhanced secure mode. Select either <b>jitc</b> or <b>non-jitc</b> to enable the enhanced secure mode in one of these sub-modes. The default is disabled.<br><br><b>Note:</b><br>As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities. |
| <b>EnableUrpFMode</b>                                                                                                                                                | Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.                                                                                                                                                                                                                                  |
| <b>EnableVxlanGwFullInterworkingMode</b><br><br><b>Note:</b><br>Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series. | Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.<br>In Base Interworking Mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.               |
| <b>EnableFlowControlMode</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series.                                                                     | Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames.<br>The default is disabled.                           |
| <b>AdvancedFeatureBwReservation</b><br><br><b>Note:</b><br>Exception: only supported on 5520 Series, VSP 7400 Series and XA1480.                                     | Enables the switch to support advanced features. The default is enabled with low level configuration. The high level means that the switch reserves the maximum bandwidth for the advanced features. The low level means that the switch reserves less bandwidth to support minimum functionality for advanced features.<br>If you change this parameter, you must restart the switch.      |
| <b>EnableDvrLeafMode</b>                                                                                                                                             | Enables the switch to be configured as a DvR Leaf. When enabled, you cannot configure the switch to operate as a DvR Controller.                                                                                                                                                                                                                                                            |

| Name                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EnableVrfScaling</b>                                                                         | <p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p><b>Important:</b><br/>If you select both this check box and the <b>EnableSpbmConfigMode</b> check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <a href="#">Release Notes for VOSS</a>.</p> |
| <b>EnableSyslogRfc5424Format</b>                                                                | <p>Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.</p>                                                                                                                                                                                                                                   |
| <b>NniMstp</b>                                                                                  | <p>Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM NNI ports. The default is disabled.</p> <p><b>Note:</b><br/>Spanning Tree is disabled on all SPBM NNIs.</p> <p>You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.</p>                                                                                                                                                                                     |
| <b>EnableIpv6EgressFilterMode</b>                                                               | <p>Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                      |

## Configure Boot Flags

### About This Task

Change the boot configuration to determine the services available after the system starts.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. Select the services you want to enable.
4. Select **Apply**.

### **Boot Config** Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SwVersion</b>                 | Specifies the software version that currently runs on the chassis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LastRuntimeConfigSource</b>   | Specifies the last source for the run-time image.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PrimaryConfigSource</b>       | Specifies the primary configuration source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>PrimaryBackupConfigSource</b> | Specifies the backup configuration source to use if the primary does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableFactoryDefaultsMode</b> | <p>Specifies whether the switch uses the factory default settings at startup.</p> <ul style="list-style-type: none"> <li>• <b>false</b>: The node does not use factory default settings at startup.</li> <li>• <b>fabric</b>: The node uses the factory default fabric mode settings at startup. Zero Touch Fabric Configuration is enabled.</li> <li>• <b>noFabric</b>: The node uses the factory default mode settings at startup.</li> </ul> <p>The default value is false. This flag is automatically reset to the default setting after the switch restarts. If you change this parameter, you must restart the switch for the change to take effect.</p> |

| Name                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>TftpRetransmit</b>                                                                           | Set TFTP retransmit timeout counter.                                                                                                                                                                                                             |
| <b>TftpTimeout</b>                                                                              | Set TFTP timeout counter.                                                                                                                                                                                                                        |
| <b>User</b>                                                                                     | Configure host user.                                                                                                                                                                                                                             |
| <b>Password</b>                                                                                 | Configure host password.                                                                                                                                                                                                                         |

## Reserve Bandwidth for Advanced Features

Use this procedure if you want the switch to support advanced features. When you enable the boot flag, you need to save and reboot with the new configuration.

### Before You Begin

Product Notice: For 5520 Series and VSP 7400 Series, you must ensure your configuration does not include reserved ports before you enable this feature. If the configuration includes reserved ports after you enable this feature and restart the switch, the switch stops loading the configuration.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. In the **AdvancedFeatureBWReservation** field, select **high** or **low** to enable the boot flag.
4. Select **Apply**.

A message appears to remind you that the configuration cannot include reserved ports, and that you must save the configuration and reboot the switch for changes to take effect.
5. Select **Yes** to continue or click **No** to cancel the change because the configuration includes reserved ports.

If you clicked No, you can modify your switch configuration to remove the reserved ports and then return to this tab to change the **AdvancedFeatureBWReservation** configuration.
6. Save the configuration, and then reboot the switch.

## Enable Jumbo Frames

### About This Task

Enable Jumbo frames to increase the size of Ethernet frames supported on the chassis.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Chassis** tab.
5. In **MTU size**, select either 1950, 9600 or 1522.
6. Click **Apply**.

## Configure the Date and Time

Configure the date and time to correctly identify when events occur on the system.

### About This Task

#### Note

According to a bill passed by the government of Russia, from October 2014 Moscow has moved from UTC+4 into UTC+3 time zone with no daylight savings. The software includes this change.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **User Set Time** tab.
5. Type and select the correct details.
6. Click **Apply**.

**User Set Time** field descriptions

Use the data in the following table to use the **User Set Time** tab.

| Name             | Description                                                   |
|------------------|---------------------------------------------------------------|
| <b>Year</b>      | Configures the year (integer 1998–2097). The default is 1998. |
| <b>Month</b>     | Configures the month. The default is 1.                       |
| <b>Date</b>      | Configures the day (integer 1–31). The default is 1.          |
| <b>Hour</b>      | Configures the hour (12am–11pm). The default is 0.            |
| <b>Minute</b>    | Configures the minute (integer 0–59). The default is 0.       |
| <b>Second</b>    | Configures the second (integer 0–59). The default is 0.       |
| <b>Time Zone</b> | Configures the time zone.                                     |

## Configure CP Limit

Configure CP Limit functionality to protect the switch from becoming congested by an excess of data flowing through one or more ports.

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select the **AutoRecoverPort** check box.
6. Click **Apply**.

**CP Limit** field descriptions

Use the data in the following table to use the **CP Limit** tab.

| Name                   | Description                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoRecoverPort</b> | Activates or disables auto recovery of the port from action taken by CP Limit or link flap features. The default value is disabled. |

## Configure CP Limit on an Extreme Integrated Application Hosting Port

**About This Task**

Perform this procedure to configure CP Limit functionality to protect the switch from becoming congested by excess data flow through Extreme Integrated Application Hosting (IAH) ports.

## Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **CP Limit** tab.
4. Select **AutoRecoverPort**.
5. Select **Apply**.

### **CP Limit** Field Descriptions

Use data in the following table to use the **CP Limit** tab.

| Name                   | Description                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoRecoverPort</b> | Enables or disables auto recovery of the Extreme Integrated Application Hosting port from action taken by CP Limit or the link flap features. The default is disabled. |

## Configure an IP Address for the Management Port

### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 85.

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF.

The configured IP subnet must be globally unique because the management protocols can go through in-band (Global Router) or out-of-band ports (Management VRF).

This procedure only applies to hardware with a dedicated, physical management interface.

### Before You Begin

- You must make a direct connection through the console port to configure a new IP address. If you connect remotely, you can view or delete the existing IP address configuration. If you delete the IP address remotely, you lose the EDM connection to the device.
- Do not configure a default route in the Management VRF.
- If you want out-of-band management, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.
- If you initiate an FTP session from a client device behind a firewall, you should set FTP to passive mode.
- The switch gives priority to out-of-band management when there is reachability from both in-band and out-of-band. To avoid a potential conflict, do not configure any overlapping between in-band and out-of-band networks.

## About This Task

Configure an IP address for the management port so that you can remotely access the device using the out-of-band (OOB) management port. The management port runs on a dedicated VRF. Redirect all commands that are run on the management port to its VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band or out-of-band ports.

### Note

Do not configure a default route in the Management VRF and instead use a static route. Inbound FTP does not work when a default route is configured at the Management VRF. When you initiate FTP, you should also set FTP to passive mode.

## Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select **MgmtRouter**, VRF 512.
4. Select **Launch VRF Context View**.

A new EDM webpage displays for the VRF context. Parameters that you cannot configure for this context appear dim.

5. In the Device Physical view, select the management port.
6. In the navigation pane, expand **Configuration > Edit**.
7. Select **Mgmt Port**.
8. Select the **IP Address** tab.
9. Select **Insert**.
10. Configure the IP address and mask.
11. Select **Insert**.
12. Collapse the VRF context view.

### **IP Address** field descriptions

Use the data in the following table to use the **IP Address** tab.

| Name                   | Description                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Specifies the slot and port for the management port.                                                                                |
| <b>Ip Address</b>      | Specifies the IP address for the management port.                                                                                   |
| <b>Net Mask</b>        | Specifies the subnet mask for the IP address.                                                                                       |
| <b>BcastAddrFormat</b> | Specifies the broadcast address format for the management port.                                                                     |
| <b>ReasmMaxSize</b>    | Specifies the size of the largest IP datagram that can be reassembled from IP fragmented datagrams received on the management port. |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>      | Specifies the VLAN ID to which the management port belongs.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>BrouterPort</b> | Specifies if the management port is a brouter port rather than a routeable VLAN. You cannot change this value after the row is created.                                                                                                                                                                                                                                                                                                                                                   |
| <b>MacOffset</b>   | Translates the IP address into a MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Edit the Management Port Parameters

### About This Task

The management port on the switch is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

#### Note

This procedure only applies to hardware with a dedicated physical management interface.

If you use EDM to configure the static routes of the management port, you do not receive a warning if you configure a non-natural mask. After you save the changes, the system deletes those static routes after the next restart, possibly causing the loss of IP connectivity to the management port.

If you are uncertain whether the mask you configure is non-natural, use the CLI to configure static routes.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Mgmt Port**.
4. Click the **General tab**.
5. Modify the appropriate settings.
6. Click **Apply**.

**General** Field Descriptions

Use the data in the following table to use the **General** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                | Specifies the slot and port number of the management port.                                                                                                                                                                                                                                                                                                                                                           |
| <b>AdminStatus</b>          | Configures the administrative status of the device as up (ready to pass packets) or down. The testing state indicates that no operational packets can be passed.                                                                                                                                                                                                                                                     |
| <b>OperStatus</b>           | Specifies the operational status of the device.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>LicenseControlStatus</b> | Shows the license status of the port: <ul style="list-style-type: none"> <li>• Locked means the port requires a Port License but one is not present on the switch.</li> <li>• Unlocked means the port requires a Port License and one is present on the switch.</li> <li>• notApplicable means the port does not require a Port License.</li> </ul>                                                                  |
| <b>Mtu</b>                  | Shows the configuration for the maximum transmission unit. The size of the largest packet which can be sent/received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.                                                                                                     |
| <b>LinkTrap</b>             | Enables or disables traps for the link status.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>IpsecEnable</b>          | Enables IPsec on the management port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                       |
| <b>PhysAddress</b>          | Shows the MAC address.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AutoNegotiate</b>        | Enables or disables Auto-Negotiation for the management port. The default varies depending on the platform: <ul style="list-style-type: none"> <li>• 5520 Series - enabled</li> <li>• VSP 4900 Series - enabled</li> <li>• VSP 7200 Series - disabled</li> <li>• VSP 7400 Series - enabled</li> <li>• VSP 8200 Series - enabled</li> <li>• VSP 8400 Series - enabled</li> <li>• VSP 8600 Series - enabled</li> </ul> |
| <b>AdminDuplex</b>          | Specifies the administrative duplex mode for the management port. The default is full.                                                                                                                                                                                                                                                                                                                               |
| <b>OperDuplex</b>           | Specifies the operational duplex configuration for this port.                                                                                                                                                                                                                                                                                                                                                        |
| <b>AdminSpeed</b>           | Specifies the administrative speed for this port. The default is 100 Mb/s.                                                                                                                                                                                                                                                                                                                                           |
| <b>OperSpeed</b>            | Shows the current operating data rate of the port.                                                                                                                                                                                                                                                                                                                                                                   |

## Configure the Management Port IPv6 Interface Parameters

**Note**

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 85.

### About This Task

Configure IPv6 management port parameters to use IPv6 routing on the port.

This procedure only applies to hardware with a dedicated, physical management interface.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Interface** tab.
5. Select **Insert**.
6. Edit the fields as required.
7. Select **Insert**.
8. Select **Apply**.

#### **IPv6 Interface** field descriptions

Use the data in the following table to use the **IPv6 Interface** tab.

| Name                     | Description                                                                                                                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>         | Identifies the unique IPv6 interface.                                                                                                                                                                                                     |
| <b>Descr</b>             | Specifies a textual string containing information about the interface. The network management system also configures the <b>Descr</b> string.                                                                                             |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                                                                          |
| <b>ReasmMaxSize(MTU)</b> | Configures the MTU for this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.                                                                                    |
| <b>PhysAddress</b>       | Specifies the physical address for the interface. For example, for an IPv6 interface attached to an 802.x link, this value is a MAC address.                                                                                              |
| <b>AdminStatus</b>       | Configures the indication of whether IPv6 is activated (up) or disabled (down) on this interface. This object does not affect the state of the interface, only the interface connection to an IPv6 stack. The default is false (cleared). |
| <b>ReachableTime</b>     | Configures the time, in milliseconds, that the system considers a neighbor reachable after it receives a reachability confirmation. The value is in a range from 0-3600000. The default value is 30000.                                   |

| Name                   | Description                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RetransmitTimer</b> | Configures the time between retransmissions of neighbor solicitation messages to a neighbor; during address resolution or neighbor reachability discovery. The value is expressed in milliseconds in a range from 0–3600000. The default value is 1000.                  |
| <b>CurHopLimit</b>     | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for the current hop limit. The default is 64. |

## Configure Management Port IPv6 Addresses

### Note

This procedure only applies to VSP 8600 Series. For other products, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 85.

### About This Task

Configure management port IPv6 addresses to add or remove IPv6 addresses from the port.

The switch supports IPv6 addressing with Ping, Telnet, and SNMP.

### Procedure

1. In the Device Physical View tab, select the management port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Mgmt Port**.
4. Select the **IPv6 Addresses** tab.
5. Select **Insert**.
6. In the **Addr** box, type the required IPv6 address for the management port.
7. In the **AddrLen** box, type the number of bits from the IPv6 address you want to advertise.
8. Select **Insert**.
9. Select **Apply**.

### *IPv6 Addresses* field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

| Name             | Description                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Specifies an index value that uniquely identifies the interface.                                                                                                                                                                                                                           |
| <b>Addr</b>      | Specifies the IPv6 address to which this entry addressing information pertains.<br>If the IPv6 address exceeds 116 octets, the object identifiers (OIDs) of instances of columns in this row is more than 128 subidentifiers and you cannot use SNMPv1, SNMPv2c, or SNMPv3 to access them. |

| Name               | Description                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddrLen</b>     | Specifies the prefix length value for this address. You cannot change the address length after creation. You must provide this field to create an entry in this table.                                                |
| <b>Type</b>        | Specifies unicast, the only supported type.                                                                                                                                                                           |
| <b>Origin</b>      | Specifies the origin of the address. The origin of the address can be one of the following: other, manual, dhcp, linklayer, or random.                                                                                |
| <b>Status</b>      | Specifies the status of the address, describing if the address can be used for communication. The status can be one of the following: preferred, deprecated, invalid, inaccessible, unknown, tentative, or duplicate. |
| <b>Created</b>     | Specifies the time this entry was created. If this entry was created prior to the last initialization of the local network management subsystem, then this option contains a zero value.                              |
| <b>LastChanged</b> | Specifies the time this entry was last updated. If this entry was updated prior to the last initialization of the local network management subsystem, then this option contains a zero value.                         |

## Automatically Reactivating the Port of the SLPP Shutdown

### About This Task

Use the following procedure to automatically reactivate the port that is shut down by the SLPP.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **CP Limit** tab.
5. Select **AutoRecoverPort** to activate auto recovery of the port from the action taken by SLPP shutdown features. The default value is disabled.
6. Click **Apply**.

## Edit Serial Port Parameters

### About This Task

Perform this procedure to specify serial port communication settings. The serial port on the device is the console port. Depending on the hardware platform, the console port displays as console or 10101.

### Procedure

1. In the Device Physical View tab, select the console port on the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Serial Port**.
4. Edit the port parameters as required.
5. Click **Apply**.

**Serial Port** Field Descriptions

Use the data in the following table to use the **Serial Port** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>  | Identifies the port as a serial port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>BaudRate</b> | <p>Specifies the baud rate of this port. Different hardware platforms support different baud rates, which also impacts the default value for each hardware platform:</p> <ul style="list-style-type: none"> <li>• 5520 Series — 115200</li> <li>• VSP 4450 Series — 9600</li> <li>• VSP 4900 Series — 115200</li> <li>• VSP 7200 Series — 9600</li> <li>• VSP 7400 Series — 115200</li> <li>• VSP 8000 Series — 9600</li> <li>• VSP 8600 Series — 115200</li> <li>• XA1400 Series — 115200</li> </ul> |
| <b>DataBits</b> | Specifies the number of data bits, for each byte of data, this port sends and receives. The default is eight.                                                                                                                                                                                                                                                                                                                                                                                         |

## Enable Port Lock

**About This Task**

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Lock a Port

### Before You Begin

- You must enable port lock before you lock or unlock a port.

### About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **General**.
- Click the **Port Lock** tab.
- In the **LockedPorts** box, click the ellipsis (...) button.
- Click the desired port or ports.
- Click **Ok**.
- In the **Port Lock** tab, click **Apply**.

### **Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

| Name               | Description                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Enable</b>      | Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.         |
| <b>LockedPorts</b> | Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock. |

## Configure Power on Module Slots

### About This Task

Use this procedure to control whether or not to supply power to specific slots that contain either switch fabric modules or input/output modules. By default, power is available to all slots.

After enabling power to specific input/output module slots, you can also configure the priority in which they are powered on. For more information, see [Configure Slot Priority](#) on page 607.

#### Note

This feature is not available for hardware platforms with fixed configurations. It is only available for platforms where the user can install modules in slots.

### Procedure

- In the Device Physical View tab, select a module.
- In the navigation pane, expand **Configuration > Edit**.
- Click **Card**.

4. Click the **Card** tab.
5. In the **SlotPower** field, select the priority level: *on* or *off*.
6. Click **Apply**.

## Configure Slot Priority

### Note

This procedure only applies to VSP 8600 Series.

### About This Task

Configure slot priority to specify which slots you want to shut down if there is insufficient power available in the chassis. By default, power is available to all slots, and the slots have the following priority:

- Slots 1, 2, SF1, SF2, and SF3 must always be *Critical* so you cannot configure them.
- Slots 3-8 are *High* by default, but you can configure any of them to *Low*.

### Note

Power is always supplied to critical slots first which are the CP modules, SF modules, and fan trays.

The slot with the lowest priority shuts down first. Slots with the same priority shut down in descending order (highest slot number first) and interface slots shut down before CP, SF modules, and fan tray slots.

For example, if slot 3 has a *low* priority and slots 4 and 5 have a *high* priority, the slot shutdown priority is as follows: 4, 5, 3. Slot 3 has the lowest priority because it was configured as *low* so it would be shut down first. Slots 4 and 5 have the same priority, but slot 5 shuts down before slot 4 because slot 4 has a higher slot number.

### Procedure

1. In the Device Physical View tab, select a module.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Card**.
4. Click the **Card** tab.
5. In the **PowerManagementPriority** field, select the priority level: *high* or *low*.
6. Click **Apply**.

## View Power Information

### About This Task

View power information to see the amount of power available and used by the chassis and all components.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Power Info** tab.

#### *Power Info field descriptions*

Use the data in the following table to use the **Power Info** tab.

| Name                  | Description                                             |
|-----------------------|---------------------------------------------------------|
| <b>TotalPower</b>     | Shows the total power for the chassis.                  |
| <b>RedundantPower</b> | Shows the redundant power for the chassis.              |
| <b>PowerUsage</b>     | Shows the power currently used by the complete chassis. |
| <b>PowerAvailable</b> | Shows the unused power.                                 |

## View Power Status

### About This Task

Perform the following procedure to view the power consumption of the modules in the chassis.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **Power Consumption** tab.

#### *Power consumption field descriptions*

Use the data in the following table to use the **Power Consumption** tab.

| Name                   | Description                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------|
| <b>Index</b>           | Displays an index value that identifies the component.                                       |
| <b>PowerStatus</b>     | Displays the power status: on or off.                                                        |
| <b>BasePower</b>       | Displays the base power required for the slot.                                               |
| <b>ConsumedPower</b>   | Displays the actual consumed power for the slot. This value is 0 if the power status is off. |
| <b>PowerPriority</b>   | Displays the priority of the slot for power management.                                      |
| <b>SlotDescription</b> | Displays the slot number.                                                                    |
| <b>CardDescription</b> | Identifies the type of module in the slot.                                                   |

## View Fan Tray Information

View fan tray information to see manufacturing information about the fans.

### Note

Not all fields are supported on all hardware platforms.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Fan Tray Info** tab.

### *Fan Tray Info* field descriptions

Use the data in the following table to use the **Fan Tray Info** tab.

| Name                | Description                                                       |
|---------------------|-------------------------------------------------------------------|
| <b>TrayId</b>       | Specifies the fan tray ID.                                        |
| <b>Description</b>  | Shows a description of the fan tray.                              |
| <b>SerialNumber</b> | Shows the serial number for the fan tray.                         |
| <b>PartNumber</b>   | Shows the part number for the fan tray.                           |
| <b>FlowType</b>     | Specifies whether the air flow is front-to-back or back-to-front. |

## View USB Port Information

### About This Task

Perform this procedure to view information about the USB port on the switch.

### Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

### Procedure

1. In the Device Physical View, select the USB port.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **USB Port**.
4. Click the **General** tab.

*General field descriptions*

Use the data in the following table to use the **General** tab.

| Name                  | Description                                                               |
|-----------------------|---------------------------------------------------------------------------|
| <b>UsbStatus</b>      | Displays the current status of USB storage: either present or notPresent. |
| <b>UsbDescription</b> | Displays a description of the USB storage.                                |

## View USB Device Information

### About This Task

Perform this procedure to view information about an inserted USB device.

#### Note

This information may not apply to your hardware model. For more information about your model features, see your hardware documentation.

### Procedure

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **USB** tab.

*USB field descriptions*

Use the data in the following table to use the USB tab.

| Name                   | Description                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>SlotDescription</b> | Specifies the slot type information.                                                                                             |
| <b>VendorId</b>        | Specifies the vendor ID for the inserted USB device.                                                                             |
| <b>Manufacturer</b>    | Specifies the manufacturer of the inserted USB device.                                                                           |
| <b>ProductId</b>       | Specifies the product ID of the inserted USB device.                                                                             |
| <b>ProductName</b>     | Specifies the product name of the inserted USB device.                                                                           |
| <b>SerialNumber</b>    | Specifies the serial number of the inserted USB device.                                                                          |
| <b>Revision</b>        | Specifies the release number of the inserted USB device.                                                                         |
| <b>MaxCurrent</b>      | Specifies the maximum power as defined by the specification for the inserted USB device. The units of measurement are milliamps. |

## View Topology Status Information

### About This Task

View topology status information (which includes MIB status information) to view the configuration status of the SynOptics Network Management Protocol (SONMP) on the system.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology** tab.

### *Topology* field descriptions

Use the data in the following table to use the **Topology** tab.

| Name             | Description                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>    | Specifies the IP address of the device.                                                                                                                                                                                  |
| <b>Status</b>    | Indicates whether topology (SONMP) is on or off for the device.                                                                                                                                                          |
| <b>NmmLstChg</b> | Specifies the value of sysUpTime, the last time an entry in the network management MIB (NMM) topology table was added, deleted, or modified, if the table did not change since the last cold or warm start of the agent. |
| <b>NmmMaxNum</b> | Specifies the maximum number of entries in the NMM topology table.                                                                                                                                                       |
| <b>NmmCurNum</b> | Specifies the current number of entries in the NMM topology table.                                                                                                                                                       |

## View the Topology Message Status

### About This Task

View topology message status to view the interconnections between Layer 2 devices in a network.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **Topology**.
3. Click the **Topology Table** tab.

### *Topology Table* Field Descriptions

Use the data in the following table to use the **Topology Table** tab.

| Name           | Description                                                                             |
|----------------|-----------------------------------------------------------------------------------------|
| <b>Slot</b>    | Specifies the slot number in the chassis that received the topology message.            |
| <b>Port</b>    | Specifies the port that received the topology message.                                  |
| <b>SubPort</b> | Specifies the channel of a channelized 40 Gbps port that received the topology message. |

| Name                   | Description                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>          | Specifies the IP address of the sender of the topology message.                                                                                                                                                                                                                                      |
| <b>SegId (RemPort)</b> | Specifies the segment identifier of the segment from which the remote agent sent the topology message. This value is extracted from the message.                                                                                                                                                     |
| <b>MacAddr</b>         | Specifies the MAC address of the sender of the topology message.                                                                                                                                                                                                                                     |
| <b>ChassisType</b>     | Specifies the chassis type of the device that sent the topology message.                                                                                                                                                                                                                             |
| <b>BkplType</b>        | Specifies the backplane type of the device that sent the topology message.                                                                                                                                                                                                                           |
| <b>LocalSeg</b>        | Indicates if the sender of the topology message is on the same Ethernet segment as the reporting agent.                                                                                                                                                                                              |
| <b>CurState</b>        | Specifies the current state of the sender of the topology message. The choices are <ul style="list-style-type: none"> <li>• topChanged—Topology information recently changed.</li> <li>• heartbeat—Topology information is unchanged.</li> <li>• new—The sending agent is in a new state.</li> </ul> |

## Configure a Forced Message Control Pattern

### About This Task

Configure a forced message control pattern to enforce configured message control actions.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Click the **Force Msg Patterns** tab.
3. Click **Insert**.
4. In the **PatternId** field, enter a pattern ID number.
5. In the **Pattern** field, enter a message control pattern.
6. Click **Insert**.

*Force Msg Patterns Field Descriptions*

Use the data in the following table to use the **Force Msg Patterns** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PatternId</b> | Specifies a pattern identification number in the range 1-32.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Pattern</b>   | Specifies a forced message control pattern of 4 characters. The software and the hardware log messages that use the first four bytes matching one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****). If you specify the wildcard pattern, all messages undergo message control. |

**View Fan Information**

View fan information to monitor the alarm status of the cooling ports in the chassis.

**Note**

This tab does not appear on the VSP 8600 Series switch.

**About This Task**

For platforms that support both back-to-front and front-to-back airflow, the airflow direction must be the same for both the power supply fans and the chassis fan.

**Procedure**

1. On the Device Physical View, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Fan Info** tab.

*Fan Info field descriptions*

Use the data in the following tables to use the **Fan Info** tab.

| Name               | Description                                  |
|--------------------|----------------------------------------------|
| <b>Description</b> | Specifies a description of the fan location. |
| <b>OperStatus</b>  | Specifies the operation status of the fan.   |
| <b>OperSpeed</b>   | Specifies the actual fan speed.              |

## Configure Ports Speeds for All VIM Ports

### Note

This procedure only applies to 5520 Series and VSP 4900 Series.

Configure all of the ports on an installed Versatile Interface Module (VIM) to operate at the same speed.

### Note

Some VIMs must operate with all ports at the same speed, while others can operate with ports at different speeds. For more information, see [Release Notes for VOSS](#). You can configure VIM ports speed only on VIMs that must operate with all ports at the same speed.

### Before You Begin

Install the VIM before performing this procedure.

### About This Task

Use this procedure to configure the speed of all ports in a multi-port VIM to operate at either 10 Gbps or 25 Gbps.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **VIM** tab.
4. Select **mbps10000** or **mbps25000**.
5. Select **Apply**.

### VIM Field Descriptions

Use the data in the following table to use the VIM tab.

| Name              | Description                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminSpeed</b> | <ul style="list-style-type: none"> <li>• <b>mbps10000</b>: Configures all ports in a multi-port VIM to operate at 10 Gbps.</li> <li>• <b>mbps25000</b>: Configures all ports in a multi-port VIM to operate at 25 Gbps.</li> </ul> <p>The default is 25 Gbps.</p> |

## View Modular SSD Information

### About This Task

Perform this procedure to display information about an installed Solid State Drive (SSD) on a switch.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **SSD** tab.

**SSD Field Descriptions**

Use the data in the following table to use the SSD tab.

| Name                   | Description                                           |
|------------------------|-------------------------------------------------------|
| <b>ProductName</b>     | Specifies Solid State Drive (SSD) product name.       |
| <b>VendorName</b>      | Specifies the SSD vendor.                             |
| <b>ManufactureDate</b> | Specifies the date on which the SSD was manufactured. |
| <b>SerialNum</b>       | Specifies the SSD serial number.                      |
| <b>PartNum</b>         | Specifies the SSD part number.                        |
| <b>DeviceVersion</b>   | Specifies the version of the SSD.                     |
| <b>TotalSize</b>       | Specifies the total memory size of the SSD.           |

**Prepare a slot for IOC Module Preconfiguration using EDM****About This Task**

Use this procedure to designate a slot in the switch for IOC Module Preconfiguration. A slot can be designated for only one module type at a time.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > Card Preconfig**.
2. Click **Insert**.
3. Enter the slot number in the **Slot** field.
4. Select the IOC Module type in the **CardType** field.
5. Select the **Lock** field to lock the slot to the specified IOC Module type.
6. Click **Insert**.

**Card Preconfig Field Descriptions**

Use the data in the following table to use the **Card Preconfig** tab.

| Field           | Description                                                                       |
|-----------------|-----------------------------------------------------------------------------------|
| <b>Slot</b>     | Specifies the slot number designated for pre-configuration.                       |
| <b>CardType</b> | Specifies the type of the IOC Module designated for the slot.                     |
| <b>Lock</b>     | If selected, the slot is locked to only accept the type of IOC Module designated. |

## DHCP option 82

The DHCP option 82 is the DHCP Relay Agent Information option. The DHCP relay agent inserts option 82 when it forwards the client-originated DHCP packets to a DHCP server. The Relay Agent Information option is organized as a single DHCP option that contains one or more sub-options that convey information known by the relay agent. The DHCP server echoes the option back to the relay agent in server-to-client replies, and the relay agent removes the option before forwarding the reply to the client.

The DHCP option 82 is added at the DHCP relay level as shown in the following image.

**Figure 35: DHCP Client-Relay-Server Architecture**

The Relay Agent Information option (code 82) is a container for specific agent-supplied suboptions; Agent Circuit ID (code 1) and Agent Remote ID (code 2). The suboptions can represent different information relevant for the relay. The fields are encoded in the following manner, where N or n is the total number of octets in the Agent Information Field (all bytes of the suboptions):

**Figure 36: Format of the Relay Agent Information**

Because at least one of the sub-options must be defined, the minimum Relay Agent Information length is two (2), and the length n of the suboption can be zero (0). The sub-options do not have to appear in any particular order. No pad suboption is defined and the Information field is not terminated with 255 suboption.

## DHCP Suboptions

The suboptions are Agent Circuit ID and Agent Remote ID.

The DHCP relay agents can add the Agent Circuit ID to terminate switched or permanent circuits. The Agent Circuit ID encodes an agent-local identifier of the circuit from which a DHCP client-to-server packet was received. Agents can use the Circuit ID to relay DHCP responses back to the proper circuit. In the switch, the Agent Circuit ID field contains the ifIndex of the interface on which the packet is received.

DHCP relay agents can add the Agent Remote ID to terminate switched or permanent circuits, and can identify the remote host end of the circuit. The switch uses the Agent Remote ID field to encode the MAC address of the interface on which the packet is received. The Agent Remote ID must be globally unique.

## Agent Operations

A DHCP relay agent adds a Relay Agent Information field as the last option in the DHCP options field of any recognized BOOTP or DHCP packet forwarded from a client to a server. However, if the End Option

255 is present, then the DHCP relay agent adds a Relay Agent information field before the End Option 255 field.

Relay agents can receive a DHCP packet from an untrusted circuit with the gateway IP address (GIADDR) set to zero to indicate that the relay agent is the first-hop router from the gateway. If a Relay Agent Information option is present in the packet, the relay agent discards the packet and increments an error counter. A trusted circuit can contain a trusted downstream network element, for example, a bridge, between the relay agent and the client. The bridge can add a relay agent option but does not set the GIADDR field. In this case, the relay agent forwards the DHCP packet per normal DHCP relay agent operations, and sets the GIADDR field to the relay address. The relay agent does not add a second relay agent option.

You can distinguish between a trusted circuit and an untrusted circuit based on the type of circuit termination equipment you use. To make a circuit trusted, set the trusted flag under DHCP for each interface.

After packets append the Relay Agent Information option, the packets that exceed the MTU or the vendor size buffer of 64 bits, are forwarded without adding the Agent Information option, and an error counter is incremented.

The relay agent or the trusted downstream network element removes the Relay Agent Information option echoed by a server that is added when forwarding a server-to-client response back to the client.

The following list outlines the operations that the relay agent does not perform:

- The relay agent does not add an Option Overload option to the packet or use the file or sname fields to add the Relay Agent Information option. The agent does not parse or remove Relay Agent Information options that can appear in the sname or file fields of a server-to-client packet forwarded through the agent.
- The relay agent does not monitor or modify client-originated DHCP packets addressed to a server unicast address; this includes the DHCP-REQUEST sent when entering the RENEWING state.
- The relay agent does not modify DHCP packets that use the IPSEC Authentication Header or IPSEC Encapsulating Security Payload.

A DHCP relay agent can receive a client DHCP packet forwarded from a BOOTP/DHCP relay agent closer to the client. This packet has a GIADDR as non-zero, and may or may not already have a DHCP Relay Agent option in it.

Relay agents configured to add a Relay Agent option which receive a client DHCP packet with a nonzero GIADDR, discards the packet if the GIADDR spoofs a GIADDR address implemented by the local agent itself. Otherwise, the relay agent forwards any received DHCP packet with a valid non-zero GIADDR without adding any relay agent options. The GIADDR value does not change.

## DHCP Relay for IPv6

---

The Dynamic Host Configuration Protocol (DHCP) for IPv6 (RFC 3315) enables DHCP servers to pass configuration parameters such as IPv6 network addresses to IPv6 nodes. DHCP supports automatic allocation of reusable network addresses and of additional configuration parameters. This protocol is a stateful counterpart to stateless address autoconfiguration, and you can use it separately or concurrently with the latter to obtain configuration parameters. For more information about stateless address autoconfiguration, see [Host autoconfiguration](#) on page 1899.

To request the assignment of one or more IPv6 addresses, a client first locates a DHCP server, and then requests the assignment of addresses and other configuration information from the server:

1. The client sends a solicit message to the All\_DHCP\_Relay\_Agents\_and\_Servers (FF02::1:2) multicast address to find available DHCP servers.
2. Any server that can meet the requirements responds with an advertise message.
3. The client then chooses one of the servers and sends a request message to the server asking for confirmed assignment of addresses and other configuration information.
4. The server responds with a reply message that contains the confirmed addresses and configuration.

If a DHCP client does not need a DHCP server to assign it an IPv6 address, the client can obtain configuration information such as a list of available DNS servers or NTP servers through a single message and reply exchanged with a DHCP server.

IPv6 DHCP clients use link-local addresses to send and receive DHCP messages. To permit a DHCP client to send a message to a DHCP server that is not attached to the same link, you must configure a DHCP relay agent on the client link to relay messages between the client and server. The operation of the relay agent is transparent to the client.

A relay agent relays messages from clients and messages from other relay agents. The switch supports DHCP Relay for IPv6. Configure at least one relay agent when the client and server are in different networks.

You must configure the relay agent to use a list of destination addresses for available DHCP servers. The software does not support IPv6 multicast for site-local and global addresses.

The DHCP relay can be a Virtual Router Redundancy Protocol (VRRP) Address. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

**Note**

DHCP cannot work on the backup VRRP if the master fails. To achieve optimum results and to leverage redundancy, you must configure DHCP on the backup VRRP.

Clients listen for DHCP messages on UDP port 546. Servers and relay agents listen for DHCP messages on UDP port 547.

## Remote ID

IPv6 DHCP Relay supports the remote ID parameter (RFC4649). After you enable remote ID on the switch, the relay agent adds information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The server can use the supplied information in the process of assigning the addresses, delegated prefixes, and configuration parameters that the client is to receive.

The remote ID option contains two fields:

- vendor ID
- MAC address of the client

The switch uses a vendor ID of 1584.

## Limitations

The following list identifies configuration limitations:

- You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.
- The maximum number of servers to which a relay can send a message from one client, is 10.
- You can configure the number of forwarding paths per system. For information on the maximum limit, see [Release Notes for VOSS](#).

## DHCP Relay Network Topology and Workflow

The following example depicts the interaction between a DHCP client and a server:

**Figure 37: DHCP Client-Relay-Server Architecture**

The following list outlines the operations that the DHCP relay agent performs to forward the message to the server :

- When a client sends a request for the IP address or configuration parameters, the server responds with the details as requested by the client.

### Note

There should be at least one relay agent when client and server are located in different networks.

- A DHCP Relay IPv6 is established only between agents within the context of each VRF and when no cross VRF interaction is present.

### Note

**All\_DHCP\_Servers** multicast address option is not implemented for IPv6, as there is no IPv6 MCAST support for site-local and global address.

---

## UDP broadcast forwarding

---

Some network applications, such as the NetBIOS name service, rely on a User Datagram Protocol (UDP) broadcast to request a service or locate a server for an application. If a host is on a network, subnet segment, or VLAN that does not include a server for the service, UDP broadcasts are by default not forwarded to the server located on a different network segment or VLAN. You can resolve this problem by forwarding the broadcasts to the server through physical or virtual router interfaces.

UDP broadcast forwarding is a general mechanism for selectively forwarding limited UDP broadcasts received on an IP interface out to other router IP interfaces as a rebroadcast or to a configured IP address. If the address is that of a server, the packet is sent as a unicast packet to this address. If the address is that of an interface on the router, the frame is rebroadcast.

After a UDP broadcast is received on a router interface, it must meet the following criteria to be eligible for forwarding:

- It must be a MAC-level broadcast.
- It must be an IP limited broadcast.
- It must be for the specified UDP protocol.
- It must have a time-to-live (TTL) value of at least 2.

For each ingress interface and protocol, the policy specifies how the UDP broadcast is retransmitted: to a unicast host address or to a broadcast address.

---

## DHCP and UDP configuration using the CLI

---

Use Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), to provide host configuration information to the workstations dynamically. Use the DHCP relay commands to configure DHCP relay behavior on a port or on a VLAN.

This section describes CLI commands for DHCP and User Datagram Protocol (UDP) configuration.

### Configure DHCP Parameters Globally

#### Before You Begin

- Configure an IP address on the interface to be used as the DHCP relay interface.

#### About This Task

Configure DHCP relay parameters for the port or the VLAN.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create the forwarding path from the client to the server:  

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D>
```

3. Enable the forwarding path from the client to the server:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> enable
```

**Note**

If the agent IP address (the first <A.B.C.D> variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running **ip dhcp-relay** within the VLAN context. However, if the first <A.B.C.D> variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.

4. Modify DHCP mode to forward BootP messages only, DHCP messages only, or both:

```
ip dhcp-relay fwd-path <A.B.C.D> <A.B.C.D> mode <bootp|bootp_dhcp|dhcp>
```

**Example**

Create the forwarding path from the client to the server. Enable the forwarding path from the client the server. Modify DHCP mode to forward both BootP and DHCP messages.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.120 192.0.2.50
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 enable
Switch:1(config)#ip dhcp-relay fwd-path 192.0.2.128 192.0.2.50 mode bootp_dhcp
```

*Variable Definitions*

The following table defines parameters for the **ip dhcp-relay fwd-path** command.

**Table 101: Variable definitions**

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fwd-path &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</i>         | Configures the forwarding path from the client to the server. The first <A.B.C.D> variable is the agent IP address configured on an interface (a locally configured IP address). The second <A.B.C.D> variable is the IP address of the DHCP server in the network. If this IP address corresponds to the locally configured IP network, the DHCP packet is broadcast out from the interface. |
| <i>fwd-path &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; disable</i> | Disables DHCP relaying on the path from the IP address to the server. This feature is disabled by default. The first <A.B.C.D> variable is the agent IP address configured on an interface (a locally configured IP address). The second <A.B.C.D> variable is the IP address of the DHCP server in the network.                                                                              |

**Table 101: Variable definitions (continued)**

| Variable                                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fwd-path &lt;A.B.C.D&gt;<br/>&lt;A.B.C.D&gt; enable</code>                             | <p>Enables DHCP relaying on the path from the IP address to the server.</p> <p>The first &lt;A.B.C.D&gt; variable is the agent IP address configured on an interface (a locally configured IP address).</p> <p><b>Note:</b></p> <p>If the agent IP address (the first &lt;A.B.C.D&gt; variable) is a VLAN or port IP address, you must enable DHCP Relay on that VLAN or port by running <b>ip dhcp-relay</b> within the VLAN context. However, if the first &lt;A.B.C.D&gt; variable is a VRRP address, you do not need to enable DHCP Relay on the VLAN or port in which the VRRP address resides.</p> <p>The second &lt;A.B.C.D&gt; variable is the IP address of the DHCP server in the network. If this IP address corresponds to the locally configured IP network, the DHCP packet is broadcast out from the interface.</p> |
| <code>fwd-path &lt;A.B.C.D&gt;<br/>&lt;A.B.C.D&gt; mode &lt;bootp bootp_dhcp dhcp&gt;</code> | <p>Modifies DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both.</p> <p>The <i>mode</i> is {bootp   bootp_dhcp   dhcp}.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Showing DHCP relay information

Display relay information to show relay information about DHCP routes and counters.

For scaling information on DHCP Relay forwarding (IPv4 or IPv6), see [Release Notes for VOSS](#).

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display information about DHCP relay forward paths:  
`show ip dhcp-relay fwd-path [vrf WORD<1-16>] [vrfids WORD<0-512>]`
3. Display information about DHCP relay counters:  
`show ip dhcp-relay counters [vrf WORD<1-16>] [vrfids WORD<0-512>]`
4. Display the options for each listed interface:  
`show ip dhcp-relay interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1#show ip dhcp-relay interface
```

```

Port Dhcp
=====
PORT VRF MAX MIN ALWAYS CIRCUIT REMOTE TRUST
NUM NAME ENABLE HOP SEC MODE BCAST ID ID CIRC

=====

Vlan Dhcp
=====
VLAN VRF MAX MIN ALWAYS CIRCUIT REMOTE TRUST

=====

All 0 out of 0 of Vlan Dhcp Entries displayed

```

Variable definitions

Use the data in the following table to use the **show ip dhcp-relay** command.

| Variable                              | Value                                                             |
|---------------------------------------|-------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | The name of the VRF.                                              |
| <code>vrfids WORD&lt;0-512&gt;</code> | The ID of the VRF. The value is an integer in the range of 0-512. |

Use the data in the following table to use the **show ip dhcp-relay interface** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |
| <code>[vlan &lt;1-4059&gt;]</code>                                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>[vrf WORD&lt;1-16&gt;]</code>                                 | Specifies the name of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>[vrfids WORD&lt;0-512&gt;]</code>                             | Specifies the ID of the VRF. The value is an integer from 0- 512.                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring DHCP option 82

Configure the DHCP option 82 to enable the circuit ID to encode an agent-local identifier of the circuit from which a DHCP client-to-server packet is received. Configure the DHCP option 82 to enable the remote ID to encode the MAC address of the interface on which the packet is received. By default, the DHCP option 82 is disabled.

### Before You Begin

- You must enable ip and dhcp-relay on the VLAN.

## About This Task

To configure the DHCP option 82 on a VLAN, you must enter the VLAN Interface Configuration mode.

To configure the DHCP option 82 on a brouter port, you must enter the GigabitEthernet Interface Configuration mode.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the circuit ID:

```
ip dhcp-relay circuitID
```

3. Enable the remote ID:

```
ip dhcp-relay remoteID
```

4. Configure the circuit as trusted:

```
ip dhcp-relay trusted
```

5. Show statistics for option 82, which is the relay agent information option:

```
show ip dhcp-relay counters option82 [vrf WORD <0-16>] [vrfids WORD
<0-512>]
```

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable the circuit ID:

```
Switch:1(config-if)# ip dhcp-relay circuitID
```

Enable the remote ID:

```
Switch:1(config-if)# ip dhcp-relay remoteID
```

Configure the circuit as trusted:

```
Switch:1(config-if)# ip dhcp-relay trusted
```

Show statistics for option 82, which is the relay agent information option:

```
Switch:1(config-if)# show ip dhcp-relay counters option82
```

*Variable definitions*

Use the data in the following table to configure the DHCP option 82.

**Table 102: Variable definitions**

| Variable         | Value                        |
|------------------|------------------------------|
| <i>circuitID</i> | Enables the Circuit ID.      |
| <i>remoteID</i>  | Enables the Remote ID.       |
| <i>trusted</i>   | Sets the circuit as trusted. |

Use the data in the following table to use the **show ip dhcp-relay counters option82 [vrf WORD <0-16>] [vrfids WORD <0-512>]** command.

| Variable                         | Value                                                                                 |
|----------------------------------|---------------------------------------------------------------------------------------|
| <i>vrf WORD &lt;0-16&gt;</i>     | Displays DHCP counters for a particular VRF. WORD <0-16> specifies the VRF name.      |
| <i>vrfids WORD &lt;0-512&gt;</i> | Displays a DHCP forward path for a particular VRF. WORD <0-512> specifies the VRF ID. |

**Configuring DHCP relay on a port or VLAN**

You can view and configure the DHCP parameters on specific ports or on a VLAN.

**Before You Begin**

- You must configure IP on the interface.

**Procedure**

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Enable DHCP parameters on a specified port or VLAN:

```
ip dhcp-relay
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/10
```

Enable DHCP parameters on a specified port or VLAN:

```
Switch:1(config-if)# ip dhcp-relay
```

*Variable definitions*

Use the data in the following table to use the **ip dhcp-relay** command.

Use the **no** operator to disable DHCP parameters on specified ports: **no ip dhcp-relay**.

**Note**

The **no ip dhcp-relay** command disables DHCP Relay, it does not delete the DHCP entry.

To configure this option to the default value, use the **default** operator with this command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>broadcast</i>                                             | Enables the device to send the server reply as a broadcast to the end station. After you disable this variable, the device sends the server reply as a unicast to the end station. Use the <b>no</b> operator to disable broadcast: <b>no ip dhcp-relay broadcast</b> .<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                       |
| <i>circuitId</i>                                             | Enables Option 82 circuit ID on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>clear-counters</i>                                        | Clears DHCP Relay counters for the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>fwd-path &lt;A.B.C.D&gt; [vrid &lt;1-255&gt;]</i>         | Creates a forward path server with a virtual router ID (or VRRP ID), a mode, and a state.<br><i>A.B.C.D</i> is the IP address.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router and is an integer from 1 to 255.<br>Use the <b>no</b> operator to delete a forward path server with a specific value and virtual router ID: <b>no ip dhcp-relay fwd-path &lt;A.B.C.D&gt; [vrid &lt;1-255&gt;]</b><br>To configure this option to the default value, use the <b>default</b> operator with this command. |
| <i>fwd-path &lt;A.B.C.D&gt; disable [vrid &lt;1-255&gt;]</i> | Disables a forward path server with a specific value and virtual router ID.<br><i>A.B.C.D</i> is the IP address.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.                                                                                                                                                                                                                                                                                        |
| <i>fwd-path &lt;A.B.C.D&gt; enable [vrid &lt;1-255&gt;]</i>  | Enables a forward path server with a specific value and virtual router ID (or VRRP ID).<br><i>A.B.C.D</i> is the IP address in the form a.b.c.d.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router and is an integer from 1 to 255.                                                                                                                                                                                                                                                                     |

| Variable                                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fw-path &lt;A.B.C.D&gt; mode &lt;bootp bootp_dhcp dhcp&gt; [vrid &lt;1-255&gt;]</code> | Configures the forward path mode for a VLAN. This command string is available only in VLAN Interface Configuration mode.<br><i>A.B.C.D</i> is the IP address in the form a.b.c.d.<br><i>mode</i> is a choice of bootp, dhcp, or bootp_dhcp.<br><i>vrid &lt;1-255&gt;</i> is the ID of the virtual router (or VRRP ID) and is an integer from 1 to 255.<br>To configure this option to the default value, use the <b>default</b> operator with this command. |
| <code>max-hop &lt;1-16&gt;</code>                                                            | Configures the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                                                                             |
| <code>min-sec &lt;0-65535&gt;</code>                                                         | Configures the minimum seconds count for DHCP. If the secs field in the BootP/DHCP packet header is greater than this value, the device relays or forwards the packet; otherwise, the packet is dropped (0 to 65535). The default is 0 seconds.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                        |
| <code>mode &lt;bootp bootp_dhcp dhcp&gt;</code>                                              | Configures DHCP mode to forward BootP messages only, DHCP messages only, or both. The default is both.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                                                                                 |
| <code>remoteId</code>                                                                        | Enables Option82 remote ID on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>trusted</code>                                                                         | Configures the DHCP circuit as trusted.                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Configuring UDP broadcast forwarding

### About This Task

By default, routers do not forward broadcasts. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts. You must set up UDP broadcast forwarding on the system. Configure UDP broadcast forwarding to forward the UDP broadcasts of network applications to the required server through physical or virtual router interfaces.

### Procedure

1. Enter protocols into a table.
2. Create policies (protocol/server pairs).
3. Assemble the policies into lists or profiles.
4. Apply the list to the appropriate interfaces.

## Configuring UDP protocols

### About This Task

Configure UDP protocols to determine which UDP broadcasts are forwarded.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure a UDP protocol:

```
ip forward-protocol udp <1-65535> WORD<1-15>
```

3. Confirm your configuration:

```
show ip forward-protocol udp interface [vrf WORD<0-16>][vrfids WORD<0-512>] portfwd [vrf WORD<0-16>][vrfids WORD<0-512>] portfwdlist <1-1000>[vrf WORD<0-16>][vrfids WORD<0-512>] vrf WORD<0-16> vrfids WORD<0-512>
```

### Example

Configure a UDP protocol and confirm your configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp 53 DNS
Switch:1(config)#show ip forward-protocol udp

=====
 Udp Protocol Tbl - GlobalRouter

137 NetBIOS NameSrv
138 NetBIOS DataSrv
```

#### Variable definitions

Use the data in the following table to use the **ip forward-protocol udp** command.

| Variable                                      | Value                                                                                                                                                                                                                            |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-65535&gt; WORD&lt;1-15&gt;</code> | Creates a new UDP protocol.<br><code>&lt;1-65535&gt; WORD&lt;1-15&gt;</code> is the UDP protocol name as a string. Use the <b>no</b> operator to delete a UDP protocol <code>no ip forward-protocol udp &lt;1-65535&gt;</code> . |
| <code>portfwd</code>                          | Displays portfwd information.                                                                                                                                                                                                    |
| <code>portfwdlist</code>                      | Displays port forward list information.                                                                                                                                                                                          |
| <code>vrf WORD&lt;0-16&gt;</code>             | Specifies the name of the VRF.                                                                                                                                                                                                   |
| <code>vrfids WORD&lt;0-512&gt;</code>         | Specifies the ID of the VRF.                                                                                                                                                                                                     |

## Configuring a UDP port forward entry

Configure a UDP port forward entry to add or remove a port forward entry.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure a UDP port forward entry:

```
ip forward-protocol udp portfwd <1-65535> {A.B.C.D}
```

3. Confirm your configuration:

```
show ip forward-protocol udp portfwd [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

### Example

Configure a UDP port forward entry:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip forward-protocol udp portfwd 150 192.0.2.10
```

### Variable definitions

Use the data in the following table to use the `ip forward-protocol udp portfwd` command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-65535&gt; {A.B.C.D}</code> | Adds a UDP protocol port to the specified port forwarding list. <code>1-65535</code> is a UDP protocol port in the range of 1-65535. <code>A.B.C.D</code> is an IP address in a.b.c.d format. Use the <b>no</b> operator to remove a protocol port forwarding entry and IP address from the list: <code>no ip forward-protocol udp portfwd &lt;1-65535&gt; &lt;A.B.C.D&gt;</code> . To configure this option to the default value, use the <b>default</b> operator with this command. |
| <code>vrf WORD&lt;0-16&gt;</code>      | Specifies the name of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>vrfids WORD&lt;0-512&gt;</code>  | Specifies the ID of the VRF.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Configuring the UDP port forwarding list

Configure the UDP port forwarding list to assign protocols and servers to the port forward list.

### About This Task

You can perform this procedure in Global Configuration mode, VLAN Interface Configuration mode, or VRF Router Configuration mode.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the UDP port forwarding list:  
`ip forward-protocol udp portfwdlist <1-1000>`

### Important

The following two steps are not available in the Global Configuration or VRF Router Configuration mode. The following two commands are available in VLAN Interface Configuration mode only.

3. Enter VLAN Interface Configuration mode:  
`interface vlan <1-4059>`
4. Configure the broadcast mask:  
`ip forward-protocol udp broadcastmask {A.B.C.D}`
5. Configure the maximum time to live:  
`ip forward-protocol udp maxttl <1-16>`
6. Confirm your configuration:  
`show ip forward-protocol udp portfwdlist <1-1000> [vrf WORD<1-16>]  
[vrfids WORD<0-512>]`

## Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the UDP port forwarding list:

```
Switch:1(config)# ip forward-protocol udp portfwdlist 1
```

Log on to the VLAN interface configuration mode:

```
Switch:1(config)# interface vlan 3
```

Configure the broadcast mask:

```
Switch:1(config-if)# ip forward-protocol udp broadcastmask 192.0.2.255
```

Configure the maximum time to live:

```
Switch:1(config-if)# ip forward-protocol udp maxttl 10
```

Confirm the configuration:

```
Switch:1(config-if)# show ip forward-protocol udp portfwdlist
```

Variable definitions

Use the data in the following table to use the **ip forward-protocol udp portfwldlist** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-1000&gt;</code>            | Creates a UDP port forwarding list in the range of 1-1000.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>&lt;1-65535&gt; {A.B.C.D}</code> | Adds a UDP protocol port to the specified port forwarding list.<br><i>1-65535</i> is a UDP protocol port in the range of 1-65535.<br><i>A.B.C.D</i> is an IP address in a.b.c.d format.<br>Use the <b>no</b> operator to remove or delete a port forwarding list ID,<br><code>no ip forward-protocol udp portfwldlist &lt;1-1000&gt; &lt;1-65535&gt; &lt;A.B.C.D&gt;</code> .<br>To configure this option to use the default value, use the <b>default</b> operator with this command. |
| <code>name WORD&lt;0-15&gt;</code>     | Changes the name of the port forwarding list.                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use the data in the following table to use the **ip forward-protocol udp** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>broadcastmask {A.B.C.D}</code>                           | Configures the interface broadcast mask (the interface broadcast mask can be different from the interface mask).<br><i>A.B.C.D</i> is an IP address in a.b.c.d format.<br>Use the <b>no</b> operator to delete the broadcast mask:<br><code>no ip forward-protocol udp broadcastmask {A.B.C.D}</code><br>To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                      |
| <code>maxttl &lt;1-16&gt;</code>                               | Configures the maximum time-to-live value (TTL) for the UDP broadcast forwarded by the interface. The range is 1-16.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>portfwldlist &lt;1-1000&gt;</code>                       | Assigns the list to the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>vlan &lt;1-4059&gt; [portfwldlist &lt;1-1000&gt;]</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br>If you use the portfwldlist variable with the VLAN variable, it assigns the list to the specified VLAN, regardless of which VLAN context you currently configure. |

## Showing UDP forward information

Show UDP forward information to view information about the UDP forwarding characteristics of the device. UDP forwarding only supports 128 entries.

### About This Task

There are four show options:

- Show the interface information
- Show the port forward information
- Show the port forward list information
- Show the protocol information

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display information about the UDP interface for all IP addresses or a specified IP address:  
show ip forward-protocol udp interface [<A.B.C.D>] [vrf WORD<0-16>] [vrfids WORD<0-512>]
3. Display the UDP port forwarding table:  
show ip forward-protocol udp portfwd [vrf WORD<0-16>] [vrfids WORD<0-512>]
4. Display the UDP port forwarding list table for the specified list or all lists on the device:  
show ip forward-protocol udp portfwddlist [vrf WORD<0-16>] [vrfids WORD<0-512>]
5. Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:  
show ip forward-protocol udp [vrf WORD<0-16>] [vrfids WORD<0-512>]

### Example

Display the UDP protocol table with the UDP port numbers for each supported or designated protocol:

```
Switch:1>enable
Switch:1#show ip forward-protocol udp

=====
 Udp Protocol Tbl - GlobalRouter
=====
UDP_PORT PROTOCOL_NAME

37 Time Service
49 TACACS Service
53 DNS
69 TFTP
137 NetBIOS NameSrv
138 NetBIOS DataSrv
```

*Variable definitions*

Use the data in the following table to use the `show ip forward-protocol udp interface` command.

**Table 103: Variable definitions**

| Variable                              | Value                                                                   |
|---------------------------------------|-------------------------------------------------------------------------|
| <A.B.C.D>                             | Specifies the IP address for the interface in a.b.c.d format.           |
| <code>vrf WORD&lt;0-16&gt;</code>     | Specifies the name of the VRF.                                          |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF and is an integer in the range of 0 to 512. |

## IPv6 DHCP Relay Configuration using CLI

---

### Configuring a DHCP Relay forwarding path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

#### Before You Begin

For a VRF other than GlobalRouter, the interface must be first associated to that VRF.

#### About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [Release Notes for VOSS](#).

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```

2. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> WORD<0-255> [enable]
```

If you configure the forwarding path globally, the relay agent address can be any configured IP address of the relay interface or the VRRP global address linked to the relay interface.

3. To configure a forwarding path on an interface, enter Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
interface vlan <1-4059>
```

4. Configure a forwarding path:

```
ipv6 dhcp-relay fwd-path WORD<0-255> [enable] [vrid WORD<1-255>]
```

If you configure the forwarding path on an interface, the relay agent address is either the smallest IP configured on the interface or the first VRRP global address configured, if the relay is the VRRP master. You do not specify the relay agent address as part of the command.

#### Note

IPv6 DHCP Relay is established only between agents within the context of each VRF.

### Example

Configure a forwarding path globally:

```
Switch:1(config)#ipv6 dhcp-relay fwd-path 1111::1111 1234::1234 enable
```

Configure a forwarding path on an interface:

```
Switch:1(config)#interface GigabitEthernet 1/1
```

```
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 enable
```

OR

Configure the VRRP master as the relay:

```
Switch:1(config-if)#ipv6 dhcp-relay fwd-path 1234::1234 vrid 12 enable
```

*Variable definitions*

Use the data in the following table to use the **ipv6 dhcp-relay fwd-path** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>enable</i>                                                           | Enables the forwarding path. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                      |
| { <i>slot/port[/sub-port]</i> [- <i>slot/port[/sub-port]</i> ] [, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vrid</i> WORD<1-255>                                                 | Specifies the VRRP ID to use the VRRP master as the relay agent interface.                                                                                                                                                                                                                                                                                                                                                 |
| WORD<0-255>                                                             | Specifies the IPv6 address of the DHCP server for the interface configuration.                                                                                                                                                                                                                                                                                                                                             |
| WORD<0-255><br>WORD<0-255>                                              | Specifies the IPv6 address of the relay agent interface and the IPv6 address of the DHCP server for the global configuration.                                                                                                                                                                                                                                                                                              |

## Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

### About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DHCP on the interface:

```
ipv6 dhcp-relay
```

3. Configure the maximum hop count:

```
ipv6 dhcp-relay max-hop <1-32>
```

4. Enable the remote ID:  

```
ipv6 dhcp-relay remote-id
```

**Example**

Configure the maximum hop count:

```
Switch:1(config-if)#ipv6 dhcp-relay max-hop 30
```

Disable the remote ID:

```
Switch:1(config-if)#no ipv6 dhcp-relay remote-id
```

*Variable definitions*

Use the data in the following table to use the **ipv6 dhcp-relay** command.

| Variable              | Value                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>max-hop</i> <1-32> | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                |
| <i>remote-id</i>      | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled |

Use the data in the following table to use the **interface** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

**Viewing DHCP Relay information**

View DHCP Relay information to display the current configuration for the forwarding path and the interface configuration.

**About This Task**

Not all parameters are available in non-default VRFs.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```

2. View DHCP Relay global information:

```
show ipv6 dhcp-relay {counters [vrf WORD<1-16> | vrfids WORD<0-512>] | fwd-path [vrf WORD<1-16> | vrfids WORD<0-512>]}
```

3. View IPv6 DHCP Relay interface configuration:

```
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | vlan <1-4059>}
```

**Note**

The **no ipv6 dhcp-relay** command disables DHCP on the interface but does not delete the entry.

**Example**

*Variable definitions*

Use the information in the following table to help you use the **show ipv6 dhcp-relay** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vlan&lt;1-4059&gt;</i>                                    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf WORD&lt;1-16&gt;</i>                                  | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids WORD&lt;0-512&gt;</i>                              | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

**DHCP and UDP configuration using Enterprise Device Manager**

Dynamic Host Configuration Protocol (DHCP), an extension of the Bootstrap Protocol (BootP), dynamically provides host configuration information to workstations. To lower administrative overhead, network managers prefer to configure a small number of DHCP servers in a central location. Using few DHCP servers requires the routers connecting to the subnets or bridge (or VLAN) domains to support the BootP/DHCP relay function so that hosts can retrieve the configuration information from servers several router hops away.

User datagram protocol (UDP) is a connectionless protocol that adds reliability and multiplexing to IP. It describes how messages reach application programs within a destination computer. Some network applications, such as the NetBIOS name service, rely on a UDP broadcast to request a service or to

locate a service. By default, broadcasts are not forwarded by a router. UDP broadcast forwarding is a generalized mechanism for the router to selectively forward UDP broadcasts.

**Important**

BootP/DHCP relays are supported only on IP routed port-based VLANs and protocol-based VLANs.

**Before You Begin**

You must enable DHCP relay on the path for port or VLAN configuration to take effect.

**Configuring DHCP on a router port or a VRF instance**

**Before You Begin**

- You must first enable BootP/DHCP relay on a port (or VLAN).
- You must enable DHCP and forwarding path.
- You must enable IP Routing on the interface.

**About This Task**

Use the DHCP tab to configure the DHCP behavior on a router port or a VRF instance. The DHCP tab is available only if the port is routed (that is, assigned an IP address).

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **DHCP Relay** tab.
5. Click **Enable** to select the DHCP option. The default is disable.
6. Configure the other parameters as needed.
7. Click **Apply**.

***DHCP** field descriptions*

Use data from the following table in the DHCP Relay tab.

| Name          | Description                                                                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b> | Lets you use BootP/DHCP on the port. The default is disable.                                                                                                                                                                                                                                 |
| <b>MaxHop</b> | Sets the maximum number of hops before a BootP/DHCP packet is discarded (1 to 16). The default is 4.                                                                                                                                                                                         |
| <b>MinSec</b> | The secs field in the BootP/DHCP packet header represents the elapsed time since the client first sent the message. If the secs field in the packet header is greater than this value, the system relays or forwards the packet; otherwise, the packet is dropped. The default is 0 seconds. |
| <b>Mode</b>   | Sets the interface to process only BootP, only DHCP, or both types of packets. The default is both.                                                                                                                                                                                          |

| Name                   | Description                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AlwaysBroadcast</b> | When enabled, the server reply is sent as a broadcast back to the end station. The default is disable.                                                                                                |
| <b>CircuitId</b>       | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                          |
| <b>RemoteId</b>        | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                           |
| <b>Trusted</b>         | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false. |

## Configuring BootP/DHCP on a VLAN or VRF instance

### Before You Begin

- You must enable IP Routing on the interface.

### About This Task

Use the DHCP Relay tab to configure the DHCP behavior on a VLAN. The DHCP Relay tab is available only if the VLAN is routed and is assigned an IP address.

### Procedure

- In the navigation tree, expand the following folders: **Configuration > VLAN**.
- Click **VLANs > Basic**.
- Select a VLAN.
- Click **IP**.
- Click the **DHCP Relay** tab.
- Select **Enable**.
- Configure the parameters as required.
- Click **Apply**.

### **DHCP Relay** field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

| Variable      | Value                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b> | Lets you use BootP/DHCP on the port. The default is disable.                                                                                              |
| <b>MaxHop</b> | Sets the maximum number of hops a BootP/DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4. |

| Variable               | Value                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MinSec</b>          | Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0. |
| <b>Mode</b>            | Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> <li>• bootp</li> <li>• dhcp</li> <li>• both</li> </ul> The default is both.                                             |
| <b>AlwaysBroadcast</b> | When enabled, the DHCP Reply packets are sent as a broadcast to the DHCP client. The default is disable.                                                                                                                |
| <b>CircuitId</b>       | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                            |
| <b>RemoteId</b>        | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                             |
| <b>Trusted</b>         | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.                   |

## Configuring DHCP relay

### About This Task

After you configure the BootP/DHCP relay on an IP interface, you can configure forwarding paths to indicate where packets are forwarded. The forwarding paths are based on the type of packet and where the packet is received.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **DHCP Relay**.
3. Click the **Globals** tab.
4. Click **Insert**.
5. In the **AgentAddr** box, type the agent address.
6. In the **ServerAddr** list, type the server address.
7. Click **Enable** to enable BootP/DHCP relay. You can enable or disable each agent server forwarding policy. The default is enabled.

- In the **Mode** box, select the type of messages to relay.

Both the mode setting for the DHCP interface and the mode setting for the agent interface determine which packets are forwarded.

- Click **Insert**.

### **Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AgentAddr</b>  | The IP address of the input interface (agent) on which the BootP/DHCP request packets are received for forwarding. This address is the IP address of either a brouter port or a VLAN for which forwarding is enabled.                                                                                                                                                                                           |
| <b>ServerAddr</b> | This parameter is either the IP address of the BootP/DHCP server or the address of another local interface. <ul style="list-style-type: none"> <li>If it is the address of the BootP/DHCP server, the request is unicast to the server address.</li> <li>If the address is one of the IP addresses of an interface on the system, the BootP/DHCP requests are broadcast out of that local interface.</li> </ul> |
| <b>Enable</b>     | Enables BootP/DHCP relay.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Mode</b>       | Specifies the type of messages relayed: <ul style="list-style-type: none"> <li>Only BootP</li> <li>Only DHCP</li> <li>Both types of messages</li> </ul> <p>The default is to forward both BootP and DHCP messages.</p>                                                                                                                                                                                          |

## Viewing DHCP relay configuration information

### About This Task

Use the DHCP Relay Interfaces tab to view configuration information about the DHCP relay. To change the configuration information, double-click the value in the field under the required interface, and enter a new value.

### Procedure

- In the navigation tree, expand the following folders: **Configuration > IP**.
- Click **DHCP Relay**.
- Click the **Interfaces** tab.

**Interfaces** field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Variable               | Value                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | A read-only interface number that represents a physical interface, or the VLAN logical interface.                                                                                                                       |
| <b>MaxHop</b>          | Sets the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The maximum number of hops is 16. The default is 4.                                                                     |
| <b>MinSec</b>          | Represents the minimum number of seconds to wait between receiving a DHCP packet and forwarding the DHCP packet to the DHCP server. A value of 0 indicates that forwarding is done immediately. The default value is 0. |
| <b>Mode</b>            | Indicates the type of DHCP packet required. The options are: <ul style="list-style-type: none"> <li>• bootp</li> <li>• dhcp</li> <li>• both</li> </ul> The default is both.                                             |
| <b>AlwaysBroadcast</b> | Indicates if DHCP Reply packets can be sent as a broadcast to the DHCP client. The default is false.                                                                                                                    |
| <b>CircuitId</b>       | Indicates whether DHCP Relay inserted the option 82 circuit ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                            |
| <b>RemotId</b>         | Indicates whether DHCP Relay inserted the option 82 remote ID information into the DHCP packets before sending the DHCP packets to the DHCP server. The default is disable.                                             |
| <b>Trusted</b>         | Indicates if DHCP packets come through a trusted DHCP circuit. Only packets with GIADDR configured to 0 and containing option 82 are forwarded if the circuit is trusted. The default value is false.                   |

Managing UDP forwarding protocols

**About This Task**

The switch configures the following protocols, by default:

- Time Service
- Terminal Access Controller Access Control System (TACACS) Service
- Domain Name System (DNS)
- Trivial file transfer protocol (TFTP)

- Network Basic Input/Output System (NetBIOS) NameSrv
- NetBIOS DataSrv

You can use these protocols to create forwarding entries and lists but you cannot delete them; you can add or remove other protocols to the list of protocols.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click **Insert**.
4. In the **PortNumber** field, type a UDP port number.  
This number defines the UDP port used by the server process as its contact port. The range is from 1 to 65535 and cannot be one of the UDP port numbers or a number previously assigned.
5. In the **Name** field, type a name for the protocol.
6. Click **Insert**.  
The protocol is added to the Protocol table. After you create a protocol, you cannot change its name or number.

### *Protocols field descriptions*

Use the data in the following table to use the **Protocols** tab.

| Name              | Description                                                                     |
|-------------------|---------------------------------------------------------------------------------|
| <b>PortNumber</b> | Defines the UDP port (1 to 65535).                                              |
| <b>Name</b>       | Specifies an administratively assigned name for this list (0 to 15 characters). |

## Managing UDP forwarding

### About This Task

You manage UDP forwarding by defining the destination addresses for the UDP protocol.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwardings** tab.
4. Click **Insert**.
5. In the Insert Forwardings dialog box, select a destination UDP port from the defined protocols in the **DestPort** box.
6. Enter a destination IP address in the **DestAddr** box.  
The destination address can be any IP server address for the protocol application or the IP address of an interface on the router.
7. Click **Insert**. The information is added to the Forwarding tab.

**Forwardings** field descriptions

Use the data in the following table to use the **Forwardings** tab.

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestPort</b>                  | Specifies the port number defined for UDP, depending upon the protocol type.                                                                                                                                                                                                                                                                                                            |
| <b>DestAddr</b>                  | Specifies the destination address can be any IP server address for the protocol application or the IP address of an interface on the router: <ul style="list-style-type: none"> <li>• If the address is that of a server, the packet is sent as a unicast packet to this address.</li> <li>• If the address is that of an interface on the router, the frame is rebroadcast.</li> </ul> |
| <b>Id</b>                        | Specifies an integer that identifies this entry internally.                                                                                                                                                                                                                                                                                                                             |
| <b>NumFwdPackets</b>             | Specifies the total number of UDP broadcast packets forwarded using this policy.                                                                                                                                                                                                                                                                                                        |
| <b>NumDropPacketsTtlExpired</b>  | Specifies the total number of UDP broadcast packets dropped because the time-to-live value (TTL) expired.                                                                                                                                                                                                                                                                               |
| <b>NumDropPacketsDestUnreach</b> | Specifies the total number of UDP broadcast packets dropped because the specified destination address was unreachable.                                                                                                                                                                                                                                                                  |

Creating the forwarding profile

**About This Task**

A forwarding profile is a collection of port and destination pairs. When you configure UDP forwarding list entries, be sure to first configure the UDP forwarding list. Then, configure your UDP forwarding list entries and assign them to a UDP forwarding list. If you do not assign a UDP forwarding list entry to at least one UDP forwarding list, the UDP forwarding list is lost after a restart.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Forwarding Lists** tab.
4. Click **Insert**.
5. In the **Id** field, type the forwarding list ID.
6. In the **Name** field, type the name of the forwarding list if required.  
The forwarding list appears in the **FwdIdList** box.
7. Click **Insert**.

**Forwarding Lists** *field descriptions*

Use the data in the following table to use the **Forwarding Lists** tab and **Insert Forwarding Lists** dialog box.

| Name             | Description                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>        | Specifies a value that uniquely identifies this list of entries (1 to 1000).                                                                                                                                                                      |
| <b>Name</b>      | Specifies an administratively assigned name for this list (0 to 15 characters).                                                                                                                                                                   |
| <b>FwdIdList</b> | Specifies the zero or more port forwarding entries associated with this list. Each list identifier is stored as 2 bytes in this array, starting from 0 bytes (size=64). Clicking on the ellipsis (...) button in this field displays the ID list. |

## Managing the broadcast interface

**About This Task**

Manage the broadcast interface by specifying and displaying which router interfaces can receive UDP broadcasts to forward.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **UDP Forwarding**.
3. Click the **Broadcast Interfaces** tab.
4. Click **Insert**.
5. In the **LocalIfAddr** field, click the ellipsis (...) to select a local interface IP address from the list, and then click **OK**.
6. In the **UdpPortFwdListId** field, click the ellipsis (...) to select a forwarding list ID from the list, and then click **OK**.
7. In the **MaxTtl** field, type the maximum number of hops an IP broadcast can take from the source device to the destination device (the default is 4; the range is 1 to 16).
8. In the **BroadCastMask** field, enter the subnet mask of the local interface that broadcasts the UDP broadcast packets.

When you configure the UDP forwarding broadcast mask, the broadcast mask must be less specific (shorter in length) or equally specific (equal in length) to the subnet mask of the IP interface on which it is configured. If the UDP forwarding broadcast mask is more specific than the subnet mask of the corresponding IP interface, UDP forwarding does not function properly.

9. Click **Insert**.

**Broadcast Interfaces** field descriptions

Use the data in the following table to use the **Broadcast Interfaces** tab.

| Name                            | Description                                                                                                                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalIfAddr</b>              | Specifies the IP address of the local router interface that receives forwarded UDP broadcast packets.                                                                                         |
| <b>UdpPortFwdListId</b>         | Specifies the number of the UDP lists or profiles that this interface is configured to forward (0 to100). A value of 0 indicates that the interface cannot forward any UDP broadcast packets. |
| <b>MaxTtl</b>                   | Specifies the maximum number of hops an IP broadcast packet can take from the source device to the destination device (the default is 4; the range is 1 to 16).                               |
| <b>NumRxPkts</b>                | Specifies the total number of UDP broadcast packets received by this local interface.                                                                                                         |
| <b>NumFwdPkts</b>               | Specifies the total number of UDP broadcast packets forwarded by this local interface.                                                                                                        |
| <b>NumDropPktsMaxTtlExpired</b> | Specifies the total number of UDP broadcast packets dropped because the time-to-live (TTL) value expired.                                                                                     |
| <b>NumDropPktsDestUnreach</b>   | Specifies the total number of UDP broadcast packets dropped because the destination was unreachable.                                                                                          |
| <b>NumDropPktsUnknownPort</b>   | Specifies the total number of UDP broadcast packets dropped because the destination port or protocol specified has no matching forwarding policy.                                             |
| <b>BroadCastMask</b>            | Specifies the subnet mask of the local interface that broadcasts the UDP broadcast packets.                                                                                                   |

Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

**About This Task**

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

**Procedure**

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

**UDP Endpoints** field descriptions

Use the data in the following table to use the **UDP Endpoints** tab.

| Name                     | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <b>LocalAddressType</b>  | Displays the local address type (IPv6 or IPv4).                         |
| <b>LocalAddress</b>      | Displays the local IPv6 address.                                        |
| <b>LocalPort</b>         | Displays the local port number.                                         |
| <b>RemoteAddressType</b> | Displays the remote address type (IPv6 or IPv4).                        |
| <b>RemoteAddress</b>     | Displays the remote IPv6 address.                                       |
| <b>RemotePort</b>        | Displays the remote port number.                                        |
| <b>Instance</b>          | Distinguishes between multiple processes connected to the UDP endpoint. |
| <b>Process</b>           | Displays the ID for the UDP process.                                    |

## IPv6 DHCP Relay Configuration using EDM

### Configuring a DHCP Relay forwarding path

Configure a forwarding path to specify the relay agent address and the DHCP server address to which to forward packets.

To use DHCP Relay for IPv6, you must configure at least one forwarding path and enable the relay on one interface.

#### Before You Begin

Change the VRF instance as required to configure a DHCP Relay forwarding path on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### About This Task

The relay agent can use the IPv6 address of the interface or the VRRP global address linked to that interface. The relay forwards the DHCP messages only if VRRP is in the Master state, otherwise the relay discards the messages.

You can configure only one relay agent on an interface. If you need to change the relay agent, you must delete all the forwarding paths with the old relay agent, and then configure the new relay agent.

For scaling information on DHCP Relay forwarding paths, see [Release Notes for VOSS](#).

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **DHCP Relay**.
3. Click the **Forward Path** tab.
4. Click **Insert**.

5. In the **AgentAddr** field, type the address of the input interface that forwards the packets.
6. In the **ServerAddr** field, type the address of the DHCP server.
7. Select **Enabled**.
8. Click **Insert**.

**Forward Path** field descriptions

Use the data in the following table to use the **Forward Path** tab.

| Name              | Description                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AgentAddr</b>  | Specifies the IP address of the input interface (relay agent) on which the DHCP request packets are received for forwarding. This address is the IPv6 or VRRP global address of either a brouter port or a VLAN for which forwarding is enabled. |
| <b>ServerAddr</b> | Specifies the IP address of the DHCP server. The request is unicast to the server address.                                                                                                                                                       |
| <b>Enabled</b>    | Enables DHCP Relay for the system. The default is disabled (clear).                                                                                                                                                                              |

## Configuring DHCP Relay for an interface

Configure the DHCP relay behavior on the interface.

### Before You Begin

Change the VRF instance as required to configure DHCP Relay for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

You can modify the DHCP Relay configuration for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **DHCP Relay**.
3. Click the **Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **Vlan**.
6. Select a port or VLAN, and then click **OK**.
7. Click **Insert**.

**Interface** field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                   | Description                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN. |
| <b>MaxHop</b>          | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                                              |
| <b>RemoteIdEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).             |

## Modifying DHCP Relay for a VLAN

Modify the existing DHCP relay behavior on the VLAN interface.

**About This Task**

You can configure only one relay for a VLAN, regardless of how many addresses are configured on that VLAN. The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IPv6**.
6. Click the **DHCP Relay** tab.
7. Double-click a cell to change the value.
8. Click **Apply**.

**DHCP** field descriptions

Use the data in the following table to use the **DHCP Relay** tab.

| Name           | Description                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b> | Shows the unique value to identify an IPv6 interface.                                                                   |
| <b>MaxHop</b>  | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32. |

| Name                   | Description                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteldEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false). |
| <b>DhcpEnabled</b>     | Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration.                                                                |

## Modifying DHCP Relay for a port

Modify the existing DHCP relay behavior on the brouter port interface.

### About This Task

The default address is the smallest address configured. If the relay is a VRRP address, the default value is the first VRRP address configured.

### Procedure

1. In the Device Physical View, select the port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click **DHCP Relay**.
5. Double-click a cell to change the value.
6. Click **Apply**.

### *DHCP Relay field descriptions*

Use the data in the following table to use the **DHCP Relay** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>         | Shows the unique value to identify an IPv6 interface. For the brouter port, the value is the ifindex of the port and, in the case of the VLAN, the value is the ifindex of the VLAN.                                                                                                                        |
| <b>MaxHop</b>          | Specifies the maximum number of hops a DHCP packet can take from the DHCP client to the DHCP server. The default is 32.                                                                                                                                                                                     |
| <b>RemoteldEnabled</b> | Enables the relay agent to add information about the relay to DHCPv6 messages before relaying the messages to the DHCP server. The default is disabled (clear or false).                                                                                                                                    |
| <b>DhcpEnabled</b>     | Enables (true) or disables (false) DHCP Relay for an interface with an existing DHCP Relay configuration.<br>This field appears on the <b>DHCP Relay</b> tab for a brouter port only if you modify an existing configuration. This field does not appear if you create a new DHCP Relay port configuration. |

The following sections provide information on the Domain Name Service (DNS) implementation for the switch.

---

## DNS fundamentals

---

This section provides conceptual material on the Domain Name Service (DNS) implementation for the switch. Review this content before you make changes to the configurable DNS options.

### DNS client

Every equipment interface connected to a Transmission Control Protocol over IP (TCP/IP) network is identified with a unique IPv4 or IPv6 address. You can assign a name to every machine that uses an IPv4 or IPv6 address. The TCP/IP does not require the usage of names, but these names make the task easier for network managers in the following ways:

- An IP client can contact a machine with its name, which is converted to an IP address, based on a mapping table. All applications that use this specific machine do not depend on the addressing scheme.
- It is easier to remember a name than a full IP address.

To establish the mapping between an IP name and an IPv4 or an IPv6 address you use the Domain Name Service (DNS). DNS is a hierarchical database that you can distribute on several servers for backup and load sharing. After you add a new hostname, update this database. The information is sent to all the different hosts. An IP client that resolves the mapping between the hostname and the IP address sends a request to one of the database servers to resolve the name.

After you establish the mapping of IP name and IP address, the application is modified to use a hostname instead of an IP address. The switch converts the hostname to an IP address.

If the entry to translate the hostname to IP address is not in the host file, the switch queries the configured DNS server for the mapping from hostname to IP address. You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

The DNS client tracks any server addresses or domain names provided from a DHCP server. If a DHCP server provides info to the DNS client, the DNS configuration is classified as dynamic. You can manually delete dynamic DNS entries, but cannot manually add dynamic DNS entries. You can view the Dynamic DNS entries with **show ip dns** or **show sys dns**. Dynamic DNS entries are not saved in the configuration file. The status monitoring of DNS occurs every 60 seconds.

DNS modifies Ping, Telnet, and copy applications. You can enter a hostname or an IP address to invoke Ping, Telnet, and copy applications.

A log/debug report is generated for all the DNS requests sent to DNS servers and all successful DNS responses received from the DNS servers.

### IPv6 Support

The Domain Name Service (DNS) used by the switch supports both IPv4 and IPv6 addresses with no difference in functionality or configuration.

---

## DNS configuration using CLI

---

This section describes how to configure the Domain Name Service (DNS) client using Command Line Interface (CLI).

DNS supports IPv4 and IPv6 addresses.

### Configuring the DNS client

#### About This Task

Configure the Domain Name Service to establish the mapping between an IP name and an IPv4 or IPv6 address. DNS supports IPv4 and IPv6 addresses with no difference in

functionality or configuration using CLI.

You can configure connection for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the DNS client:  

```
ip domain-name WORD<0-255>
```
3. (Optional) Add addresses for primary, secondary, or tertiary DNS servers:  

```
ip name-server <primary|secondary|tertiary> WORD<0-46>
```
4. (Optional) Delete addresses for primary, secondary, or tertiary DNS servers:  

```
no ip name-server <primary|primary-dynamic|secondary|secondary-dynamic|tertiary|tertiary-dynamic> WORD<0-46>
```
5. View the DNS client system status:  

```
show ip dns
```

#### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Add addresses for a tertiary DNS server:

```
Switch:1(config)# ip name-server tertiary 254.104.201.141
```

Delete address for a secondary dynamic DNS server:

```
Switch:1(config)#no ip name-server secondary-dynamic 192.0.2.12
```

### Variable Definitions

The following table defines parameters for the **ip domain-name** command.

| Variable            | Value                                                                                    |
|---------------------|------------------------------------------------------------------------------------------|
| <i>WORD</i> <0–255> | Configures the default domain name.<br><i>WORD</i> <0–255> is a string 0–255 characters. |

The following table defines parameters for the **ip name-server** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>primary secondary tertiary WORD</i> <0–46> | Configures the primary, secondary, or tertiary DNS server address. Enter the IP address in a.b.c.d format for IPv4 or hexadecimal format (string length 0–46) for IPv6. You can specify the IP address for only one server at a time; you cannot specify all three servers in one command. Use the no operator before this parameter, no <b>ip name-server</b> <primary secondary tertiary> |

## Querying the DNS host

### About This Task

Query the DNS host for information about host addresses.

You can enter either a hostname, an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration using CLI.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View the host information:  
`show hosts WORD`<0–256>

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

View the host information:

```
Switch:1(config)# show hosts 192.0.2.1
```

### Variable Definitions

The following table defines parameters for the **show hosts** command.

| Variable                       | Value                                                                                                                                                                                                                                                                                                             |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;0-256&gt;</code> | Specifies one of the following: <ul style="list-style-type: none"> <li>the name of the host DNS server as a string of 0-256 characters.</li> <li>the IP address of the host DNS server in a.b.c.d format.</li> <li>The IPv6 address of the host DNS server in hexadecimal format (string length 0-46).</li> </ul> |

## DNS configuration using EDM

This section describes how to configure the Domain Name Service (DNS) using Enterprise Device Manager (EDM).

DNS supports IPv4 and IPv6 addresses with no difference in functionality or configuration except for the following. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

### Configure the DNS Client

#### About This Task

You can configure connections for up to three different DNS servers—primary, secondary and tertiary. First the primary server is queried, and then the secondary, and finally the tertiary.

DNS supports IPv4 and IPv6 addresses. Under the **DNS Servers** tab, in the **DnsServerListAddressType** box, you must select **ipv4** or **ipv6**.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Servers** tab.
4. Click **Insert**.
5. In the **DnsServerListType** box, select the DNS server type.
6. In the **DnsServerListAddressType** box, select the IP version.
7. In the **DnsServerListAddress** box, enter the DNS server IP address.
8. Click **Insert**.

**DNS Servers** Field Descriptions

Use the data in the following table to use the **DNS Servers** tab.

| Name                             | Description                                                                                                                                                                        |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DnsServerListType</b>         | Configures the DNS server as primary, secondary, or tertiary.<br>OR<br>Removes a DNS server as primary, primaryDynamic, secondary, secondaryDynamic, tertiary, or tertiaryDynamic. |
| <b>DnsServerListAddressType</b>  | Configures the DNS server address type as IPv4 or IPv6.                                                                                                                            |
| <b>DnsServerListAddress</b>      | Specifies the DNS server address.                                                                                                                                                  |
| <b>DnsServerListStatus</b>       | Specifies the status of the DNS server.                                                                                                                                            |
| <b>DnsServerListRequestCount</b> | Specifies the number of requests sent to the DNS server.                                                                                                                           |
| <b>DnsServerListSuccessCount</b> | Specifies the number of successful requests sent to the DNS server.                                                                                                                |

## Query the DNS Host

**About This Task**

Query the DNS host for information about host addresses.

You can enter either a hostname or an IPv4 or IPv6 address. If you enter the hostname, this command shows the IP address that corresponds to the hostname and if you enter an IP address, this command shows the hostname for the IP address. DNS supports IPv4 addresses with no difference in functionality or configuration in this procedure.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **DNS**.
3. Click the **DNS Host** tab.
4. In the **HostData** text box, enter the DNS host name, IPv4 or the IPv6 address.
5. Click **Query**.

**DNS Host** Field Descriptions

Use the data in the following table to use the **DNS Host** tab.

| Name                   | Description                                                                    |
|------------------------|--------------------------------------------------------------------------------|
| <b>HostData</b>        | Enter hostname or host IPv4 or IPv6 address to be identified.                  |
| <b>HostName</b>        | Identifies the host name. This variable is a read-only field.                  |
| <b>HostAddressType</b> | Identifies the address type of the host.                                       |
| <b>HostAddress</b>     | Identifies the host IP address. This variable is a read-only field.            |
| <b>HostSource</b>      | Identifies the DNS server IP or host file. This variable is a read-only field. |

|                                                      | XA1400 Series   | Not Supported      |

## Distributed Virtual Routing (DvR) Fundamentals

Distributed Virtual Routing (DvR) is a technology for router redundancy in a fabric deployment where IP subnets are stretched across multiple switches. DvR provides Default Gateway Redundancy and optimizes traffic flows to avoid traffic tromboning due to inefficient routing, thereby increasing the total routing throughput.

DvR can be deployed in Campus environments for stretching IP subnets between multiple aggregation layer switches and also simplifies data center deployments by introducing a Controller-Leaf architecture. In this architecture, Layer 3 configuration is required only on the Controller nodes, whereas the Leaf nodes require only Layer 2 configuration. All Layer 3 configuration is automatically distributed to the Leaf nodes by the Controller nodes.

For typical Campus DvR deployments, configure aggregation layer switches as DvR Controllers. Wiring closet access switches are then typically dual-homed to a pair of DvR Controllers.

IP subnets, which stretch between aggregation layer switches and multiple wiring closets, enable seamless IP roaming for wireless users while at the same time ensure optimal traffic forwarding. To optimize automation, Fabric Attach is typically deployed between wiring closet and aggregation switches. In this construct, there would likely be no DvR Leaf configured.

In fabric deployments, DvR replaces VRRP (with VRRP-BackupMaster or RSMLT). The operator can choose for each I-SID/IP subnet what router redundancy method to use.

To migrate to a DvR-enabled I-SID/IP subnet, all member fabric switches of this I-SID must be either DvR Controllers or DvR Leafs. You can connect non fabric switches to DvR Leafs and DvR Controllers with manual configuration or Fabric Attach configuration. Until all fabric switches that are members of the I-SID/IP subnet are DvR-enabled, use VRRP or RSMLT as the router redundancy protocol.

## DvR Domain

To enable multi-site DvR deployments, a DvR domain concept has been introduced. Within a DvR domain, a set of up to eight DvR Controllers control the DvR domain Leaf switches. A domain can also include just DvR controllers without DvR Leafs. Typically, a DvR domain is restricted to one physical location. Traffic leaving this physical location always passes through DvR Controllers.

A DvR domain is a logical group of switches or nodes that are DvR enabled. These nodes are not physically connected but are connected over the SPB Fabric such that each node is aware of the BMAC addresses of all other nodes within the domain. A DvR domain does not contain nodes that are not DvR enabled. However, those nodes can co-exist with other DvR enabled nodes within the same SPB Fabric network.

You configure a common DvR domain ID for all nodes belonging to a DvR domain. This domain ID translates internally to a Domain Data Distribution (DDD) I-SID. All switch nodes that share the same DvR domain ID or DDD ISID receive the Layer 3 information that is distributed from all other nodes belonging to that DvR domain.

A DvR domain can contain multiple Layer 3 VSNs and Layer 2 VSNs. Layer 2 and Layer 3 VSNs can span multiple DvR domains.

A DvR domain typically has the following members:

1. DvR Controller(s)
2. DvR Leaf nodes

For scaling information on the number of Controllers and Leaf nodes to configure in a DvR domain, see [Release Notes for VOSS](#).

## DvR Controller

In a DvR domain, the Controller nodes are the central nodes on which Layer 3 is configured. They own all the Layer 3 configuration and push the configuration information to the Leaf nodes within the SPB network.

A DvR domain can have one or more controllers for redundancy and you must configure every Layer 2 VSN (VLAN) and Layer 3 VSN within the domain, on the Controller(s). A node that you configure as a DvR Controller is considered the controller for all the Layer 2 and Layer 3 VSNs configured on that node. A Controller is configured with its own subnet IP address for every DvR enabled Layer 2 VSN within the domain.

All Layer 2 VSNs on a DvR Controller need not be DvR enabled. A controller can be configured with individual Layer 2 VSNs that are DvR disabled.

The Layer 3 configuration data that is pushed to the Leaf nodes include the Layer 3 IP subnet information for all Layer 2 VSNs within the DvR domain. It also includes the IP routes learned or redistributed by the Controllers from networks outside the SPB network, into the DvR Domain. Controllers also send information on whether Multicast is enabled on a specific DvR enabled Layer 2 VSN, and the version of IGMP. DvR Controllers inject a default route into the DvR domain for external route reachability. Use route policies to inject specific routes into a DvR domain or inject host routes into OSPF or BGP.

A Controller can only belong to one DvR domain, based on the domain ID that you configure on the node.

DvR Controllers include all DvR Leaf functions, thus a Leaf node free deployment is a valid network deployment. Especially if you use DvR in Campus deployments to replace VRRP or RSMLT, a Controller-only deployment, as Fabric Attach server nodes, is a valid deployment option.

## DvR Leaf Node

DvR Leaf nodes are typically data center top of the rack (TOR) Fabric switches that aggregate physical and virtual servers or storage devices. DvR Leaf nodes operate in a reduced configuration mode, where Layer 3 is not configured locally, but pushed to them from the DvR Controller(s) within the domain. You need to configure only the IS-IS infrastructure and the Layer 2 VSNs on the Leaf nodes.

A DvR Leaf node also monitors local host attachments and communicates updates about the current state of those host attachments to the DvR domain. All DvR nodes exchange host attachment information using the DvR host distribution protocol, which leverages a DvR domain I-SID.

DvR leaf nodes are managed in-band through a local loopback address, which is exchanged using the IP Shortcut protocol.

### *Eligibility Criteria for a Leaf Node*

A Leaf node must support the following criteria:

- configuration of basic parameters of IP Multicast over Fabric Connect, such as the system ID, nickname, B-VLANs, SPBM instance, area, peer system ID and virtual BMAC
- configuration of a physical port as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an MLT as either an SPB NNI interface, a FLEX-UNI interface or an FA interface
- configuration of an SMLT as a Flex-UNI Interface or an FA Interface
- configuration of Layer 2 VSN I-SID instances of type ELAN
- configuration of FLEX-UNI end-points as part of a Layer 2 VSN
- FA Server functionality on FA enabled interfaces
- SMLT and vIST
- configuration of a in-band management interface for in-band management of the node

## Configuration Limitations

The DvR Controller and the DvR Leaf node have the following configuration limitations:

- On a Controller, for any VLAN, you can either configure DvR or VRRP but not both. Similarly, you can either configure DvR or RSMLT but not both.
- On a leaf node, you cannot configure the following:
  - Layer 3 (for example, IP interfaces, IP routing and VRFs). You can only perform Layer 2 configuration.
  - platform VLANs. You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.
- On a Controller, you cannot configure the following:
  - dynamic routing protocols like OSPF, RIP and BGP on a DVR enabled VLAN.
  - static routes such that the next-hop exists on any DVR enabled VLAN.

## Summary of Controller and Leaf Node Functions

A DvR Controller performs the following functions:

- pushes Layer 3 configuration data (IPv4 Unicast and Multicast) to the Leaf nodes for all the Layer 2 VSNs or subnets within the DvR domain.
- pushes the Layer 3 learned host routes (host routes learned on its own UNI ports) and route data learned through route redistribution or route policies, to the Leaf nodes.
- configures learned remote host routes from other Controllers and Leaf nodes, on its own device.

A DvR enabled Leaf node performs the following functions:

- configures the gateway MAC when the gateway IPv4 address is learned.
- pushes the Layer 3 learned remote host routes to other Controllers and Leaf nodes in the domain.
- configures learned remote host routes from other Controllers and Leaf nodes on its own device.
- configures ECMP routes (in the datapath only) for the Layer 2 VSN subnets, with each next hop as the Controller in the DvR domain.
- configures learned routes from the Controllers that are redistributed using DvR.
- handles host route response packet interception based on the Controller VLAN MAC or the gateway MAC.

## DvR backbone

The DvR backbone is automatically established among the DvR Controllers from all DvR domains. Every Controller node has an edge gateway to its DvR domain, to the DvR backbone and all other non-DvR domains within the network.

Controllers exchange host route information such that any host can be reached in a shortcut switched manner, irrespective of its location. For these host route information exchanges, controllers use an automatically assigned backbone I-SID. Local subnets to the Controllers are automatically injected into the DvR host route exchanges.

To redistribute DvR host routes into OSPF or BGP, you can configure route policies. These host routes are not injected into IS-IS.

### DvR Backbone Members

You can configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone. This enables the node to receive redistributed DvR host routes from all DvR Controllers in the SPB network, just like a DvR Controller. However, unlike the Controller, you can neither configure a DvR interface on this node nor can the node inject its host routes into the DvR domain.

## DvR operation

In a DvR domain, DvR enabled Controller(s) handle the learning and distribution of Layer 3 configuration and route data to the DvR enabled Leaf nodes. The Leaf nodes in turn, use this data to automatically create distributed Layer 3 datapaths on themselves. In this way, Layer 3 configuration and learning remains only with the Controller(s) and there are distributed Layer 3 datapaths at the edges of the fabric network. This allows for destination lookups at the edge to happen quickly, and traffic is sent directly to their destinations without multiple lookups.

An important benefit of DvR is that only minimal configuration is required on the Leaf node. Based on the Layer 2 VSN that the Leaf node is a part of, all Layer 3 configuration information (IPv4 Unicast and Multicast configuration) is pushed from the Controllers in the domain. Thus the leaf nodes, although basically Layer 2 configured switches, become fully layer 3 capable devices.

**Figure 38: SPB Fabric network with central Layer 3 Controller and distributed Layer 3 datapath at the edges**

## ARP Learning

When DvR is enabled on a Controller, it initiates ARP requests for traffic to be routed to unknown destination hosts.

DvR enabled Controllers learn ARP requests from:

- DvR enabled Leaf nodes (here the Leaf node owns the ARPs)
- its own local UNI ports. Here, the controller owns the ARPs
- other DvR enabled Controllers

DvR enabled Leaf nodes learn ARP requests from:

- its own local UNI ports (here the Leaf node owns the ARPs)
- other DvR enabled Leaf nodes (that own the ARPs) and respond to ARP requests on their UNI ports
- DvR enabled Controllers (that own the local UNI ARPs)

Controllers only distribute ARP entries that are locally learned on its own UNI ports, to other DvR enabled nodes in the domain.

## dvr-leaf-mode boot flag

To configure a node to operate as a DvR Leaf node, you must first enable the `dvr-leaf-mode` boot flag.

- The `dvr-leaf-mode` boot flag is disabled by default. You must explicitly enable this flag before you configure a switch node to operate as a Leaf node.
- After you enable or disable the boot flag, you must save the configuration and reboot with the saved configuration, for the changes to take effect.

### Important

A node on which the `dvr-leaf-mode` boot flag is enabled cannot be configured as a DvR Controller.

## In-band management

Use in-band management to manage a DvR enabled Leaf node that does not have an out-of-band management port or a console port.

For in-band management of the node within the management subnet (for example, from a Controller node), you must configure a unique IPv4 address to be used as the in-band management IP address, on that node. This IPv4 address functions like a CLIP address.

## DvR deployment scenarios

The following sections describe typical deployments of the DvR infrastructure.

### *DvR deployment in a single data center*

The following topology shows DvR deployment in a single data center. This deployment consists of a single DvR domain comprising a Controller layer and a Leaf node layer. The Controller layer has two controllers (for redundancy), which are deployed closer to the boundary of the DvR domain and the rest of the SPB Fabric network. The DvR Leaf nodes or Top of Rack (TOR) switches are typically access or edge switches.

All switches that belong to the DvR domain are configured with the same DvR domain ID and communicate with each other over a predefined I-SID.

The Controller nodes control the Leaf nodes and also build the gateway between the DvR domain and the rest of the Fabric infrastructure. So traffic is either routed between the Leaf nodes, or through the Controllers, to the rest of the fabric infrastructure.

Two IP subnets (Layer 2 VSNs), yellow and green, span the Leaf nodes. Each subnet is configured with a virtual IP address that is shared among all Controller and Leaf nodes that belong to the subnet. The Controller and Leaf nodes are configured with routing interfaces to the subnets, as shown in the figure.

DvR works by enabling each Leaf node or Top of Rack (TOR) switch to bi-directionally route traffic for each IP subnet of which it is a member. This is done by distributing the Layer 3 configuration information (IP Unicast, IP Multicast and virtual IP configuration) needed to handle Layer 3 routing, from the Controllers to the Leaf nodes. Configuration information is pushed over the DvR Domain I-SID, as indicated by the blue arrows in the above figure.

Routing between the two IP subnets is achieved directly at the Leaf nodes when the Layer 3 distributed datapath is programmed at the Leaf Nodes, based on the Layer 3 configuration data that is pushed. Thus traffic within and between IP subnets is shortcut switched without having to traverse the central routing nodes, as shown in the figure below, if there are direct physical connections between them.

Thus, in a DvR deployment, all virtual IP and Layer 3 configuration is performed on the Controller nodes and pushed to the Leaf nodes, so that the Leaf nodes though basically Layer 2 configured switches, become fully layer 3 capable devices.

#### *DvR deployment in a dual data center*

The following example deployment shows two data centers each having its own DvR domain, connected through a backbone.

All nodes in data center Campus 1 belong to DvR domain shown in green, and the nodes in the data center Campus 3 belong to the DvR domain shown in orange. The two DvR domains are individually managed, so in this scenario, the controllers colored orange manage the orange Leaf nodes and the controllers colored green manage the green Leaf nodes. However, subnets can still be stretched across the DvR domains (and possibly between buildings), as shown in the figure.

Each DvR domain learns its own Layer 3 data and distributes this information to its own Leaf nodes. Layer 3 host information that is redistributed from other DvR Domains is learned by the Controllers only (through inter-DvR domain redistribution) and is programmed on the Leaf nodes in the same domain, but not in the other Domain. For example, Layer 3 information redistributed from domain 2 is learned by all controllers including the domain 1 controllers, but this information is not distributed to the Leaf nodes in domain 1. Hosts in one DvR domain can reach the hosts in the other DvR domain only through the Controllers.

**Figure 39: Shortest path routing between servers in different data centers**

All controllers in all domains are always part of the DvR backbone by default, as they are connected by the SPB Fabric. The DvR backbone connects many DvR domains.

Thus DvR can scale to multiple campuses, allowing a simplified way to deploy a large scale fully-routed infrastructure.

## DvR Route Redistribution

The following sections describe redistribution of IPv4 local and static routes from DvR Controllers into the DvR domain. It also describes redistribution of host routes that are learned on DvR enabled VLANs, to BGP and OSPF. You can configure route policies to control the selection of routes to be distributed. You can also configure IS-IS accept policies on DvR Controllers and non-DvR BEBs, to determine which DvR host routes to accept into the routing-table from the DvR backbone.

### *Redistribution of IPv4 Local and Static Routes*

The DvR feature supports redistribution of IPv4 local and static routes into the DvR domain.

#### Note

For every VRF instance and the Global Router, the Controller automatically injects a default route to the Leaf node, with a next hop as the advertising Controller. However, if you require only local or static routes to be advertised to the Leaf nodes, you can manually disable the injection of default routes on the Controller.

On a DvR Controller, you can configure (enable or disable) the redistribution of direct or static routes. Direct routes are redistributed with the route type as internal. Static routes are redistributed with the route type as external. You can apply route policies on the Controller to selectively permit the redistribution of these routes and also configure a metric value for the route that is redistributed. The

default metric for imported local routes is 1. For static routes, the configured route metric or cost is honored.

You can configure redistribution of static and direct routes from the Global Router, or within a VRF instance. For redistributed routes, the Controller configures the Layer 3 VSN as that of the VRF redistributing the route, and the next hop BEB as the system ID of the Controller injecting the route into the DvR domain.

The following example demonstrates how a DvR Leaf node benefits from the redistribution of local and static routes.

By default, if the injection of default routes is enabled on a DvR Controller, the DvR Leaf node can only route traffic to other nodes within the DvR enabled subnet. For the Leaf node to reach networks outside of the DvR enabled subnet, the Controllers must redistribute local and static routes from non-DvR subnets into the DvR domain. In the following figure, the DvR Leaf L1 can route traffic only to nodes in the DvR enabled subnet 10.10.10.0/24. To be able to reach hosts in VLAN 20 (20.20.20.0/24) or VLAN 30 (30.30.30.0/24), redistribution of local routes into DvR is required at each of the Controllers C1 and C2. For the Leaf node to reach hosts in remote networks 40.40.40.0/24 or 50.50.50.0/24, redistribution of static routes to the DvR domain is required.

You can apply route policies to control which local or static routes are to be redistributed into the DvR domain.

**Figure 40: Redistribution of IPv4 local and static routes**

#### *Redistribution of Routes to OSPF or BGP*

For non-SPB routers to benefit from the host accessibility information learned within a DvR domain, DvR supports the redistribution of host routes into OSPF or BGP. Redistribution of these host routes is only by the DvR Controllers and only for the intra-domain host routes within the DvR enabled subnets.

A DvR Controller can redistribute host routes for all hosts from a DvR domain into OSPF or BGP. You can also apply route policies on the Controller to select the routes to be redistributed. The Controller supports redistribution of routes from the Global Router or within a VRF instance. You can also configure the metric of the route before redistribution.

The following example demonstrates the benefit of redistribution of routes to BGP.

Consider a 10.1.0.0/16 network with a stretched Layer 2 VSN spanning two data centers. On the campus side of the network, BGP peering is configured between a non-Extreme router and one or more routers in the data center. BGP advertises the network route 10.1.0.0/16 to the campus BGP routers. Depending on which edge router the traffic is delivered to, it is possible that traffic from a host on the campus traverses the WAN a second time to reach the server that is physically connected to one segment of the data center, as shown in the following figure.

**Figure 41: Inefficient traffic flow**

Redistribution of the host routes from the DvR Controller to BGP solves this problem.

The following figure shows two DvR domains (shown in green and orange) configured at each data center. Each campus edge router establishes a BGP peering session with one or more Controllers in each data center (DvR domain). This enables BGP to advertise more specific routes to the campus BGP router so that the optimal routing path is always taken. So, there is no need for traffic to traverse the WAN multiple times. Also, in the case of server movement within or between data centers, the updated DvR host routes are propagated to BGP, thus ensuring that traffic flowing into the data center continues along the most optimal path.

For example, in the following figure, only the Controller attached to the Leaf node where the 10.1.0.111 server exists, advertises its accessibility over the 10.1.0.111/32 route. Similarly, the DvR Controller associated with the Leaf node connected to the 10.1.0.222 server advertises the 10.1.0.222/32 host route.

**Figure 42: Traffic flow optimized with route redistribution**

Controllers in each data center learn all host routes through the DvR backbone, but since those routes belong to different DvR domains, they are not all eligible for redistribution to OSPF or BGP.

#### *Route Redistribution and IS-IS Accept Policies*

DvR route redistribution leverages IS-IS accept policies to control (accept or reject) DvR routes learned from the DvR backbone. You can configure accept policies on both Controllers and non-DvR BEBs in the SPB network.

For more information about accept policies, see [IS-IS Accept Policies](#) on page 1242.

#### *DvR Deployment for Wireless Roaming in Campus Deployments*

In fabric deployments where IP subnets/I-SIDs stretch between multiple buildings, you can use DvR instead of VRRP or RSMLT to avoid traffic tromboning issues. This deployment is supported with non-fabric switches that have Fabric Attach enabled, or switches that do not support Fabric Attach. You can use VSP 4450 Series as DvR Leafs in this context as well. IP subnets can stretch across one or multiple DvR domains as shown in the following figure.

**Figure 43: Wireless roaming in Campus**

## DvR Limitations

Review the following limitations and behavioral characteristics associated with DvR.

- The DvR feature does not affect out-of-band management on a switch chassis, if the chassis supports it.
- The DvR feature does not support a non-DvR BEB in a DvR enabled Layer 2 VSN.
- The number of host route records that can be stored in the datapath of a Leaf node is limited to the scaling capacity of the switch node. Different switch platforms have different scaling capacities.

For information on the scaling capacities of different platforms, see [Release Notes for VOSS](#).

- You must first disable DvR on a Controller or Leaf node, before you attempt to change the domain ID of the node.
- You cannot configure IGMP snooping on DvR enabled nodes.
- DvR is only supported for IPv4.
- DvR is only supported in warm standby High Availability mode on the VSP 8600 Series.

### Configuration Limitations on a DvR Controller

- If you are using two different IP addresses for the DvR VLAN and the DvR GW IP, you must first configure a gateway IPv4 address and then configure an IP interface for the VLAN before you enable DvR on a Layer 2 VSN (VLAN). Both the VLAN IP address and the gateway IPv4 address must be in the same subnet.

For more information, see [Enable DvR on a Layer 2 VSN \(VLAN\)](#) on page 3856 and [Configure a Single IP Address for All DvR Controllers on a VLAN Subnet](#) on page 3857.

- You cannot configure VRRP on a DvR VLAN.

#### Note

A DvR VLAN is a VLAN configured on a DvR Controller with a VLAN IP address, a VLAN/I-SID, the DvR gateway IP address, and DvR enabled. This Layer 3 configuration for the DvR VLAN (the DvR gateway IP address and this DvR subnet) is pushed to the DvR Leaf nodes. The DvR gateway IP address must be the same address across all DvR Controllers for that DvR VLAN.

- You cannot configure RSMLT on a DvR VLAN.
- You cannot configure SPB-PIM Gateway (SPB-PIM GW) on a DvR VLAN.
- DvR-enabled VLAN/ISIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/ISID and use dynamic or static routing. Use a non-DvR VLAN/ISID instead to connect an external router.

### Configuration Limitations on a DvR Leaf

- Enabling the **DvR-leaf-mode** boot flag before you configure a node as a DvR Leaf, automatically removes all existing non-DvR configuration on the node such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.
- You cannot configure SPB-PIM GW on a Leaf node. The configuration is supported only on a DvR Controller.
- You cannot configure Microsoft NLB on a Leaf node.
- You cannot configure Fabric Extend on a Leaf node.
- You cannot configure the VXLAN Gateway on a Leaf node.
- You cannot configure a T-UNI on a Leaf node.
- You cannot configure IPv4 multicast on a Leaf node. The configuration is supported only on a DvR Controller.
- You can configure only one instance of vIST on a Leaf node pair. Also, you cannot configure vIST on Leaf nodes from different domains.
- You cannot configure platform VLANs on a Leaf node. Only configuration of SPBM B-VLANs is supported.
- You cannot configure IP Shortcuts and IP Multicast over Fabric Connect on Leaf nodes. This configuration is pushed from the DvR Controllers in the domain.

- You must manually configure an I-SID on a Layer 2 VSN, on the Leaf node. This configuration is not pushed from a DvR Controller.
- DvR-enabled VLAN/ISIDs are for host connectivity only; you cannot connect a router to a DvR-enabled VLAN/ISID and use dynamic or static routing. Use a non-DvR VLAN/ISID instead to connect an external router.

## Migrate from VRRP to DvR

### About This Task

If you have a VRRP network with a mix of existing routers that do not support DvR and VOSS devices that do support DvR, you can migrate your VRRP network to DvR using this high-level process. This migration process assumes the following design:

- Existing routers are the VRRP masters.
- Existing routers are the default gateways for all subnets.
- Fabric Connect network with DvR-capable nodes where DvR is configured globally, but not on I-SIDs, on the VOSS devices; and VOSS devices operate in Layer 2 mode for the VRRP VLANs that need to be migrated.

#### Important

When you configure DvR on Controllers with existing VRRP VLANs, ensure there is no VRRP VLAN with VRID 37 or VRID 38. VRID 37 conflicts with the DvR gateway MAC used by all DvR nodes. The DvR gateway MAC is a constant value 00:00:5e:00:01:25; VRRP VRID 37 translates to the same MAC. Similarly, VRRP VRID 38 translates to 00:00:5e:00:01:26, and is used within DvR. If you have a VRRP VLAN with either of these VRIDs, change the VRID to a different value.

### Procedure

1. Enable VRRP interfaces on the DvR Controllers but keep VRRP mastership on the existing routers.
2. Change VRRP mastership on the VLAN or IP Subnet in question on the DvR Controller by applying a higher priority than the current master.

#### Note

You can easily fall back to the original VRRP master to change VRRP priorities back.

3. Disable VRRP on the existing routers.

- Subnet by subnet (VLAN/I-SID), delete VRRP interfaces on all DvR Controllers first (this includes removing VRRP and removing the VLAN IP address), and then configure DvR interfaces (this includes adding the DVR-GW-IP, enabling DvR, and then adding the VLAN IP address) on the VLAN/I-SID instead. This might lead to a short traffic interruption.

### Note

For each VLAN/I-SID, ensure that VRRP is disabled on all nodes before you configure DvR interfaces on the Controllers for the VLAN/I-SID.

Keep in mind that you can only enable DvR on VLAN or I-SIDs where all participating BEBs are DvR-capable.

Anytime when falling back, you can delete the DvR interface on the I-SID (this includes disabling DvR, removing the DVR-GW-IP and removing the VLAN IP address) and configure the VRRP interface again (this includes adding the VLAN IP address and adding VRRP again), however, ensure you delete the DvR interfaces on all Controllers first before you enable VRRP again.

### Example

Start with VRRP VLAN:

```
vlan create 250 name vlan_test250 type port-mstprstp 0
vlan i-sid 250 111250
interface vlan 250
ip address 192.0.2.3 255.255.255.0
interface vlan 250
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
ip vrrp 10 enable
exit
```

Change to DvR VLAN:

```
interface vlan 250
no ip vrrp address 10 192.0.2.1
no ip address 192.0.2.3
exit
interface vlan 250
dvr gw-ipv4 192.0.2.1
dvr enable
ip address 192.0.2.3 255.255.255.0
exit
```

Change back to VRRP VLAN:

```
interface vlan 250
no dvr enable
no dvr gw-ipv4
no ip address 192.0.2.3
exit
interface vlan 250
ip address 192.0.2.3 255.255.255.0
ip vrrp version 2
ip vrrp address 10 192.0.2.1
ip vrrp 10 priority 180
ip vrrp 10 backup-master enable
```

```
ip vrrp 10 enable
exit
```

## DvR configuration using the CLI

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Command Line Interface (CLI).

### Configuring a DvR Controller

#### About This Task

Configuring a node as a DvR Controller enables DvR globally on that node.

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as the Controller of that domain. A Controller can belong to only one DvR domain.

#### Note

For a node to perform the role of both a Controller and a Leaf within a DvR domain, you must configure it as a Controller.

#### Before You Begin

- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Ensure that the `dvr-leaf-mode` boot flag is disabled on the node.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

#### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a DvR Controller.

```
dvr controller <1-255>
```
3. (Optional) Disable DvR on a DvR Controller.

```
no dvr controller
```

#### Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain.

However the switch retains the VLAN specific configuration and you can view the information using the command **show running-config**.

4. View a summary of the Controller configuration. Enter:

```
show dvr
```

## Example

Configure a node as a DvR Controller:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller 5
Switch:1(config)#show dvr
```

```

```

### Variable definitions

Use the data in the following table to use the **dvr controller** command.

| Variable | Value                                                                  |
|----------|------------------------------------------------------------------------|
| <1-255>  | Specifies the domain ID of the DvR domain that the controller belongs. |

## Disabling injection of default routes on a Controller

### About This Task

By default, a DvR Controller injects default routes into the DvR domain and all the Leaf nodes in that domain learn these routes with the next hop as the Controller that advertised them.

You can however disable default route injection for the GRT or a specific VRF on a Controller, to override this behavior.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```

2. Disable default route injection for the GRT or a specific VRF, on the Controller.

On the GRT:

```
dvr controller inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for the GRT into the domain.

On a VRF instance:

```
dvr inject-default-route-disable
```

The `default` or the `no` operator enables injection of default routes for a specific VRF into the domain.

3. Verify the configuration.

On the GRT:

```
show dvr
```

On a VRF instance:

```
show dvr l3vsn
```

## Example

Disable injection of default routes for the GRT on a Controller.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller inject-default-route-disable
Switch:1(config)#show dvr

## Configuring DvR route redistribution

### About This Task

Configure redistribution of direct or static routes into the DvR domain, on the Global Router or for a specific VRF instance.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
2. Configure route redistribution of direct routes:
  - a. Configure route redistribution of direct routes on a VRF. The route type is internal.
 

```
dvr redistribute direct [metric <0-65535>] |[route-map WORD<1-64>]
```
  - b. Enable route redistribution.
 

```
dvr redistribute direct enable
```
  - c. Apply the configuration:
 

```
dvr apply redistribute direct
```
  - d. (Optional) Disable route redistribution of direct routes.
 

```
no dvr redistribute direct
```
3. Configure route redistribution of static routes:
  - a. Configure route redistribution of static routes on a VRF. The route type is external.
 

```
dvr redistribute static [metric <0-65535>] |[route-map WORD<1-64>]
```
  - b. Enable route redistribution.
 

```
dvr redistribute static enable
```
  - c. Apply the configuration.
 

```
dvr apply redistribute static
```
  - d. (Optional) Disable route redistribution of static routes.
 

```
no dvr redistribute static
```
4. Verify the route redistribution configuration. You can also verify it on a specific VRF instance.
 

```
show dvr redistribute [vrf WORD<1-16>]
```

### Example

Configure route redistribution of direct and static routes on the Global Router. Ensure that you apply the configuration.

```

Switch:1>enable
Switch:1#configure terminal

```

Enter configuration commands, one per line. End with CNTL/Z.

```
Switch:1(config)#dvr redistribute static
Switch:1(config)#dvr redistribute static metric 200
Switch:1(config)#dvr redistribute static enable
Switch:1(config)#dvr apply redistribute static
```

```
Switch:1(config)#dvr redistribute direct
Switch:1(config)#dvr redistribute direct metric 100
Switch:1(config)#dvr redistribute direct enable
Switch:1(config)#dvr apply redistribute direct
```

Verify configuration on the Global Router:

```
Switch:1(config)#show dvr redistribute
=====
 DVR Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE ENABLE RPOLICY

STAT 200 External TRUE -
LOC 100 Internal TRUE -
```

Configure redistribution of direct and static routes on the specific VRF instance `vrf1`. Ensure that you apply the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#dvr redistribute static
Switch:1(router-vrf)#dvr redistribute static metric 20000
Switch:1(router-vrf)#dvr redistribute static enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

```
Switch:1(router-vrf)#dvr redistribute direct
Switch:1(router-vrf)#dvr redistribute direct metric 10000
Switch:1(router-vrf)#dvr redistribute direct enable
Switch:1(router-vrf)#exit
Switch:1(config)#dvr apply redistribute static
```

Verify configuration on `vrf1`:

```
Switch:1(router-vrf)#show dvr redistribute vrf vrf1
=====
 DVR Redistribute List - VRF vrf1
=====
SOURCE MET MTYPE ENABLE RPOLICY

STAT 20000 External TRUE -
LOC 10000 Internal TRUE -
```

### Variable definitions

Use the data in the following table to use the **dvr redistribute direct** or the **dvr redistribute static** commands.

| Variable                    | Value                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------|
| <i>enable</i>               | Enables DvR route redistribution on the VRF instance. Route redistribution is enabled by default. |
| <i>metric</i> <0-65535>     | Specifies the DvR route redistribution metric.                                                    |
| <i>route-map</i> WORD<1-64> | Specifies the route policy for DvR route redistribution.                                          |

Use the data in the following table to use the **show dvr redistribute** command.

| Variable              | Value                   |
|-----------------------|-------------------------|
| <i>vrf</i> WORD<1-16> | Specifies the VRF name. |

## Clearing DvR host entries

### About This Task

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch, either locally on its UNI port or dynamically from other nodes in the DvR domain.

#### Note

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the DvR host entries.

```
clear dvr host-entries [ipv4 {A.B.C.D}] | [l2isid <0-16777215>] |
[l3isid <0-16777215>]
```

### Example

In this example, you clear host entries for IP address 50.0.1.0 to clear host entries for IP addresses 50.0.1.2 and 50.0.1.3.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear dvr host-entries 50.0.1.0
```

*Variable definitions*

Use the data in the following table to use the **clear dvr host-entries** command.

| Variable      | Value                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------|
| <i>ipv4</i>   | Specifies the IP address (IPv4) of the DvR host entries to clear.                                |
| <i>l2isid</i> | Specifies the Layer 2 VSN I-SID of the DvR host entries to clear<br>The range is 1 to 16777215.  |
| <i>l3isid</i> | Specifies the Layer 3 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215. |

## Configuring a DvR Leaf

### About This Task

Perform this procedure to create a DvR domain with the domain ID that you specify, and configure the role of the node as a Leaf node. Configuring a node as a DvR Leaf automatically enables DvR globally on the node.

A Leaf node can belong to only one DvR domain.

#### Note

For a node to perform the role of both a Controller and a Leaf within the domain, you must configure it as a Controller.

#### Note

You must enable the VRF-scaling boot configuration flag on a DvR Leaf node, if more than 24 VRFs are required in the DvR domain.

For additional scaling information, see [Release Notes for VOSS](#).

### Before You Begin

- You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node.

To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

#### Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure a node as a DvR Leaf.  

```
dvr leaf <1-255>
```
3. (Optional) Disable DvR on a DvR Leaf.  

```
no dvr Leaf
```

**Caution**

Disabling DvR on a Leaf node removes its membership with the DvR domain and all the dynamic content learned from the Controllers of that domain.

4. View a summary of the Leaf configuration.  

```
show dvr
```

**Example**

Configure a node as a DvR Leaf:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch2:1(config)#boot config flags dvr-leaf-mode
Switch2:1(config)#save config
Switch2:1(config)#reset

Switch2:1(config)#dvr Leaf 5
Switch2:1(config)#show dvr

*Variable definitions*

Use the data in the following table to use the **dvr leaf** command.

| Variable | Value                                                                     |
|----------|---------------------------------------------------------------------------|
| <1-255>  | Specifies the domain ID of the DvR domain to which the Leaf node belongs. |

## Configuring vIST on a DvR Leaf node pair

### Before You Begin

Ensure that the nodes are configured as DvR Leaf nodes, before you configure vIST.

### About This Task

When you configure vIST on a DvR Leaf node pair, the switch generates an I-SID from the configured cluster ID. This I-SID is unique across the SPB network as long as the cluster ID is unique across the SPB network, for the vIST pair. You can configure only one instance of vIST on the Leaf node pair.

To configure vIST, both nodes must be Leaf nodes. You cannot configure vIST, for example, on a Controller-Leaf node pair.

Also both the nodes must belong to the same DvR domain. vIST configuration over Leaf nodes in different domains is not supported.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure vIST on the Leaf nodes:

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
{A.B.C.D} cluster-id <1-1000>
```

3. (Optional) Disable vIST on the DvR Leaf node pair.

```
no dvr leaf virtual-ist
```

#### Caution

Disabling DvR on a Leaf node in a vIST pair removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

If DvR is re-enabled on the node, you must manually configure vIST on that node again.

4. View a summary of vIST configuration on the Leaf nodes.

```
show dvr
```

### Example

Configure vIST on DvR Leaf nodes, with IP addresses 51.51.51.1 and 51.51.51.2 respectively:

```
Switch2:1>enable
Switch2:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch2:1(config)#dvr leaf virtual-ist 51.51.51.1 peer-ip 51.51.51.2 cluster-id 255
Switch2:1#show dvr

### Variable definitions

Use the data in the following table to use the **dvr leaf virtual-ist** command.

| Variable                            | Value                                                                          |
|-------------------------------------|--------------------------------------------------------------------------------|
| {<A.B.C.D/X <A.B.C.D><br><A.B.C.D>} | Specifies the local IP (IPv4) address and subnet mask of the node.             |
| {<A.B.C.D>}                         | Specifies the IP address (IPv4) of the vIST peer.                              |
| <1-1000>                            | Specifies the cluster ID of vIST.<br>It is set to 0 if vIST is not configured. |

## Configure a Management VLAN on a DvR Leaf Node

### About This Task

You cannot configure a platform VLAN directly on a DvR leaf node. However, you can configure a VLAN Management Instance on a DvR leaf node. After you configure the management VLAN, you can configure a platform VLAN.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a management VLAN and associate it with an existing port-based VLAN:

```
mgmt vlan <2-4059>
```

#### Note

If you attempt to configure a VLAN ID that is already in use by DVR for created DVR interfaces, the following error message displays:

```
Error: This vlan id is already used by DVR. Please configure another vlan id for the mgmt vlan
```

3. Create a platform VLAN:

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63>
[color <0-32>]
```

4. Enter VLAN Management Instance mode:

```
mgmt vlan
```

5. Enable the management VLAN:

```
enable
```

### Variable Definitions

The following table defines parameters for the **mgmt vlan** command.

| Variable | Value                                                                            |
|----------|----------------------------------------------------------------------------------|
| <2-4059> | Specifies the existing port-based VLAN ID to associate with the management VLAN. |

The following table defines parameters for the **vlan create** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                                                | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <i>name</i> WORD<0-64>                                                  | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| <i>type</i> port-<br><i>mstp</i> prstp <0-63><br>[ <i>color</i> <0-32>] | Creates a VLAN by port: <ul style="list-style-type: none"> <li>• &lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li>• <i>color</i> &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul> <p><b>Note:</b><br/>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.</p>                                                               |

## Delete a Management VLAN on a DvR Leaf Node

You must perform deletion steps in the correct order.

If you attempt to delete the Management Instance VLAN before you delete the platform VLAN, the following error message displays:

```
Error: On a DVR leaf, the vlan must be deleted before the mgmt vlan instance
```

If you attempt to delete the platform VLAN before disabling the Management Instance VLAN, the following error message displays:

```
Error: Cannot delete vlan if mgmt vlan interface is enabled
```

### About This Task

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter VLAN Management Instance mode:  

```
mgmt vlan
```
3. Disable the management VLAN:  

```
no enable
```
4. Delete the platform VLAN:  

```
no vlan <2-4059>
```
5. Delete the management VLAN:  

```
no mgmt vlan
```

*Variable Definitions*

The following table defines parameters for the **no vlan** command.

**Table 106:**

| Variable | Value                                                |
|----------|------------------------------------------------------|
| <2-4059> | Specifies the ID of the platform VLAN to be deleted. |

## Moving a vIST Leaf node pair from one domain to another

### About This Task

Use this procedure to move a vIST Leaf node pair from one DvR domain to another.

For vIST to work properly, both Leaf nodes must be in the same domain.

### Procedure

1. Disable IS-IS on each vIST peer Leaf node, to remove the node from the SPB network.  

```
no router isis enable
```
2. Disable DvR on each Leaf node.  

```
no dvr leaf
```

#### Caution

Disabling DvR on a Leaf node in a vIST pair automatically removes all vIST configuration on that node, but not on the pair. The node on which DvR is disabled also loses its membership with the DvR domain and all the dynamic content learned from the Controllers in that domain.

When you re-enable DvR on the node, you must manually configure vIST on that node again.

3. Configure each node as a DvR Leaf node, with the new domain ID.  
 Ensure that you configure both nodes as Leaf nodes and with the same domain ID.  

```
dvr leaf <1-255>
```
4. Configure vIST on the DvR Leaf nodes.  

```
dvr leaf virtual-ist {<A.B.C.D/X|<A.B.C.D> <A.B.C.D>} peer-ip
{A.B.C.D} cluster-id <1-1000>
```

5. Enable IS-IS on each vIST peer Leaf node, to add back the node to the SPB network.

```
router isis enable
```

### Example

Consider two vIST peer Leaf nodes Switch1 (IP address 51.51.51.1) and Switch2 (51.51.51.2) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of existing Leaf configuration on each node.

```
Switch1:1(config)#show dvr

## Moving a vIST Controller pair from one domain to another

### About This Task

Use this procedure to move a vIST Controller node pair from one DvR domain to another.

For vIST to work properly, both Controller nodes must be in the same domain.

### Procedure

1. Disable IS-IS on each vIST peer Controller node, to remove the node from the SPB network.

```
no router isis enable
```

2. Disable DvR on each Controller node:

```
no dvr controller
```

#### Caution

Disabling DvR on a DvR Controller destroys the domain ID and all dynamic content learned within the DvR domain. However, the switch retains the VLAN specific configuration which you can view using the command **show running-config**.

3. Configure each node as a DvR Controller node, with the new domain ID. Ensure that you configure both nodes as Controller nodes and with the same domain ID.

```
dvr controller <1-255>
```

4. Enable IS-IS on each vIST peer Controller node, to add back the node to the SPB network.

```
router isis enable
```

### Example

Consider two vIST peer Controller nodes `Switch1` (IP address 51.51.51.3) and `Switch2` (51.51.51.4) that belong to a DvR domain (with domain ID 4), that you need to move to another domain (with domain ID 5).

View a summary of Controller configuration on each node:

```
Switch1:1(config)#show dvr
```

```

## Configuring a non-DvR BEB to join the DvR backbone

### About This Task

Configure a non-DvR backbone edge bridge (BEB) to join the DvR backbone so that it can receive redistributed DvR host routes from all DvR Controllers in the SPB network.

#### Note

On a non-DVR BEB, the redistributed host routes from the DvR backbone are not automatically installed in the IP routing table. To utilize the backbone host routes to optimize traffic forwarding (forwarding in the data plane), you must explicitly configure an IS-IS accept policy with a backbone route policy using the command **accept backbone-route-map <route-map-name>**, and specifying a suitable route-map to select the list or range of DvR backbone host routes to be installed in the routing table.

For more information on configuring an IS-IS accept policy with a backbone route policy, see [Configuring IS-IS Accept Policies](#) on page 1259.

### Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure a non-DvR BEB to join the DvR backbone.
 

```
[no] [[default] backbone enable
```
3. Verify the configuration using the following commands.
  - `show dvr backbone-members`
  - `show dvr backbone-members non-dvr-beb`
  - `show dvr backbone-entries`
  - `show isis`

### Example

```
Switch3:1>enable
Switch3:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#router isis
Switch3:1(config-isis)#show dvr
```

```

## DvR show commands

The following section explains the show commands for DvR.

### Viewing DvR summary

Use this procedure to view a summary of the DvR configuration on a DvR Controller or a DvR Leaf.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View a summary of DvR configuration:  
show dvr

#### Example

View the information on a DvR Controller:

```

Switch:1#show dvr

=====
 DVR Summary Info
=====
Domain ID : 5
Domain ISID : 16678219
Backbone ISID : 16678216
Role : Controller
My SYS ID : 00:bb:00:00:81:21
Operational State : Up
GW MAC : 00:00:5e:00:01:25
InjectDefaultRouteDisable (GRT) : Enabled

```

View the information on a DvR Leaf:

```

Switch2:1#show dvr

=====
 DVR Summary Info
=====
Domain ID : 5
Domain ISID : 16678219
Role : Leaf
My SYS ID : 00:bb:00:00:71:23
Operational State : Up

```

```

GW MAC : 00:00:5e:00:01:25
Inband Mgmt Clip IP : 72.54.44.1
Virtual Ist local address : 51.51.51.1
Virtual Ist local subnet mask : 255.255.255.0
Virtual Ist peer address : 51.51.51.2
Virtual Ist cluster-id : 255
Virtual Ist ISID : 16677226

```

**Job aid**

Use the data in the following table to use the **show dvr** command output.

On a Controller:

| Field                     | Descriptions                                                                                             |
|---------------------------|----------------------------------------------------------------------------------------------------------|
| Domain ID                 | Specifies the domain ID of the DvR domain to which the Controller belongs.                               |
| Domain I-SID              | Specifies the DvR domain I-SID.<br>The range is 16678217 to 16678727.                                    |
| Backbone I-SID            | Specifies the backbone I-SID.<br>The value is 16678216.                                                  |
| Role                      | Specifies the role of the node in the DvR domain, namely Controller.                                     |
| My SYS ID                 | Specifies the MAC address of the Controller.                                                             |
| Operational State         | Specifies the operational state of the Controller.                                                       |
| GW MAC                    | Specifies the gateway MAC address.                                                                       |
| InjectDefaultRouteDisable | Specifies whether injection of default routes is disabled on the Controller.<br>The default is disabled. |

On a Leaf node:

| Field                         | Descriptions                                                                          |
|-------------------------------|---------------------------------------------------------------------------------------|
| Domain ID                     | Specifies the domain ID of the DvR domain to which the Leaf node belongs.             |
| Domain I-SID                  | Specifies the DvR domain I-SID.<br>The range is 16678217 to 16678727.                 |
| Role                          | Specifies the role of the node in the DvR domain, namely Leaf.                        |
| My SYS ID                     | Specifies the MAC address of the Leaf node.                                           |
| Operational State             | Specifies the operational state of the Leaf node.                                     |
| GW MAC                        | Specifies the gateway MAC address.                                                    |
| Inband Mgmt Clip IP           | Specifies the in-band management CLIP IP address.                                     |
| Virtual Ist local address     | Specifies the local IP address of the node, if vIST is configured.                    |
| Virtual Ist local subnet mask | Specifies the subnet mask of the local IP address of the node, if vIST is configured. |
| Virtual Ist peer address      | Specifies the IP address of the peer node, in the vIST pair.                          |

| Field                  | Descriptions                                    |
|------------------------|-------------------------------------------------|
| Virtual Ist cluster-id | Specifies the cluster ID if vIST is configured. |
| Virtual Ist ISID       | Specifies the I-SID if vIST is configured.      |

### Viewing members of a DvR domain

#### About This Task

View the members of all DvR domains, namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays those members of the DvR domain to which it belongs.

#### Before You Begin

Ensure that you enable DvR globally on the node.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. show dvr members [controller|leaf]

#### Example

View all members of a DvR domain:

```
Switch:1#show dvr members

=====
DVR Members (Domain ID: 255)
=====
System Name Nick-Name Nodal MAC Role

Leaf-4:110 0.41.10 00:bb:00:00:41:10 Leaf
Leaf-1:Q:123 0.71.23 00:bb:00:00:71:23 Leaf
Leaf-2:K:124 0.71.24 00:bb:00:00:71:24 Leaf
Leaf-3:K:125 0.71.25 00:bb:00:00:71:25 Leaf
Ctrl-1:Q:121 0.81.21 00:bb:00:00:81:21 Controller
Ctrl-2:Q:122 0.81.22 00:bb:00:00:81:22 Controller

6 out of 6 Total Num of DVR Members displayed
=====
```

View member DvR Controllers:

```
Switch:1#show dvr members controller

=====
DVR Members (Domain ID: 255)
=====
System Name Nick-Name Nodal MAC Role

Ctrl-1:Q:121 0.81.21 00:bb:00:00:81:21 Controller
Ctrl-2:Q:122 0.81.22 00:bb:00:00:81:22 Controller

2 out of 6 Total Num of DVR Members displayed
=====
```

View member DvR Leaf nodes:

```
Switch:1#show dvr members leaf

=====
 DVR Members (Domain ID: 255)
=====
System Name Nick-Name Nodal MAC Role

Leaf-4:110 0.41.10 00:bb:00:00:41:10 Leaf
Leaf-1:Q:123 0.71.23 00:bb:00:00:71:23 Leaf
Leaf-2:K:124 0.71.24 00:bb:00:00:71:24 Leaf
Leaf-3:K:125 0.71.25 00:bb:00:00:71:25 Leaf

4 out of 6 Total Num of DVR Members displayed
=====
```

### Job aid

Use the data in the following table to use the **show dvr members** command output.

| Field       | Descriptions                                                                            |
|-------------|-----------------------------------------------------------------------------------------|
| System Name | Specifies the system name of the DvR member (Controller or Leaf node).                  |
| Nick-Name   | Specifies the nick name of the DvR member.                                              |
| Nodal MAC   | Specifies the nodal MAC address of the DvR member.                                      |
| Role        | Specifies the role of the DvR member within the DvR domain, that is Controller or Leaf. |

### Viewing DvR interfaces

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. The Leaf nodes display DvR interface information that is pushed from the Controllers, for example, subnet routes or gateway IP addresses for the Layer 2 VSNs.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:  
enable

- View the DvR interface information.

On a Controller:

```
show dvr interfaces [l3isid <0-16777215>] [vrf WORD<1-16>] [vrfrids
WORD<0-512>]
```

On a Leaf node:

```
show dvr interfaces [l3isid <0-16777215>]
```

Viewing the DvR interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

### Example

View DvR interfaces on a Controller node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID, VRF, or VRF ID.

```
Switch:1#show dvr interfaces

=====
DVR Interfaces
=====
Interface Mask L3ISID VRFID L2ISID VLAN GW IPv4 Admin SPBMC IGMP
State State Version

50.0.1.2 255.255.0.0 55500 1 50500 500 50.0.1.1 enable disable 2
1 out of 1 Total Num of DVR Interfaces displayed
=====
```

View DvR interfaces on a Leaf node:

You can view DvR interface information on all interfaces or for a specific Layer 3 I-SID. Viewing the interface information for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr interfaces l3isid 401

=====
DVR Interfaces
=====

40.3.0.0 255.255.0.0 401 2 10403 79 40.3.1.11
40.4.0.0 255.255.0.0 401 2 10404 80 40.4.1.11
4 out of 4 Total Num of DVR Interfaces displayed
=====
```

### Variable definitions

Use the data in the following table to use the **show dvr interfaces** command.

| Variable      | Value                                                                            |
|---------------|----------------------------------------------------------------------------------|
| <i>l3isid</i> | Specifies the Layer 3 I-SID of the DvR interface.<br>The range is 0 to 16777215. |
| <i>vrf</i>    | Specifies the VRF name.                                                          |
| <i>vrfids</i> | Specifies the VRF ID.<br>The range is 0 to 512.                                  |

### Job aid

Use the data in the following table to use the **show dvr interfaces** command output.

| Field        | Descriptions                                                                                                                   |
|--------------|--------------------------------------------------------------------------------------------------------------------------------|
| Interface    | Specifies the VLAN IP address (IPv4) of the DvR interface.                                                                     |
| Mask         | Specifies the subnet mask of the VLAN IP address.                                                                              |
| L3ISID       | Specifies the Layer 3 I-SID of the DvR interface.<br>The range is 0 to 16777215.                                               |
| VRFID        | Specifies the VRF ID of the DvR interface                                                                                      |
| L2ISID       | Specifies the Layer 2 I-SID of the DvR interface.<br>The range is 1 to 16777215.                                               |
| VLAN         | Specifies the VLAN ID of the DvR interface.                                                                                    |
| GW IPv4      | Specifies the DvR gateway IP address (IPv4).                                                                                   |
| Admin State  | Specifies the administrative state of the DvR interface.<br><br><b>Note:</b><br>This field displays only on a Controller node. |
| SPBMC State  | Specifies the SBPMC state of the DvR interface.                                                                                |
| IGMP version | Specifies the version of IGMP running on the DvR interface.                                                                    |

### Viewing DvR host entries

#### About This Task

View DvR host entries (IPv4 remote host routes) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its Switched UNI port or dynamically from other nodes within the DvR domain.

#### Before You Begin

Ensure that you enable DvR globally on the node.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`

## 2. View the DvR host entries.

On a Controller:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid
<1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]] [[vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr host-entries [domain-id <1-255>] [[ipv4 {A.B.C.D}]] [[l2isid
<1-16777215>]] [[l3isid <0-16777215>]] [[nh-as-mac]] [[type <1-2>]]
```

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

### Example

View DvR host entries on either a Controller or a Leaf node.

Viewing the DvR host entries for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr host-entries domain-id 255 l3isid 55500
```

```

### Variable definitions

Use the data in the following table to use the **show dvr host-entries** command.

| Variable         | Value                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>domain-id</i> | Specifies the domain ID of the DvR host entry. The range is 1 to 255.                                                       |
| <i>ipv4</i>      | Specifies the IP address (IPv4) of the DvR host entry.                                                                      |
| <i>l2isid</i>    | Specifies the Layer 2 VSN I-SID of the DvR host entry. The range is 1 to 16777215.                                          |
| <i>l3isid</i>    | Specifies the Layer 3 VSN I-SID of the DvR host entry. The range is 0 to 16777215.                                          |
| <i>nh-as-mac</i> | Specifies the MAC address of the next hop node instead of the system name.                                                  |
| <i>type</i>      | Specifies the host type of the DvR host entry. A value of 1 indicates local hosts and a value of 2 indicates dynamic hosts. |
| <i>vrf</i>       | Specifies the VRF name of the DvR host entry.                                                                               |
| <i>vrfids</i>    | Specifies the VRF ID of the DvR host entry. The range is 0 to 512.                                                          |

**Job aid**

Use the data in the following table to use the **show dvr host-entries** command output.

| Field            | Descriptions                                                       |
|------------------|--------------------------------------------------------------------|
| IP-ADDRESS       | Specifies the IP address of the DvR host entry (IPv4 remote ARP).  |
| HOST MAC-ADDRESS | Specifies the MAC address of the DvR host entry (IPv4 remote ARP). |
| L3VSN ISID       | Specifies the Layer 3 VSN I-SID of the DvR host entry.             |
| VRFID            | Specifies the VRF ID of the DvR host entry.                        |
| L2VSN ISID       | Specifies the Layer 2 VSN I-SID of the DvR host entry.             |
| PORT             | Specifies the port of the DvR host entry.                          |
| DOMAIN ID        | Specifies the DvR domain ID of the DvR host entry.                 |
| TYPE             | Specifies the host type of the DvR host entry.                     |
| NEXT HOP         | Specifies the next hop system MAC address of the DvR host entry.   |

*Viewing DvR routes***About This Task**

View the DvR routes (IPv4 network routes) on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. The Leaf nodes display the IP subnet routes that are learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. Leaf nodes also display routes that are redistributed by Controllers (direct routes, static routes and the default route), into the DvR domain.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR routes.

On a Controller:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac] |
[vrf WORD<1-16>]|[vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr routes [ipv4 {A.B.C.D}]|[l3isid <0-16777215>]|[nh-as-mac]
```

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

## Example

View DvR routes on either a Controller or a Leaf node.

Viewing the DvR routes for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr routes

DVR Routes

DEST MASK NEXT L3VSN L2VSN
HOP VRFID ISID ISID TYPE COST

50.0.0.0 255.255.0.0 Ctrl-1:8400:121 0 55500 50500 - 1

1 out of 1 Total Num of DVR Routes displayed

TYPE Legend: E=Ecmp Route
```

View DvR routes where the next hop MAC address is displayed instead of the system name:

```
Switch:1#show dvr routes nh-as-mac

=
DVR Routes

=

DEST MASK NEXT L3VSN L2VSN
HOP VRFID ISID ISID TYPE COST

-
50.0.0.0 255.255.0.0 00:bb:00:00:01:02 0 55500 50500 - 1

1 out of 1 Total Num of DVR Routes displayed

-
TYPE Legend: E=Ecmp Route
```

## Variable definitions

Use the data in the following table to use the **show dvr routes** command.

| Variable                         | Value                                                                        |
|----------------------------------|------------------------------------------------------------------------------|
| <i>ipv4 {A.B.C.D}</i>            | Specifies the IP address (IPv4) of the DvR route.                            |
| <i>l3isid &lt;0-16777215&gt;</i> | Specifies the Layer 3 I-SID of the DvR route.<br>The range is 0 to 16777215. |
| <i>nh-as-mac</i>                 | Specifies the MAC address of the next hop node instead of the system name.   |
| <i>vrf</i>                       | Specifies the VRF name of the DvR route.                                     |
| <i>vrfids</i>                    | Specifies the VRF ID of the DvR route.<br>The range is 0 to 512.             |

**Job aid**

Use the data in the following table to use the **show dvr routes** command output.

| Field      | Descriptions                                                                |
|------------|-----------------------------------------------------------------------------|
| DEST       | Specifies the IPv4 destination address of the DvR route.                    |
| MASK       | Specifies the subnet mask of the IPv4 destination address of the DvR route. |
| NEXT HOP   | Specifies the host name of the next hop BEB, in the DvR route.              |
| VRFID      | Specifies the VRF ID of the DvR route.                                      |
| L3VSN ISID | Specifies the Layer 3 VSN I-SID of the DvR route.                           |
| L2VSN ISID | Specifies the Layer 2 VSN I-SID of the DvR route.                           |
| TYPE       | Specifies the route type of the DvR route.                                  |
| COST       | Specifies the SPB cost of the DvR route.                                    |

*Viewing DvR database information***About This Task**

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the L2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

**Before You Begin**

Ensure that DvR is enabled globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. View the DvR database.

On a Controller:

```
show dvr database [ipv4 {A.B.C.D}]|[l3isid<0-16777215>]|[nh-as-mac] |
[vrf WORD<1-16>]|[vrfids WORD<0-512>]
```

On a Leaf node:

```
show dvr database [ipv4 {A.B.C.D}]|[l3isid<0-16777215>]|[nh-as-mac]
```

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

**Example**

View the DvR database on either a Controller or a Leaf node.

Viewing the DvR database for a specific VRF or VRF ID is not supported on a DvR Leaf node.

```
Switch:1#show dvr database

### Variable definitions

Use the data in the following table to use the **show dvr database** command.

| Variable                   | Value                                                                              |
|----------------------------|------------------------------------------------------------------------------------|
| <i>ipv4</i> {A.B.C.D}      | Specifies the IP address (IPv4) of the DvR database entry.                         |
| <i>l3isid</i> <0-16777215> | Specifies the Layer 3 I-SID of the DvR database entry. The range is 0 to 16777215. |
| <i>nh-as-mac</i>           | Specifies the MAC address of the next hop node instead of the system name.         |
| <i>vrf</i>                 | Specifies the VRF name of the DvR database entry.                                  |
| <i>vrfids</i>              | Specifies the VRF ID of the DvR database entry. The range is 0 to 512.             |

### Job aid

Use the data in the following table to use the **show dvr database** command output.

| Field              | Descriptions                                                                          |
|--------------------|---------------------------------------------------------------------------------------|
| DEST               | Specifies the address type of the IPv4 destination address of the DvR database entry. |
| MASK               | Specifies the destination mask of the DvR database entry.                             |
| NEXT HOP           | Specifies the MAC address of the next hop BEB, in the DvR database entry.             |
| VRFID              | Specifies the VRF ID for the database entry.                                          |
| L3VSN ISID         | Specifies the Layer 3 VSN I-SID of the DvR database entry.                            |
| L2VSN ISID         | Specifies the Layer 2 VSN I-SID of the DvR database entry.                            |
| OUTGOING INTERFACE | Specifies the outgoing interface (port or MLT) of the DvR database entry.             |
| SPB COST           | Specifies the SPB cost of the DvR database entry.                                     |
| PREFIX COST        | Specifies the prefix cost of the DvR database entry.                                  |
| AGE                | Specifies the uptime since creation of the DvR database table entry.                  |

## Viewing DvR backbone entries

### About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

#### Note

DvR backbone entries can be viewed only on a Controller. Viewing backbone entries is not applicable on a Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View DvR backbone entries:  
show dvr backbone-entries [adv-controller WORD<1-255>] | [domain-id <1-255>] | [host-mac-address 0x00:0x00:0x00:0x00:0x00:0x00] | [ipv4 {A.B.C.D}] | [l2isid <1-16777215>] | [l3isid <0-16777215>] | [next-hop WORD<1-255>] | [nh-as-mac]

### Example

View all DvR backbone entries:

```
Switch:1#show dvr backbone-entries
```

```
=====

## Variable definitions

Use the data in the following table to use the **show dvr backbone entries** command.

| Variable                                                        | Value                                                                     |
|-----------------------------------------------------------------|---------------------------------------------------------------------------|
| <i>adv-controller</i> <i>WORD</i> <1-255>                       | Specifies the system name of the advertising Controller.                  |
| <i>domain-id</i> <1-255>                                        | Specifies the domain ID of the DvR backbone entry. The range is 1 to 255. |
| <i>host-mac-address</i><br><i>0x00:0x00:0x00:0x00:0x00:0x00</i> | Specifies the host MAC address of the DvR backbone entry.                 |
| <i>ipv4</i> { <i>A.B.C.D</i> }                                  | Specifies the IP address (IPv4) of the DvR backbone entry.                |

| Variable                                | Value                                                                              |
|-----------------------------------------|------------------------------------------------------------------------------------|
| <code>l2isid &lt;1-16777215&gt;</code>  | Specifies the Layer 2 I-SID of the DvR backbone entry. The range is 1 to 16777215. |
| <code>l3isid &lt;0-16777215&gt;</code>  | Specifies the Layer 3 I-SID of the DvR backbone entry. The range is 0 to 16777215. |
| <code>next-hop WORD&lt;1-255&gt;</code> | Specifies the system name of the next hop node.                                    |
| <code>nh-as-mac</code>                  | Specifies the MAC address of the next hop node instead of the system name.         |

**Job aid**

Use the data in the following table to use the **show dvr backbone-entries** command output.

| Field            | Descriptions                                                              |
|------------------|---------------------------------------------------------------------------|
| IP-ADDRESS       | Specifies the IPv4 address of the DvR backbone host.                      |
| HOST MAC-ADDRESS | Specifies the MAC address of DvR backbone host.                           |
| L3VSN ISID       | Specifies the Layer 3 VSN I-SID of the DvR backbone host.                 |
| L2VSN ISID       | Specifies the Layer 2 VSN I-SID of the DvR backbone host.                 |
| DOMAIN ID        | Specifies the domain ID of the DvR backbone host.                         |
| ADV-CONTROLLER   | Specifies the host name of the advertising Controller.                    |
| NEXT HOP         | Specifies the MAC address of the next hop backbone host in the DvR route. |

*Viewing DvR backbone members*

**About This Task**

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

**Before You Begin**

Ensure that DvR is enabled globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. View DvR backbone member information:  
`show dvr backbone-members [controller|non-dvr-beb]`

**Example**

View all DvR backbone members:

```
Switch:1#show dvr backbone-members

DVR BB Members

```

```

System Name Nick-Name Nodal MAC Role Domain Id

DVR-D2-C1-40 0.82.40 00:00:82:84:40:00 NON-DVR-BEB 2
Ctrl-2:8200:122 0.81.22 00:bb:00:00:81:22 Controller 2

2 out of 2 Total Num of DVR Backbone Members displayed

```

View backbone members that are DvR controllers:

```

Switch:1#show dvr backbone-members controller

=====
DVR BB Members (Domain ID: 255)
=====
System Name Nick-Name Nodal MAC Role Domain Id

Ctrl-2:8200:122 0.81.22 00:bb:00:00:81:22 Controller 2

1 out of 2 Total Num of DVR Backbone Members displayed

```

View backbone members that are non-DvR BEBs:

```

Switch:1#show dvr backbone-members non-dvr-beb

=====
DVR BB Members
=====
System Name Nick-Name Nodal MAC Role Domain Id

DVR-D2-C1-40 0.82.40 00:00:82:84:40:00 NON-DVR-BEB 2

1 out of 2 Total Num of DVR Backbone Members displayed

```

### Variable definitions

Use the data in the following table to use the **show dvr backbone-members** command.

| Variable           | Value                                                |
|--------------------|------------------------------------------------------|
| <i>controller</i>  | Specifies backbone members that are DvR Controllers. |
| <i>non-dvr-beb</i> | Specifies backbone members that are non-DvR BEBs.    |

### Job aid

Use the data in the following table to use the **show dvr backbone-members** command output.

| Field       | Description                                                 |
|-------------|-------------------------------------------------------------|
| System Name | Specifies the system name of the DvR backbone member.       |
| Nick-Name   | Specifies the nick name of the DvR backbone member.         |
| Nodal MAC   | Specifies the nodal MAC address of the DvR backbone member. |
| Role        | Specifies the role of the DvR backbone member.              |
| Domain Id   | Specifies the domain ID of the backbone member.             |

*Viewing Layer 3 VSN information***About This Task**

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View the Layer 3 VSN information:  
show dvr l3vsn [l3isid <0-16777215>] | [vrf WORD<1-16>] | [vrfids WORD<0-512>]

**Example**

View Layer 3 VSN information on a DvR Controller:

```
Switch:1#show dvr l3vsn

=====
 DVR L3VSN
=====
VRF ID L3VSN ISID VRF NAME INJECT-DEFAULT-ROUTE-DISABLE

1 55500 vrf600 Disabled
2 55501 vrf601 Disabled
3 55502 vrf602 Disabled
4 55503 vrf603 Disabled

4 out of 4 Total Num of DVR L3VSN displayed
=====
```

View Layer 3 VSN information on a DvR Leaf node:

```
Switch2:1#show dvr l3vsn

=====
 DVR L3VSN
=====
VRF ID L3VSN ISID VRF NAME

1 55500 vrf600
2 55501 vrf601
3 55502 vrf602

3 out of 3 Total Num of DVR L3VSN displayed
=====
```

## Variable definitions

Use the data in the following table to use the **show dvr l3vsn** command.

| Variable                               | Value                                                                     |
|----------------------------------------|---------------------------------------------------------------------------|
| <code>l3isid &lt;0-16777215&gt;</code> | Specifies the Layer 3 VSN I-SID.<br>The range is 0 to 16777215.           |
| <code>vrf WORD&lt;1-16&gt;</code>      | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |
| <code>vrfids WORD&lt;0-512&gt;</code>  | Specifies the VRF ID of the VRF.                                          |

## Job aid

Use the data in the following table to use the **show dvr l3vsn** command output on a DvR Controller.

| Field                        | Description                                                               |
|------------------------------|---------------------------------------------------------------------------|
| VRF ID                       | Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID.   |
| L3VSN ISID                   | Specifies the Layer 3 VSN I-SID.                                          |
| VRF NAME                     | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |
| INJECT-DEFAULT-ROUTE-DISABLE | Specifies whether injection of default routes is disabled.                |

Use the data in the following table to use the **show dvr l3vsn** command output on a DvR Leaf node.

| Field      | Description                                                               |
|------------|---------------------------------------------------------------------------|
| VRF ID     | Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID.   |
| L3VSN ISID | Specifies the Layer 3 VSN I-SID.                                          |
| VRF NAME   | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |

## Viewing DvR domain redistribution information

### About This Task

View DvR domain redistribution information on a Controller or a Leaf node.

#### Note

You can view DvR domain redistribution information only on a DvR Controller.  
An error message displays if you attempt to view this information on a DvR Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. View DvR domain redistribution information:  
show dvr redistribute [vrf WORD<1-16>] | [vrfids WORD<0-512>]

## Example

View DvR domain redistribution information on a Controller:

```
Switch:1#show dvr redistribute
=====
DVR Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE ENABLE RPOLICY

STAT 1 External TRUE -
```

View DvR domain redistribution information for a particular VRF.

```
Switch:1#show dvr redistribute vrf vrf1
=====
DVR Redistribute List - VRF vrf1
=====
SOURCE MET MTYPE ENABLE RPOLICY

STAT 20000 External TRUE -
LOC 10000 Internal TRUE -
```

## Variable definitions

Use the data in the following table to use the **show dvr redistribute** command.

| Variable                  | Definitions                      |
|---------------------------|----------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF name.          |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF ID of the VRF. |

## Job aid

Use the data in the following table to use the **show dvr redistribute** command output.

| Field  | Description                                                             |
|--------|-------------------------------------------------------------------------|
| SOURCE | Specifies the source of the DvR route redistribution.                   |
| MET    | Specifies the DvR route redistribution metric. The range is 0 to 65535. |
| MTYPE  | Specifies the DvR route redistribution metric type.                     |

| Field   | Description                                                                |
|---------|----------------------------------------------------------------------------|
| ENABLE  | Specifies whether DvR route redistribution is enabled on the VRF instance. |
| RPOLICY | Specifies the route policy for DvR route redistribution.                   |

## Configuring a DvR solution

The following section describes a simple configuration example to configure Distributed Virtual Routing (DvR) over a Fabric Connect (SPB) network.

### About This Task

In this example, you configure two DvR Controllers (with IP addresses 10.133.226.101 and 10.133.226.102) and two DvR Leaf nodes (with IP addresses 10.133.226.103 and 10.133.226.104), in a single DvR domain with domain ID 9. Hosts connect to the DvR nodes as shown in the figure.

### Before You Begin

On the switches to be configured as DvR Controllers:

- Ensure that you configure Fabric Connect.
- Ensure that you configure IP Shortcuts on the node. This is necessary for proper functioning of the node as a DvR Controller.
- Verify that the `dvr-leaf-mode` boot flag is disabled on the node. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

On the switches to be configured as DVR Leaf nodes:

- Ensure that you configure Fabric Connect.

## Procedure

### DvR Controller configuration — Controller 1 and Controller 2:

1. Verify configuration of Fabric Connect on each of the switches to be configured as the DvR Controllers.

The following examples show verification on one of the switches. Perform this verification on both switches.

- a. Verify the SPB configuration:

```
Switch1:1>en
Switch1:1#show spbm
 spbm : enable
 ethertype : 0x8100
 nick-name server : enable
 nick-name allocation : static
 nick-name server range : B.00.00-B.FF.FF

Switch1:1#show isis spbm

=====
 ISIS SPBM Info
=====
SPBM B-VID PRIMARY NICK LSDB IP IPV6 MULTICAST SPB-PIM-GW
INSTANCE VLAN NAME TRAP

1 4051-4052 4051 0.10.01 disable enable disable enable disable

=====
 ISIS SPBM SMLT Info
=====

 FAN Member : No

```

## 2. Configure the DvR Controllers.

- a. Configure Controller 1 (IP address 10.133.226.101) with DvR domain ID 9.

```

Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#dvr controller 9
Switch:1(config)#show dvr

=====

```

**Layer 2 VSN (VLAN) configuration on the DvR Controllers:**

3. Configure Layer 2 VSN on the DvR Controllers, Controller 1 and Controller 2.
  - a. Configure platform VLANs on Controller 1 (VLAN ID=200 and VLAN ID=202). Associate the VLANs with the I-SIDs 20200 and 20202 respectively. Configure gateway IPv4 addresses 20.0.1.1 and 20.2.1.1 respectively, and enable DvR on those interfaces.

```
Switch1:1(config)#vlan create 200 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 200 20200
Switch1:1(config)#interface vlan 200
Switch1:1(config)#dvr gw-ipv4 20.0.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.0.1.2 255.255.0.0

Switch1:1(config)#vlan create 202 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 202 20202
Switch1:1(config)#interface vlan 202
Switch1:1(config)#dvr gw-ipv4 20.2.1.1
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 20.2.1.2 255.255.0.0
Switch1:1(config)#exit
Switch1:1#
```

- b. Configure the platform VLANs on Controller 2. Ensure that you configure the same gateway IPv4 addresses on the corresponding VLANs, as on Controller 1.

```
Switch2:1(config)#vlan create 200 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 200 20200
Switch2:1(config)#interface vlan 200
Switch2:1(config)#dvr gw-ipv4 20.0.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.0.1.3 255.255.0.0

Switch2:1(config)#vlan create 202 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 202 20202
Switch2:1(config)#interface vlan 202
Switch2:1(config)#dvr gw-ipv4 20.2.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 20.2.1.3 255.255.0.0
Switch2:1(config)#exit
Switch2:1#
```

- c. Verify Layer 2 VSN (VLAN) configuration on the Controllers. The following example shows the verification on Controller 1. Perform this verification on both Controllers.

View the DvR interfaces.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). You can also view the administrative state of these interfaces on the Controller.

```
Switch1:1#show dvr interfaces

=====
DVR Interfaces
=====

```

| Interface | Mask        | L3ISID | VRVID | L2ISID | VLAN | GW IPv4  | Admin State | SPBMC State | IGMP Version |

### Layer 3 configuration on the DvR Controllers

4. Configure Layer 3 (VRF) on the DvR Controllers, Controller 1 and Controller 2.
  - a. Configure Layer 3 on Controller 1. As part of this configuration, you configure a VRF `vrf501` and associate it with a DvR VLAN.

```
Switch1:1(config)#ip vrf vrf501 vrfid 501
Switch1:1(config)#vlan create 501 type port-mstprstp 0
Switch1:1(config)#vlan i-sid 501 50501
Switch1:1(config)#interface Vlan 501
Switch1:1(config)#vrf vrf501
Switch1:1(config)#dvr gw-ipv4 50.1.1.1
```

```
Switch1:1(config)#dvr enable
Switch1:1(config)#ip address 50.1.1.2 255.255.0.0

Switch1:1(config)#router vrf vrf501
Switch1:1(router-vrf)#i-sid 55501
Switch1:1(router-vrf)#ipvpn enable
Switch1:1(router-vrf)#exit
Switch1:1(config)#
```

- b. Configure Layer 3 on Controller 2.

```
Switch2:1(config)#ip vrf vrf501 vrfid 501
Switch2:1(config)#vlan create 501 type port-mstprstp 0
Switch2:1(config)#vlan i-sid 501 50501
Switch2:1(config)#interface Vlan 501
Switch2:1(config)#vrf vrf501
Switch2:1(config)#dvr gw-ipv4 50.1.1.1
Switch2:1(config)#dvr enable
Switch2:1(config)#ip address 50.1.1.3 255.255.0.0

Switch2:1(config)#router vrf vrf501
Switch2:1(router-vrf)#i-sid 55501
Switch2:1(router-vrf)#ipvpn enable
Switch2:1(router-vrf)#exit
Switch2:1(config)#
```

- c. Verify Layer 3 configuration. The following example shows verification on Controller 1. Perform this verification on both Controllers.

View the DvR host entries.

```
Switch2:1(config)#show dvr host-entries l3isid 55501

### DvR Leaf configuration – Leaf 1 and Leaf 2

- Configure the boot flag `dvr-leaf-mode` on the switches to be configured as DvR Leaf nodes.

#### Caution

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all existing non-DvR configuration on the switch, such as platform VLANs and their IP address configuration, CLIP configuration, routing protocol configuration and VRF configuration. The gateway IPv4 address, if configured, is also removed.

On switch with IP address 10.133.226.104, configure the boot flag and reboot the switch.

```

Switch3:1>en
Switch3:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch3:1(config)#boot config flags dvr-leaf-mode
Switch3:1(config)#save config
Switch3:1(config)#reset

```

On switch with IP address 10.133.226.105, configure the boot flag and reboot the switch.

```

Switch4:1>en
Switch4:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch4:1(config)#boot config flags dvr-leaf-mode
Switch4:1(config)#save config
Switch4:1(config)#reset

```

- After the switches come back up, configure the nodes as DvR Leaf nodes. Configure switch with IP address 10.133.226.104 as DvR Leaf 1; verify the configuration.

```

Switch3:1(config)#dvr Leaf 9
Switch3:1(config)#show dvr

## DvR Configuration Using the EDM

The following sections describe configuration of Distributed Virtual Routing (DvR) using the Enterprise Device Manager (EDM).

### Configure a DvR Controller or a DvR Leaf Globally

#### About This Task

Configure a node to perform the role of either a Controller or a Leaf, within the DvR domain.

#### Before You Begin

#### Important

##### For DvR Leaf Configuration only:

You must enable the `dvr-leaf-mode` boot flag before you configure a node as a DvR Leaf node. Navigate to **Configuration > Edit > Chassis**. On the **Boot Config** tab, select **EnableDvrLeafMode**.

Ensure that you save the current configuration on the switch, before you enable the flag. Enabling the flag removes all non-DvR configuration on the switch.

#### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Globals** tab.
4. Enter the domain ID in the **DomainId** field.

#### Note

A Controller or a Leaf node can belong to only one DvR domain.

5. Select the role of the node in the **Role** field.
6. (Optional) On a Controller node, disable injection of default routes into the DvR domain. Select **InjectDefaultRouteDisable**.

#### Note

This field applies only to Controllers. Attempting to select this field on a Leaf node displays an error message.

7. Update the fields as necessary, and then click **Apply** to save your configuration.

**Globals** Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Field                                                                                                    | Descriptions                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainId</b>                                                                                          | Uniquely identifies the domain that the node belongs to.<br>The range for a Controller or a Leaf is 1 to 255. Set to 0 if is not configured.                                                                                                                                                                             |
| <b>Role</b>                                                                                              | Specifies the role of the node in the domain, that is, either a Controller or a Leaf.                                                                                                                                                                                                                                    |
| <b>Enable</b>                                                                                            | Specifies whether DvR is enabled on the node. Configuring a Controller or Leaf sets this parameter to true.                                                                                                                                                                                                              |
| <b>DomainIsid</b>                                                                                        | Uniquely identifies the domain I-SID that the node belongs to.<br>The range is 16678217 to 16678727. 0 indicates that is not configured.                                                                                                                                                                                 |
| <b>BackboneIsid</b>                                                                                      | Uniquely identifies the backbone ISID that the node belongs to.<br>The valid backbone I-SID is 16678216. It is set to 0 if is not configured.                                                                                                                                                                            |
| <b>GatewayMac</b>                                                                                        | Specifies the Gateway MAC address used by all Domains.                                                                                                                                                                                                                                                                   |

## View DvR Routes

### About This Task

View the DvR routes (host routes and the IPv4 network routes) that are learned on a DvR Controller or a Leaf node.

Controllers display all the IP subnet routes configured for that DvR domain. Leaf nodes display the IP subnet routes learned from the Controller(s) for the L2 VSNs in the DvR Domain. Leaf nodes also display any redistributed routes into the DvR Domain that are learned from the Controllers (direct routes, static routes and the default route).

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Routes** tab.
4. To filter the rows based on the specific criteria, click **Filter**.

### *Routes field descriptions*

Use the data in the following table to use the **Routes** tab.

| Name                  | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| <b>DestIpAddrType</b> | Specifies the IPv4 destination address type of the DvR route.   |
| <b>DestIpAddr</b>     | Specifies the IPv4 destination address of the DvR route.        |
| <b>DestMask</b>       | Specifies the destination mask of the DvR route.                |
| <b>L3lsid</b>         | Specifies the L3 I-SID of the DvR route.                        |
| <b>EcmpIndex</b>      | Specifies the ECMP index for the ECMP routes of the DvR route.  |
| <b>NextHopMac</b>     | Specifies the MAC address of the next hop BEB in the DvR route. |
| <b>L2lsid</b>         | Specifies the L2 I-SID of the DvR route.                        |
| <b>VrfId</b>          | Specifies the VRF ID.                                           |
| <b>Cost</b>           | Specifies the SPB cost of the DvR route.                        |

| Name               | Description                                                    |
|--------------------|----------------------------------------------------------------|
| <b>NextHopName</b> | Specifies the host name of the next hop BEB, in the DVR route. |
| <b>Type</b>        | Specifies the route type of the DVR route.                     |

## View Members of a DvR Domain

### About This Task

View the members of all DvR domains namely the Controllers and Leaf nodes.

You can view this information on either a Controller or a Leaf node. Both the Controller and the Leaf node displays the members of the DvR domain to which it belongs.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **DVR**.
3. Select the **Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

### *Members* field descriptions

Use the data in the following table to use the **Members** tab.

| Name              | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the system ID or the nodal MAC address of this DvR member.   |
| <b>SysName</b>    | Specifies the system name of this DvR member.                          |
| <b>NickName</b>   | Specifies the nick name of this DvR member.                            |
| <b>Role</b>       | Specifies the DvR role (Controller or Leaf) of this DvR member.        |
| <b>DomainId</b>   | Specifies the domain ID of the DvR domain that this member belongs to. |

## View DvR Backbone Members

### About This Task

DvR backbone members are either DvR Controllers or non-DvR BEBs that receive redistributed host routes from all other DvR Controllers in the SPB network.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Backbone Members** tab.
4. (Optional) To filter the rows based on specific criteria, click **Filter**.

### **Backbone Members** field descriptions

Use the data in the following table to use the **Backbone Members** tab.

| Name              | Description                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the system ID or the nodal MAC address of this DvR backbone member.                                         |
| <b>SysName</b>    | Specifies the system name of this DvR backbone member.                                                                |
| <b>NickName</b>   | Specifies the nick name of this DvR backbone member.                                                                  |
| <b>Role</b>       | Specifies the role of this DvR backbone member. It is either a DvR Controller or a non-DvR BEB.                       |
| <b>DomainId</b>   | Specifies the domain ID of the DvR domain that this backbone member belongs to. The domain ID is 0 for a non-DvR BEB. |

## View DvR Interfaces

### About This Task

View the DvR interfaces on either a Controller or a Leaf node.

On Controllers, DvR interfaces are created when you configure IP on a DvR enabled Layer 2 VSN (VLAN, I-SID). Only Controllers display the administrative state of the interfaces because this is where you enable or disable the interfaces. On a Leaf node, the DvR interface information that the Controllers push, for example, subnet routes and the gateway IP addresses for the Layer 2 VSNs, are displayed.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Interfaces** tab.
  - Click **Filter** to filter rows based on specific filter criteria.

**Interfaces** field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                  | Description                                                                    |
|-----------------------|--------------------------------------------------------------------------------|
| <b>VlanIpAddrType</b> | Specifies the VLAN IP address type of the DvR interface.                       |
| <b>VlanIpAddr</b>     | Specifies the VLAN IP address (IPv4) of the DvR interface.                     |
| <b>L3Isid</b>         | Specifies the Layer 3 I-SID of the DvR interface. The range is 1 to 16777215.  |
| <b>L2Isid</b>         | Specifies the Layer 2 I-SID of the DvR interface. The range is 1 to 16777215.  |
| <b>VlanIpMask</b>     | Specifies the VLAN IP address mask of the DvR interface.                       |
| <b>VrfId</b>          | Specifies the VRF ID of the DvR interface. The VRF ID is 0 for the GRT.        |
| <b>VlanId</b>         | Specifies the VLAN ID of the DvR interface.                                    |
| <b>GwIpAddrType</b>   | Specifies the address type of the DvR gateway IP address (IPv4).               |
| <b>GwIpAddr</b>       | Specifies the DvR gateway IP address (IPv4).                                   |
| <b>AdminState</b>     | Specifies the administrative state of the DvR interface.                       |
| <b>SpbmcState</b>     | Specifies the state of IP Multicast over Fabric Connect, on the DvR interface. |
| <b>IgmpVersion</b>    | Specifies the version of IGMP that runs on the DvR interface.                  |

## View DvR Host Entries

**About This Task**

View DvR host entries (IPv4 remote ARPs) on either a Controller or a Leaf node. The node displays the host entries learned either locally on its UNI port or dynamically from other nodes in the DvR domain.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Host Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

**Host Entries** field descriptions

Use the data in the following table to use the **Host Entries** tab.

| Name               | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| <b>IpAddrType</b>  | Specifies the address type of the DvR host entry (IPv4 remote ARP). |
| <b>IpAddr</b>      | Specifies the IPv4 address of the DvR host entry.                   |
| <b>Mask</b>        | Specifies the subnet mask of the DvR host entry.                    |
| <b>L3Isid</b>      | Specifies the Layer 3 I-SID of the DvR host entry.                  |
| <b>MacAddr</b>     | Specifies the MAC address of the DvR host entry.                    |
| <b>L2Isid</b>      | Specifies the Layer 2 I-SID of the DvR host entry.                  |
| <b>VrfId</b>       | Specifies the VRF ID associated with the DvR host entry.            |
| <b>Port</b>        | Specifies the port of the DvR host entry.                           |
| <b>DomainId</b>    | Specifies the DvR domain ID of the DvR host entry.                  |
| <b>Type</b>        | Specifies the host type of the DvR host entry.                      |
| <b>NextHopName</b> | Specifies the next hop system name of the DvR host entry.           |
| <b>NextHopMac</b>  | Specifies the next hop system MAC address of the DvR host entry.    |
| <b>ClearEntry</b>  | Clears the entry if the configured value is true.                   |

## Clear DvR Host Entries

**About This Task**

Clear DvR host entries (IPv4 remote host routes) on a Controller. The host entries are learned on the switch either locally on its UNI port or dynamically from other nodes in the DvR domain.

**Note**

You can clear DvR host entries only on a DvR Controller.

An error message displays if you attempt clearing of host entries on a DvR Leaf node.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Clear Host Entries** tab.
4. Update the fields as necessary, and then click **Apply** to save your configuration.

**Clear Host Entries** field descriptions

Use the data in the following table to use the **Clear Host Entries** tab.

| Name               | Description                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ClearAll</b>    | Select to clear all DvR host entries.                                                                                                                     |
| <b>ClearIpv4</b>   | Specifies the IPv4 address of the DvR host entries to clear.<br>The IPv4 address must not be the VLAN IP address on any Controller within the DvR domain. |
| <b>ClearL2Isid</b> | Specifies the Layer 2 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215.                                                          |
| <b>ClearL3Isid</b> | Specifies the Layer 3 VSN I-SID of the DvR host entries to clear.<br>The range is 0 to 16777215.                                                          |

## View Layer 3 VSN Information

**About This Task**

View VRFs corresponding to Layer 3 (routed) VSN I-SIDs on either a Controller or a Leaf node.

**Before You Begin**

Ensure that you enable DvR globally on the node.

**Procedure**

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **L3-VSN** tab.

Click **Filter** to filter rows based on specific filter criteria.

**L3-VSN** field descriptions

Use the data in the following table to use the **L3-VSN** tab.

| Name                             | Description                                                               |
|----------------------------------|---------------------------------------------------------------------------|
| <b>VrfId</b>                     | Specifies the VRF ID of the VRF corresponding to the Layer 3 VSN I-SID.   |
| <b>Isid</b>                      | Specifies the Layer 3 VSN I-SID.                                          |
| <b>VrfName</b>                   | Specifies the VRF name of the VRF corresponding to the Layer 3 VSN I-SID. |
| <b>InjectDefaultRouteDisable</b> | Specifies whether injection of default routes is disabled.                |

## View the DvR Database

### About This Task

View all DvR routes on a Controller or a Leaf node.

The Controller node displays all the IP subnet routes configured for that DvR domain. A Leaf node displays all IP subnet routes learned from the Controller(s) for the Layer 2 VSNs in the DvR Domain. It also displays the Host Routes (ARPs) learned from other DvR enabled nodes.

### Before You Begin

Ensure that you enable DvR on the node.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **DVR**.
3. Click the **Database** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### *Database field descriptions*

Use the data in the following table to use the **Database** tab.

| Name                     | Description                                                                           |
|--------------------------|---------------------------------------------------------------------------------------|
| <b>DestIpAddrType</b>    | Specifies the address type of the IPv4 destination address of the DvR database entry. |
| <b>DestIpAddr</b>        | Specifies the IPv4 destination address of the DvR database entry.                     |
| <b>DestMask</b>          | Specifies the destination mask of the DvR database entry.                             |
| <b>L3Isid</b>            | Specifies the Layer 3 I-SID of the DvR database entry.                                |
| <b>EcmpIndex</b>         | Specifies the ECMP index for the DvR database entry.                                  |
| <b>NextHop</b>           | Specifies the MAC address of the next hop BEB, in the DvR database entry.             |
| <b>L2Isid</b>            | Specifies the Layer 2 I-SID of the DvR database entry.                                |
| <b>VrfId</b>             | Specifies the VRF ID for the DvR database entry.                                      |
| <b>OutgoingInterface</b> | Specifies the outgoing interface (port or MLT) of the DvR database entry.             |
| <b>SpbCost</b>           | Specifies the SPB cost of the DvR database entry.                                     |
| <b>PrefixCost</b>        | Specifies the prefix cost of the DvR database entry.                                  |

| Name               | Description                                                                   |
|--------------------|-------------------------------------------------------------------------------|
| <b>NextHopName</b> | Specifies the host name of the next hop BEB, in the DvR database table entry. |
| <b>Age</b>         | Specifies the uptime since creation of the DvR database table entry.          |

## View DvR Backbone Entries on a Controller

### About This Task

View the DvR backbone entries (redistributed host routes) learned from all Controllers in all DvR domains.

#### Note

You can view DvR backbone entries only on a Controller. Viewing backbone entries does not apply to a Leaf node.

### Before You Begin

Ensure that you enable DvR globally on the node.

### Procedure

1. In the navigation pane, expand **Configuration** > **Edit** folders.
2. Select **DVR**.
3. Select the **Backbone Entries** tab.
4. (Optional) To filter the rows based on the specific criteria, click **Filter**.

### **Backbone Entries** field descriptions

Use the data in the following table to use the **Backbone Entries** tab.

| Name                     | Description                                                            |
|--------------------------|------------------------------------------------------------------------|
| <b>IpAddrType</b>        | Specifies the address type of the DvR backbone host (IPv4 remote ARP). |
| <b>IpAddr</b>            | Specifies the IPv4 address of the DvR backbone host.                   |
| <b>L3Isid</b>            | Specifies the L3 I-SID of the DvR backbone host.                       |
| <b>DomainId</b>          | Specifies the domain ID of the DvR backbone host.                      |
| <b>EcmpIndex</b>         | Specifies the ECMP index of the DvR backbone host.                     |
| <b>HostMacAddr</b>       | Specifies the MAC address of DvR backbone host.                        |
| <b>L2Isid</b>            | Specifies the L2 I-SID of the DvR backbone host.                       |
| <b>AdvControllerName</b> | Specifies the host name of the advertising Controller.                 |

| Name                 | Description                                                               |
|----------------------|---------------------------------------------------------------------------|
| <b>AdvController</b> | Specifies the host MAC address of the advertising Controller.             |
| <b>NextHopName</b>   | Specifies the host name of the next hop Backbone host in the DvR route.   |
| <b>NextHopMac</b>    | Specifies the MAC address of the next hop Backbone host in the DvR route. |

## EAPoL

Extensible Authentication Protocol over LAN (EAPoL or EAP) is a port-based network access control protocol. EAP provides security by preventing users from accessing network resources before they are authenticated. The EAP authentication feature prevents users from accessing a network to assume a valid identity and access confidential material or launch denial-of-service attacks.

You can use EAP to set up network access control on internal LANs and to exchange authentication information between an end station or server that connects to a switch and an authentication server

(such as a RADIUS server). This security feature extends the benefits of remote authentication to internal LAN clients. For example, if a new client PC fails the authentication process, EAP prevents the new client PC from accessing the network.

## EAP terminology

This section lists some components and terms used with EAP-based security.

- Supplicant—a device, such as a PC, that applies for access to the network.
- Authenticator—software on a switch that authorizes or rejects a Supplicant attached to the other end of a LAN segment.
  - Port Access Entity (PAE)—software that controls each port on the device. The PAE, which resides on the switch, supports the Authenticator functionality.
  - Controlled Port—any port on the device with EAP enabled.
- Authentication Server—a RADIUS server that provides AAA services to the authenticator.

## EAP Configuration Considerations

This section lists EAP configuration considerations.

- You must configure at least one EAP RADIUS server and shared secret fields.
- You cannot configure EAP on ports that are currently configured for the following:
  - Shared segments
  - MultiLink Trunking
- Change the authentication status to `auto` for each port that you want to control. The `auto` setting automatically authenticates the port according to the results of the RADIUS server. The default authentication setting for each port is `authorized`.
- When multiple clients are authenticated on the same port, the priority of the latest incoming client is applied on the port, and this priority is retained until all the clients log out on that port.

### Configuration Process

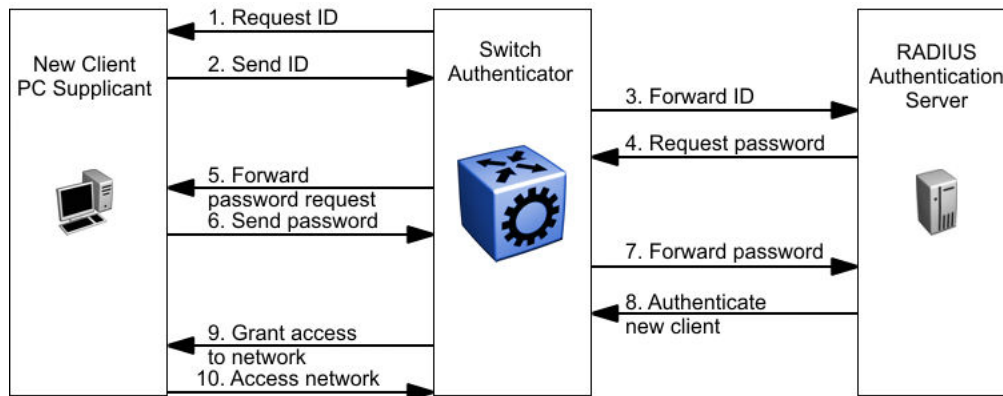

The Authenticator facilitates the authentication exchanges that occur between the Supplicant and the Authentication Server. The Authenticator PORT ACCESS ENTITY (PAE) encapsulates the EAP message into a RADIUS packet, and then sends the packet to the Authentication Server.

The Authenticator manages the access to controlled port. At system initialization, or when a Supplicant initially connects to one of the controlled ports on the device, the system blocks data traffic of the Supplicant until gets authenticated. After the Authentication Server notifies the Authenticator PAE about the success or failure of the authentication, the Authenticator decides whether to permit/deny the traffic of client on controlled port.

non-EAPoL (NEAP) frames transmit according to the following rules:

- If authentication succeeds, the client blocked from accessing is allowed to the controlled port, which means the system allows all the incoming and outgoing traffic from that client through the port.
- If authentication fails, client is blocked from accessing, which means both incoming and outgoing traffic is not allowed to client.

The following figure illustrates how the switch, configured with EAP, reacts to a new network connection.

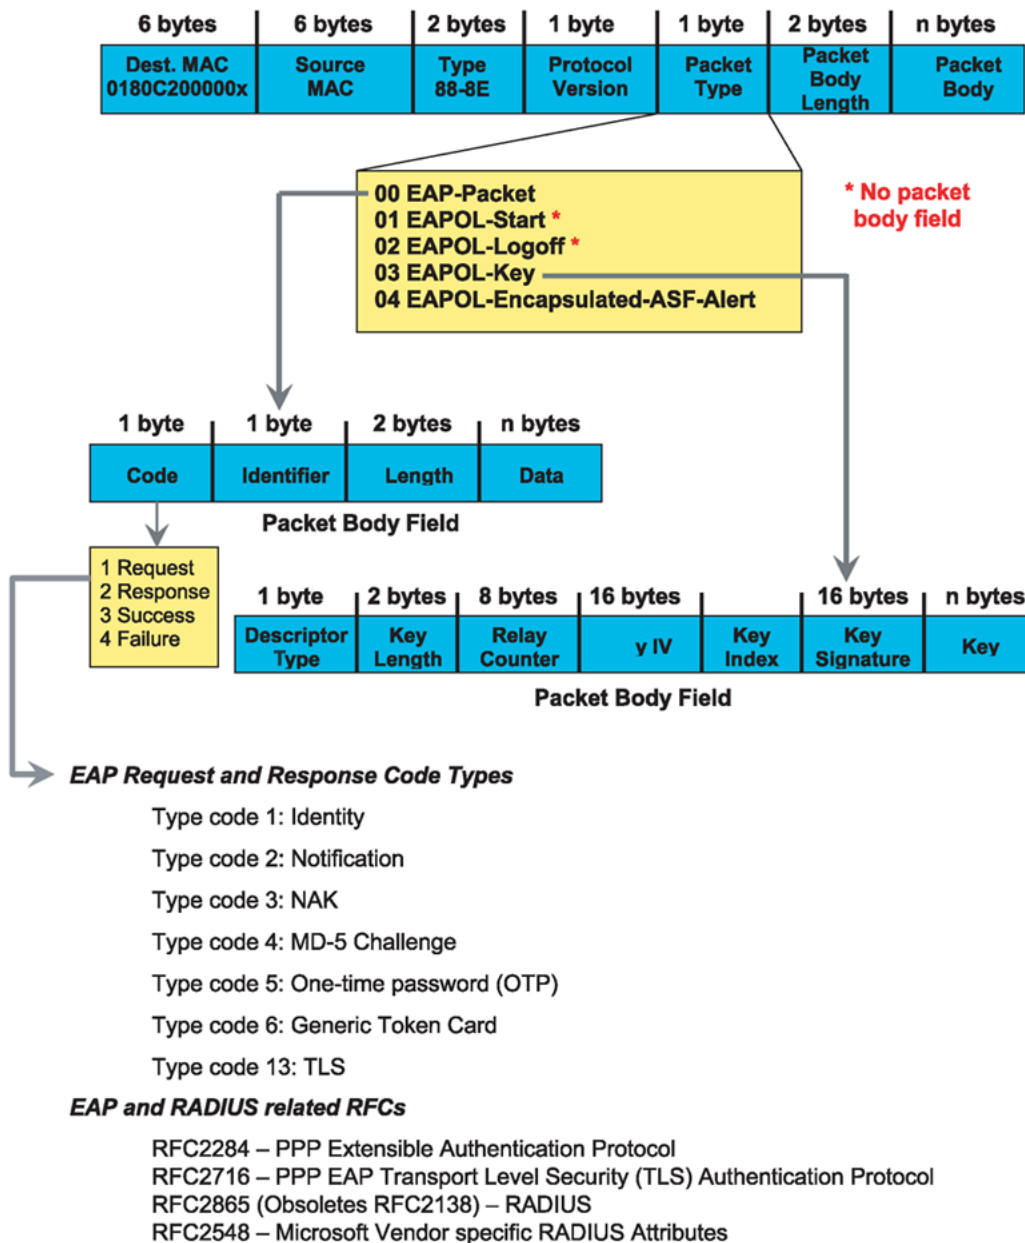

**Figure 44: EAP configuration example**

In the preceding figure, the switch uses the following steps to authenticate a new client:

1. The switch detects a new connection on one of its EAP-enabled ports and requests a user ID from the new client PC.
2. The new client sends its user ID to the switch.
3. The switch uses RADIUS to forward the user ID to the RADIUS server.
4. The RADIUS server responds with a request for the password of the user.
5. The switch forwards the request from the RADIUS server to the new client.
6. The new client sends an encrypted password to the switch, within the EAP packet.
7. The switch forwards the EAP packet to the RADIUS server.
8. The RADIUS server authenticates the password.
9. The switch grants the new client access to the network.
10. The new client accesses the network.

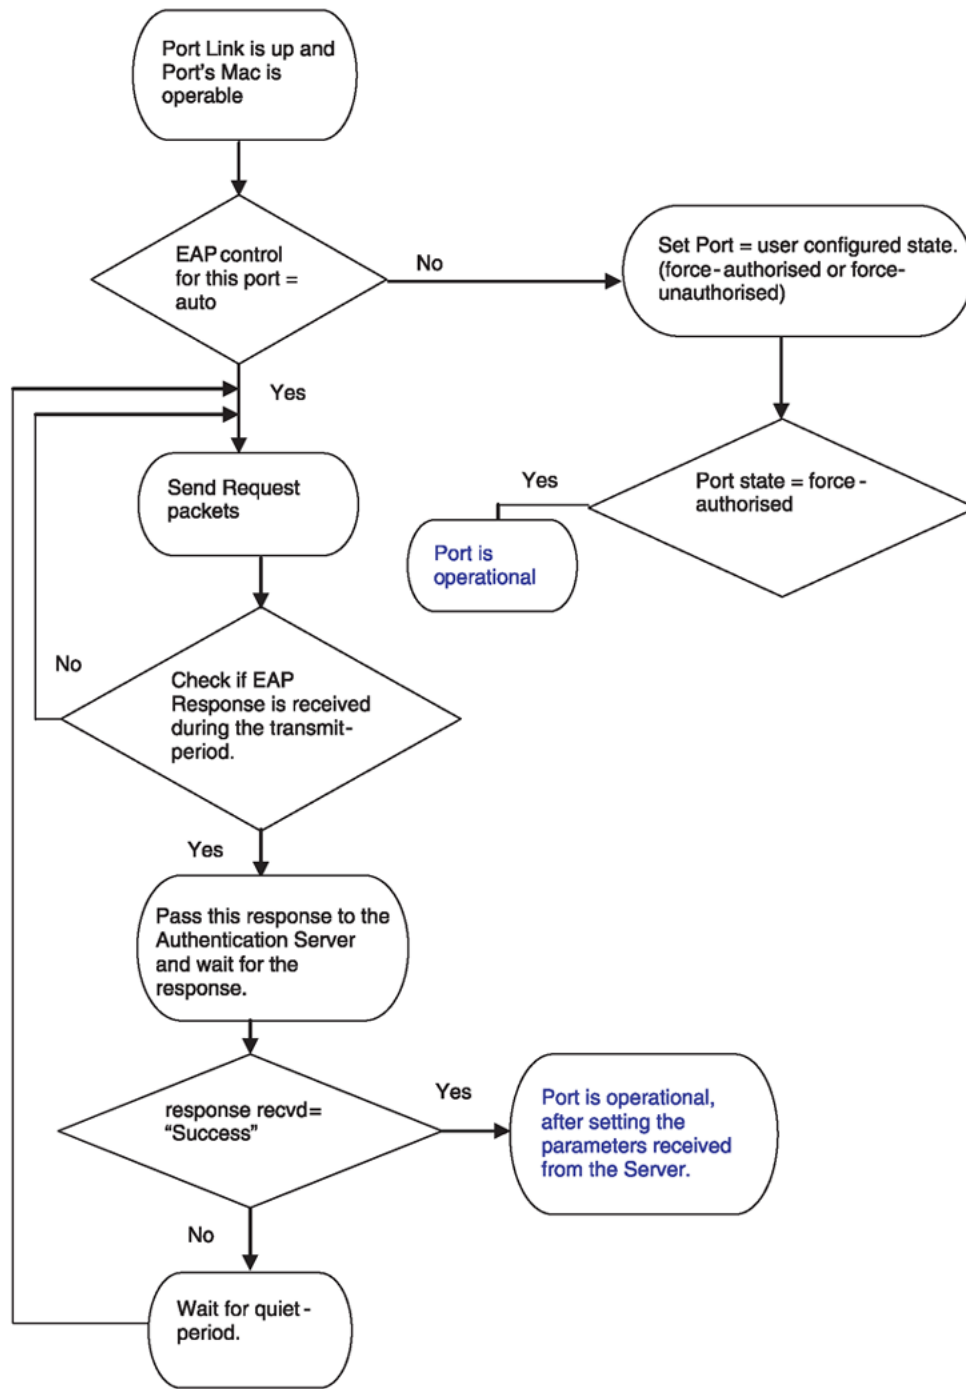

If the RADIUS server cannot authenticate the new client, it denies the new client access to the network.

The following figure shows the Ethernet frames and the corresponding codes for EAP as specified by 802.1x.

**Figure 45: 802.1x Ethernet frame**

The following figure shows the flow diagram for EAP on a switch.

**Figure 46: EAP flow diagram**

### EAP System Requirements

The following are the minimum system requirements for EAP:

- RADIUS server

- Client software that supports EAP

You must specify the RADIUS server that supports EAP as the primary RADIUS server for the switch. You must configure your switch for VLANs and EAP security.

If you configure EAP on a port, the following limitations apply:

- You cannot enable EAP on ports that belong to an MLT group.
- You cannot add EAP-enabled ports to an MLT group.
- You can configure a total of 32 MAC clients, EAP and NEAP hosts, on an EAP-enabled port. Two MAC clients per port is a typical configuration.
- You cannot configure EAP on MLT/LACP interfaces.
- You cannot add EAP-enabled ports to an MLT/LACP group.
- You cannot enable VLACP on EAP enabled ports.
- Manual VLAN changes on a EAP enabled port is restricted.
- You cannot change the VLAN port tagging on EAP enabled ports.
- You cannot configure the default VLAN ID. Use the Guest VLAN configuration to access unauthenticated devices.
- You cannot enable MACsec on EAP enabled ports.
- You cannot enable EAP on NNI interfaces.
- You cannot egress mirror an EAP PDU.
- Do not use EAP with a brouter port.
- Ping to and from services between nodes over the NNI will work even when it contains only EAP enabled ports with no authenticated clients on it.
- MHSa and Fail Open VLAN are mutually exclusive.
- Fail-Open I-SID is not supported in MHSa mode.
- You cannot change the EAP operation mode on EAP enabled ports.
- You cannot configure private VLANs as Fail Open VLAN or Guest VLAN.
- You cannot configure spbm-BVLAN as Fail Open VLAN or Guest VLAN.
- You cannot delete a VLAN if the VLAN is configured as Fail Open VLAN or Guest VLAN.

## EAP Dynamic VLAN Assignment

If you configure a RADIUS server to send a VLAN ID in the Access-Accept response, the EAP feature dynamically changes the VLAN configuration of the port by adding the port to the specified VLAN.

EAP dynamic VLAN assignment affects the following VLAN configuration values:

- Port membership
- Port priority
- Default VLAN ID

When you disable EAP on a port that was previously authorized, VLAN configuration values for that port are restored directly from the nonvolatile random access memory (NVRAM) of the device.

You can set up your Authentication Server (RADIUS server) for EAP dynamic VLAN assignments. You can use the Authentication Server to configure user-specific settings for VLAN memberships and port priority.

When you log on to a system that is configured for EAP authentication, the Authentication Server recognizes your user ID and notifies the device to assign preconfigured (user-specific) VLAN membership and port priorities to the device. The configuration settings are based on configuration parameters that were customized for your user ID and previously stored on the Authentication Server.

**Note**

Static entries like IGMP, ARP, FDB configured on a port of a VLAN interface, will not be retained if the port is assigned a same VLAN by the RADIUS server and the client authenticated on the port gets disconnected or unauthenticated.

## Multiple Host Multiple VLAN

With the MHMV feature, you can assign multiple authenticated devices to different VLANs on the same EAP-enabled port using device MAC addresses. Using RADIUS VLAN attributes, different clients can access different VLANs. This separates traffic for different MAC clients.

In MHMV mode, the port-priority assigned by the RADIUS server is configured by MAC address for each authenticated client. After configuration, the QoS level on the port does not change.

Use MHMV to assign multiple authenticated devices to different VLANs on the same port. Clients can access different VLANs access using the MAC address of the devices. Different clients with different level of access (unauthorized to authorized) in different VLANs and with different QoS priorities, can exist on the same port.

With MHMV, EAP Multihost VLAN supports tagged and untagged ports. A port can be a member of multiple tagged and untagged VLANs.

In MHMV mode, MAC based VLANs support traffic separation between different authenticated MAC clients. MAC based VLAN traffic separation applies only to untagged VLAN traffic. If the data traffic is tagged and if VLAN is configured on the port, then the traffic is forwarded to the VLAN associated with the tag.

### *Multiple Host Multiple VLAN Usage*

The following example illustrates the usage scenario for a MHMV port with n unauthenticated clients:

- Clients (n) connect to a switch port. The maximum number of clients (EAP + NEAP) allowed on a port is 8192.
- EAP is enabled and the default operation mode is MHMV.
- Modify client counters to authenticate n clients.
- Initial VLANs are the VLANs which are manually set up before EAP is enabled.
- Port default VLAN ID is equal to one of the initial VLAN ID.
- All clients are unauthenticated, hence the clients cannot access the network.

The following figure represents the functionality when clients are not authenticated.

**Note**

The clients cannot access the network as they are not authenticated.

When client PC1 authenticates, there are two scenarios:

1. Client PC1 does not receive RADIUS VLAN attribute:
  - There are no changes to the port membership and port default VLAN ID.
  - PC1 is the only client that is allowed access to the initial VLANs.
  - A VLAN MAC rule is added that associates the MAC with the default VLAN ID.
  - If the VLAN is configured on the port, then the tagged traffic from PC1 is forwarded to the VLAN associated with the tag.
  - Untagged traffic from PC1 is forwarded to the port default VLAN.
2. Client PC1 receives RADIUS VLAN attribute:
  - The port is left in all initial VLANs and added to the VLAN corresponding to the RADIUS VLAN attribute.
  - Port default VLAN remains unchanged.
  - A VLAN MAC based rule is configured for client PC1.
  - Using the VLAN MAC based capabilities, the untagged traffic from PC1 goes to the RADIUS assigned VLAN 1 as shown in the figure below.

- Client PC1 can access all initial VLANs using tagged frames.
- The remaining clients stay unauthenticated and cannot access any VLANs.

The following figure represents the functionality when client PC1 authenticates.

#### Note

PC1 is authenticated with RADIUS VLAN 1. The other clients cannot access the network as they are unauthenticated.

When a client disconnects the following happens:

- The MAC VLAN rule is removed from the switch.
- If the RADIUS VLAN attribute was used with the client was authenticated and no other clients are authenticated on that RADIUS VLAN, then the port is removed from the VLAN.
- The RADIUS accounting attribute Acct-Terminate-Cause indicates how a session was terminated.
- The RADIUS accounting attribute Event-Timestamp indicates the time that an event occurred on the Network Access Server (NAS).

## EAP Functionality on Flex UNI Ports

After you enable EAP on a port, all client MACs (MHMV mode) must be authenticated by the RADIUS server in order to have network access. In Multiple Host Multiple VLAN (MHMV) mode, the RADIUS server allocates a MAC to I-SID binding to each client that connects to the switch and uses it to transmit

traffic. The binding is not between the MAC and the VLAN. Untagged S-UNIs generated from the RADIUS server for a MAC or MACs are considered as MAC-based S-UNIs.

The RADIUS server also provides the VLAN:I-SID binding for the MAC, which results in the addition of an untagged Switched UNI (S-UNI) for that particular I-SID. Only the MAC or MACs that receive the I-SID from the RADIUS server can transmit traffic to Extensible Authentication Protocol (EAP)-enabled Flex UNI ports.

The switch uses MAC-based S-UNIs with EAP-enabled Flex UNI ports in MHMV mode only.

The MAC-based S-UNI model does not apply to MHSA mode. In Multiple Host Single Authentication (MHSA) mode used in the untagged S-UNI model that exists on VOSS switches. S-UNIs generated from the information obtained from the RADIUS server are considered as classic or default untagged S-UNIs.

**Note**

EAP is not supported on MLT/SMLTs. Only the EAP I-SIDs are synchronized between one vIST peer and another vIST peer. S-UNIs are not synchronized with the vIST peer.

EAP with Flex UNI is supported on Distributed Virtual Routing (DvR) Leafs. An untagged S-UNI (where the system learns MACs based on the I-SID to MAC binding) must have a platform VLAN associated with it. If a default untagged S-UNI is used, the corresponding S-UNI must be received from the DvR Controllers.

## EAP and Fabric Attach

With Extensible Authentication Protocol (EAP) and Fabric Attach (FA), FA-capable switches can forward traffic from EAP/NEAP clients over the SPB cloud. The traffic for authenticated clients is mapped to I-SIDs received from RADIUS server.

You must configure the desired bindings for EAP/NEAP clients on the RADIUS server. When confirming the authentication request, the RADIUS server also sends the corresponding binding for the EAP/NEAP client.

The FA Proxy sends to the FA Server the binding received from the RADIUS server. If the FA Server rejects all the bindings, the client is disconnected. EAP clients are moved from AUTHENTICATED state to HELD state.

On an FA Server, when an EAP/NEAP device is authenticated and an FA binding is received from the RADIUS server, a Switched UNI (S-UNI) is created.

After an EAP/NEAP client is disconnected, the switch cleans-up the binding associated with the client, if no other EAP/NEAP client on that port uses it.

EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port.

FA clients that generate S-UNI bindings must be used with EAP MHSA mode, while FA clients that do not generate S-UNI bindings should be used with EAP MHMV mode.

## MAC Move Detection on EAP Ports

The MAC moves mechanism detects when a MAC address migrates from one port to another port, such as:

- EAPoL-enabled port to EAPoL-enabled port
- EAPoL-enabled port to non-EAPoL (NEAP)-enabled port
- non EAPoL-enabled port to EAPoL-enabled port

When a MAC address migrates from one port to another port, the new EAPoL-enabled port triggers a new RADIUS authentication. New bindings are applied on the new EAPoL-enabled port. The old port detects the MAC is moved and automatically deletes the old binding or bindings.

The Mac moves mechanism works between vIST peers when a MAC address on one peer migrates to the other peer but only if the I-SID in which the MAC address is learned exists on the new and the old peer.

## Auto-sense Ports

EAP and NEAP is integrated with Auto-sense infrastructure. If a RADIUS server is configured on the switch, Auto-sense-enabled ports activate EAP and NEAP authentication automatically.

For more information about Auto-sense functionality, see [Auto-sense](#) on page 18.

## RADIUS-Assigned VLAN or VLAN:I-SID Bindings

RADIUS-assigned VLAN and VLAN:I-SID bindings provide greater flexibility and a more centralized assignment. The RADIUS server can dynamically assign VLANs or VLAN:I-SID bindings to a port.

Use VLAN attributes for RADIUS assignments in VLAN mode. This mode applies when the EAP-enabled port does not have Flex-UNI enabled.

Use VLAN:ISID attributes for RADIUS assignments in I-SID mode. This mode applies when the EAP-enabled port does have Flex-UNI enabled.

For more information, see [RADIUS Attributes](#) on page 750.

## RADIUS Configuration Prerequisites for EAP

Connect the RADIUS server to a force-authorized port. This ensures that the port is always available and not tied to whether or not the device is EAP-enabled.

## RADIUS Accounting for EAP

The switch provides the ability to account EAP and NEAP sessions using the RADIUS accounting protocol. A user session is defined as the time frame between when a user is authenticated until the user is unauthenticated.

The following table summarizes the accounting events and information logged.

**Table 108: Summary of accounting events and information logged**

| Event                        | RADIUS attributes    | Description                                                                                                                                                              |
|------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| User is authenticated by EAP | Acct-Status-Type     | Start                                                                                                                                                                    |
|                              | Nas-IP-Address       | IP address to represent the switch                                                                                                                                       |
|                              | Nas-Port             | Port number on which the user is EAP or NEAP authorized                                                                                                                  |
|                              | Acct-Session-ID      | Unique string representing the session                                                                                                                                   |
|                              | User-Name            | EAP user name or NEAP MAC                                                                                                                                                |
| User logs off                | Acct-Status-Type     | Stop                                                                                                                                                                     |
|                              | Nas-IP-Address       | IP address to represent the switch                                                                                                                                       |
|                              | Nas-Port             | Port number on which the user is EAP or NEAP unauthorized                                                                                                                |
