smtp domain-name WORD<1-254>
```

10. Verify the configuration:

```
show smtp [event-id]
```

### Examples

Configure the SMTP client to use TCP port 26 to communicate with an SMTP server that is using port 26. Add two receiver email addresses, configure the server information using an IPv4 address, and enable the SMTP feature. Finally, configure an SMTP domain name, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#smtp port 26
Switch:1(config)#smtp receiver-email add test1@default.com,test2@default.com
Switch:1(config)#smtp server 192.0.2.1
Switch:1(config)#smtp enable
Switch:1(config)#smtp domain-name test mailer
Switch:1(config)#show smtp
=====
SMTP Information
=====
SMTP Status: Enabled
Server Address: 192.0.2.1
Server Port: 26
Status send Timer: 30 (seconds)
Sender Email: LabSwitch@default.com
Domain Name: test mailer
Receiver Emails: test1@default.com
 test2@default.com
```

Add an event ID to the list for which the switch sends email notification on a log event. Verify the configuration.

```
Switch:1(config)#smtp event-id add 0x0000c5ec
Switch:1(config)#show smtp event-id

*Variable Definitions*

The following table defines parameters for the **smtp port** command.

| Variable  | Value                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-65535> | <p>Specifies the TCP port on the switch that the SMTP client uses to communicate with the SMTP server. The default value is 25.</p> <p><b>Note:</b><br/>                     You must disable the SMTP feature before you can change an existing SMTP port configuration.<br/>                     The port you specify must match the port that the SMTP server uses.</p> |

The following table defines parameters for the **smtp receiver-email** command.

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>add</i><br>WORD<3-1274>    | <p>Adds an email address to the recipient list. The recipients receive the email notification generated by the switch.</p> <p>You must configure at least one email recipient and can create a maximum of five email recipients. You can specify multiple addresses in a single command by separating them with a comma.</p> <p>You cannot use quotation marks (") or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC 5321.</p> <p>The maximum length for the address is 254 characters.</p> |
| <i>remove</i><br>WORD<3-1274> | <p>Removes an email address from the recipient list. The recipients receive the email notification generated by the switch. You can specify multiple addresses in a single command by separating them with a comma.</p> <p>You cannot use quotation marks (") or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC 5321.</p> <p>The maximum length for the address is 254 characters.</p>                                                                                                      |

The following table defines parameters for the **smtp server** command.

| Variable            | Value                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-256> | Specifies the SMTP server address. You can use either a hostname or IPv4 address. If you use a hostname, you must configure the DNS client on the switch. |

The following table defines parameters for the **smtp sender-email** command.

| Variable            | Value                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <3-254> | Specifies the email address that the system displays it in the From field of the message that the switch generates. By default, the switch uses < <i>SystemName</i> >@default.com. |

The following table defines parameters for the **smtp event-id** command.

| Variable                    | Value                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>add WORD</i> <1-1100>    | Adds a log event to the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma.<br>The event ID can be up to 10 digits in hexadecimal format.      |
| <i>remove WORD</i> <1-1100> | Removes a log event from the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma.<br>The event ID can be up to 10 digits in hexadecimal format. |

The following table defines parameters for the **smtp status-send-timer** command.

| Variable       | Value                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0   30-43200> | Specifies the interval, in seconds, at which the switch sends status information. The default is 30 seconds. A value of 0 means the switch does not send status information. |

The following table defines parameters for the **smtp domain-name** command.

| Variable            | Value                                                               |
|---------------------|---------------------------------------------------------------------|
| <i>WORD</i> <1-254> | Specifies the SMTP host name or IPv4 address (string length 1-254). |

The following table defines parameters for the **show smtp** command.

| Variable        | Value                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>event-id</i> | Shows a list of active event IDs for which the switch generates email notification. The command output includes the default list of IDs and IDs you specifically add or remove. |

## Log Configuration Using EDM

Use log files and messages to perform diagnostic and fault management functions. This section provides procedures to configure and use the logging system in Enterprise Device Manager (EDM).

### Configure the System Log

#### About This Task

Configure the system log to track all user activity on the device. The system log can send messages of up to ten syslog hosts.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **System Log**.
3. In the **System Log** tab, select **Enable**.
4. Configure the maximum number of syslog hosts.
5. Configure the IP header type for the syslog packet.
6. Click **Apply**.

#### **System Log** Field Descriptions

Use the data in the following table to use the **System Log** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>    | Enables or disables the syslog feature. If you select this variable, this feature sends a message to a server on a network that is configured to receive and store diagnostic messages from this device. You can configure the type of messages sent. The default is enabled.                                                                                                                                                                                                                                                                |
| <b>MaxHosts</b>  | Specifies the maximum number of remote hosts considered active and can receive messages from the syslog service. The range is 0–10 and the default is 5.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OperState</b> | Specifies the operational state of the syslog service. The default is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Header</b>    | Specifies the IP header in syslog packets to circuitlessIP or default. <ul style="list-style-type: none"> <li>• If the value is default, the IP address of the VLAN is used for syslog packets that are transmitted in-band using input/output (I/O) ports.</li> <li>• If the value is circuitlessIP, the circuitless IP address is used in the IP header for all syslog messages (in-band or out-of-band). If you configure multiple circuitless IPs, the first circuitless IP configured is used.</li> </ul> The default value is default. |

## Configure the System Log Table

### About This Task

Use the system log table to customize the mappings between the severity levels and the type of alarms.

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration except in the following case. When you configure the system log table, under the **System Log Table** tab, you must select **ipv4** or **ipv6**, in the **AddressType** box. The **Address** box supports both IPv4 and IPv6 addresses.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **System Log**.
3. Click the **System Log Table** tab.
4. Click **Insert**.
5. Configure the parameters as required.
6. Click **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Click **Apply**.

### **System Log Table** Field Descriptions

Use the data in the following table to use the **System Log Table** tab.

| Name                      | Description                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                 | Specifies the ID for the syslog host. The range is 1–10.                                                                                     |
| <b>AddressType</b>        | Specifies if the address is an IPv4 or IPv6 address.                                                                                         |
| <b>Address</b>            | Specifies the IP address of the syslog host. You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses. |
| <b>UdpPort</b>            | Specifies the UDP port to use to send messages to the syslog host (514–530). The default is 514.                                             |
| <b>Enable</b>             | Enables or disables the sending of messages to the syslog host. The default is disabled.                                                     |
| <b>HostFacility</b>       | Specifies the syslog host facility used to identify messages (local0 to local7). The default is local7.                                      |
| <b>Severity</b>           | Specifies the message severity for which syslog messages are sent. The default is info warning error fatal.                                  |
| <b>MapInfoSeverity</b>    | Specifies the syslog severity to use for INFO messages. The default is info.                                                                 |
| <b>MapWarningSeverity</b> | Specifies the syslog severity to use for WARNING messages. The default is warning.                                                           |
| <b>MapErrorSeverity</b>   | Specifies the syslog severity to use for ERROR messages. The default is error.                                                               |
| <b>MapFatalSeverity</b>   | Specifies the syslog severity to use for FATAL messages. The default is emergency.                                                           |

| Name                                  | Description                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MapMfgSeverity</b>                 | Specifies the syslog severity to use for Accelar manufacturing messages. The default is notice.                                                                                          |
| <b>SecureForwardingTcpPort</b>        | Specifies the TCP port to use for secure forwarding for a particular host. The default is 1025.                                                                                          |
| <b>SecureForwardingMode</b>           | Enables or disables secure forwarding of syslog over remote port forwarding. The supported values are tls and none. The default is none, which means that secure forwarding is disabled. |
| <b>SecureForwardingServerCertName</b> | Specifies the server certificate name. Certificate validation is done only if the server certificate name is configured.                                                                 |

## Configure Email Notification

Configure the SMTP feature to generate email notifications for component failures, critical conditions, or general system health status.

### About This Task

The SMTP feature is disabled by default.

### Before You Begin

- To identify the SMTP server by hostname, you must first configure a DNS client on the switch.

### Procedure

- In the navigation pane, expand **Configuration > Edit**.
- Select **SMTP**.
- Select the **Globals** tab.
- In the **ServerAddress** field, configure the SMTP server address.
- In the **ReceiverEmailsList** field, add email recipients.

#### Note

You must configure at least one recipient.

- (Optional) In the **SenderEmail** field, configure a sender email address to use an address other than the default.
- In the **DomainName** field, configure an SMTP domain name.
- In the **Port** field, configure the TCP port that the client uses to open a connection with the SMTP server.
- (Optional) In the **SystemStatusSendTimer** field, configure the status update interval.
- Select **enable** to enable the SMTP client.
- (Optional) In the **LogEventIds** field, add or remove log events to the default list that generates an email notification.
- Select **Apply**.

*Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServerAddressType</b>     | Specifies the type of server address as either an IPv4 address or a hostname. If you use a hostname, you must configure the DNS client on the switch.                                                                                                                                                                                                                                                                                                                                             |
| <b>ServerAddress</b>         | Specifies the SMTP server address. You can use either a hostname or an IPv4 address. If you use a hostname, you must configure the DNS client on the switch.                                                                                                                                                                                                                                                                                                                                      |
| <b>ReceiverEmailsList</b>    | Specifies the recipient list. The recipients receive the email notification generated by the switch. You must configure at least one email recipient and can create a maximum of five email recipients. You can specify multiple addresses in a single command by separating them with a comma. You cannot use quotation marks (") or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC5321. The maximum length for the address is 254 characters. |
| <b>NumOfEmails</b>           | Shows the total number of addresses in <b>ReceiverEmailsList</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SenderEmail</b>           | Specifies the email address that the system displays it in the From field of the message that the switch generates. By default, the switch uses <i>SystemName@default.com</i> .                                                                                                                                                                                                                                                                                                                   |
| <b>DomainName</b>            | Specifies the SMTP domain name. The maximum length is 254 characters.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Port</b>                  | <p>Specifies the TCP port on the switch that the SMTP client uses to communicate with the SMTP server. The default value is 25.</p> <p><b>Note:</b><br/>You must disable the SMTP feature before you can change an existing SMTP port configuration. The port you specify must match the port that the SMTP server uses.</p>                                                                                                                                                                      |
| <b>SystemStatusSendTimer</b> | Specifies the interval, in seconds, at which the switch sends status information. The default is 30 seconds. A value of 0 means the switch does not send status information.                                                                                                                                                                                                                                                                                                                      |
| <b>Enable</b>                | Enables or disables the SMTP feature. By default, SMTP is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Name                        | Description                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LogEventIds</b>          | Specifies the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma.<br>The event ID can be up to 10 digits in hexadecimal format. |
| <b>NumOfEventIds</b>        | Shows the total number of IDs in <b>LogEventIds</b> .                                                                                                                                                                |
| <b>DefaultLogEventIds</b>   | Shows the default list of event IDs that generate email notification.                                                                                                                                                |
| <b>NumOfDefaultEventIds</b> | Shows the total number of IDs in <b>DefaultLogEventIds</b> .                                                                                                                                                         |

## SNMP Trap Configuration Using CLI

### Configuring an SNMP Host

Configure an SNMP host so that the system can forward SNMP traps to a host for monitoring. You can use SNMPv1, SNMPv2c, or SNMPv3. You configure the target table parameters (security name and model) as part of the host configuration.

#### Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Configure an SNMPv1 host:  

```
snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]
```
- Configure an SNMPv2c host:  

```
snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>]] [filter WORD<1-32>]
```
- Configure an SNMPv3 host:  

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|authNoPriv|AuthPriv} WORD<1-32> [inform [timeout <1-2147483647>] [retries <0-255>]] [filter WORD<1-32>]
```
- Ensure that the configuration is correct:  

```
show snmp-server host
```

#### Example

Configure the target table entry. Configure an SNMPv3 host.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server host 192.0.2.207 port 162 v2c ReadView inform timeout 1500
retries 3 mms 484
```

```
Switch:1(config)#snmp-server host 192.0.2.207 port 163 v3 authPriv Lab3 inform timeout
1500 retries 3
```

### Variable Definitions

The following table defines parameters for the **snmp-server host** command.

| Variable                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>inform</i> [ <i>timeout</i> <1-2147483647>] [ <i>retries</i> <0-255>] [ <i>mms</i> <0-2147483647>] | Sends SNMP notifications as inform (rather than trap). To use all three options in one command, you must use them in the following order: <ol style="list-style-type: none"> <li><i>timeout</i> &lt;1-2147483647&gt; specifies the timeout value in seconds with a range of 1-214748364.</li> <li><i>retries</i> &lt;0-255&gt; specifies the retry count value with a range of 0-255.</li> <li><i>mms</i> &lt;0-2147483647&gt; specifies the maximum message size as an integer with a range of 0-2147483647.</li> </ol> |
| <i>filter</i> WORD<1-32>                                                                              | Specifies the filter profile to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>noAuthNoPriv</i>   <i>authNoPriv</i>   <i>AuthPriv</i>                                             | Specifies the security level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>port</i> <1-65535>                                                                                 | Specifies the host server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| WORD<1-32>                                                                                            | Specifies the security name, which identifies the principal that generates SNMP messages.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| WORD<1-256>                                                                                           | Specifies either an IPv4 or IPv6 address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Configuring an SNMP Notify Filter Table

Configure the notify table to select management targets to receive notifications, as well as the type of notification to send to each management target.

### Before You Begin

- For more information about the notify filter table, see RFC3413.

### Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create a new notify filter table:

```
snmp-server notify-filter WORD<1-32> WORD<1-32>
```
- Ensure that the configuration is correct:

```
show snmp-server notify-filter
```

### Example

```
Switch:1(config)#snmp-server notify-filter profile3 99.3.6.1.6.3.1.1.4.1
Switch:1(config)#show snmp-server notify-filter
```

| Notify Filter Configuration |                       |      |
|-----------------------------|-----------------------|------|
| Profile Name                | Subtree               | Mask |
| profile1                    | +99.3.6.1.6.3.1.1.4.1 | 0x7f |
| profile2                    | +99.3.6.1.6.3.1.1.4.1 | 0x7f |
| profile3                    | +99.3.6.1.6.3.1.1.4.1 | 0x7f |

Variable Definitions

The following table defines parameters for the **snmp-server notify-filter** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-32> <i>WORD</i> <1-32> | Creates a notify filter table.<br>The first instance of <i>WORD</i> <1-32> specifies the name of the filter profile with a string length of 1-32.<br>The second instance of <i>WORD</i> <1-32> identifies the filter subtree OID with a string length of 1-32.<br>If the subtree OID parameter uses a plus sign (+) prefix (or no prefix), this indicates include. If the subtree OID uses the minus sign (-) prefix, it indicates exclude.<br>You do not calculate the mask because it is automatically calculated. You can use the wildcard character, the asterisk (*), to specify the mask within the OID. You do not need to specify the OID in the dotted decimal format; you can alternatively specify that the MIB parameter names and the OIDs are automatically calculated. |

Configure SNMP Interfaces

Note

This procedure only applies to VSP 8600 Series.

Configure an interface to send SNMP traps. If the switch has multiple interfaces, configure the IP interface from which the SNMP traps originate.

Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the destination and source IP addresses for SNMP traps:  
`snmp-server sender-ip {A.B.C.D} {A.B.C.D}`
3. If required, send the source address (sender IP) as the sender network in the notification message:  
`snmp-server force-trap-sender enable`
4. If required, force the SNMP and IP sender flag to use the same value:  
`snmp-server force-iphdr-sender enable`

Example

```
Switch:1(config)#snmp-server sender-ip 192.0.2.2 192.0.2.5
Switch:1(config)#no snmp-server force-iphdr-sender enable
```

### Variable Definitions

The following table defines parameters for the **snmp-server** command.

| Variable                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sender-ip <A.B.C.D> <A.B.C.D><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Configures the SNMP trap receiver and source IP addresses. Specify the IP address of the destination SNMP server that receives the SNMP trap notification in the first IP address. Specify the source IP address of the SNMP trap notification packet that is transmitted in the second IP address. If this address is 0.0.0.0, the system uses the IP address of the local interface that is closest (from an IP routing table perspective) to the destination SNMP server. |
| force-iphdr-sender enable<br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series.     | Automatically configures the SNMP and IP sender to the same value. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                  |
| force-trap-sender enable<br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series.      | Sends the configured source address (sender IP) as the sender network in the notification message.                                                                                                                                                                                                                                                                                                                                                                           |
| authentication-trap enable                                                                         | Activates the generation of authentication traps.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| login-success-trap enable                                                                          | Activates the generation of traps for successful login.                                                                                                                                                                                                                                                                                                                                                                                                                      |

The following table defines parameters for the **snmp-server host** command.

| Variable          | Value                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------|
| WORD<1-256>       | Specifies either an IPv4 or IPv6 address.                                                 |
| port <1-65535>    | Specifies the host server port number.                                                    |
| WORD<1-32>        | Specifies the security name, which identifies the principal that generates SNMP messages. |
| filter WORD<1-32> | Specifies the filter profile to use.                                                      |

## Enabling SNMP Trap Logging

Use SNMP trap logging to send a copy of all traps to the syslog server.

### Before You Begin

- You must configure and enable the syslog server.

### About This Task

**Note**

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable SNMP trap logging:  

```
snmplog enable
```
3. (Optional) Disable SNMP trap logging:  

```
no snmplog enable
```
4. View the contents of the SNMP log:  

```
show logging file module snmplog
```

### Example

Enable SNMP trap logging and view the contents of the SNMP log:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmplog enable
Switch:1(config-app)#show logging file module snmp
CP1 [02/06/15 22:39:58.530:UTC] 0x00004595 00000000 GlobalRouter SNMP INFO Boot

### Variable Definitions

The following table defines parameters for the **snmplog** command.

| Variable      | Value                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------|
| <i>enable</i> | Enables the logging of traps.<br>Use the command <code>no snmplog enable</code> to disable the logging of traps. |

## SNMP Trap Configuration Using EDM

### Configure an SNMP Host Target Address

Configure a target table to specify the list of transport addresses to use in the generation of SNMP messages.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Target Table**.
3. In the **Target Table** tab, click **Insert**.
4. In the **Name** box, type a unique identifier.
5. In the **TDomain** box, select the transport type of the address. Select either **ipv4Tdomain** or **ipv6Tdomain**.
6. In the **TAddress** box, type the transport address and User Datagram Protocol (UDP) port.
7. In the **Timeout** box, type the maximum round trip time.
8. In the **RetryCount** box, type the number of retries to be attempted.
9. In the **TagList** box, type the list of tag values.
10. In the **Params** box, type the SnmpAdminString.
11. In the **TMask** box, type the mask.
12. In the **MMS** box, type the maximum message size.
13. Click **Insert**.

#### **Target Table** Field Descriptions

Use the data in the following table to use the **Target Table** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>       | Specifies a unique identifier for this table. The name is a community string.                                                                                                                                                                                                                                                                    |
| <b>TDomain</b>    | Specifies the transport type of the address. <b>ipv4Tdomain</b> specifies the transport type of address is an IPv4 address. <b>ipv6Tdomain</b> specifies the transport type of address is IPv6. The default is ipv4Tdomain.                                                                                                                      |
| <b>TAddress</b>   | Specifies the transport address in xx.xx.xx.xx:port format, for example: 192.1.2.12:162, where 162 is the trap listening port on the system 192.1.2.12.                                                                                                                                                                                          |
| <b>Timeout</b>    | Specifies the maximum round trip time required to communicate with the transport address. The value is in 1/100 seconds from 0–2147483647. The default is 1500. After the system sends a message to this address, if a response (if one is expected) is not received within this time period, you can assume that the response is not delivered. |
| <b>RetryCount</b> | Specifies the maximum number of retries if a response is not received for a generated message. The count can be in the range of 0–255. The default is 3.                                                                                                                                                                                         |

| Name           | Description                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TagList</b> | Contains a list of tag values used to select target addresses for a particular operation. A tag refers to a class of targets to which the messages can be sent.                                             |
| <b>Params</b>  | Contains SNMP parameters used to generate messages to send to this transport address. For example, to receive SNMPv2C traps, use TparamV2.                                                                  |
| <b>TMask</b>   | Specifies the mask. The value can be empty or in six-byte hex string format. Tmask is an optional parameter that permits an entry in the TargetAddrTable to specify multiple addresses.                     |
| <b>MMS</b>     | Specifies the maximum message size. The size can be zero, or 484–2147483647. The default is 484. Although the maximum message size is 2147483647, the device supports the maximum SNMP packet size of 8192. |

## Configure Target Table Parameters

### About This Task

Configure the target table to configure the security parameters for SNMP. Configure the target table to configure parameters such as SNMP version and security levels.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Target Table**.
3. Click the **Target Params Table** tab.
4. Click **Insert**.
5. In the **Name** box, type a target table name.
6. From the **MPModel** options, select an SNMP version.
7. From the **Security Model** options, select the security model.
8. In the **SecurityName** box, type `readview` or `writeview`.
9. From the **SecurityLevel** options, select the security level for the table.
10. Click **Insert**.

### **Target Params Table** Field Descriptions

Use the data in the following table to use the **Target Params Table** tab.

| Name                 | Description                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Identifies the target table.                                                                                                                                                                                                                  |
| <b>MPModel</b>       | Specifies the message processing model to use to generate messages: SNMPv1, SNMPv2c, or SNMPv3/USM.                                                                                                                                           |
| <b>SecurityModel</b> | Specifies the security model to use to generate messages: SNMPv1, SNMPv2c, or USM. You can receive an inconsistentValue error if you try to configure this variable to a value for a security model that the implementation does not support. |

| Name                 | Description                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------|
| <b>SecurityName</b>  | Identifies the principal on whose behalf SNMP messages are generated.                               |
| <b>SecurityLevel</b> | Specifies the security level used to generate SNMP messages: noAuthNoPriv, authNoPriv, or authPriv. |

## Configure SNMP Notify Filter Profiles

### About This Task

Configure the SNMP table of filter profiles to determine whether particular management targets receive particular notifications.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Notify Table**.
3. Click the **Notify Filter Table** tab.
4. Click **Insert**.
5. In the **NotifyFilterProfileName** box, type a name for the notify filter profile.
6. In the **Subtree** box, type subtree location information in x.x.x.x.x.x.x.x format.
7. In the **Mask** box, type the mask location in hex string format.
8. From the **Type** options, select **included** or **excluded**.
9. Click **Insert**.

### **Notify Filter Table** Field Descriptions

Use the data in the following table to use the **Notify Filter Table** tab.

| Name                           | Description                                                                                                                                                                                   |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NotifyFilterProfileName</b> | Specifies the name of the filter profile used to generate notifications.                                                                                                                      |
| <b>Subtree</b>                 | Specifies the MIB subtree that, if you combine it with the mask, defines a family of subtrees, which are included in or excluded from the filter profile. For more information, see RFC 2573. |
| <b>Mask</b>                    | Specifies the bit mask (in hexadecimal format) that, in combination with the subtree, defines a family of subtrees, which are included in or excluded from the filter profile.                |
| <b>Type</b>                    | Indicates whether the family of filter subtrees are included in or excluded from a filter. The default is included.                                                                           |

## Configure SNMP Notify Filter Profile Table Parameters

### Before You Begin

- The notify filter profile exists.

### About This Task

Configure the profile table to associate a notification filter profile with a particular set of target parameters.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Notify Table**.
3. Click the **Notify Filter Profile Table** tab.
4. Click **Insert**.
5. In the **TargetParamsName** box, type a name for the target parameters.
6. In the **NotifyFilterProfileName** box, type a name for the notify filter profile.
7. Click **Insert**.

### *Notify Filter Profile Table Field Descriptions*

Use the data in the following table to use the **Notify Filter Profile Table** tab.

| Name                           | Description                                                                |
|--------------------------------|----------------------------------------------------------------------------|
| <b>TargetParamsName</b>        | Specifies the unique identifier associated with this entry.                |
| <b>NotifyFilterProfileName</b> | Specifies the name of the filter profile to use to generate notifications. |

## Enable Authentication Traps

### About This Task

Enable the SNMP agent process to generate authentication-failure traps.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **General**.
3. Click the **Error** tab.
4. Select **AuthenticationTraps**.
5. Click **Apply**.

**Error Field Descriptions**

Use the data in the following table to use the **Error** tab.

| Name                       | Description                                                                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthenticationTraps</b> | Enables or disables the sending of traps after an error occurs. The default is disabled.                                                                                      |
| <b>LastErrorCode</b>       | Specifies the last reported error code.                                                                                                                                       |
| <b>LastErrorSeverity</b>   | Specifies the last reported error severity:<br>0= Informative Information<br>1= Warning Condition<br>2= Error Condition<br>3= Manufacturing Information<br>4= Fatal Condition |

**View the Trap Sender Table****About This Task**

Use the Trap Sender Table tab to view source and receiving addresses.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **Trap Sender Table** tab.

**Trap Sender Table Field Descriptions**

Use the data in the following table to use the **Trap Sender Table** tab.

| Name               | Description                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RecvAddress</b> | IP address for the trap receiver. This is a read-only parameter that contains the IP address configured in the TAddress field in the TargetTable. |
| <b>SrcAddress</b>  | Source IP address to use when sending traps. This IP address will be inserted into the source IP address field in the UDP trap packet.            |

## MACsec fundamentals

MAC Security (MACsec) is based on the IEEE 802.1ae standard that allows authorized systems in a network to transmit data confidentially and to protect against data transmitted or modified by unauthorized devices.

You can use MACsec for core and enterprise edge switches to do the following:

- Secure site-to-site connectivity between data centers.
- Provide data security on links that run over public ground.
- Provide data security on links that run outside the physically secure boundaries of a site.

You can use MACsec on access switches to secure host-to-switch connectivity, and host-to-switch connectivity in an environment where both trusted and untrusted hosts co-exist.

In addition to host level authentication, MACsec capable LANs provide data origin authentication, data confidentiality, and data integrity between authenticated hosts or systems. MACsec protects data from external hacking while the data passes through the public network to reach a receiver host.

MACsec enabled hosts encrypt and decrypt every frame exchanged between them using a MACsec key. The source MACsec host encrypts data frames, and the destination MACsec host decrypts the frames, ensuring delivery of the frame in its original condition to the recipient host. This ensures secure data communication.

You can configure MACsec encryption over any type of point-to-point Ethernet or emulated Ethernet connection, which includes:

- Dark fiber
- Conventional wavelength-division multiplexing/dense wavelength-division multiplexing (CWDM/DWDM) service
- Multiprotocol label switching (MPLS) point-to-point (ELINE)
- Provider Backbone Bridge Traffic Engineering (PBB-TE)

You can configure MACsec on physical ports only. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).

**Note**

For VSP 8600 Series Release 6.2 and later, MACsec is not supported on channelized ports.

You configure a pre-shared key on either end of the MACsec link. The pre-shared key is an interface parameter, not a switch-wide parameter.

**Note**

MACsec encrypts all packets. If you configure MACsec on one or more MultiLink Trunking (MLT) port members on one side, you must configure MACsec on the same port members on the other side. If you do not do this, the port can physically be enabled, but any overlying protocols can be disabled. You do not have to provision MACsec on all MLT port members, but if you configure MACsec on an MLT port member on one side, you must also provision MACsec on the corresponding MLT port on the other side.

One way to detect a mismatch of MACsec configuration is to use Virtual Link Aggregation Control Protocol (VLACP) on the links. If VLACP is enabled on an MKA-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

MACsec provides security at the data link layer or the physical layer. It provides enhancements at the MAC service sub layer for its operation and services to the upper layer.

MACsec is an interface-level feature and is disabled by default.

## MACsec keys

MACsec provides industry-standard security through secure point-to-point Ethernet links. The point-to-point links are secured after matching security keys.

Security keys are of two types:

- Connectivity Association Key (CAK), which is a configured pre-shared key.

**Important**

The switch supports the configuration of a pre-shared key to enable MACsec using the static connectivity association key (CAK) security mode.

The CAK must be identical across both ends of MACsec links.

- Secure Association Key (SAK):
  - Static SAKs: SAKs are static short-lived keys derived from the CAK or pre-configured for a particular secure channel (SC). MACsec uses a timer to refresh these keys so that the key and the session are secure.
  - Dynamic SAKs: MACsec Key Agreement (MKA) protocol generates SAKs. The MKA protocol determines which switch on the point-to-point link becomes the key server. The key server then generates SAKs and distributes them to the switch at the other end of the point-to-point link.

MACsec uses derived keys to encrypt or decrypt data at each end of the MACsec links.

### *Integrity Check Verification (ICV)*

MACsec ensures data integrity using Integrity Check Verification (ICV). MACsec introduces an 8-byte or 16-byte SecTag after the Ethernet header, and an 8-byte or 16-byte calculated ICV after the Encrypted Payload. MACsec computes the ICV for the entire frame, starting from the Ethernet header, SecTag until the Checksum. The receiving side recalculates the ICV after data decryption, and verifies if the received ICV and computed ICV match. If the ICVs do not match, it indicates that data is modified, and MACsec drops the frame.

## MACsec Security Modes

The static Connectivity Association Key (CAK) security mode is the only supported MACsec security mode on the platform, and is also the most common mode to enable MACsec.

When you use the static CAK security mode to enable MACsec, you configure a connectivity association on both ends of the link. Secure Association Keys (SAK) establish the MACsec relationship between the switches on each end of the Ethernet link. The SAKs include a connectivity association key name (CKN) and its own CAK. The MACsec CKN and CAK are configured in a connectivity association, and the CAK must match on both ends of the link to initially enable MACsec.

To ensure link security, the system periodically refreshes keys based on traffic volume and link speed.

To enable MACsec at the port level, you must first associate the port to the connectivity association. You complete the configuration within the connectivity association, but outside of the secure channel.

#### Note

If you use MKA, you must apply MKA profile to a port before you associate it with a Connectivity Association (CA). After you associate the port with a CA, you cannot enable MKA on the port.

When you use the static CAK security mode, the system automatically creates two secure channels, one for inbound traffic and another for outbound traffic. You cannot configure any parameters in the automatically created secure channels.

The CAK security mode ensures security by frequently refreshing to a new random security key, and by only sharing the security key between the two devices on the MACsec-secured point-to-point link.

MACsec provides options to encrypt all data, or configure a confidentiality offset, which specifies the number of unencrypted bytes in a frame that precede MACsec encryption.

You can configure the following optional features:

- Data encryption — If you disable encryption, MACsec forwards traffic in clear text. You can view that data that is not encrypted in the Ethernet frame that travels across the link. Even if you disable encryption the MACsec header applies to the frame and integrity checks make sure that traffic has not been tampered with.
- Confidentiality offset — If encryption is enabled, and an offset is not configured, all traffic in the connectivity is encrypted. The confidentiality offset specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 bytes and 50 bytes. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4

header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header are not encrypted.

## Connectivity Associations and Secure Channels

You configure MACsec in connectivity associations (CA). You can enable MACsec after you associate a connectivity association with an interface. To use the static Connectivity Association Key (CAK) security mode to enable MACsec, you must create, and configure connectivity associations on both ends of the link.

### Tip

Configure the Connectivity Association key name (CKN) in multiples of 4 characters to avoid MKA interoperability issues between VOSS switches and EXOS switches. For example, Macsecma (8 characters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.

A CA is a logical representation of a MACsec domain within a network. Each connectivity association is associated with a CAK. MACsec links are associated with a CA to establish end-to-end MACsec communication. Every MACsec enabled interface is a member of one CA. Switch ports are members of a CA, and can only be a member of one CA.

A secure channel (SC) is a unidirectional channel that connects two endpoints of MACsec. A secure channel is a long-term relationship that persists through the sequence of secure associations.

A secure association (SA) is a short-lived relationship within an SC. MACsec identifies each SA by AN, and supported secure association key (SAK), which is derived from the CAK or generated by the MKA key server. Both ends of the MACsec link use the SAK to encrypt and decrypt the frames. SAKs are frequently refreshed for security reasons. Periodically changing SAs allows the use of fresh keys without terminating the SC relationship.

For static MACsec, you configure CAs. SCs and SAs are internally created in the hardware.

For MKA MACsec, you configure CAs. SCs and SAs are internally created in the hardware based on the information provided by the MKA key server.

## MACsec 2AN and 4AN mode

MACsec 2AN mode implementations use two security associations (SA) for each secure channel (SC) and symmetric keys on both MACsec endpoints. The keys are symmetric because they are both derived from the same connectivity association key (CAK).

MACsec 4AN mode generates four Secure Associations Keys (SAK) per secure channel. It uses enhanced hashing algorithm to derive eight SAKs, and uses asymmetric keys on both ends. You can use the **macsec connectivity-association** command to configure different (asymmetric) transmit keys for each endpoint by using the *key-parity* keyword. If you do not specify a value for *key-parity*, the connectivity association is created in 2AN mode. For more information about configuring MACsec transmit keys, see [Configuring a connectivity association](#).

## MACsec components

MACsec has three major components:

- **Security entity (SecY)**

SecY is the entity that operates the MACsec protocol within the system. You configure a secure connectivity association (CA) to meet the requirements of MACsec for connectivity between stations that attach to an individual LAN. Unidirectional secure channels (SC) support each CA. Each SC supports secure transmission of frames by use of symmetric key cryptography from one of the systems to all others in the CA.

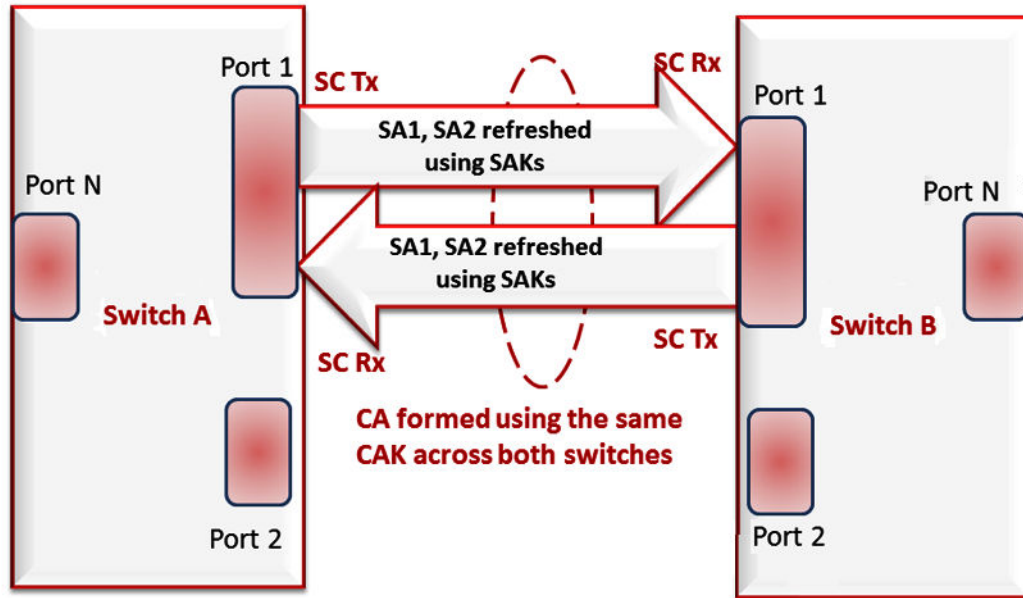

Each SecY transmits frames conveying secure MACsec service requests on a single SC, and receives frames conveying secure service indications on separate SCs, one for each of the other SecYs that participate in the secure CA.

A connectivity association (CA) is a logical representation of a MACsec domain within a network. Each connectivity association is associated with a connectivity association key (CAK). MACsec links are associated with a CA to establish end-to-end MACsec communication. Every MACsec enabled interface is a member of one connectivity association. Switch ports are members of a connectivity association, and can only be a member of one connectivity association.

A secure channel (SC) is a unidirectional channel that connects two endpoints of MACsec. A secure channel is a long-term relationship that persists through the sequence of secure associations. An SC is a unidirectional point-to-multipoint communication, and can persist through Secure Association Key (SAK) changes. A sequence of Secure Associations (SAs) support each SC and allow for the periodic use of fresh keys without terminating the relationship. A single secret key or a set of keys support each SA, where the cryptographic operations used to protect one frame require more than one key. A Secure Channel Identifier (SCI) identifies each SC. An SCI is comprised of a unique 48-bit universally administered MAC address, identifying the system to which the transmitting SecY belongs, concatenated with a 16-bit port number, identifying the SecY within that system.

The SCI concatenated with a two-bit AN identifies each SA. The Secure Association Identifier (SAI) that is created allows the receiving SecY to identify the SA. It also allows the SAK used to decrypt and authenticate the received frame. The AN, and hence the SAI, are unique only for the SAs that can be used or recorded by participating SecYs at any instant.

**Figure 185: MACsec relationship**

- **Key agreement entity (KaY)**

The KaY in MACsec is responsible for CAK and SAK computations, distributions and maintenance. CAK is a global key that is persistent until the CA exists. When you configure the CAK, ensure that it is identical across MACsec links.

In static SAK mode, SAKs are short-lived keys derived from the CAK, or pre-configured for a particular SC. MACsec uses a timer to refresh SAKs so that the key, as well the session, is secure.

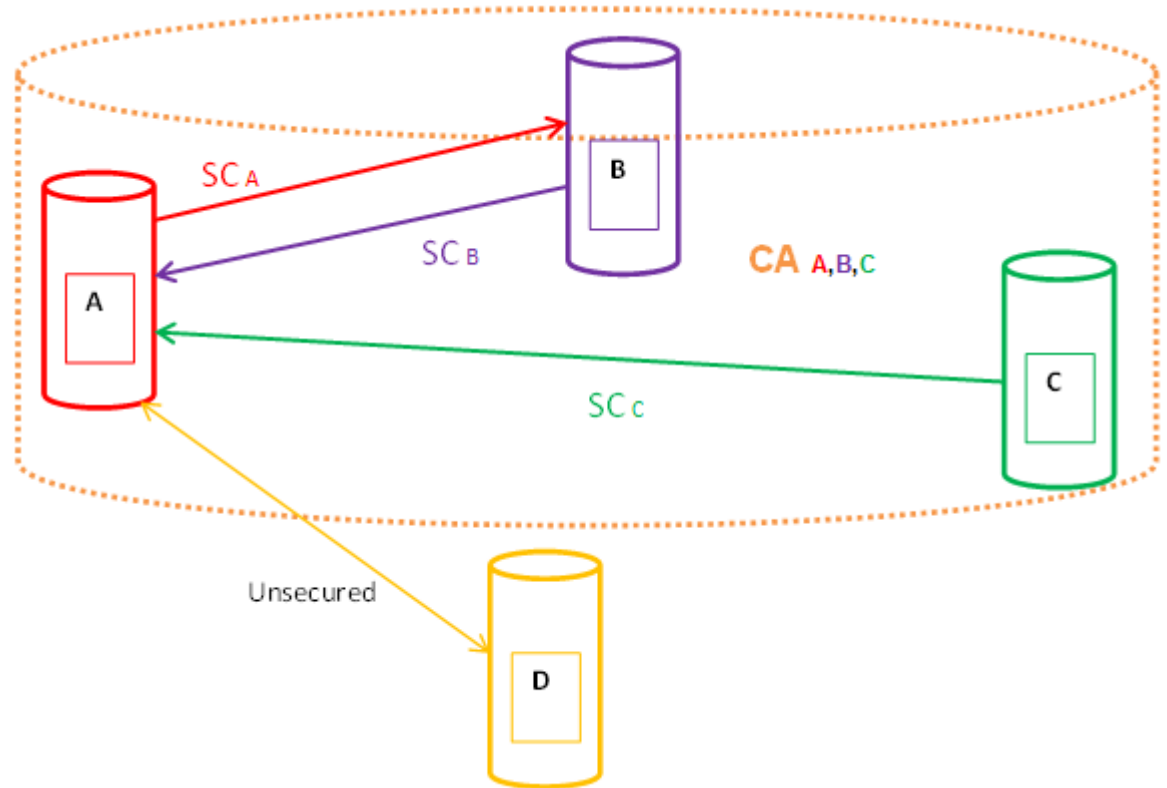

In dynamic SAK mode, the MKA key server generates SAKs. The key server maintains the ethernet link by periodically generating and distributing SAKs across the point-to-point link as long as MACsec is enabled.

- **Integrity check verification or Cryptographic entity**

The Cryptographic entity provides integrity check protection and validation for frames transmitted or received through the SecY layer. The integrity check verification (ICV) is calculated for the frame source address/destination address (SA/DA), SecTag, User Payload, and Cyclic Redundancy Check (CRC). The calculated ICV is appended at the end-of-frame, recalculated at the receiver side of MACsec link and validated to see if they are equal. The frames that pass the integrity check are further processed, while the system drops the frames that fail the integrity check.

MACsec configuration provides an option to encrypt the user payload. There is also the option to start the encryption from N bytes after the Ethernet header.

In the following figure, CA connects switches A, B, and C by their respective SC and SAK. Switch D cannot participate in the secure communication between A, B, or C as switch D does not know the SAK.

## MACsec Key Agreement Protocol

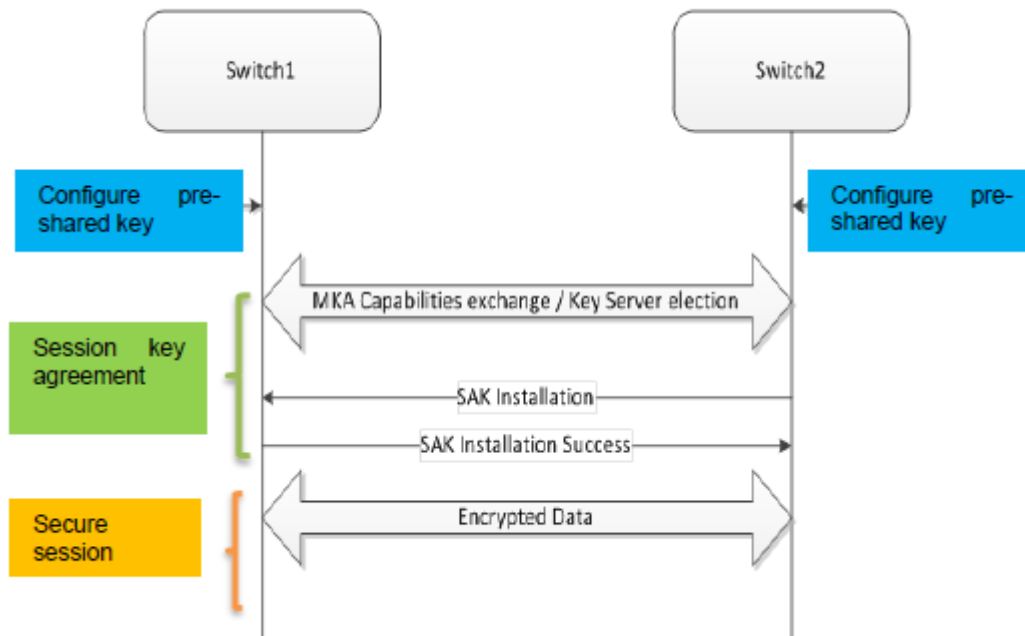

MKA protocol performs key server election and generates Secure Association Keys (SAK). SAKs and other MKA information is distributed in MACsec Key Agreement Protocol Data Units (MKPDU) between peers in the Connectivity Association (CA).

Initially you configure pre-shared keys on both ends of an Ethernet link, including values for the CAK and the connectivity association key name (CKN). The CAK and CKN values must match at both ends of the link.

You enable the MKA process by configuring pre-shared keys. MKA performs peer detection, identifies a live peer, and elects the peer with the highest priority as the key server.

The key server generates and distributes SAKs. After the key server and the peer successfully install the generated SAKs, the link can securely transmit encrypted data. The key server maintains the secure link by periodically generating and distributing SAKs for as long as MACsec is enabled.

The following figure illustrates the deployment of MACsec using MKA protocol.

**Figure 186: Switch to switch MACsec deployment scenario**

You can create and configure an MKA profile and then apply that profile to a port. After applying the profile to the port and associating the port with a connectivity association, you can enable MKA on the port and optionally assign a value for actor priority.

**Note**

If you enable MKA MACsec on a port, traffic is not sent or received on that link until the MKA session is active.

You can configure an MKA actor priority value for each MKA participant. You select priority values from the range 0x00 to 0xff, where lower numbers indicate higher priority. Each participant advertises an actor priority value, and the participant advertising the highest priority is elected as the key server. If there is a tie for the highest priority, the participant with the highest priority MAC address is selected.

**Note**

Do not configure both peers in an MKA session with an actor priority value of 0xff. If both peers are configured with an actor priority value of 0xff, key server election fails.

You can enable replay protect and configure a replay window size to protect against out of sequence packets. Window size specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, the packet is dropped.

Confidentiality offset specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 and 50. Configuring the offset to 30 allows an IPv4 header and TCP/UDP header to remain unencrypted, while configuring the offset to 50 allows an IPv6 header and TCP/UDP header to remain unencrypted.

### *MKA Interoperability with EXOS*

Switches configured with MKA MACsec in VOSS Release 8.1 can interoperate with Release 30.3 or later ExtremeXOS switches.

**Tip**

Configure the Connectivity Association key name (CKN) in multiples of 4 characters to avoid MKA interoperability issues between VOSS switches and EXOS switches. For example, Macsecma (8 characters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.

## MACsec Encryption Cipher Suites

MACsec cipher suites specify a set of encryption algorithms used to encrypt traffic on an Ethernet link that is secured with Media Access Control Security (MACsec).

MACsec supports two cipher suites, the GCM-AES-128 with a maximum key length of 128 bits and the GCM-AES-256 with a maximum key length of 256 bits. The default cipher suite is the GCM-AES-128. The 256-bit algorithm provides enhanced data security and also includes the security provided by the 128-bit algorithm.

**Note**

Not all VOSS products support both a 128 bit cipher suite and a 256 bit cipher suite. For information about product support, see [Table 157](#) on page 2249.

Both the GCM-AES-128 and GCM-AES-256 cipher suites use a 32-bit packet number (PN) as part of the unique initial value for every packet transmitted with a given secure association key (SAK). The system refreshes the SAK when all the permutations of the 32-bit PN are exhausted.

You typically configure a MACsec cipher suite at the port level on the switch. The configuration is optional. When you configure a cipher suite, ensure that you configure the same cipher suite on both MACsec peers.

## MACsec Operation

As shown in the following figure, a host that connects to Switch A sends an Ethernet frame to a host that connects to Switch B. Switch A encrypts the frame, excluding the Ethernet header and optionally the 802.1Q header. Switch A also appends MACsec information like SecTag and ICV to the encrypted payload and transmits the frame using normal frame transmission. This process ensures data confidentiality.

Switch B decrypts the frame once received. Switch B recalculates the ICV using a MACsec key and the SecTag present in the frame. If the ICV present in the received frame matches the recalculated ICV, the switch processes the frame. If the two ICVs do not match, the switch discards the frame. This process ensures data origin authenticity and data integrity.

The encryption and decryption algorithms follow either the AES-GCM-128 standard or the AES-GCM-256 standard depending on the configured cipher suite. The default is the AES-GCM-128 standard.

The MACsec connectivity association key (CAK) between switches A and B are statically pre-configured.

### Important

MACsec will be operational between two switches across Point-to-Point Connectivity only when the switches are either directly connected or across a network cloud that provides P2P connectivity between the two switches.

For example, in the following figure you can enable MACsec between two switches across a network cloud where P2P connectivity between the switches is provided via services such as P2P, MPLS, Layer 2 VPN (ELINE), or connectivity across Dark Fiber. However, it is important to note that MACsec will not be operational between two switches across a network cloud if the intermediate routers/switches need to inspect the VLAN tag or IP header for service classification. This is because MACsec encrypts the entire data frame including the VLAN header and as such the intermediate switches/routers will not have visibility into the same to perform service classification.

**Figure 187: MACsec operation**

## MACsec configuration using CLI

### Configure MACsec Encryption on a Port

Use the following procedure to enable or disable encryption on a MACsec capable port. The default is disabled.

#### About This Task

If you disable encryption, MACsec forwards traffic in clear text. You can view that data that is not encrypted in the Ethernet frame that travels across the link. Even if you disable encryption the MACsec header applies to the frame and integrity checks make sure that traffic has not been tampered with.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MACsec encryption on the port:

```
macsec encryption enable
```

3. Disable MACsec encryption on the port:

```
no macsec encryption enable
```

## Example

Configure MACsec encryption on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#macsec encryption enable
```

## Configuring a MACsec Cipher Suite on a Port

### Note

Configuring a MACsec cipher suite is optional and is not supported on all hardware platforms. For more information on the physical hardware restrictions, see your hardware documentation.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a MACsec encryption cipher suite:

```
macsec cipher-suite {gcm-aes-128 | gcm-aes-256}
```

The default cipher suite is GCM-AES-128.

Ensure that you configure the same cipher suite on both MACsec peers.

3. Verify the configuration:

```
show macsec status {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Example

Configure the 256-bit MACsec cipher suite on the port 1/2 and verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#macsec cipher-suite gcm-aes-256
Switch:1>show macsec status 1/3

=====
MACSEC Port Status
=====
Profile MACSEC Encryption Replay Replay Encryption Cipher CA MKA-
PortId Status Status Protect Protect W'dow Offset Suite Name Name

1/3 enabled disabled disabled -- none AES-128 SMLTCONN mkaprol
```

The system displays the following error message if you attempt to configure a cipher suite on a port that is not MACsec capable.

```
Switch:1>enable
Switch:1(config)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#macsec cipher suite gcm-aes-256

Error: port 1/2, Port is not MACSec capable. No MACSec configurations allowed on port
```

The system displays the following error message if your hardware does not support the MACsec 256-bit cipher suite.

```
Switch:1>enable
Switch:1(config)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 5/1
Switch:1(config-if)#macsec cipher-suite gcm-aes-256

Error: port 5/1, MACSec cipher-suite cannot be modified on port. Cipher-suite is by
default AES-128
```

### Variable Definitions

The following table defines parameters for the **macsec cipher-suite** command.

| Variable                                 | Definition                                                                                                                                                                                                                                                                                                         |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{gcm-aes-128   gcm-aes-256}</code> | Configures the cipher suite for encrypting traffic with MACsec.<br>The supported cipher suites are: <ul style="list-style-type: none"> <li>AES-GCM-128, with a maximum key length of 128 bits</li> <li>AES-GCM--256, with a maximum key length of 256 bits</li> </ul> The default is the AES-GCM-128 cipher suite. |

## Configure a Connectivity Association

Use the following procedure to configure a connectivity association (CA) in static Connectivity Association Key (CAK) security mode with static Secure Association Keys (SAK).

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a CA:

```
macsec connectivity association WORD <5-16> connectivity-association-
key WORD<10-32> [key-parity even|odd]
```

#### Note

If you do not specify a key-parity value, the CA is created in 2AN mode.  
This applies only to platforms that support 2AN mode.

#### Note

The parameter `[key-parity even|odd]` applies only to static MACsec configurations.

3. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

4. Associate a port with a CA:

```
macsec connectivity-association WORD<5-16>
```

## Example

Configure a connectivity association and enable MACsec on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#macsec connectivity-association caname1 connectivity-association-key
1029384756abcdef key-parity even
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#macsec connectivity-association caname12
```

### Variable Definitions

The following table defines parameters for the **macsec** command.

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>connectivity-association</i> <i>WORD</i> <5-16>      | Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN).<br><br><b>Tip:</b><br>Configure the CKN in multiples of 4 characters to avoid MKA interoperability issues between VOSS switches and EXOS switches. For example, Macsecma (8 characters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid. |
| <i>connectivity-association-key</i> <i>WORD</i> <10-32> | Specifies the connectivity-association key (CAK) as a 32-character hexadecimal string.                                                                                                                                                                                                                                                                                                                                                                        |
| <i>key-parity</i> <even   odd>                          | Specifies Tx key parity using the following values: <ul style="list-style-type: none"> <li>even — generates even-numbered keys for Tx</li> <li>odd — generates odd-numbered keys for Tx</li> </ul> <b>Note:</b><br>If you do not specify a key-parity value, the connectivity association (CA) is created in 2AN mode.<br>This parameter applies only to platforms that support 4AN mode.                                                                     |

The following table defines parameters for the **interface gigabitethernet** command.

| Variable                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| { <i>slot/port</i> [/ <i>sub-port</i> ]}[- <i>slot/port</i> [/ <i>sub-port</i> ]]<br>[,...] | Specifies the port that you want to associate with the CA. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Update the Connectivity Association for a port

Use the following procedure to change the Connectivity Association (CA) to which a port is associated.

## Before You Begin

Ensure that the new CA is created at the global level. For information about configuring a CA, see [Configure a Connectivity Association](#) on page 2264.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable MACsec on the port:

```
no macsec enable
```

3. Change the CA to which the port is associated:

```
macsec connectivity-association WORD<5-16>
```

4. Enable MACsec on the port:

```
macsec enable
```

## Example

Change the CA to which a port is associated:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#no macsec enable
Switch:1(config-if)#macsec connectivity-association caname12
Switch:1(config-if)#macsec enable
```

### Variable Definitions

The following table defines parameters for the **macsec** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>connectivity-association</i><br><i>WORD&lt;5-16&gt;</i> | <p>Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN).</p> <p><b>Tip:</b><br/>Configure the CKN in multiples of 4 characters to avoid MKA interoperability issues between VOSS switches and EXOS switches. For example, Macsecma (8 characters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.</p> |

The following table defines parameters for the **interface gigabitethernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port to associate with the connectivity association (CA). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## View MACsec Status

Perform this procedure to view MACsec status.

### About This Task

This command displays the status for the following:

- MACsec status
- MACsec encryption status
- MACsec encryption cipher suite, if supported on your hardware platform
- The associated Connectivity Association (CA) name

#### Note

If you do not specify a port number, the information on all MACsec capable interfaces is displayed.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View the MACsec status:  
`show macsec status {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
3. Display all MACsec related information:  
`show macsec`

#### Examples

#### Note

The switch does not support replay protect.

View MACsec status:

```
Switch:1#show macsec status

=====
MACSEC Port Status
=====
Profile MACSEC Encryption Replay Replay Encryption Cipher CA MKA-
PortId Status Status Protect Protect W'dow Offset Suite Name Name
=====
```

```

1/1 enabled disabled disabled -- none AES-128 SMLTCONN mkaprol
1/2 disabled disabled disabled -- none AES-128 Nil --
1/3 disabled disabled disabled -- none AES-128 Nil --
1/4 disabled disabled disabled -- none AES-128 Nil --
1/5 disabled disabled disabled -- none AES-128 Nil --
1/6 disabled disabled disabled -- none AES-128 Nil --
1/7 disabled disabled disabled -- none AES-128 Nil --
1/8 disabled disabled disabled -- none AES-128 Nil --
1/9 disabled disabled disabled -- none AES-128 Nil --
1/10 disabled disabled disabled -- none AES-128 Nil --
1/11 disabled disabled disabled -- none AES-128 Nil --
1/12 disabled disabled disabled -- none AES-128 Nil --
1/13 disabled disabled disabled -- none AES-128 Nil --

--More-- (q = quit)

```

View MACsec status on port 1/1:

```

Switch:1>show macsec status 1/1

=====
MACSEC Port Status
=====
MACSEC Encryption Replay Replay Encryption Cipher CA MKA-
Profile
PortId Status Status Protect Protect W'dow Offset Suite Name Name

1/1 enabled disabled disabled -- none AES-128 SMLTCONN mkaprol

```

Display all MACsec information:

```

Switch:1#show macsec

=====
MACSEC Connectivity Associations Info
=====

1/2 disabled disabled disabled -- none AES-128 Nil
1/3 enabled enabled disabled -- ipv4Offset(30) AES-256 caname33
1/4 enabled enabled disabled -- ipv4Offset(30) AES-128 caname34
1/5 disabled disabled disabled -- none AES-128 Nil
1/6 disabled disabled disabled -- none AES-128 Nil

--More-- (q = quit)

```

## View the MACsec Connectivity Association Details

Perform this procedure to view the MACsec connectivity association (CA) details.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the MACsec CA details:  
show macsec connectivity-association [WORD<5-15>]

### Note

This command displays the MACsec CA details, including the MD5 hashed value of the CA key.

### Example

View the MACsec connectivity association details:

```
Switch:1>show macsec connectivity-association
=====
MACSEC Connectivity Associations Info
=====

```

| Connectivity Association Name | Connectivity Association Key Hash | AN_Mode / TxKeyParity | Port Members |
|-------------------------------|-----------------------------------|-----------------------|--------------|
| caname50                      | ba6b005bef79e7b95f3e08181e2501ce  | 2AN / NA              | 1/49         |
| caname51                      | 5b41f44ecaa54f3873e781557b39230b  | 4AN / odd             |              |
| caname15                      | 053f26fb96b011191f2da28849f08677  | 4AN / Even            | 1/50         |

```
Switch:1#show macsec statistics 1/50 secure-channel inbound

```

**Note**

For MACsec Key Agreement (MKA) MACsec, the **show macsec statistics** [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] **secure-channel** [**inbound** | **outbound**] command displays only the statistics for the current Secure Association (SA), instead of displaying the statistics for all SAs created under that Secure Channel.

## Configure Static MACsec using CLI

Use the following procedures to configure static MACsec using the Command Line Interface (CLI).

### Enable Static MACsec on a Port

Use the following procedure to enable MACsec with static Secure Association Keys (SAK) on a port.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MACsec on the port:

```
macsec enable
```

#### Variable Definitions

The following table defines parameters for the **macsec enable** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...] | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Configure the Confidentiality Offset on a Port

Use the following procedure to configure the confidentiality offset on a port. The default is disabled.

## About This Task

The confidentiality offset provides a way to start encryption after a few bytes following the Ethernet header. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4 header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header are not encrypted.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure confidentiality offset on the port:

```
macsec confidentiality-offset <30-50>
```

3. Disable the confidentiality offset on the port:

```
no macsec confidentiality-offset
```

## Example

Configuring the confidentiality offset on the port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#macsec confidentiality-offset 30
```

## Variable Definitions

The following table defines parameters for the **macsec confidentiality-offset** command.

| Variable | Value                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------|
| <30-50>  | Specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 and 50. |

The following table defines parameters for the **interface gigabitethernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port that you want to associate with the connectivity association (CA).<br>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configure MKA MACsec using CLI

Use the following procedures to configure MACsec Key Agreement (MKA) MACsec using the Command Line Interface (CLI).

### Create an MKA Profile

#### About This Task

Use the following procedure to create a MACsec Key Agreement (MKA) profile. Creating an MKA profile changes the CLI command mode to mka profile mode.

You can also use this procedure to enter mka profile CLI command mode for an existing MKA profile.

#### About This Task

##### Note

This procedure only applies to VSP 8400 Series.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create an MKA profile:  

```
macsec mka profile WORD<1-16>
```

##### Note

An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec mka profile extreme19
Switch:1(mka-profile)#
```

## Variable Definitions

The following table defines parameters for the **macsec mka profile** command.

| Variable   | Value                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<1-16> | Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive. |

*Apply an MKA Profile to a Port*

### Before You Begin

You must configure an MKA profile globally before you can apply it to a port.

#### Note

This procedure only applies to VSP 8400 Series.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply an MKA profile to the port:

```
macsec mka profile WORD<1-16>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#macsec mka profile test030519
```

## Variable Definitions

The following table defines parameters for the **macsec mka profile** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| WORD<1-16>                                                         | Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.                                                                                                                                                                                                         |

### Configure MKA Actor Priority

#### About This Task

The MKA participant with the highest actor priority is designated as the key server.

#### Before You Begin

#### Note

This procedure only applies to VSP 8400 Series.

- You must enable MKA globally.
- You must apply an MKA profile to the port.
- You must disable MKA on the port before you configure a value for actor priority. Enable MKA on the port after you configure an actor priority value.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a value for actor priority:

```
macsec actor-priority <0x00-0xff>
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/4
Switch:1(config-if)#macsec actor-priority 0x0f
```

## Variable Definitions

The following table defines parameters for the **macsec actor-priority** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0x00-0xff>                                           | Specifies a hexadecimal value for actor priority, which determines key server selection. Lower values indicate a higher priority. The default is 10.                                                                                                                                                                                                          |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Enable MKA on a Port

#### Before You Begin

#### Note

This procedure only applies to VSP 8400 Series.

- You must apply an MKA profile to a port before it can be enabled.
- Before you enable MKA on a port, the port must be a member of a connectivity association.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MKA on a port:

```
macsec mka enable
```

#### Example

```
Switch:1#enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#macsec mka enable
```

## Variable Definitions

The following table defines parameters for the **macsec mka enable** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configure MKA Confidentiality Offset

### About This Task

Use the following procedure to configure the confidentiality offset for an MKA profile. The confidentiality offset specifies the number of unencrypted bytes that precede MACsec encryption.

### About This Task

#### Note

This procedure only applies to VSP 8400 Series.

### Procedure

1. Enter mka profile Configuration mode:
 

```
enable

configure terminal

macsec mka profile WORD<1-16>
```
2. Configure a value for confidentiality offset:
 

```
confidentiality-offset <30-50>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec mka profile test030519
Switch:1(mka-profile)#confidentiality-offset 30
```

## Variable Definitions

The following table defines parameters for the **confidentiality-offset** command.

| Variable                      | Value                                                                                                                                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-16&gt;</code> | Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.                                                     |
| <code>&lt;30   50&gt;</code>  | Specifies the number of bytes after the Ethernet header from which data encryption begins. Possible values are 30 (IPv4 plus TCP/UDP header) and 50 (IPv6 plus TCP/UDP header). The default is no offset. |

*Configure MKA Replay Protect***About This Task**

Use the following procedure to configure replay protect for an MKA profile. Replay protect provides a configurable window that accepts a specified number of out of sequence frames.

**About This Task****Note**

This procedure only applies to VSP 8400 Series.

**Procedure**

1. Enter mka profile Configuration mode:
 

```
enable

configure terminal

macsec mka profile WORD<1-16>
```
2. Enable replay protection and configure the window size:
 

```
replay-protect enable window-size <5-500>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec mka profile test030519
Switch:1(mka profile)#replay-protect enable window-size 200
```

**Variable Definitions**

The following table defines parameters for the **replay-protect** command.

| Variable            | Value                                                                                                                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable              | Enables replay protection on an MKA profile. The default is disabled.                                                                                                                                                                            |
| window-size <5-500> | Specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, the packet is dropped. |
| WORD<1-16>          | Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.                                                                                            |

*Display MKA Profiles***About This Task**

Use the following procedure to display information about all MKA profiles configured on the switch. Optionally, you can view information about a specific MKA profile.

## About This Task

### Note

This procedure only applies to VSP 8400 Series.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all MKA profiles on the switch:  

```
show macsec mka profile
```
3. (Optional) Display a specific MKA profile:  

```
show macsec mka profile WORD<1-16>
```

## Examples

The following example displays MACsec MKA profile information:

```
Switch:1#show macsec mka profile

=====
MACsec MKA Profile
=====
Profile Profile Cipher Confidentiality Replay Window Port
Name Id Suite Offset Protect Size

test030519 1 gcm-aes-128 30 Enabled 200 1/3
test031519 2 gcm-aes-128 50 Enabled 225 1/4
test032019 3 gcm-aes-128 30 Enabled 240 2/2

All 3 out of 3 Total Num of MACsec MKA Profiles displayed
=====
```

The following example displays MACsec MKA information for a specific profile.

```
Switch:1#show macsec mka profile test030519

=====
MACsec MKA Profile
=====
Profile Profile Cipher Confidentiality Replay Window Port
Name Id Suite Offset Protect Size

test030519 1 gcm-aes-128 30 Enabled 200 1/3
=====
```

## Variable Definitions

The following table defines parameters for the **show macsec mka profile** command.

| Variable   | Value                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<1-16> | Specifies the MKA profile name. An MKA profile name can consist only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive. |

*Display MKA Participants***About This Task**

Use the following procedure to display information about all participants in an MKA session. You can also display MKA information for a specific port participating in an MKA session.

**About This Task****Note**

This procedure only applies to VSP 8400 Series.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display information about all participants in an MKA session:  

```
show macsec mka participant
```
3. (Optional) Display MKA information for a specific port participating in an MKA session:  

```
show macsec mka participant {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]} [verbose]
```

**Examples**

The following example displays information for all participants in an MKA session.

```
Switch:1(config)#show macsec mka participant
```

```
=====
MACsec MKA Participants
=====
```

| Port Id | CA Name  | MKA-Profile Name | MKA Enable | Actor Priority |
|---------|----------|------------------|------------|----------------|
| 1/3     | CA120022 | extreme030519    | Enabled    | A              |
| 1/4     | CA121023 | extreme031519    | Enabled    | 14             |
| 2/2     | CA122024 | extreme032019    | Enabled    | 1E             |

```
=====
```

The following example displays information for a specific port participating in an MKA session.

```
Switch:1(config)#show macsec mka participant 1/3
```

```
=====
MACsec MKA Participant
=====
```

| Port Id | CA Name  | MKA-Profile Name | MKA Enable | Actor Priority |
|---------|----------|------------------|------------|----------------|
| 1/3     | CA120022 | extreme030519    | Enabled    | A              |

```
=====
```

## Variable Definitions

The following table defines parameters for the **show macsec mka participant** command.

**Table 158:**

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| verbose                                                             | Displays detailed information for a specific port participating in an MKA session.                                                                                                                                                                                                                                                                            |

## MACsec configuration using EDM

Use the following procedures to configure MACsec in EDM.

### Configure Connectivity Associations

Use the following procedure to configure connectivity associations (CA) using EDM.

#### Note

- You can configure MACsec on physical ports *only*. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).
- MACsec encryption and decryption algorithms follow either the AES-GCM-128 or the AES-GCM-256 standard, depending on the configured MAC-sec cipher suite. The default is the AES-GCM-128 standard.

#### Procedure

- In the navigation pane, expand **Configuration > Edit**.
- Select **Chassis**.
- Select the **MACSec** tab.
- Select **Insert**.
  - In **AssociationName**, type the connectivity-association name.
  - In **AssociationKey**, type the value of the connectivity-association key.

#### Note

The system displays the connectivity-association key as an MD5-hashed text in the MAC security table.

- c. In **AssociationTxKeyParity**, select an option for Tx key parity.

**Note**

Tx key parity configuration applies only to static MACsec configurations.

- d. Select **Insert** to save the configuration.  
5. Select **Apply**.

### MACSec Field Descriptions

Use the data in the following table to use the **MACSec** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AssociationName</b>        | Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN).<br><br><b>Tip:</b><br>Configure the CKN in multiples of 4 characters to avoid MKA interoperability issues between VOSS switches and EXOS switches. For example, Macsecma (8 characters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.   |
| <b>AssociationKey</b>         | Specifies the connectivity-association key (CAK) as a 32-character hexadecimal string.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>AssociationPortMembers</b> | Specifies the set of ports for which this connectivity association is associated.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AssociationTxKeyParity</b> | Specifies Tx key parity using the following values: <ul style="list-style-type: none"> <li>• <b>None</b> — key parity is not specified</li> </ul> <b>Note:</b><br>The none value only applies to platforms that support 2AN mode. If you do not specify a key parity value, the system defaults to 2AN mode. <ul style="list-style-type: none"> <li>• <b>Even</b> — generates even-numbered keys</li> <li>• <b>Odd</b> — generates odd-numbered keys</li> </ul> |

## Associate a Port with a Connectivity Association

Use the following procedure to associate a port with a connectivity association (CA) using EDM. You can optionally configure a MACsec encryption cipher suite on the port.

For the VSP 4450 Series, you can associate connectivity associations to device ports 1/49 and 1/50 only.

#### Note

You can configure MACsec on physical ports *only*. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).

#### Note

MACsec encryption and decryption algorithms follow either the AES-GCM-128 or the AES-GCM-256 standard, depending on the configured MAC-sec cipher suite. The default is the AES-GCM-128 standard.

### Procedure

1. On the **Device Physical View** tab, click on one or more ports that you want to associate with the connectivity association.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **MACsec** tab.
5. In **CAName**, type the connectivity-association name.
6. In **OffsetValue**, select the value of confidentiality offset to be achieved.
7. Select **EncryptionEnable** to enable encryption for the frames transmitted on the port.
8. Select **MACsec Enable** to enable MACsec on the port.
9. (Optional) In **CipherSuite**, select the MACsec encryption cipher suite.
10. Select **Apply**.

### MACsec Field Descriptions

Use the data in the following table to configure the **MACsec** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CAName</b>           | Specifies the name of the connectivity association attached to the port or interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OffsetValue</b>      | Offsets MACsec encryption in an IPv4 TCP/UDP header or IPv6 TCP/UDP header. The confidentiality offset provides a way to start encryption after a few bytes following the Ethernet header. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4 header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header is not encrypted. |
| <b>EncryptionEnable</b> | Specifies the encryption status per port. Use this field to enable or disable encryption for each MACsec capable port.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                 | Description                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MACsec Enable</b> | Enables or disables MACsec on the port.                                                                                                                                                                                                                                                                                                   |
| <b>CipherSuite</b>   | Configures the cipher suite for encrypting traffic with MACsec.<br>The following cipher suites are supported: <ul style="list-style-type: none"> <li>AES-GCM-128 standard, with a maximum key length of 128 bits</li> <li>AES-GCM-256 standard, with a maximum key length of 256 bits</li> </ul> The default is the AES-GCM-128 standard. |

## Configure MKA MACsec using EDM

Use the following procedures to configure MKA MACsec using EDM.

### Note

You must configure MKA MACsec by performing procedures in the following order:

1. [Apply an MKA Profile to a Port](#) on page 2284
2. [Associate a Port with a Connectivity Association](#) on page 2281
3. [Enable MKA on a Port](#) on page 2284

If you apply a Connectivity Association to a port before you apply an MKA profile to the port, the port is considered to be configured with static MACsec and an error occurs.

### Configure an MKA Profile

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **MACSec MKA Profile** tab.
4. Select **Insert**.
5. For **Id**, type an MKA ID value.
6. For **Name**, type the profile name.
7. (Optional) Select **ReplayProtectEnable** to enable replay protect.
8. (Optional) For **ReplayProtectWindow**, type a value for the replay protect window size.
9. (Optional) From the **OffsetValue** options, select a level for confidentiality offset.
10. Select **Insert**.

#### MACSec MKA Profile Field Descriptions

Use the data in the following table to use the **MACSec MKA Profile** tab.

| Name        | Description                                                  |
|-------------|--------------------------------------------------------------|
| <b>Id</b>   | Specifies a unique identification number for an MKA profile. |
| <b>Name</b> | Specifies the profile name.                                  |

| Name                       | Description                                                                                                                                                                                                                              |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReplayProtectEnable</b> | Specifies whether replay protect is enabled. The default is disabled.                                                                                                                                                                    |
| <b>ReplayProtectWindow</b> | Specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, it is dropped. |
| <b>OffsetValue</b>         | Specifies the number of bytes after the Ethernet header from which data encryption begins. The default is no offset.                                                                                                                     |
| <b>PortMembers</b>         | Specifies the ports that are members of an MKA profile.                                                                                                                                                                                  |

### *Apply an MKA Profile to a Port*

#### **Before You Begin**

You must configure an MKA profile globally before you can apply it to a port.

#### **About This Task**

Use the following procedure to apply a MACsec Key Agreement (MKA) profile on a port.

#### **Procedure**

1. In the Device Physical View, select the port to which you want to apply an MKA profile.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **MACsec MKA** tab.
5. For **MACsecMKAProfileName**, select the name of the MKA profile you want to apply.
6. Select **Apply**.

#### **MACsec MKA Field Descriptions**

Use the data in the following table to use the **MACsec MKA** tab.

| Name                        | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <b>MACsecMKAProfileName</b> | Specifies the MKA profile name.                               |
| <b>MKA Enable</b>           | Enables the MKA profile on the port. The default is disabled. |

### *Enable MKA on a Port*

#### **Before You Begin**

Ensure that you apply an MKA profile to the port and associate the port with a Connectivity Association (CA) before you enable MKA on the port.

## About This Task

Use the following procedure to enable a MACsec Key Agreement (MKA) profile on a port.

### Procedure

1. In the Device Physical View, select the port to which you want to apply an MKA profile.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **MACsec MKA** tab.
5. For **MACsecMKAProfileName**, select the name of the MKA profile you want to apply.
6. Select **MKA Enable** to enable MKA on the port.
7. Select **Apply**.

### MACsec MKA Field Descriptions

Use the data in the following table to use the **MACsec MKA** tab.

| Name                        | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <b>MACsecMKAProfileName</b> | Specifies the MKA profile name.                               |
| <b>MKA Enable</b>           | Enables the MKA profile on the port. The default is disabled. |

### Configure MKA Actor Priority

#### About This Task

Use the following procedure to configure an actor priority value for a port. The MKA participant with the highest actor priority is designated as the key server.

#### Note

Ensure that peers in an MKA connection are not configured with the same actor priority value.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **MACSec MKA Participants** tab.
4. Select a port.
5. For **ActorsPriority**, double-click the field and type a value for **ActorsPriority**.

### MACSec MKA Participants Field Descriptions

| Name                  | Description                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------|
| <b>PortNumber</b>     | Specifies the port number of the MKA session participant.                                     |
| <b>CAName</b>         | Specifies the Connectivity Association (CA) name associated with the MKA session participant. |
| <b>MKAProfileName</b> | Specifies the name of the MKA profile.                                                        |

| Name                  | Description                                                          |
|-----------------------|----------------------------------------------------------------------|
| <b>MKA Enable</b>     | Specifies whether MKA is enabled for the port.                       |
| <b>ActorsPriority</b> | Specifies a hexadecimal value for actor priority. The default is 10. |

## MACsec Performance

**Table 159: MACsec product support**

| Feature                                                                                                                                              | Product         | Release introduced                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MACsec 2AN mode<br><br><b>Note:</b><br>VOSS 5.0 officially removed the replay protection commands. ## MACsec Statistics

MAC Security (MACsec) is an IEEE 802® standard that allows authorized systems in a network to transmit data confidentially and to take measures against data transmitted or modified by unauthorized devices.

The switch supports the following statistics that provide a measure of MACsec performance.

**Table 160: General MACsec statistics**

| Statistics       | Description                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TxUntaggedPkts   | Specifies the number of transmitted packets without the MAC security tag (SecTAG), with MACsec disabled on the interface.                                         |
| TxTooLongPkts    | Specifies the number of transmitted packets discarded because the packet length is greater than the Maximum Transmission Unit (MTU) of the Common Port interface. |
| RxUntaggedPkts   | Specifies the number of received packets without the MAC security tag (SecTAG), with MACsec not operating in strict mode.                                         |
| RxNoTagPkts      | Specifies the number of received packets without the MAC security tag (SecTAG), with MACsec operating in strict mode.                                             |
| RxBadTagPkts     | Specifies the number of received packets discarded with an invalid SecTAG or with a zero value Packet Number (PN)/invalid Integrity Check Value (ICV).            |
| RxUnknownSCIPkts | Specifies the number of packets received with an unknown Secure Channel Identifier (SCI) and with MACsec not operating in strict mode.                            |

**Table 160: General MACsec statistics (continued)**

| Statistics    | Description                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|
| RxNoSCIPkts   | Specifies the number of packets received with an unknown Secure Channel Identifier (SCI) and with MACsec operating in strict mode.    |
| RxOverrunPkts | Specifies the number of packets discarded because the number of received packets exceeded the cryptographic performance capabilities. |

**Table 161: Secure-channel inbound MACsec statistics**

| Statistics    | Description                                                                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UnusedSAPkts  | Specifies the summation of received unencrypted packets on all SAs of this secure channel, with MACsec not in strict mode.                                                                                                                                                                                           |
| NoUsingSAPkts | Specifies the summation of received packets that were discarded along with either encrypted packets or packets that were received with MACsec operating in strict mode.                                                                                                                                              |
| LatePkts      | Specifies the number of packets received that have been discarded for this Secure Channel (SC) with Replay Protect enabled.<br><br><b>Note:</b><br>Replay Protect is supported only by MACsec configurations using MACsec Key Agreement (MKA) protocol.                                                              |
| NotValidPkts  | Specifies the summation of packets that were discarded in all SAs of the SC because they were not valid with one of the following conditions: <ul style="list-style-type: none"> <li>• MACsec was operating in strict mode</li> <li>• The packets received were encrypted but contained erroneous fields.</li> </ul> |
| InvalidPkts   | Specifies the summation of all packets received that were not valid for this SC, with MACsec operating in check mode.                                                                                                                                                                                                |
| DelayedPkts   | Specifies the summation of packets for this SC, with the Packet Number (PN) of the packets lower than the lower bound replay protection PN.<br><br><b>Note:</b><br>Replay Protect is supported only by MACsec configurations using MKA protocol.                                                                     |
| UncheckedPkts | The total number of packets for this SC that: <ul style="list-style-type: none"> <li>• were encrypted and failed the integrity check</li> <li>• were not encrypted and failed the integrity check</li> <li>• were received when MACsec validation was not enabled</li> </ul>                                         |
| OKPkts        | Specifies the total number of Integrity Check Validated (ICV) packets for all SAs of this Secure Channel. The number of octets of User Data recovered from received frames that were integrity protected but not encrypted.                                                                                          |

**Table 161: Secure-channel inbound MACsec statistics (continued)**

| Statistics      | Description                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------|
| OctetsValidated | Specifies the number of octets of plain text recovered from received packets that were integrity protected but not encrypted. |
| OctetsDecrypted | Specifies the number of octets of plain text recovered from received packets that were integrity protected and encrypted.     |

**Table 162: Secure-channel outbound MACsec statistics**

| Statistics      | Description                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------|
| ProtectedPkts   | Specifies the number of integrity protected but not encrypted packets for this transmitting SC.                  |
| EncryptedPkts   | Specifies the number of integrity protected and encrypted packets for this transmitting SC.                      |
| OctetsProtected | Specifies the number of plain text octets that are integrity protected but not encrypted on the transmitting SC. |
| OctetsEncrypted | Specifies the number of plain text octets that are integrity protected and encrypted on the transmitting SC.     |

**Table 163: MACsec Key Agreement statistics**

| Statistics            | Description                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------|
| MKPDUs Validated & Rx | Specifies the number of MACsec Key Agreement Protocol Data Units (MKPDU) validated and received. |
| Rx Distributed SAK    | Specifies the number of Secure Association Keys (SAK) received.                                  |
| MKPDUs Transmitted    | Specifies the number of MKPDUs transmitted.                                                      |
| Tx Distributed SAK    | Specifies the number of SAKs transmitted.                                                        |

*Interoperability behaviors*

If your static key MACsec configuration involves interoperability with VSP 4900 Series, VSP 8200 Series, VSP 8400 Series, VSP 7200 Series, VSP 7400 Series, 5520 Series (only front panel ports), and VIMs, you might see the following display inconsistencies for MACsec statistics:

- one side can show delayed packets on the Ingress side
- one side can throw an Ingress Key expiry log message or it might never show an Ingress Key expiry log message

## View MACsec Statistics using CLI

Use the following procedures to view statistics for MACsec using the Command Line Interface (CLI).

### Note

For MACsec Key Agreement (MKA) MACsec, the **show macsec statistics** [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] **secure-channel** [**inbound** | **outbound**] command displays only the statistics for the current Secure Association (SA), instead of displaying the statistics for all SAs created under that Secure Channel.

### Viewing MACsec Statistics

Perform this procedure to view the MACsec statistics.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the general MACsec statistics:  
show macsec statistics [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
3. View the secure-channel inbound MACsec statistics:  
show macsec statistics [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] secure-channel inbound
4. View the secure-channel outbound MACsec statistics:  
show macsec statistics [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] secure-channel outbound

#### Example

Display general MACsec statistics, inbound MACsec statistics, and outbound MACsec statistics:

### Note

Slot and port information can differ depending on hardware platform. For more information, see the hardware documentation for your platform.

The switch supports MACsec on specific ports. For more information, see your hardware documentation.

### Note

Display inconsistencies might occur for MACsec statistics when different ports interoperate with one another.

```
Switch:1>enable

### Clear MACsec Statistics

#### About This Task

You have the option to clear MACsec statistics for all ports, or clear MACsec statistics for a specific port. Clearing MACsec statistics can be useful for debugging purposes.

#### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Clear all MACsec statistics:  
macsec clear-stats
3. (Optional) Clear MACsec statistics for a specific port:  
macsec clear-stats port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}

#### Example

Clear all MACsec statistics:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec clear-stats

```

Clear MACsec statistics for a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec clear-stats port 1/3
```

### Variable Definitions

Use the data in the following table to use the **clear macsec-stats** command.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## View MKA MACsec Statistics using CLI

Use the following procedures to view statistics for MKA MACsec using the Command Line Interface (CLI).

### Display MKA Statistics

#### Note

This procedure only applies to VSP 8400 Series.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display MKA statistics for a specific port:

```
show macsec mka statistics {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Example

The following example displays MACsec MKA statistics for a port.

```
Switch:1>show macsec mka statistics 3/5
```

```
=====
 MKPDU Statistics on interface 3/5
=====
```

```

MKPDUs Validated & Rx : 1630
Rx Distributed SAK : 2
MKPDUs Transmitted : 1694
Tx Distributed SAK : 0
=====
```

## Variable Definitions

Use the data in the following table to use the **show macsec mka statistics** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Clear MKA Statistics

### About This Task

You have the option to clear MKA statistics for all ports, or clear MKA statistics for a specific port. Clearing MKA statistics can be useful for debugging purposes.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Clear all MKA statistics:  

```
macsec mka clear-stats
```
3. (Optional) Clear MKA statistics for a specific port:  

```
macsec mka clear-stats port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Example

Clear all MKA statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec mka clear-stats
```

Clear MKA statistics for a specific port:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#macsec mka clear-stats port 1/3
```

## Variable Definitions

Use the data in the following table to use the `macsec mka clear-stats` command.

| Variable                                                                | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## View MACsec Statistics using EDM

Use the following procedures to view statistics for static MACsec using EDM.

### Note

For MACsec Key Agreement (MKA) MACsec, the procedures View Secure Channel Inbound Statistics and View Secure Channel Outbound Statistics display only the statistics for the current Secure Association (SA), instead of displaying the statistics for all SAs created under that Secure Channel.

### View MACsec Interface Statistics

Use this procedure to view the MACsec interface statistics using EDM.

#### Procedure

1. In the Device Physical View tab, select one or more ports for which you need to view the MACsec interface statistics.

The switch supports MACsec on specific ports. For more information, see your hardware documentation.

2. In the navigation pane, expand the **Edit > Port > General** folders.
3. Select the **MACsec Interface Stats** tab.

### Note

Use the **Clear Stats** button to clear MACsec interface statistics. The **Clear Stats** button is available to clear single-port as well as multiple-port MACsec interface statistics.

## MACsec Interface Stats Field Descriptions

The following table describes the fields in the **MACsec Interface Stats** tab.

| Field                 | Description                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TxUntaggedPkts</b> | Specifies the number of transmitted packets without the MAC security tag (SecTAG), with MACsec disabled on the interface.                                         |
| <b>TxTooLongPkts</b>  | Specifies the number of transmitted packets discarded because the packet length is greater than the maximum transmission unit (MTU) of the common port interface. |

| Field                   | Description                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RxUntaggedPkts</b>   | Specifies the number of received packets without the MAC security tag (SecTAG), with MACsec <i>not</i> operating in strict mode.                            |
| <b>RxNoTagPkts</b>      | Specifies the number of received packets without the MAC security tag (SecTAG), with MACsec operating in strict mode.                                       |
| <b>RxBadTagPkts</b>     | Specifies the number of received packets discarded with an invalid SecTAG, or with a zero value packet number (PN), or invalid Integrity Check Value (ICV). |
| <b>RxUnknownSCIPkts</b> | Specifies the number of packets received with an unknown secure channel identifier (SCI), and with MACsec <i>not</i> operating in strict mode.              |
| <b>RxNoSCIPkts</b>      | Specifies the number of packets received with an unknown secure channel identifier (SCI), and with MACsec operating in strict mode.                         |
| <b>RxOverrunPkts</b>    | Specifies the number of packets discarded because the number of received packets exceeded the cryptographic performance capabilities.                       |

### View Secure Channel Inbound Statistics

Use this procedure to view the secure channel (SC) inbound statistics using EDM.

#### Procedure

1. In the Device Physical View tab, select one or more ports for which to view the SC inbound statistics.  
The switch supports MACsec on specific ports. For more information, see your hardware documentation.
2. In the navigation pane, expand **Edit > Port > General**.
3. Select the **SC Inbound Stats** tab.

#### Note

Use the **Clear Stats** button to clear single-port secure channel inbound statistics. The **Clear Stats** button is not available to clear multiple-port secure channel inbound statistics.

### SC Inbound Stats Field Descriptions

The following table describes the fields in the **SC Inbound Stats** tab.

| Field                | Description                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UnusedSAPkts</b>  | Specifies the summary of received unencrypted packets on all SAs of this secure channel, with MACsec <i>not</i> in strict mode.                                                                                                                                                                                     |
| <b>NoUsingSAPkts</b> | Specifies the summary of received packets that were discarded along with either encrypted packets or packets that were received with MACsec operating in strict mode.                                                                                                                                               |
| <b>LatePkts</b>      | Specifies the number of packets received that have been discarded for this secure channel (SC) with Replay Protect enabled.<br><br><b>Note:</b><br>Replay Protect is supported only by MACsec configurations using MACsec Key Agreement (MKA) protocol.                                                             |
| <b>NotValidPkts</b>  | Specifies the summary of packets that were discarded in all SAs of the SC because they were not valid with one of the following conditions: <ul style="list-style-type: none"> <li>• MACsec was operating in strict mode.</li> <li>• The packets received were encrypted but contained erroneous fields.</li> </ul> |
| <b>InvalidPkts</b>   | Specifies the summary of all packets received that were not valid for this SC, with MACsec operating in <i>check</i> mode.                                                                                                                                                                                          |
| <b>DelayedPkts</b>   | Specifies the summary of packets for this SC, with the packet number (PN) of the packets lower than the lower bound replay protection PN.<br><br><b>Note:</b><br>Replay Protect is supported only by MACsec configurations using MACsec Key Agreement (MKA) protocol.                                               |
| <b>UncheckedPkts</b> | The total number of packets for this SC that: <ul style="list-style-type: none"> <li>• Were encrypted and failed the integrity check.</li> <li>• Were <i>not</i> encrypted and failed the integrity check.</li> <li>• Were received when MACsec validation was not enabled.</li> </ul>                              |
| <b>AcceptedPkts</b>  | Specifies the total number of Integrity Check Validated (ICV) packets for all SAs of this Secure Channel. The number of octets of User Data recovered from received frames that were integrity protected but not encrypted.                                                                                         |

| Field                  | Description                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>OctetsValidated</b> | Specifies the number of octets of plain text recovered from received packets that were integrity protected but not encrypted. |
| <b>OctetsDecrypted</b> | Specifies the number of octets of plain text recovered from received packets that were integrity protected and encrypted.     |

### View Secure Channel Outbound Statistics

Use this procedure to view the secure channel (SC) outbound statistics using EDM.

#### Procedure

1. In the Device Physical View tab, select one or more ports for which you need to view the SC outbound statistics.  
The switch supports MACsec on specific ports. For more information, see your hardware documentation.
2. In the navigation pane, expand the **Edit > Port > General** folders.
3. Select the **SC Outbound Stats** tab.

#### Note

Use the **Clear Stats** button to clear single-port secure channel outbound statistics. The **Clear Stats** button is not available to clear multiple-port secure channel outbound statistics.

### SC Outbound Stats Field Descriptions

The following table describes the fields in the **SC Outbound Stats** tab.

| Field                  | Description                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>ProtectedPkts</b>   | Specifies the number of integrity protected but not encrypted packets for this transmitting SC.                  |
| <b>EncryptedPkts</b>   | Specifies the number of integrity protected and encrypted packets for this transmitting SC.                      |
| <b>OctetsProtected</b> | Specifies the number of plain text octets that are integrity protected but not encrypted on the transmitting SC. |
| <b>OctetsEncrypted</b> | Specifies the number of plain text octets that are integrity protected and encrypted on the transmitting SC.     |

### View MKA MACsec Statistics using EDM

Use the following procedure to view statistics for MKA MACsec using EDM.

### Display MKA Statistics for a Port

**Note**

This procedure only applies to VSP 8400 Series.

**Procedure**

1. In the Device Physical View, select the port or ports for which to display MKA statistics.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **MACsec MKA Stats** tab.
5. (Optional) Select **Clear Stats** to clear MKA MACsec statistics for the selected port or ports. Clearing MKA MACsec statistics can be useful for debugging purposes.

**MACsec MKA Stats Field Descriptions**

Use the data in the following table to use the **MACsec MKA Stats** tab.

| Name                        | Description                                                   |
|-----------------------------|---------------------------------------------------------------|
| <b>MKPDUValidatedPkts</b>   | Specifies the number of MKPDU packets received and validated. |
| <b>RxDistributedSAKPkts</b> | Specifies the number of SAK packets received.                 |
| <b>MKPDUTransmittedPkts</b> | Specifies the number of MKPDU packets transmitted.            |
| <b>TxDistributedSAKPkts</b> | Specifies the number of SAK packets transmitted.              |

This section provides the concepts and procedures you need to configure MultiLink Trunking (MLT) and Split MultiLink Trunking (SMLT).

## Virtual Inter-Switch Trunk (vIST)

**Table 164: Virtual Inter-Switch Trunk product support**

| Feature                                                               | Product         | Release introduced |
|-----------------------------------------------------------------------|-----------------|--------------------|
| Switch cluster (multi-chassis LAG) -Virtual Inter-Switch Trunk (vIST) | 5420 Series     | VOSS 8.4           |
|                                                                       | 5520 Series     | VOSS 8.2.5         |
|                                                                       | VSP 4450 Series | VOSS 4.1           |
|                                                                       | VSP 4900 Series | VOSS 8.1           |
|                                                                       | VSP 7200 Series | VOSS 4.2.1         |
|                                                                       | VSP 7400 Series | VOSS 8.0           |
|                                                                       | VSP 8200 Series | VSP 8200 4.0       |
|                                                                       | VSP 8400 Series | VOSS 4.2           |
|                                                                       | VSP 8600 Series | VSP 8600 6.1       |
| XA1400 Series                                                         | Not Supported   |                    |

Split MultiLink Trunking provides subsecond failover when a switch fails. Virtual Inter-Switch Trunk (vIST) improves upon that Layer 2 and Layer 3 resiliency by using a virtualized IST channel through the SPBM cloud. The vIST channel carries the vIST control traffic and data traffic during an SMLT failover. This feature dramatically improves resiliency over other methods.

Because vIST uses a virtual channel and because IS-IS runs over it, vIST eliminates the potential single point of failure with a dedicated MLT. The vIST channel is always up as long as there is SPBM connectivity between the vIST peers.

vIST interoperates between any two devices that support vIST, and the devices do not have to be of the same type.

vIST creates a virtualized channel through the SPBM cloud, and this channel connects two SMLT devices to form a virtualized Switch Cluster. Note that the SPBM cloud can consist of as few as two nodes.

#### Important

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

#### Note

- Users may observe a momentary increase in activity when a MAC delete message is received from a peer. This is due to vIST engaging in MAC learning activities. This is a normal operational procedure.
- For proper traffic flow, if a Layer 2 VSN is created on one vIST peer, it must also be created on the other vIST peer. For more information on Layer 2 VSN, see [Layer 2 VSN configuration](#) on page 1227.

## vIST configuration note

If you need to update the vIST VLAN IP address on vIST peers by deleting and recreating the vIST vlan IP address (for example, as part of maintenance), ensure that you update one vIST BEB at a time.

#### Caution

Always perform vIST configuration updates under no traffic. Otherwise, it results in traffic loss.

Before you begin updating a device, as a first step, isolate the device by shutting down all the links and failing over the traffic to its vIST peer. Then, delete and recreate the vIST VLAN IP on the device and save your configuration. When bringing the device back into operation, first unshut those NNI ports that bring up vIST, followed by the SMLT configured ports, and then all the remaining ports, to prevent network loops or duplicate traffic.

For information on vIST configuration, see [Creating a Virtual IST](#) on page 2325 or [Create a Virtual IST using EDM](#) on page 2345.

## vIST operational note

When you enable IST and boot the chassis, the SMLT enabled trunk ports (SMLT ports) are automatically locked. A timeout mechanism automatically unlocks the SMLT ports when the IST control channel fails to establish within a reasonable amount of time. The timeout mechanism prevents the SMLT ports from being locked forever. Initially 240 seconds are allowed for the switch to determine the IST VLAN status.

The IST VLAN is considered up if at least one port is forwarding traffic and an ARP entry is populated for the IP address of the IST peers. Once the IST VLAN is up, the timeout value is reset to 60 seconds. The IST control channel must be up within the timeout period. If the timeout period is exceeded, then the SMLT ports are automatically unlocked and a message is logged stating that the SMLT ports are unlocked due to a timeout.

**Note**

If the IST filter is enabled before the timeout, then the IST filter is unaffected and remains enabled.

If a virtual BMAC mismatch occurs between two vIST peers, incorrect information can show in CLI regarding the ports that the client information is learned on, such as MAC addresses or IPv6 neighbor addresses. This can occur before the mismatch is detected, because the two peers receive traffic from each other and learn the information on the local ports. Each vIST peer synchronizes the information as learned locally, even when learned from vIST peer. You can resolve the mismatch by changing the virtual BMAC on one of the vIST peers, but the traffic might remain affected. After confirming the mismatch is resolved from a log report, you can resolve the traffic issue by disabling and enabling the router ISIS on both vIST peers.

## Simplified Virtual-IST

---

Simplified Virtual-IST (vIST) is for conventional switch clustering deployments that use SMLT and not SPB. The Simplified vIST feature provides a single CLI command to enable the virtual IST for SMLT deployments.

- Simplified vIST is available for conventional multicast deployments with PIM and IGMP only when the boot flag (**spbm-config-mode**) is disabled.

**Important**

PIM is supported with Simplified vIST only, not with SPB vIST.

- When the spbm-config-mode boot flag is enabled (default setting), Simplified vIST is not available. This means that you continue to configure SPB/IS-IS for vIST as described in [Creating a Virtual IST on page 2325](#) and [Create a Virtual IST using EDM on page 2345](#).
- Simplified vIST requires that the two vIST devices be directly connected.
- For legacy IGMP snooping and IGMP snooping over Simplified vIST, the IGMP sender information is NOT synchronized across the vIST. This means that **show ip igmp sender** displays the sender record only on the switch that the multicast stream actually ingresses.
- In Simplified vIST mode, you should not use LACP on vIST MLT.

**Note**

For Simplified vIST deployment, if a VLAN is part of an SMLT it must be configured on both the IST peers.

**Important**

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of a header size increase.

For configuration information, see [Configuring Simplified vST in SMLT topologies](#) on page 2330 or [Configuring Simplified vST in SMLT topologies](#) on page 2347.

For information about how to configure Simplified vST with multicast, see [Enabling multicast on the switch](#) on page 1401.

## MultiLink Trunking

**Table 165: MultiLink Trunking product support**

| Feature                                                 | Product         | Release introduced |
|---------------------------------------------------------|-----------------|--------------------|
| MultiLink Trunking (MLT) / Link Aggregation Group (LAG) | 5420 Series     | VOSS 8.4           |
|                                                         | 5520 Series     | VOSS 8.2.5         |
|                                                         | VSP 4450 Series | VSP 4000 4.0       |
|                                                         | VSP 4900 Series | VOSS 8.1           |
|                                                         | VSP 7200 Series | VOSS 4.2.1         |
|                                                         | VSP 7400 Series | VOSS 8.0           |
|                                                         | VSP 8200 Series | VSP 8200 4.0       |
|                                                         | VSP 8400 Series | VOSS 4.2           |
|                                                         | VSP 8600 Series | VSP 8600 4.5       |
|                                                         | XA1400 Series   | VOSS 8.0.50        |

MultiLink Trunking (MLT) is a point-to-point connection that aggregates multiple ports to logically act like a single port with aggregated bandwidth. Grouping multiple ports into a logical link provides a higher aggregate on a switch-to-switch or switch-to-server application.

To include ports as trunk group members of an MLT, you must statically configure the ports.

### MLT traffic distribution algorithm

You can use a multilink trunk to aggregate bandwidth between two switches. The MLT algorithm ensures that each packet in a flow does not arrive out of sequence, and that a flow always traverses the same link path.

The hashing algorithm uses the following packet fields and the incoming interface (source) port number to calculate the index to outgoing (destination) port number in an MLT:

| Traffic type                        | Hashing algorithm                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| IPv4 traffic                        | Hash Key = [Destination IP Address (32 bits), Source IP Address (32 bits), Source TCP/UDP Port, Destination TCP/UDP port] |
| IPv4 traffic without TCP/UDP header | Hash Key = [Source IP Address (32 bits), Destination IP address (32 bits)]                                                |

| Traffic type                        | Hashing algorithm                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPv6 traffic                        | Hash Key = [Destination IPv6 Address (128 bits), Source IPv6 address (128 bits), Source TCP/UDP Port, Destination TCP/UDP port]                                                                                                                                                                                                                                 |
| IPv6 traffic without TCP/UDP header | Hash Key = [Source IP Address (128 bits), Destination IP address (128 bits)]                                                                                                                                                                                                                                                                                    |
| Mac-In-Mac transit traffic          | For VSP 7400 Series:<br>Hash Key = [Destination IP Address (32 bits), Source IP Address (32 bits), Source Port (8 bits), BackBone Destination MAC Address (48 bits), BackBone Source Mac Address (48 bits)]<br>For all other platforms:<br>Hash Key = [Source Port (8 bits), BackBone Destination MAC Address (48 bits), BackBone Source Mac Address (48 bits)] |
| Layer 2 Non-IP traffic              | Hash Key = [Destination MAC Address (48 bits), Source MAC Address(48 bits)]                                                                                                                                                                                                                                                                                     |

## MultiLink trunking and autonegotiation interaction

To use MLT with the switch, you can have ports running at different speeds. After you use MLT with LACP, LACP dynamically checks for proper speed on all port members. You do not need to have similar physical connection types. After you use autonegotiation with MLT and not LACP, you need to ensure that all ports run at the same speed.

## MLT configuration rules

Multilink trunks adhere to the following rules. Unless otherwise stated, these rules also apply to MLT with LACP.

- You cannot configure an MLT name that uses all numbers, for example, 222.
- Multilink trunk ports support mixed speed links, for example, one link can be 10Gb and another 1Gb. However, no weighting of traffic distribution occurs so if you mix links of different operational speeds, you can overload the lower speed link or under utilize a higher speed link.

This rule applies to multilink trunks only. MLT with LACP does not support different link speeds.

- All multilink trunk ports must be in the same Spanning Tree Group (STG) unless the port is tagged. Use tagging so ports can belong to multiple STGs, as well as multiple VLANs.
- After the port is made a member of MLT, it inherits the properties of the MLT and hence the STG properties are inherited from the VLAN associated with that MLT. After you remove the port from MLT or after you delete the MLT, the ports are removed from the MLT STG and added into the default STG.
- MLT is compatible with Multiple Spanning Tree Protocol (MSTP) (IEEE 802.1s) and Rapid Spanning Tree Protocol (RSTP) (IEEE 802.1w).
- Tagging (IEEE 802.1Q) is supported on a multilink trunk.

Multilink trunks have the following general features and requirements:

- Supports MLT groups with as many as 8 ports belonging to a single multilink trunk. For more information about the number of MLT groups supported for each hardware platform, see [VOSS Release Notes](#).
- Apply filters individually to each port in a multilink trunk.

With MSTP or RSTP enabled, ports in the same multilink trunk operate as follows:

- The designated port sends the Bridge Protocol Data Unit (BPDU).
- The multilink trunk port ID is the ID of the lowest numbered port.
- If identical BPDUs are received on all ports, the multilink trunk mode is forwarding.
- If ports do not receive BPDUs on a port or BPDU and port tagging do not match, the individual port is taken offline.
- Path cost is inversely proportional to the active multilink trunk bandwidth.

## MLT with LACP LAG rules

The Link Aggregation Group (LAG) adheres to the following rules:

- All LAG ports operate in full-duplex mode.
- All LAG ports operate at the same data rate.
- All LAG ports must belong to the same set of VLANs.
- Link aggregation is compatible with MSTP, and RSTP.
- Assign all LAG ports to the same MSTP or RSTP groups.
- You can configure a LAG with up to 24 ports, but only a maximum of 8 can be active at a time.
- After you configure a multilink trunk with LACP, you cannot add or delete ports or VLANs manually without first disabling LACP.

## Split MultiLink Trunking

Split MultiLink Trunking (SMLT) is an option that improves Layer 2 and Layer 3 resiliency. The following sections discuss SMLT in more detail.

### SMLT overview

Split MultiLink Trunking is an option that improves Layer 2 (bridged) resiliency by providing for the addition of switch failure redundancy with subsecond failover, on top of all standard MLT link failure protection and flexible bandwidth scaling functionality. Use Split MultiLink Trunking to connect a device that supports some form of link aggregation, be it a switch or a server, to two distinct separate SMLT endpoints or switches. These SMLT devices form a virtualized Switch Cluster through the SPBM cloud and are referred to as a Virtual Inter-Switch Trunk (vIST) Core Switch pair.

Switch Clusters are always formed as a pair, but you can combine pairs of clusters in either a square or full-mesh fashion to increase the size and port density of the Switch Cluster. If you configure SMLT in a Layer 3 or routed topology, the configuration is referenced as Routed SMLT (RSMLT).

For information about Routed SMLT, see [RSMLT](#) on page 2876.

You can form SMLT connections through single links from the Switch Cluster to the edge connection, standard MLTs, or MLTs with LACP. Optionally, SMLT links can have VLACP enabled as well. You can mix these various link connections. Within the same Switch Cluster, you can configure both SMLT and RSMLT to allow a mixture of both Layer 2 and Layer 3 VLANs.

Split MultiLink Trunking networks do not need to use RSTP or MSTP to enable loop-free triangle topologies because SMLT inherently avoids loops due to its superior enhanced link aggregation protocol. The loop-free link is accomplished by having two aggregation switches, displays it as a single device to edge switches, which dual-home to the aggregation switches. The aggregation switches interconnect using a Virtual Inter-Switch trunk (vIST), exchanging addressing and state information (permitting rapid fault detection and forwarding path modification). Split MultiLink Trunking is designed for Layer 2 network connectivity, but you can configure in Layer 3 networks by working with VRRP or RSMLT Layer 2 edge.

## SMLT advantages

SMLT eliminates all single points of failure and creates multiple paths from all user access switches to the network core. In case of failure, SMLT recovers as quickly as possible using all capacity. SMLT provides a transparent and interoperable solution that requires no modification on the part of the majority of existing user access devices.

SMLT improves the reliability of Layer 2 networks that operate between user access switches and the network center aggregation switch by providing:

- load sharing among all links
- fast failover in case of link failure
- elimination of single points of failure
- fast recovery in case of node failure
- transparent and interoperable solutions
- removal of MSTP and RSTP convergence issues

## SMLT, MSTP, and RSTP

Networks designed to have user access switches dual-home to two aggregation switches, and have VLANs spanning two or more user access switches, experience the following design constraints:

- no load sharing exists over redundant links
- network convergence is slow in case of failure

With the introduction of SMLT, all dual-home Layer 2 frame-switched network devices with dual homes are no longer dependent on the MSTP or RSTP for loop detection. A properly designed SMLT network inherently does not have logical loops.

SMLT solves the spanning tree problem by combining two aggregation switches into one logical MLT entity, thus making it transparent to all types of edge switches. In the process, it provides quick convergence, while load sharing across all available trunks.

If you use STP mode on a switch that is in an SMLT configuration, you can experience traffic loss for 30 seconds if you change the port membership of the MLT, even if the port is in a down state. The traffic

loss is because the convergence time for STP is 30 seconds. Use MSTP or RSTP on all switches in SMLT configurations.

## SMLT topologies

The following are the three generic topologies in which you can deploy SMLT, depending on the resiliency and redundancy required:

- a triangle topology
- a square topology
- a full-mesh topology

## SMLT and Virtual Inter-Switch Trunk (vIST)

The following illustration shows an SMLT configuration with a pair of switches as aggregation systems (E and F) and four separate switches as user access switches (A, B, C, and D).

### Note

In the following figure, the pair of aggregation switches (E and F) are connected by a Virtual Inter-Switch Trunk (vIST). This means that although the system displays these two switches to be directly connected, they could be anywhere within the SPBM cloud.

**Figure 188: SMLT aggregation switches and operations**

You must connect SMLT aggregation switches through vIST. For example, user access switches B and C connect to the aggregation systems through multilink trunks split between the two aggregation systems. As shown above, the implementation of SMLT only requires two SMLT-capable aggregation switches.

Aggregation switches use vIST to do the following:

- Confirm that they are alive and exchange MAC address forwarding tables.
- Send traffic between single switches attached to the aggregation switches.
- Serve as a backup if one SMLT link fails.

Because SMLT requires vIST, use multiple links on vIST to ensure reliability and high availability. Use Gigabit Ethernet links for vIST connectivity to provide enough bandwidth for potential cross traffic.

For more information about vIST, see [Virtual Inter-Switch Trunk \(vIST\)](#) on page 2300.

A vIST multilink trunk must contain at least two physical ports.

## Other SMLT aggregation switch connections

The figure above includes end stations that connect to each of the switches. In this example, a, b1, b2, c1, c2, and d are clients and printers, while e and f are servers and routers.

User access switches B and C can use a method to determine which link of the multilink trunk connections to use to forward a packet, as long as the same link is used for a Source Address and Destination Address (SA/DA) pair. The packet is routed correctly regardless of whether B or C knows the DA. SMLT aggregation switches always send traffic directly to a user access switch, and only use vIST for traffic that they cannot forward in another, more direct way.

## SMLT environment traffic flow rules

Traffic flow in an SMLT environment adheres to the following rules:

- If a packet is received from a vIST trunk port, it is not forwarded to an active SMLT group in order to prevent network loops.
- After a packet is received, the system performs a look-up on the forwarding database. If an entry exists, and if the entry was learned locally from the SMLT or through the vIST as a remote SMLT, it is forwarded to the local port (the packet must not be sent to the vIST for forwarding unless there is no local connection). Unknown and Broadcast packets flood out all ports that are members of this VLAN.
- For load sharing purposes in an SMLT configuration, the switch obeys the MLT traffic distribution algorithm.

## SMLT traffic flow examples

The following traffic flow examples are based on the figure above.

### Example 1: Traffic flow from a to b1 or b2

Assuming a and b1/b2 are communicating through Layer 2, traffic flows from A to switch E and is forwarded over its direct link to B. Traffic coming from b1 or b2 to a is sent by B on one of its multilink trunk ports.

B can send traffic from b1 to a on the link to switch E, and traffic from b2 to a on the link to F. In the case of traffic from b1, switch E forwards the traffic directly to switch A, while traffic from b2, which arrived at F, is forwarded across the vIST to E and then to A.

### Example 2: Traffic flow from b1/b2 to c1/ c2

Traffic from b1/b2 to c1/c2 is always sent by switch B through its multilink trunk to the core. No matter at which switch E or F arrives at, it is sent directly to C through the local link.

### Example 3: Traffic flow from a to d

Traffic from a to d (and d to a) is forwarded across vIST because it is the shortest path. The link is treated as a standard link; SMLT and vIST parameters are not considered.

## Example 4: Traffic flow from f to c1/c2

Traffic from f to c1/c2 is sent out directly from F. Return traffic from c1/c2 passes through one active VRRP Master for each IP subnet. The traffic is passed across vIST if switch C sends it to E.

## SMLT and vIST traffic flow example

In an SMLT environment, the two aggregation switches share the same forwarding database by exchanging forwarding entries using the vIST. The entry for 00:E0:7B:B3:04:00 is shown on switch C as an entry learned on MLT-1, but because SMLT Remote is true, this entry was actually learned from switch B. On B, that same entry is shown as directly learned through MLT-1 because SMLT Remote is false.

The following illustration shows the network topology.

**Figure 189: Network topology for traffic flow example**

After a packet arrives at switch C destined for 00:E0:7B:B3:04:00, if the SMLT Remote status is true, the switch tries to send the packet to MLT-1 rather than through vIST. Traffic rarely traverses vIST unless there is a failure. If this same packet arrives at B, it is then forwarded to MLT-1 on the local ports.

## SMLT and LACP support

The switch fully supports IEEE 802.3ad LACP on MLTs and on a pair of SMLT systems.

With LACP the switch provides a standardized external link aggregation interface to third-party vendor IEEE 802.3ad implementations. This protocol extension provides dynamic link aggregation mechanisms. Only dual-home devices benefit from this enhancement.

Advantages of this protocol extension include the following:

- MLT peers and SMLT client devices can be both network switches and a type of server or workstation that supports link bundling through IEEE 802.3ad.
- Single link and multilink trunk solutions support dual-home connectivity for attached devices, so that you can build dual-home server farm solutions.

## Supported SMLT/LACP scenarios

SMLT/IEEE link aggregation interaction supports all known SMLT scenarios in which an IEEE 802.3ad SMLT pair connects to SMLT clients, or in which two IEEE 802.3ad SMLT pairs connect to each other in a square or full-mesh topology.

## Unsupported SMLT/LACP scenarios

Some of the unsupported SMLT/LACP scenarios include the following factors, which lead to failure:

- Incorrect port connections.
- Mismatched MLT IDs assigned to SMLT client. SMLT switches can detect if MLT IDs are not consistent. The SMLT aggregation switch, which has the lower IP address, does not allow the SMLT port to become a member of the aggregation thereby avoiding misconfigurations.
- The SMLT client switch does not have automatic aggregation enabled (LACP disabled). SMLT aggregation switches can detect that aggregation is not enabled on the SMLT client, thus no automatic link aggregation is established until the configuration is resolved.

## SMLT and the Virtual Router Redundancy Protocol

Use Virtual Router Redundancy Protocol (VRRP) to have one active primary router for each IP subnet, with all other network VRRP interfaces operating in backup mode.

The VRRP has only one active routing interface enabled. Users that access switches aggregated into two SMLT switches send their shared traffic load (based on source and destination MAC or IP addresses) on all uplinks towards the SMLT aggregation switches.

### Note

A VRRP virtual IP address must not be the same as the VLAN IP address of the device.

The VRRP is less efficient if you use it with SMLT. All other interfaces are in backup (standby) mode. In this case, all traffic is forwarded over the vIST link towards the primary VRRP switch. All traffic that arrives at the VRRP backup interface is forwarded, so there is not enough bandwidth on the vIST link to carry all the aggregated riser traffic. However, an enhancement to VRRP overcomes this issue by ensuring that the vIST trunk is not used in such a case for primary data forwarding.

## SMLT and VRRP BackupMaster

The VRRP BackupMaster acts as an IP router for packets destined for the logical VRRP IP address. The system directly routes all traffic to the destined subnetwork and not through Layer 2 switches to the VRRP master. This avoids a potential limitation in the available vIST bandwidth.

To avoid potential frame duplication problems, you can only use the VRRP BackupMaster feature for SMLT on interfaces that you configure for SMLT. You cannot use VRRP BackupMaster with hubs to avoid frame duplication or on brouter or VLAN interfaces.

If you use an SMLT with routing on SMLT aggregation switches, use VRRP for default gateway redundancy. In a VRRP environment, one switch is active and the other is a backup. In an SMLT environment, you can enable the VRRP BackupMaster and use an active-active concept. The VRRP

BackupMaster router routes traffic that is received on the SMLT VLAN and avoids traffic flow across the vIST. This provides true load-sharing abilities.

Follow these guidelines if you use VRRP BackupMaster with SMLT:

- The VRRP virtual IP address and the VLAN IP address cannot be the same.
- Configure the hold-down timer for VRRP to a value that is approximately one hundred and fifty percent of the Interior Gateway Protocol (IGP) convergence time to allow the IGP enough time to reconverge following a failure. For example, if OSPF takes 40 seconds to reconverge, configure the hold-down timer to 60 seconds.
- Enable hold-down times on both VRRP sides (Master and BackupMaster).

## SMLT and SLPP

You can use Simple Loop Prevention Protocol (SLPP) to prevent loops in an SMLT network. SLPP focuses on SMLT networks but works with other configurations. Always use SLPP in an SMLT environment.

### Note

If SLPP is used in a vIST environment, it must be enabled on both the vIST peers. Because, when an SLPP packet of a vIST peer is looped through UNI ports to the other device, that device will shut down its UNI port due to receiving SLPP packets from its peer. A device's own SLPP packets will go over a vIST connection but will not be forwarded by its vIST peer back onto its UNI ports.

For square and full-mesh configurations that use a routed core, create a separate core VLAN. Enable SLPP on the core VLAN and the square or full mesh links between switch clusters. This configuration detects loops created in the core and loops at the edge do not affect core ports. If you use RSMLT between the switch clusters, enable SLPP on the RSMLT VLAN. Because you enable SLPP only on one or two VLANs in the core, changing the RX threshold values will not be necessary.

The SLPP design is to shut down the port where the SLPP packets originate or to shut down the vIST peer switch port, after the counter reaches the threshold. A loop can still occur after ports are shut down. SLPP can shut down all SMLT ports on a triangle SMLT topology, which results in isolating the edge switch.

## SLPP Guard

**Table 166: SLPP Guard product support**

| Feature    | Product         | Release introduced |
|------------|-----------------|--------------------|
| SLPP Guard | 5420 Series     | VOSS 8.4           |
|            | 5520 Series     | VOSS 8.2.5         |
|            | VSP 4450 Series | VOSS 6.1           |
|            | VSP 4900 Series | VOSS 8.1           |
|            | VSP 7200 Series | VOSS 6.1           |
|            | VSP 7400 Series | VOSS 8.0           |
|            | VSP 8200 Series | VOSS 6.1           |
|            | VSP 8400 Series | VOSS 6.1           |
|            | VSP 8600 Series | VSP 8600 6.2       |
|            | XA1400 Series   | VOSS 8.0.50        |

Use SLPP Guard with SMLT to provide additional loop protection to protect wiring closets from erroneous connections.

SLPP Guard requires Simple Loop Prevention Protocol (SLPP) to be configured in the core of the network. SLPP detects loops in the SMLT network. Because SMLT networks disable Spanning Tree (STP), Rapid Spanning Tree (RSTP), or Multiple Spanning Tree Protocol (MSTP) for participating ports, SLPP Guard provides additional network loop protection, extending the loop detection to individual edge access ports.

SLPP Guard can be configured on MLT or LAG ports. If the edge switch with SLPP Guard enabled receives an SLPP-PDU packet on a port, SLPP Guard operationally disables the port for the configured timeout interval and appropriate log messages and SNMP traps are generated. If the disabled port does not receive any SLPP-PDU packets after the configured timeout interval expires, the port automatically reenables and generates a local log message, a syslog message, and SNMP traps, if configured.

## MLT and SMLT Configuration Requirements

Use the information in this section to understand the considerations and guidelines while configuring link aggregation into your network.

### Note

Static MAC is not supported against SMLT.

## MLT with LACP

After you configure MLT with LACP, you must enable the aggregation parameter. After you enable the aggregation parameter, the LACP aggregator maps one-to-one to the specified multilink trunk.

The following lists the steps that are involved to configure MLT with LACP:

1. Assign a numeric key to the ports you want to include.
2. Configure the LAG for aggregation.
3. Enable LACP on the port.
4. Create an MLT and assign to it the same key as in step 1.

The multilink trunk with LACP only aggregates ports whose key matches its own.

The newly created MLT with LACP adopts the VLAN membership of its member ports after the first port is attached to the aggregator associated with this LAG. After a port detaches from an aggregator, the associated LAG port deletes the member from its list.

After a multilink trunk is configured with LACP, you cannot add or delete ports manually without first disabling LACP. You can add or remove VLANs to an MLT without manually disabling LACP.

The following list identifies expected configuration behavior for all platforms when you add VLANs to an LACP-enabled MLT:

- If only one port is part of the MLT/LAG, use the **vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}** command to add newer VLANs to the LAG.
- If two or more ports with several VLANs are active members of the MLT/LAG, you must use the **mlt <1-512> vlan <1-4059>** command to add new VLANs.
- If at least one port is active on the MLT/LAG (LACP), and you need to add a second port that is physically up and has the same key, you must use the **mlt <1-512> vlan <1-4059>** command. The port values must match otherwise the new port enters the churn condition.
- If the switch displays a persistent error that you cannot change the port VLAN membership, you must correct the configuration during a maintenance window:
  1. Shutdown the ports.
  2. Disable LACP on the ports.
  3. Add all VLANs to the port members being aggregated.
  4. Enable LACP on the ports.
  5. Enable the ports.

To enable tagging on ports belonging to a LAG, disable LACP on the port, and then enable tagging and LACP on the port.

If you enable Open Shortest Path First (OSPF) routing on a port, do not set the LACP periodic transmission timer to less than 1 second.

## MLT with LACP and SMLT

You can configure Split MultiLink Trunking (SMLT) with MLT, or with MLT with LACP. Follow these guidelines while you configure SMLT with LACP:

- If you configure LACP for SMLT, you must configure the same LACP smlt-sys-id on both sides. After you configure the LACP system ID for SMLT, configure the same LACP smlt-sys-id on both aggregation switches to avoid loss of data. Configure the LACP smlt-sys-id to be the base MAC

address of one of the aggregate switches, and include the MLT-ID. Configure the same system ID on both of the SMLT core aggregation switches.

- If you use LACP in an SMLT square configuration, the LACP ports must have the same keys for that SMLT LAG; otherwise, the aggregation can fail if a switch fails.
- If an SMLT aggregation switch has LACP enabled on some of its multilink trunks, do not change the LACP system priority.
- After you configure SMLT links, set the multicast packets per-second value to 6000 pps.
- To avoid traffic loss when an SMLT goes down during a CP switchover, distribute multiple SMLT links across different slots.
- To avoid unnecessary processing, do not enable LACP on vISTs . Use VLACP if an optical network between the SMLT core switches requires a failure detection mechanism.

Using the LACP `smlt-sys-id` enables you to use a third-party switch as a wiring closet switch in an SMLT configuration. This enhancement provides an option for the administrator to configure the SMLT Core Aggregation Switches to always use the system ID. In this way, the SMLT Core Aggregation Switch always uses the same LACP key regardless of the state of the SMLT Core Aggregation Switch neighbor (or the vIST link). Therefore no change in LAGs must occur on the attached device regardless of whether the device is a server or a third-party switch. This situation does not affect edge switches used in SMLT configurations. The actor system priority of `LACP_DEFAULT_SYS_PRIO`, the actor system ID the user configures, and an actor key equal to the MLT-ID are sent to the wiring closet switch. Configure the system ID to be the base MAC address of one of the aggregate switches along with its MLT-ID. The administrator must ensure that the same value for the system ID is configured on both of the SMLT Core Aggregation Switches.

You can configure the LACP `smlt-sys-id` used by SMLT core aggregation switches. After you set the LACP system ID for SMLT, configure the same LACP `smlt-sys-id` on both aggregation switches to avoid the loss of data.

The LACP System ID is the base MAC address of the switch, which is carried in Link Aggregation Control Protocol Data Units (LACPDU). If two links interconnect two switches that run LACP, each switch knows that both links connect to the same remote device because the LACPDUs originate from the same System ID. If you enable the links for aggregation using the same key, LACP can dynamically aggregate them into an MLT LAG.

If SMLT is used between the two switches, they act as one logical switch. Both aggregation switches must use the same LACP System ID over the SMLT links so that the edge switch sees one logical LACP peer, and can aggregate uplinks towards the SMLT aggregation switches. This process automatically occurs over the vIST connection, where the base MAC address of one of the SMLT aggregation switches is chosen and used by both SMLT aggregation switches.

However, if the switch that owns that Base MAC address restarts, the vIST goes down, and the other switch reverts to using its own Base MAC address as the LACP System ID. This action causes all edge switches that run LACP to think that their links are connected to a different switch. The edge switches stop forwarding traffic on their remaining uplinks until the aggregation can reform (which can take several seconds). Additionally, after the restarted switch comes back on line, the same actions occur, thus disrupting traffic twice.

The solution to this problem is to statically configure the same LACP smlt-sys-id MAC address on both aggregation switches.

#### Note

The SMLT ID is always the same as the MLT ID. For instance, both sides can have an MLT 10, but once SMLT is enabled on both sides it will function as an SMLT. Until SMLT is enabled on both peers however, it will function as a normal MLT.

## MLT with LACP and Spanning Tree

Only the physical link state or its LACP peer status affects LACP module operation. After a link is enabled or disabled, an LACP module is notified. The MSTP or RSTP forwarding state does not affect LACP module operation. LACPDUs can be sent if the port is in an MSTP or RSTP blocking state.

Unlike legacy MultiLink trunks, configuration changes (such as speed and duplex mode) to a LAG member port are not applied to all member ports in the multilink trunks. The changed port is removed from the LAG and the corresponding aggregator, and the user is alerted that the configuration is created.

#### Important

Link Aggregation Control Protocol, as defined by IEEE, is a protocol that exists between two bridge endpoints; therefore, the LACP PDUs are terminated at the next Server Provider (SP) interface.

## Link Aggregation Scaling

For the latest applicable scaling information, see [VOSS Release Notes](#) for the version of the software running on the switch.

## SMLT and VLACP

Use Virtual Link Aggregation Control Protocol (VLACP) for all SMLT access links configured as MultiLink Trunks to ensure both end devices can communicate. The switch does not support LACP and VLACP on the same links simultaneously.

VLACP for SMLT also protects against CPU failures by causing traffic to switch or reroute to the SMLT peer if the CPU fails or stops responding.

The following table provides the values for VLACP in an SMLT environment:

**Table 167: VLACP values**

| Parameter     | Value |
|---------------|-------|
| SMLT access   |       |
| Timeout       | Short |
| Timer         | 500ms |
| Timeout scale | 5     |

**Table 167: VLACP values (continued)**

| Parameter     | Value             |
|---------------|-------------------|
| VLACP MAC     | 01:80:C2:00:00:0F |
| SMLT core     |                   |
| Timeout       | Short             |
| Timer         | 500ms             |
| Timeout scale | 5                 |
| VLACP MAC     | 01:80:C2:00:00:0F |
| vIST          |                   |
| Timeout       | Long              |
| Timer         | 10000             |
| Timeout scale | 3                 |
| VLACP MAC     | 01:80:C2:00:00:0F |

## SMLT with NNI Ports

If you want to modify SMLTs that contain NNI ports, do the modification during maintenance windows. Otherwise, if you create or delete SMLTs that contain NNI ports running MSTP, IS-IS adjacencies that connect to those ports can bounce even if the SMLT is not used.

## MLT and Private VLANs

The switch supports private VLANs and E-Tree configuration. MLT and private VLANs operate as follows:

- When using static MLT, configure the private-vlan as part of the overall MLT configuration, not at the port member level. All ports in the MLT use the private VLAN type for that MLT.
- When using LACP, configure the private-vlan at the interface level.
- When the private VLAN port type is trunk, the MLT automatically becomes tagged.
- If there are other non-private VLANs using the MLT configured as isolated, the following message is displayed: `All non private VLANs using this interface will be removed once this mlt becomes isolated. Do you wish to continue (y/n) ?`
- If there are other non-private VLANs using the MLT configured as promiscuous, the following message is displayed: `All non private VLANs using this interface will be removed once this mlt becomes promiscuous. Do you wish to continue (y/n) ?`

## MLT and SMLT link aggregation configuration using the CLI

This section describes how to configure and manage link aggregation using the CLI, including MultiLink Trunking (MLT), to increase the link speed and redundancy for higher availability.

Configure link aggregation to provide link level redundancy and increase load sharing. MultiLink Trunking (MLT) is a link aggregation technology that you can use to group several physical Ethernet

links into one logical Ethernet link to provide fault-tolerance and high-speed links between routers, switches, and servers. Split MultiLink Trunking (SMLT) is an option that improves Layer 2 (bridged) resiliency.

## Configure an MLT

Perform this procedure to create and configure an MLT.

### Before You Begin

See [MLT and SMLT Configuration Requirements](#) on page 2313 to understand the commands you can use to add VLANs to an LACP-enabled MLT. Ensure you use the correct command to avoid the LACP churn condition.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create an MLT:  

```
mlt <1-512>
```
3. (Optional) Set the private VLAN type for the MLT:  

```
mlt <1-512> private-vlan <isolated|promiscuous|trunk>
```
4. Add a VLAN to the MLT:  

```
mlt <1-512> vlan <1-4059>
```
5. (Optional) Change the name of the MLT:  

```
mlt <1-512> name WORD<0-20>
```
6. Enable trunking on the MLT:  

```
mlt <1-512> encapsulation dot1q
```
7. Enable the MLT:  

```
mlt <1-512> enable
```
8. Display the MLT configuration:  

```
show mlt <1-512>
```

### Examples

Create MLT 40. Configure the private VLAN type for MLT 40 to isolated. Add VLAN 10 to the MLT. Enable the MLT.

```
Switch:1(config)#mlt 40
Switch:1(config)#mlt 40 private-vlan isolated
Switch:1(config)#mlt 40 vlan 10
Switch:1(config)#mlt 40 enable
```

Display the MLT configuration:

```
Switch:1(config)#show mlt 40
```

```
=====

### Variable definitions

Use the data in the following table to use the **mlt** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                                       | Creates and enables a new MLT.                                                                                                                                                                                                                                                                                                                                                       |
| <i>encapsulation dot1q</i>                                          | Enables trunking on the MLT.                                                                                                                                                                                                                                                                                                                                                         |
| <i>member {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Adds ports to the MLT. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>&lt;1-512&gt;</i>                                                | Specifies the MLT ID.                                                                                                                                                                                                                                                                                                                                                                |
| <i>name WORD&lt;0-20&gt;</i>                                        | Configures the name for the MLT.                                                                                                                                                                                                                                                                                                                                                     |
| <i>private-vlan {isolated promiscuous trunk}</i>                    | Specifies a private VLAN type for the MLT.                                                                                                                                                                                                                                                                                                                                           |
| <i>vlan &lt;1-4059&gt;</i>                                          | Specifies a VLAN ID to add to the MLT.                                                                                                                                                                                                                                                                                                                                               |

## Viewing MLT Statistics

### About This Task

View MLT statistics to display MultiLinkTrunking statistics for the switch or for the specified MLT ID.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View MLT statistics:  

```
show mlt stats [<1-512>]
```

**Example**

```
Switch:1#show mlt stats

=====
 Mlt Interface
=====

--More-- (q = quit)
```

*Variable Definitions*

Use the data in the following table to help you use the **show mlt stats** command.

| Variable | Value                 |
|----------|-----------------------|
| <1-512>  | Specifies the MLT ID. |

**Viewing MLT port members**

View the port members in the specified MLT, or for all MLTs.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. View information about the specified MLT:
 

```
show mlt [<1-512>]
```

**Example****Note**

The **show mlt [<1-512>]** command displays remote port members only if the MLTs are configured on vIST peers that use the same MLT ID.

If the MLT is between two devices that use the same MLT ID, but they are not vIST peers, **show mlt [<1-512>]** does not display the remote port members in the output.

In this first example, MLT 512 is an MLT between two vIST peers with the same ID used on both peers. In this case, the output displays the remote port members.

```
Switch:1(config)# show mlt 512
```

```

### Variable definitions

Use the data in the following table to use the **show mlt error collision** command.

| Variable | Value                                              |
|----------|----------------------------------------------------|
| <1-512>  | Specifies the MLT ID. The value ranges from 1-512. |

## Adding ports to an MLT LAG

Perform this procedure to add ports to an MLT LAG.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add ports to an MLT LAG:

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Example

Add port 1/24 to MLT 40:

```
Switch:1(config)# mlt 40 member 1/24
```

### Variable definitions

Use the data in the following table to use the **mlt** command.

| Variable                   | Value                          |
|----------------------------|--------------------------------|
| <i>enable</i>              | Creates and enables a new MLT. |
| <i>encapsulation dot1q</i> | Enables trunking on the MLT.   |

| Variable                                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>member {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Adds ports to the MLT. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>&lt;1-512&gt;</code>                                                | Specifies the MLT ID.                                                                                                                                                                                                                                                                                                                                                                |
| <code>name WORD&lt;0-20&gt;</code>                                        | Configures the name for the MLT.                                                                                                                                                                                                                                                                                                                                                     |
| <code>private-vlan {isolated promiscuous trunk}</code>                    | Specifies a private VLAN type for the MLT.                                                                                                                                                                                                                                                                                                                                           |
| <code>vlan &lt;1-4059&gt;</code>                                          | Specifies a VLAN ID to add to the MLT.                                                                                                                                                                                                                                                                                                                                               |

## Removing ports from an MLT LAG

Remove ports from an MLT LAG.

### About This Task

#### Important

Before removing a port member from an MLT, you must first disable the port. This ensures that the other side brings its corresponding port member down. This achieves parity on both sides and avoids traffic disruptions.

The shutdown port requires that you enter the interface GigabitEthernet configuration mode. However, to remove ports from an MLT LAG, you can enter any configuration mode.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable the ports:

```
shutdown port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. Remove ports from an MLT LAG:

```
no mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Example**

Remove port 1/24 from MLT 40:

```
Switch:1(config)# interface GigabitEthernet 1/24
```

```
Switch:1(config-mlt)# shutdown port 1/24
```

```
Switch:1(config-mlt)# no mlt 40 member 1/24
```

*Variable definitions*

Use the data in the following table to use the **mlt** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-512>                                               | Specifies which MLT to add the ports to.                                                                                                                                                                                                                                                                                                                                                             |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Specifies the ports to add to the MLT. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

**Create an SMLT from an Existing MLT**

Create an SMLT from an existing MLT to split physical ports between two switches to improve resiliency and provide active load sharing.

**Before You Begin**

- Create an MLT before you create a split in the MLT.

**Procedure**

1. Log on to the MLT Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface mlt <1-512>
```

2. Create an SMLT from an existing MLT:

```
smlt
```

**Important**

To create an SMLT from an existing MLT, first shut down the MLT ports. Configure the MLT as SMLT, and then enable the ports again.

Failure to perform this operation can lead to ports in STP blocked state and traffic loss.

**Important**

If you want to remove SMLT configuration from the MLT on a vIST switch, first shut the SMLT MLT ports on its vIST peer.

Failure to perform this operation can lead to Layer 2 loops.

**Important**

- If you are configuring SMLT with vIST, all the SMLT VLANs associated with vIST must have an I-SID.

**Example**

Create an SMLT on MLT 1:

```
Switch:1(config)#interface mlt 1
```

```
Switch:1(config-mlt)#smlt
```

## Virtual interswitch trunk (vIST)

### *Creating a Virtual IST*

Use this procedure to create a virtual IST (vIST).

vIST creates a virtualized channel through the SPBM cloud, and this channel connects two SMLT devices to form a virtualized Switch Cluster. Note that the SPBM cloud can consist of as few as two nodes.

**Important**

- When you create a vIST, VLANs assigned to SMLT ports must have an I-SID assigned.
- If you assign a VLAN to an I-SID on one SMLT-BEB node, then you must create the same VLAN and assign it to the same I-SID on the peer SMLT-BEB node even if no devices are connected to this second node.
- The vIST VLAN must also be associated with an I-SID. You can use the same vIST VLAN in another part of your network, but the I-SID associated with the vIST VLAN must not be used anywhere else.

**Note**

Simplified Virtual-IST (vIST) is for non-SPB customers who use SMLT with legacy IST. Simplified VIST is available for legacy multicast deployments only when the boot flag (**spbm-config-mode**) is disabled.

For more information, see [Configuring Simplified vIST in SMLT topologies](#) on page 2330 .

**About This Task**

The following list provides an overview of the configuration steps:

- Enable SPBM and IS-IS globally.
- Configure SPBM and IS-IS.
- Configure an Layer 2 VSN by assigning an I-SID to the C-VLAN, which is used by the vIST.

For information about SPBM and IS-IS, see [SPBM and IS-IS Infrastructure Fundamentals](#) on page 893.

**Important**

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a vIST:

```
virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
```

3. Verify your vIST configuration:

```
show virtual-ist
```

**Example**

The configuration example contains annotations (in parenthesis) to explain the configuration information.

**Figure 190: SMLT with vIST configuration example**

**Note**

This configuration example is for vIST peer B.

```
#
ISIS SPBM CONFIGURATION

### Variable definitions

Use the data in the following table to use the **ist peer-ip** command.

| Variable  | Value                                                                                          |
|-----------|------------------------------------------------------------------------------------------------|
| <A.B.C.D> | Specifies the peer IP address—the IP address of the vIST VLAN on the other aggregation switch. |
| <1-4059>  | Specifies the VLAN ID for this vIST.                                                           |

### Viewing vIST Statistics

View virtual IST (vIST) statistics for the switch.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the vIST statistics:  
show virtual-ist stat
3. To clear the vIST statistics:  
clear virtual-ist stats

## Example

```
Switch:1#show virtual-ist stat

### Editing a virtual IST

If you need to change the virtual IST (vIST) **peer-ip** or **vlan**, use this procedure to delete the vIST first.

#### Note

- You must disable IS-IS globally before deleting a vIST, and then re-enable it after creating a new vIST.
- You do not have to set the SMLT peer system ID or the virtual B-MAC to 0 before you change the vIST peer IP address or VLAN ID number.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Disable IS-IS globally:  
`no router isis enable`
3. Delete the vIST:  
`no virtual-ist peer-ip`
4. Create a vIST:  
`virtual-ist peer-ip <A.B.C.D> vlan <1-4059>`
5. Enable IS-IS globally:  
`router isis enable`

### Configuring Simplified vIST in SMLT topologies

This procedure shows how to configure Simplified vIST in an SMLT environment. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

#### Important

When you enable Simplified vIST with the **virtual-ist enable** command, two VLANs are automatically created to support vIST. The VLAN IDs are: 4086 and 4087.

### Before You Begin

SPBM must not be enabled on the vIST peers.

### About This Task

#### Important

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of a header size increase.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable the boot flag:

```
no boot config flags spbm-config-mode
```

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-mode
is changed to disable, removes SPBM configurations from the
configuration file.
```

3. Save the configuration, and then reboot the switch.

### Important

Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.

4. Create the vIST VLAN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

```
interface vlan <1-4059>
```

```
ip address <A.B.C.D/X>
```

5. Configure the vIST peer address and VLAN:

```
virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
```

6. Configure the SMLT MLT:

```
mlt <1-512> enable
```

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

```
interface mlt <1-512>
```

```
smlt
```

## 7. Configure the vIST MLT:

```
mlt <1-512> enable

mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}

mlt <1-512> encapsulation dot1q

interface mlt <1-512>

virtual-ist enable
```

**Note**

The **virtual-ist enable** command enables Simplified vIST and is only available when the **spbm-config-mode** boot flag is disabled.

## 8. Create a customer VLAN and assign the SMLT MLT ID:

```
vlan create <2-4059>

vlan mlt <1-4059> <1-512>

interface vlan <1-4059>

ip address <A.B.C.D/X>
```

**Example**

```
enable
configure terminal
no boot config flags spbm-config-mode
```

Save the configuration and reboot the switch.

```
virtual-ist peer-ip 192.0.2.1 vlan 50

mlt 3 enable
mlt 3 member 1/35,1/36
interface mlt 3
smlt
exit
mlt 5 enable
mlt 5 member 2/15,2/17
mlt 5 encapsulation dot1q
interface mlt 5
virtual-ist enable
exit
vlan create 50 type port-mstprstp 0
interface vlan 50
ip address 192.0.2.2 255.255.255.0 1
exit
vlan create 100
vlan mlt 100 3
interface vlan 100
ip address 198.51.100.1 255.255.255.0 2
exit
```

## Viewing all ports configured for SMLT

View all ports for an SMLT to ensure the correct ports are configured.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View all ports configured for SMLT:  
show smlt mlt

### Example

```
Switch:1#show smlt mlt
```

```
=====
 Mlt SMLT Info
=====
MLT ADMIN CURRENT
ID TYPE TYPE

 1 smlt smlt
 4 smlt smlt
```

### Variable definitions

Use the data in the following table to use the **show smlt** command.

| Variable | Value                                            |
|----------|--------------------------------------------------|
| mlt      | Displays SMLT information for the MLT interface. |

## Viewing information about collision errors

View information about collision errors to obtain information about collision errors in the specified MLT, or for all MLTs.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View information about collision errors:  
show mlt error collision [<1-512>]

### Example

```
Switch:1#show mlt error collision 4
```

```
=====
 Mlt Collision Error
=====
MLT -----COLLISIONS-----
ID SINGLE MULTIPLE LATE EXCESSIVE

 40 0 0 0 0
```

*Variable definitions*

Use the data in the following table to use the **show mlt error collision** command.

| Variable | Value                                              |
|----------|----------------------------------------------------|
| <1-512>  | Specifies the MLT ID. The value ranges from 1-512. |

## Viewing information about Ethernet errors

View information about Ethernet errors to display information about the types of Ethernet errors sent and received by a specific MLT or all MLTs.

### About This Task

#### Important

The IMAC columns refer to internal MAC address errors.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View information about Ethernet errors:  
show mlt error main [<1-512>]

### Example

```
Switch:1#show mlt error main 40
```

```
=====
 Mlt Ethernet Error
=====
MLT ALIGN FCS IMAC IMAC CARRIER FRAMES SQETEST DEFER
ID ERROR ERROR TRNSMIT RECEIVE SENSE TOOLONG ERROR TRNSMSS

40 0 0 0 0 0 0 0 0
```

*Variable definitions*

Use the data in the following table to use the **show mlt error main** command.

| Variable | Value                                              |
|----------|----------------------------------------------------|
| <1-512>  | Specifies the MLT ID. The value ranges from 1-512. |

## SLPP Guard configuration

This section provides the procedures to configure Simple Loop Prevention Protocol (SLPP) Guard.

#### Important

Enable SLPP Guard on the edge switches of an SMLT network and SLPP on the aggregation layer switches.

### Configuring SLPP Guard

Configure SLPP Guard on MLT and LAG ports to provide additional network loop protection.

SLPP Guard is disabled by default.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SLPP Guard on the port:

```
slpp-guard enable
```

3. (Optional) Configure the timeout value on the port:

```
slpp-guard timeout {<10-65535> | 0}
```

#### Example

```
Switch:1(config-if)#slpp-guard enable
Switch:1(config-if)#slpp-guard timeout 120
```

#### Variable definitions

Use the data in the following table to use the **slpp-guard** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeout <0   10-65535> | Specifies the time period, in seconds, for which SLPP Guard disables the port. After the timeout period expires, the switch reenables the port. The timeout value can be 0 or a value ranging from 10 to 65535. With a value of 0, the port remains disabled until it is manually re-enabled. The default timeout value is 60 seconds. |

#### Reenabling an operationally disabled port

Reenable a port that has been operationally disabled by SLPP Guard.

#### Note

You cannot reenoble a disabled port if the timer count has not reached its timeout value. Either wait until it reaches the timeout or disable SLPP Guard for that port and then re-enable it.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Reenable SLPP Guard on the port:

```
slpp-guard enable
```

3. (Optional) Configure the timeout value on the port:

```
slpp-guard timeout {<10-65535> | 0}
```

## Example

```
Switch:1(config-if)#slpp-guard enable
Switch:1(config-if)#slpp-guard timeout 120
```

## Variable definitions

Use the data in the following table to use the **slpp-guard** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeout <0   10-65535> | Specifies the time period, in seconds, for which SLPP Guard disables the port. After the timeout period expires, the switch reenables the port. The timeout value can be 0 or a value ranging from 10 to 65535. With a value of 0, the port remains disabled until it is manually re-enabled. The default timeout value is 60 seconds. |

## Viewing SLPP Guard status

View current SLPP Guard settings.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display SLPP Guard status:

```
show slpp-guard {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

## Example

```
Switch:1#>show slpp-guard
```

```
=====
 SLPP Guard
=====
SLPP-guard Ethertype: 0x8102
=====
 Port Interface
=====
```

| Port | Link | Oper | SLPP-guard | State      | Timeout | TimerCount | ORIGIN |
|------|------|------|------------|------------|---------|------------|--------|
| 1/1  | Up   | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/2  | Up   | Down | Enabled    | N/A        | 120     | N/A        | RADIUS |
| 1/3  | Up   | Up   | Enabled    | Monitoring | 60      | N/A        | RADIUS |
| 1/4  | Up   | Down | Enabled    | N/A        | 120     | N/A        | RADIUS |
| 1/5  | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/6  | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/7  | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/8  | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/9  | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/10 | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/11 | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |
| 1/12 | Down | Down | Disabled   | N/A        | 60      | N/A        | RADIUS |

### Note

The TimerCount column in the preceding example output indicates the time, in seconds, that elapses after SLPP Guard disables a port. When the value TimerCount value equals the Timeout value, the switch re-enables the port.

### Variable definitions

Use the data in the following table to use the **show slpp-guard** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## MLT and SMLT Link Aggregation Configuration using EDM

Configure link aggregation to provide link level redundancy and increase load sharing. MultiLink Trunking (MLT) is a link aggregation technology that you can use to group several physical Ethernet links into one logical Ethernet link to provide fault-tolerance and high-speed links between routers, switches, and servers. Split MultiLink Trunking (SMLT) is an option that improves Layer 2 (bridged) resiliency.

### Adding a multilink or LACP trunk

Perform this procedure to add a multilink or LACP trunk.

#### About This Task

#### Important

Ensure that all ports that belong to the same MLT/LACP group use the same port speed, for example, 1 Gbit/s, even if autonegotiation is used. This requirement is not enforced by the software.

When you add a VLAN to a dynamic MLT, only the active ports of the MLT are added as port members of the VLAN. Ports configured with the same aggregation key, but not active, are not added to the

VLAN. If these inactive ports become active later, the system does not automatically add them to the VLAN port member list.

You must add all inactive ports to the VLAN. If you do not add the inactive ports to the VLAN, when they become active later, hashing can result in choosing a newly active port for traffic forwarding. Because the port is not a port member of the VLAN, traffic will be dropped. When you add the VLAN to the MLT, also add the inactive aggregation ports to the VLAN. You may have to disable LACP on the inactive ports before you can add them to the VLAN. Because the ports are inactive, disabling LACP does not cause a traffic interruption.

Similarly when you remove a VLAN from a dynamic MLT, all active ports of the MLT are removed from the VLAN port member list but the inactive members are not removed. You must remove the inactive aggregation members from the VLAN.

If you later configure a port for the same aggregation, you must add this port to all VLANs that are members of the MLT.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **MultiLink/LACP Trunks** tab.
4. Click **Insert**.
5. In the **Id** box, type the ID number of the MLT.
6. In the **PortType** section, select **access** or **trunk**.
7. In the **Name** box, type a name for the MLT, or accept the default.
8. In the **PortMembers** box, click the (...) button.
9. In the **Port Editor: PortMembers** dialog box, select the desired ports.
10. Click **Ok**.
11. In the **VlanIdList** box, click the (...) button,
12. In the **VlanIdList** dialog box, select the desired VLANs.
13. Click **Ok**.
14. In the **MltType** section, select the MLT type.
15. In the **Aggregatable** box, select **enable** or **disable**.
16. In the **PrivateVlanType** box, select **trunk**, **isolated**, or **promiscuous**.
17. Click **Insert**.

The MLT is added to the MultiLink/LACP Trunks tab in the MLT\_LACP box.

### **MultiLink/LACP Trunks** Field Descriptions

Use the data in the following table to use the **MultiLink/LACP Trunks** tab

| Name            | Description                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>       | Specifies a unique value for this MLT.                                                                                                         |
| <b>PortType</b> | Specifies the value to access or trunk port. If the aggregatable field is set to enable, this field is read-only. The default value is access. |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                     | Configures the name given to the MLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>PortMembers</b>              | <p>Assigns ports to the MLT. All ports in an MLT must have the same settings for speed and duplex, but can have different media types. All untagged ports must belong to the same STG. Up to eight same-type ports can belong to a single MLT. If the aggregatable field is set to enable, this field becomes read-only.</p> <p><b>Important:</b><br/>Ensure that all ports that belong to the same MLT/LACP group use the same port speed, for example, 1 Gbps, even if autonegotiation is enabled.</p> |
| <b>VlanIdList</b>               | Indicates to which ports the VLANs belong. If the aggregation field is set to enable, this field is read-only.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>MltType</b>                  | <p>Specifies the type of MLT</p> <ul style="list-style-type: none"> <li>• normalMLT (default)</li> <li>• istMLT</li> <li>• splitMLT</li> </ul>                                                                                                                                                                                                                                                                                                                                                           |
| <b>RunningType</b>              | Specifies the MLT running type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>IfIndex</b>                  | Specifies the interface of the trunk.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ClearLinkAggregate</b>       | Clears the link aggregate, disabling and reenabling the trunk.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DesignatedPort</b>           | Specifies the designated port of this trunk.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Aggregatable</b>             | Enables or disables link aggregation. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AggOperState</b>             | Specifies the aggregation state of the trunk.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AggTimeOfLastOperChange</b>  | Specifies the time value since the interface entered its current operational state.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>PeerPortMembersList</b>      | Specifies the peer ports connected to the local ports of this trunk.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>EntryOwner</b>               | Defines the owner of the MLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DatapathProgrammingState</b> | Defines the datapath programming state of the MLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PrivateVlanType</b>          | Specifies the type of private VLAN for the MLT.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>FlexUniEnable</b>            | Specifies whether the Flex UNI is enabled or disabled on the port. The default value is disable.                                                                                                                                                                                                                                                                                                                                                                                                         |

## Adding ports to an MLT

Add ports to an MLT to insert MultiLink/LACP trunks.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **MultiLink/LACP Trunks** tab.
4. In the **PortMembers** column, double-click the field associated with the MLT to which you want to add ports to.
5. Select the port numbers to add, or click **All** to add all ports to the MLT.  
Up to 16 same-type ports can belong to a single MLT.
6. Click **Ok**.
7. Click **Apply**.

## Viewing SMLT Statistics

View SMLT statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **MLT/LACP**.
3. Select the **Ist/SMLT Stats** tab.

### **IST/SMLT Stats** Field Descriptions

The following table describes parameters on the **IST/SMLT Stats** tab.

| Name                             | Description                                                                                     |
|----------------------------------|-------------------------------------------------------------------------------------------------|
| <b>SmltIstDownCnt</b>            | The number of times the session between the two peering switches has gone down since last boot. |
| <b>SmltHelloTxMsgCnt</b>         | The count of transmitted hello messages.                                                        |
| <b>SmltHelloRxMsgCnt</b>         | The count of received hello messages.                                                           |
| <b>SmltLearnMacAddrTxMsgCnt</b>  | The count of transmitted learned MAC address messages.                                          |
| <b>SmltLearnMacAddrRxMsgCnt</b>  | The count of received learned MAC address messages.                                             |
| <b>SmltMacAddrAgeOutTxMsgCnt</b> | The count of transmitted aging out MAC address messages.                                        |
| <b>SmltMacAddrAgeOutRxMsgCnt</b> | The count of received aging out MAC address messages.                                           |
| <b>SmltMacAddrAgeExpTxMsgCnt</b> | The count of transmitted MAC address age expired messages.                                      |
| <b>SmltMacAddrAgeExpRxMsgCnt</b> | The count of received MAC address age expired messages.                                         |

| Name                                 | Description                                             |
|--------------------------------------|---------------------------------------------------------|
| <b>SmltStgInfoTxMsgCnt</b>           | The count of transmitted STG information messages.      |
| <b>SmltStgInfoRxMsgCnt</b>           | The count of received STG information messages.         |
| <b>SmltDelMacAddrTxMsgCnt</b>        | The count of transmitted MAC address deleted messages.  |
| <b>SmltDelMacAddrRxMsgCnt</b>        | The count of received MAC address received messages.    |
| <b>SmltSmltDownTxMsgCnt</b>          | The count of transmitted SMLT down messages.            |
| <b>SmltSmltDownRxMsgCnt</b>          | The count of received SMLT down messages.               |
| <b>SmltUpTxMsgCnt</b>                | The count of transmitted SMLT up messages.              |
| <b>SmltUpRxMsgCnt</b>                | The count of received SMLT up messages.                 |
| <b>SmltSendMacTblTxMsgCnt</b>        | The count of sent send MAC table messages.              |
| <b>SmltSendMacTblRxMsgCnt</b>        | The count of received send MAC table messages.          |
| <b>SmltIcmpTxMsgCnt</b>              | The count of sent IGMP messages.                        |
| <b>SmltIcmpRxMsgCnt</b>              | The count of received IGMP messages.                    |
| <b>SmltPortDownTxMsgCnt</b>          | The count of sent port down messages.                   |
| <b>SmltPortDownRxMsgCnt</b>          | The count of received port down messages.               |
| <b>SmltReqMacTblTxMsgCnt</b>         | The count of sent MAC table request messages.           |
| <b>SmltReqMacTblRxMsgCnt</b>         | The count of received MAC table request messages.       |
| <b>SmltRxUnknownMsgTypeCnt</b>       | The count of received unknown message type messages.    |
| <b>SmltPortTblSyncReqTxMsgCnt</b>    | The count of sent sync request messages.                |
| <b>SmltPortTblSyncReqRxMsgCnt</b>    | The count of received sync request messages.            |
| <b>SmltPortTblSyncTxMsgCnt</b>       | The count of sent sync messages.                        |
| <b>SmltPortTblSyncRxMsgCnt</b>       | The count of received sync messages.                    |
| <b>SmltPortUpdateTxMsgCnt</b>        | The count of sent update messages.                      |
| <b>SmltPortUpdateRxMsgCnt</b>        | The count of received update messages.                  |
| <b>SmltEntryUpdateTxMsgCnt</b>       | The count of sent entry update messages.                |
| <b>SmltEntryUpdateRxMsgCnt</b>       | The count of received entry update messages.            |
| <b>SmltDialectNegotiateTxMsgCnt</b>  | The count of sent protocol ID messages.                 |
| <b>SmltDialectNegotiateRxMsgCnt</b>  | The count of received protocol ID messages.             |
| <b>SmltUpdateRespTxMsgCnt</b>        | The count of sent update response messages.             |
| <b>SmltUpdateRespRxMsgCnt</b>        | The count of received update response messages.         |
| <b>SmltTransQHighWaterMarkMsgCnt</b> | The count of transaction queue high watermark messages. |
| <b>SmltPollCountHighWaterMarkCnt</b> | The count of poll count high watermark.                 |

## Viewing MLT Interface Statistics

### About This Task

Use MLT interface statistics tab to view interface statistics for the selected MLT.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **MLT/LACP**.
3. Click the **MultiLink/LACP Trunks** tab.
4. Select an MLT.
5. Click **Graph**.

### **MultiLink/LACP Trunks** Field Descriptions

Use the data in the following table to use the **MultiLink/LACP Trunks** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InOctets</b>       | Specifies the total number of octets received on the MLT interface, including framing characters.                                                                                                                                                                                          |
| <b>OutOctets</b>      | Specifies the total number of octets transmitted out of the MLT interface, including framing characters.                                                                                                                                                                                   |
| <b>InUcastPkts</b>    | Specifies the number of packets delivered by this MLT to higher level protocols that were not addressed to a multicast or broadcast address at this sublayer.                                                                                                                              |
| <b>OutUcastPkts</b>   | Specifies the number of packets that higher-level protocols requested be transmitted that were not addressed to a multicast address at this MLT. This total number includes discarded or unsent packets.                                                                                   |
| <b>InMulticastPkt</b> | Specifies the number of packets delivered to this MLT that were addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both Group and Functional addresses.                                                                                     |
| <b>OutMulticast</b>   | Specifies the total number of packets that higher-level protocols requested be transmitted, and that were addressed to a multicast address at this MLT, including those that were discarded or unsent. For a MAC layer protocol, this number includes both Group and Functional addresses. |
| <b>InBroadcastPkt</b> | Specifies the number of packets delivered to this MLT that were addressed to a broadcast address at this sublayer.                                                                                                                                                                         |
| <b>OutBroadcast</b>   | Specifies the total number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this MLT, including those that were discarded or not sent.                                                                                   |
| <b>InLsmPkts</b>      | Specifies the total number of Link State Messaging (LSM) packets delivered on this MLT.                                                                                                                                                                                                    |
| <b>OutLsmPkts</b>     | Specifies the total number of Link State Messaging (LSM) packets transmitted on this MLT.                                                                                                                                                                                                  |

## Viewing MLT Ethernet Error Statistics

### About This Task

Use MLT Ethernet error statistics to view the error statistics.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **MLT/LACP**.
3. Click the **MultiLink/LACP Trunks** tab.
4. Select an MLT, and then click **Graph**.
5. Click the **Ethernet Errors** tab.

### **Ethernet Errors** Field Descriptions

Use the data in the following table to use the **Ethernet Errors** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AlignmentErrors</b>   | Specifies the frame count frames received on a particular MLT that is not an integral number of octets in length and does not pass the FCS check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.                                                  |
| <b>FCSErrors</b>         | Specifies the frame count received on an MLT that is an integral number of octets in length, but does not pass the Frame Check Sequence (FCS) check. The count represented by an instance of this object increments when the FrameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.                                              |
| <b>IMacTransmitError</b> | Specifies the frame count for which transmission on a particular MLT fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object.                                                                                                                                                                                                                          |
| <b>IMacReceiveError</b>  | Specifies the frame count for which reception on a particular MLT fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object.<br>The precise meaning of the count represented by an instance of this object is implementation specific. In particular, an instance of this object can represent receive errors on a particular interface that are not otherwise counted. |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CarrierSenseError</b>  | Specifies the number of times that the carrier sense condition was lost or never asserted when attempting to transmit a frame on a particular MLT. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.                                                                                                                          |
| <b>FrameTooLong</b>       | Specifies the frame count received on a particular MLT that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC. |
| <b>SQETestError</b>       | Specifies the number of times that the SQE test error message is generated by the PLS sublayer for a particular MLT. The SQE test error message is defined in section 7.2.2.2.4 of ANSI/ IEEE 802.3-1985.                                                                                                                                                                                                                                                            |
| <b>DeferredTransmiss</b>  | Specifies the frame count for which the first transmission attempt on a particular MLT is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.                                                                                                                                                                                                                                    |
| <b>SingleCollFrames</b>   | Specifies a count of successfully transmitted frames on a particular MLT for which transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts object, the ifOutMulticastPkts object, or the ifOutBroadcastPkts object, and is not counted by the corresponding instance of the MultipleCollisionFrames object.                             |
| <b>MultipleCollFrames</b> | Specifies the successfully transmitted frame count on a particular MLT for which transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts object, the ifOutMulticastPkts object, or the ifOutBroadcastPkts object, and is not counted by the corresponding instance of the SingleCollisionFrames object.                               |
| <b>LateCollisions</b>     | Specifies the number of times that a collision is detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512 corresponds to 51.2 microseconds on a 10 Mb/s system. A late collision included in a count represented by an instance of this object is also considered as a generic collision for purposes of other collision-related statistics.                                                                                    |
| <b>ExcessiveCollis</b>    | Specifies the frame count for which transmission on a particular MLT fails due to excessive collisions.                                                                                                                                                                                                                                                                                                                                                              |

## Viewing trunks

Perform this procedure to view the MLT-based SMLT configuration.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **SMLT**.

- Click the **SMLT Info** tab.

### **SMLT Info** field descriptions

Use the data in the following table to use the **SMLT Info** tab.

| Name               | Description                               |
|--------------------|-------------------------------------------|
| <b>Id</b>          | Shows the MLT ID for this SMLT Read-only. |
| <b>MltType</b>     | Shows the MLT type of this trunk.         |
| <b>RunningType</b> | Shows the SMLT running type.              |

## Create a Virtual IST using EDM

vIST creates a virtualized channel through the SPBM cloud, and this channel connects two SMLT devices to form a virtualized Switch Cluster. Note that the SPBM cloud can consist of as few as two nodes.

### Important

- When you create a vIST, VLANs assigned to SMLT ports must have an I-SID assigned.
- If you assign a VLAN to an I-SID on one SMLT-BEB node, then you must create the same VLAN and assign it to the same I-SID on the peer SMLT-BEB node even if no devices are connected to this second node.
- The vIST VLAN must also be associated with an I-SID. You can use the same vIST VLAN in another part of your network, but the I-SID associated with the vIST VLAN must not be used anywhere else.

### Note

Simplified Virtual-IST (vIST) is for non-SPB customers who use SMLT with legacy IST. Simplified VIST is available only for legacy multicast deployments when the boot configuration flag (**spbm-config-mode**) is disabled.

### Before You Begin

- Enable SPBM and IS-IS globally.
- Configure SPBM and IS-IS.
- Configure a Layer 2 VSN by assigning an I-SID to the C-VLAN, which is used by the vIST.

### About This Task

### Important

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of the header size increase when transmitting packets over the SPBM cloud.

### Procedure

- In the navigation pane, expand the **Configuration > VLAN > MLT/LACP** folders.
- Select the **Virtual IST** tab.

3. In the **PeerIp** field, type the peer IP address.
4. In the **VlanId** field, enter a VLAN ID.
5. Select **Apply**.

### **Virtual IST** field descriptions

Use the data in the following table to help you configure the **Virtual IST** tab.

| Name                 | Description                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>SessionStatus</b> | Displays the status of the vIST session.                                                                 |
| <b>PeerIp</b>        | Specifies the peer IP address, which is the IP address of the vIST VLAN on the other aggregation switch. |
| <b>VlanId</b>        | Configures a vIST VLAN ID number.                                                                        |

## Editing a virtual IST

If you need to change the virtual IST **PeerIp** or **VlanId**, use this procedure to delete the vIST first.

### Note

- You must disable IS-IS globally before deleting a vIST, and then re-enable it after creating a new vIST.
- You do not have to set the SMLT peer system ID or the virtual B-MAC to 0 before you change the virtual IST peer IP address or VLAN ID number.

### Procedure

1. Disable IS-IS globally.
  - a. In the navigation pane, expand the following folders: **Configuration > IS-IS > IS-IS**.
  - b. Click the **Globals** tab.
  - c. In the **AdminState** field, click **off**.
  - d. Click **Apply**.
2. Delete the vIST.
  - a. In the navigation pane, expand the following folders: **Configuration > VLAN > MLT/LACP**.
  - b. Click the **Virtual IST** tab.
  - c. Click **Apply**.
3. Create a vIST:
  - a. In the navigation pane, expand the following folders: **Configuration > VLAN > MLT/LACP**.
  - b. Click the **Virtual IST** tab.
  - c. In the **PeerIp** field, enter the peer IP address.
  - d. In the **VlanId** field, enter a VLAN ID.
  - e. Click **Apply**.

4. Enable IS-IS globally.
  - a. In the navigation pane, expand the following folders: **Configuration > IS-IS > IS-IS**.
  - b. Click the **Globals** tab.
  - c. In the **AdminState** field, click **on**.
  - d. Click **Apply**.

## Configuring Simplified vIST in SMLT topologies

This procedure shows how to configure Simplified vIST in an SMLT environment. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

### Important

When you enable Simplified vIST with the **virtual-ist enable** command, two VLANs are automatically created to support vIST. The VLAN IDs are: 4086 and 4087.

### Before You Begin

SPBM must not be enabled on the vIST peers.

### About This Task

### Important

Do not change the system MTU to less than the default value of 1950 bytes. The system MTU must be 1950 or jumbo because of a header size increase.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit > Chassis** folders.
2. Click the **Boot Config** tab.
3. Clear the **EnableSpbmConfigMode** field to disable the boot flag.

The system responds with the following messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-mode
is changed to disable, removes SPBM configurations from the
configuration file.
```

4. Click **Apply**.

5. Save the configuration, and then reboot the switch.

**Important**

A change to the **EnableSpmConfigMode** boot flag requires a reboot for the change to take effect.

6. Configure the SMLT MLT:
  - a. Expand the **Configuration > VLAN** folders.
  - b. Click **MLT/LACP**.
  - c. Click the **MultiLink/LACP Trunks** tab.
  - d. Click **Insert**.
  - e. In the **Id** box, type the ID number of the MLT.
  - f. In the **PortType** section, select access or trunk.
  - g. In the **Name** box, type a name for the MLT, or accept the default.
  - h. In the **PortMembers** box, click the (...) button.
  - i. In the **Port Editor: PortMembers** dialog box, select the desired ports.
  - j. Click **Ok**.
  - k. In the **VlanIdList** box, click the (...) button.
  - l. In the **VlanIdList** dialog box, select the desired VLANs.
  - m. Click **Ok**.
  - n. In the **MltType** section, select splitMLT
  - o. Click **Insert**.

The switch adds the SMLT MLT to the MultiLink/LACP Trunks tab in the MLT\_LACP box.

7. Configure the vIST MLT:
  - a. Repeat steps 6.a on page 2348 to 6.o to configure the MLT.
  - b. Click **virtualistMLT** to enable Simplified vIST.
  - c. Click **Insert**.
8. Create the vIST VLAN:
  - a. Expand the **Configuration > VLAN > VLANs** folders.
  - b. In the **Basic** tab, click **Insert**.
  - c. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
  - d. In the **MstpInstance** box, click the down arrow, and then choose an MSTI instance from the list.
  - e. In the **Type** box, select **byPort**.
  - f. In the **PortMembers** box, click the (...) button.
  - g. In the **Port Editor: PortMembers** dialog box, select the desired ports.
  - h. Click **OK**.
  - i. Click **Insert**.
  - j. Select the vIST VLAN from the list of VLANs, and then click **IP**.
  - k. Click **Insert**.
  - l. Configure the IP address for the vIST VLAN.
9. Repeat step 8 to create an SMLT VLAN and assign the SMLT MLT ID to it. Do not use the vIST MLT ID.

## SLPP Guard configuration

This section provide the procedures to configure Simple Loop Prevention Protocol (SLPP) Guard using EDM.

### Important

Enable SLPP Guard on the edge switches of an SMLT network and SLPP on the aggregation layer switches.

### Configuring SLPP Guard

Configure SLPP Guard on MLT and LAG ports to provide additional network loop protection.

SLPP Guard is disabled by default.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **SLPP**.
3. Click the **SLPP Guard** tab.
4. In the port row, double-click the cell in the **Enabled** column.
5. Select true from the drop-down list to enable SLPP Guard, or false to disable SLPP Guard for the port.
6. (Optional) In the port row, double-click the cell in the **Timeout** column.
7. (Optional) Type a value in the **Timeout** field.
8. Click **Apply**.
9. On the toolbar, click **Refresh** to update the work area data display.

### SLPP Guard Ethernet type field descriptions

Use the data in the following table to use the **SLPP Guard** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b> | Specifies the port on which to configure SLPP Guard.                                                                                                                                                                                                                                                                                       |
| <b>Enable</b>  | Enables (true) or disables (false) SLPP Guard for the port.<br>The default is disabled.                                                                                                                                                                                                                                                    |
| <b>Timeout</b> | Specifies the time period, in seconds, for which SLPP Guard disables the port. After the timeout period expires, the switch re-enables the port. The timeout value can be 0 or a value ranging from 10 to 65535. With a value of 0, the port remains disabled until it is manually re-enabled.<br>The default Timeout value is 60 seconds. |
| <b>Status</b>  | Displays the SLPP Guard status for the port.                                                                                                                                                                                                                                                                                               |

| Name               | Description                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TimerCount</b>  | Indicates the time, in seconds, that elapses after SLPP Guard disables a port. When the TimerCount value equals the Timeout value, the switch re-enables the port.                                                                                              |
| <b>GuardOrigin</b> | Specifies the origin of SLPP Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul> |

### *Reenabling an operationally disabled port*

Reenable a port that has been operationally disabled by SLPP Guard.

#### Note

You cannot reenabling a disabled port if the timer count has not reached its timeout value. Either wait until it reaches the timeout or disable SLPP Guard for that port and then re-enable it.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **SLPP**.
3. Click the **SLPP Guard** tab.
4. In the port row, double-click the cell in the **Enabled** column.
5. Select true from the drop-down list to enable SLPP Guard, or false to disable SLPP Guard for the port.
6. (Optional) In the port row, double-click the cell in the **Timeout** column.
7. (Optional) Type a value in the **Timeout** field.
8. Click **Apply**.
9. On the toolbar, click **Refresh** to update the work area data display.

### *Viewing SLPP Guard status*

View current SLPP Guard settings.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **SLPP**.
3. Click the **SLPP Guard** tab.

### **SLPP Guard Ethernet type field descriptions**

Use the data in the following table to use the **SLPP Guard** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>     | Specifies the port on which to configure SLPP Guard.                                                                                                                                                                                                                                                                                    |
| <b>Enable</b>      | Enables (true) or disables (false) SLPP Guard for the port.<br>The default is disabled.                                                                                                                                                                                                                                                 |
| <b>Timeout</b>     | Specifies the time period, in seconds, for which SLPP Guard disables the port. After the timeout period expires, the switch re-enables the port. The timeout value can be 0 or a value ranging from 10 to 65535. With a value of 0, the port remains disabled until it is manually re-enabled. The default Timeout value is 60 seconds. |
| <b>Status</b>      | Displays the SLPP Guard status for the port.                                                                                                                                                                                                                                                                                            |
| <b>TimerCount</b>  | Indicates the time, in seconds, that elapses after SLPP Guard disables a port. When the TimerCount value equals the Timeout value, the switch re-enables the port.                                                                                                                                                                      |
| <b>GuardOrigin</b> | Specifies the origin of SLPP Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                         |

## MLT Configuration Examples

This section contains configuration examples for configuring MultiLink Trunking (MLT) and MLT with Link Aggregation Control Protocol (LACP) using the Command Line Interface (CLI).

### Note

Examples and network illustrations in this document might illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

## MultiLink Trunking

This configuration example shows you how to create a multilink trunk and a Virtual Local Area Network (VLAN) between two switches.

The following illustration shows you an MLT within a VLAN used to carry user traffic.

**Figure 191: MLT within a VLAN**

*Switch A and B configuration*

Configure MLT 10 on VLAN 100 on each device.

```
#
MLT CONFIGURATION
#

mlt 10 enable
interface mlt 10
exit
#
VLAN CONFIGURATION
#
vlan create 100 name VLAN-MLT-10 type port-mstprstp 0 color 1
vlan mlt 100 10
vlan members 100 1/1-1/4 portmember
```

## MultiLink Trunking with Link Aggregation Control Protocol

This configuration example shows you how to configure and enable a multilink trunk with LACP.

You must configure all aggregatable ports to use the same aggregator key so they can form an MLT.

The following illustration shows you an MLT created with LACP within a VLAN used to carry user traffic.

**Figure 192: MLT within a VLAN**

The following procedures show you how to configure both switches.

*Switch A and B configuration*

Configure the two devices to connect with MLT with LACP.

```
#
MLT CONFIGURATION
#

mlt 10 enable
interface mlt 10
lACP enable key 10
exit
#
VLAN CONFIGURATION
#
vlan create 100 name VLAN-MLT-10" type port-mstprstp 0 color 1
vlan mlt 100 1
vlan mlt 100 10
vlan members 100 1/1-1/4 portmember

#
PORT CONFIGURATION - PHASE II
#

interface GigabitEthernet 1/1
lACP key 10 aggregation enable
```

```
lacp enable
exit
interface GigabitEthernet 1/2
lacp key 10 aggregation enable
lacp enable
exit
```

## MLT network topology and configuration reference

The following reference information contains examples of MLT network topology and configuration. The same topologies apply to MLT with LACP.

### Note

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

### Example 1: Switch-to-switch MLT

The following illustration shows two multilink trunks (MLT1 and MLT2) connecting three switches.

**Figure 193: Switch-to-switch multilink trunks configuration**

In this example, you can configure each trunk with multiple switch ports to increase bandwidth and redundancy. If traffic between switch-to-switch connections approaches single port bandwidth limitations, you can create a multilink trunk to supply the additional bandwidth required to improve performance, as well as providing physical link layer redundancy.

### Example 2: Switch-to-server MLT

In this example, File server 1 uses dual MAC addresses, with one MAC address for each Network Interface Card (NIC). No multilink trunk is configured on File server 1. File server 2 is a single MAC server (with a four-port NIC) configured as multilink trunk configuration MLT1.

The following illustration shows a typical switch-to-server multilink trunk configuration.

**Figure 194: Switch-to-server multilink trunk configuration**

In this example, one port on File server 1 is blocked and unused and File server 2 benefits from aggregated bandwidth on multilink trunk T1.

### Example 3: Client/Server MLT

In this example, both servers are connected directly to the switch. File server 2 is connected through multilink trunk MLT 1. The switch-to-switch connections are through MLT 2, MLT 3, and MLT 4. Clients access data from the servers (File server 1 and File server 2) and receive maximized bandwidth through MLT 1, MLT 2, MLT 3, and MLT 4.

The following illustration shows how you can use multilink trunks in a client/server configuration.

**Figure 195: Client/server multilink trunk configuration**

# Network Operating System Personalities

**Table 168: Network operating system personality product support**

| Feature                 | Product         | Release introduced |
|-------------------------|-----------------|--------------------|
| Dual-boot personalities | 5420 Series     | VOSS 8.4           |
|                         | 5520 Series     | VOSS 8.2.5         |
|                         | VSP 4450 Series | Not Supported      |
|                         | VSP 4900 Series | Not Supported      |
|                         | VSP 7200 Series | Not Supported      |
|                         | VSP 7400 Series | Not Supported      |
|                         | VSP 8200 Series | Not Supported      |
|                         | VSP 8400 Series | Not Supported      |
|                         | VSP 8600 Series | Not Supported      |
|                         | XA1400 Series   | Not Supported      |

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. These hardware products ship with a default NOS personality but you can select a non-default personality. After you log in using the default NOS username and password for the first time, you can respond to an initialization question to change the NOS personality.

The following table identifies universal hardware products capable of running VOSS and indicates the default NOS personality.

**Table 169: Universal hardware with VOSS support**

| Product     | NOS support                  | Documentation                                                                                                                                                                                        |
|-------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5520 Series | ExtremeXOS (default)<br>VOSS | <ul style="list-style-type: none"> <li>• <a href="#">ExtremeSwitching 5520 Series Quick Reference</a></li> <li>• <a href="#">ExtremeSwitching 5520 Series Hardware Installation Guide</a></li> </ul> |

---

## Network Operating System Selection

---

The primary method to select a NOS personality is by using ExtremeCloud IQ or Extreme Management Center. To select a NOS personality using ExtremeCloud IQ, see [Read Me First – Universal Hardware](#). If the network is not accessible, or if you do not use Extreme Networks management software, you can also change the NOS personality manually by using CLI commands in the running NOS.

The procedure in this document includes the commands you use if the personality is VOSS and you need to change the NOS personality manually. To change the personality to VOSS, see the documentation for the running NOS.

---

## VOSS Default Behavior

---

The following list provides details about the default behavior after you deploy a universal hardware product with the VOSS personality:

- Port behavior:
  - All ports are isolated members of private VLAN 4040 and 4049.
  - The Segmented Management Instance Management VLAN and Management OOB interfaces are enabled.
  - All ports are administratively enabled.
  - To provide loop protection, no switching occurs between ports.
- DHCP:
  - DHCP client requests are cycled between In-Band, all ports untagged, and Out-of-Band ports.
- DNS:
  - The DHCP client issues a DNS query on the interface selected by Zero Touch Deployment to look for ExtremeCloud IQ. For information about Zero Touch Deployment, see [Zero Touch Deployment](#) on page 43.
  - You can then use ExtremeCloud IQ to upgrade or change the switch configuration. If you do not use ExtremeCloud IQ, you can use Extreme Management Center or on-switch VOSS user interfaces.

---

## Network Operating System Personality Configuration using CLI

---

### Change the Network Operating System Personality

Use this procedure on a VOSS switch to change the Network Operating System (NOS) personality.

The primary method to select a NOS personality for the switch is by using ExtremeCloud IQ. If the network is not accessible, or if you do not use Extreme Networks management software, you can change the NOS personality by using VOSS CLI commands.

#### **Before You Begin**

Use FTP to transfer the NOS image to the `/intflash/` directory in the VOSS file system.

## About This Task

If you change the NOS personality, the system deletes all configuration, licensing, and log files that pertain to the previous NOS personality.

If a power interruption occurs during a personality change, the system restarts the process after you restore power to the switch.

As part of the NOS personality change, you must restart the switch. If, during the restart, the system detects a failure, the NOS personality does not change. After the original NOS restarts, it logs an error message and raises a persistent alarm.

### Note

You can store only two software releases on 5420 Series and 5520 Series. If you attempt to add a third software release, you are prompted for a confirmation to overwrite the non-primary release. You can also use the **software add <filename> -y** command to bypass the confirmation question and automatically overwrite the non-primary release.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Unpack the NOS image:

```
software add WORD<1-99> -y
```

### Note

The .voss file is removed after the **software add** command runs.

3. Install the NOS image:

```
software activate WORD<1-99>
```

4. Confirm you want to change the NOS personality by entering **Y**.

5. Confirm the new image has been added and will become active after the next restart:

```
show software
```

### Important

If you decide not to change the NOS personality, before you restart the switch, you can run the **software activate** command again with the primary release as the image name and the system cancels the NOS personality change.

6. Restart the switch.

## Example

Change the NOS personality to ExtremeXOS.

```
5520-24W-VOSS:1>enable
5520-24W-VOSS:1#software add summit_arm-31.1.0.540.xos
EXOS image validated successfully
Adding EXOS software - /intflash/summit_arm-31.1.0.540.xos
Extraction of /intflash/summit_arm-31.1.0.540.xos to /intflash/release/
summit_arm-31.1.0.540.xos successful
5520-24W-VOSS:1#show software
=====
```

```

 software releases in /intflash/release/
=====
summit_arm-31.1.0.540.xos
5520.v8.2.5int030 (Primary Release)

Auto Commit : enabled
Commit Timeout : 10 minutes
5520-24W-VOSS:1#software activate summit_arm-31.1.0.540.xos
Executing software activate for version summit_arm-31.1.0.540.xos.
Validated EXOS software
WARNING: The specified image is for the EXOS Network Operating System and the VOSS
Network Operating System
is currently running.
If you continue, all data including configurations, logs and debugs will be cleared,
except for the license activation
status. EXOS will be installed and VOSS image files will be removed. Do you want to
continue (y/n) ?y

```

### Variable Definitions

The following table defines parameters for the **software** command.

| Variable                           | Value                                                                                                                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>activate</i> <i>WORD</i> <1-99> | Specifies the software version to copy to the boot flash file.                                                                                                                    |
| <i>add</i> <i>WORD</i> <1-99>      | Specifies the software version to unpack.                                                                                                                                         |
| -y                                 | Suppresses the confirmation message to automatically overwrite the non-primary image. If you omit this parameter, you must confirm the action to overwrite the non-primary image. |

|                           | XA1400 Series   | Not Supported                      | Not Applicable     |

**Note**

DEMO FEATURE - NTPv4 Master Mode and Restrict is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [VOSS Feature Support Matrix](#).

The following sections provide information on NTPv3 and NTPv4. If your platform supports both versions, the default is NTPv3.

**Important**

For NTPv4:

- The switch can operate as both NTPv4 client and NTPv4 server.
- The server selection algorithm can deem a server to be unfit to sync even though there is connectivity.
- It can take several iterations (intervals) for the server to sync.
- You need to configure a Segmented Management Instance on applicable switches before you use NTPv4.

## NTP fundamentals

---

This section provides conceptual material about the Network Time Protocol (NTP). Review this content before you make changes to the NTP configuration.

### NTP Overview

NTP synchronizes the internal clocks of various network devices across large, diverse networks to universal standard time. NTP protocol runs over the User Datagram Protocol (UDP), which in turn runs over IP.

The NTPv3 specification is documented in RFC 1305 and supports IPv4 addresses.

**Note**

NTPv3 is only supported on VSP 8600 Series.

The NTPv4 specification is documented in RFC 5905 and supports both IPv4 and IPv6 addresses.

Every network device relies on an internal system clock to maintain accurate time. On local devices, the internal system clock is typically manually set to within a minute or two of the actual time and is rarely reset at regular intervals. Many local clocks are battery-backed devices that use room temperature clock oscillators that can drift as much as several seconds each day. NTP adjusts the time of the devices so that they synchronize within a millisecond (ms) on LANs and up to a few tens of milliseconds on WANs relative to Coordinated Universal Time (UTC).

The NTP client on the switch supports only unicast client mode. In this mode, the NTP client sends NTP time requests to other remote time servers in an asynchronous fashion. The NTP client collects four samples of time from each remote time server. A clock selection algorithm determines the best server among the selected samples based on stratum, delay, dispersion and the last updated time of the remote server. The real time clock (RTC) is adjusted to the selected sample from the chosen server.

*NTP Terms*

A peer is a device that runs NTP software. However, this implementation of NTP refers to peers as remote time servers that provide time information to other time servers on the network and to the local NTP client. An NTP client refers to the local network device, the switch, that accepts time information from other remote time servers.

## NTP system implementation model

NTP is based on a hierarchical model that consists of a local NTP client that runs on the switch and on remote time servers. The NTP client requests and receives time information from one or more remote time servers. The local NTP client reviews the time information from all available time servers and synchronizes its internal clock to the time server whose time is most accurate. The NTP client does not forward time information to other devices that run NTP.

Two types of time servers exist in the NTP model: primary time servers and secondary time servers. A primary time server is directly synchronized to a primary reference source, usually a wire or radio clock that is synchronized to a radio station that provides a standard time service. The primary time server is the authoritative time source in the hierarchy, meaning that it is the one true time source to which the other NTP devices in the subnet synchronize their internal clocks.

A secondary time server uses a primary time server or one or more secondary time servers to synchronize its time, forming a synchronization subnet. A synchronization subnet is a self-organizing, hierarchical master-backup configuration with the primary servers at the root and secondary servers of decreasing accuracy at successive levels.

The following figure shows NTP time servers forming a synchronization subnet.

**Figure 196: NTP time servers forming a synchronization subnet**

In the NTP model, the synchronization subnet reconfigures in a hierarchical primary-secondary configuration to produce accurate and reliable time, even if one or more primary time servers or the path between them fails. This feature applies in a case in which all the primary servers on a partitioned subnet fail, but one or more backup primary servers continue to operate. If all of the primary time servers in the subnet fail, the remaining secondary servers synchronize among themselves.

## Time distribution within a subnet

NTP distributes time through a hierarchy of primary and secondary servers, with each server adopting a stratum, see [NTP system implementation model](#) on page 2363. A stratum defines how many NTP hops away a particular secondary time server is from an authoritative time source (primary time server) in the synchronization subnet. A stratum 1 time server is located at the top of the hierarchy and is directly attached to an external time source, typically a wire or radio clock; a stratum 2 time server receives its time through NTP from a stratum 1 time server; a stratum 3 time server receives its time through NTP from a stratum 2 time server, and so forth.

Each NTP client in the synchronization subnet chooses as its time source the server with the lowest stratum number with which it is configured to communicate through NTP. This strategy effectively builds a self-organizing tree of NTP speakers. The number of strata is limited to 15 to avoid long synchronization loops.

NTP avoids synchronizing to a remote time server with inaccurate time. NTP never synchronizes to a remote time server that is not itself synchronized. NTP compares the times reported by several remote time servers.

## Synchronization

Unlike other time synchronization protocols, NTP does not attempt to synchronize the internal clocks of the remote time servers to each other. Rather, NTP synchronizes the clocks to universal standard time, using the best available time source and transmission paths to that time source.

Use the **show NTP statistics** command to verify the NTP synchronization status. NTP uses the following criteria to determine the best available time server:

- The time server with the lowest stratum.
- The time server closest in proximity to the primary time server (reduces network delays).
- The time server that offers the highest claimed precision.

NTP accesses several (at least three) servers at the lower stratum level because it can apply an agreement algorithm to detect a problem on the time source.

## NTP Modes of Operation

NTP uses unicast client mode to enable time servers and NTP clients to communicate in the synchronization subnet. The switch supports only unicast client mode.

After you configure a set of remote time servers (peers), NTP creates a list that includes each time server IP address. The NTP client uses this list to determine the remote time servers to query for time information.

After the NTP client queries the remote time servers, the servers respond with various timestamps, along with information about their clocks, such as stratum, precision, and time reference. The NTP client reviews the list of responses from all available servers and chooses one as the best available time source from which to synchronize its internal clock.

The following figure shows how NTP time servers operate in unicast mode.

**Figure 197: NTP Time Servers Operating in Unicast Client Mode**

### *NTP Master Mode*

**Note**

DEMO FEATURE - NTPv4 Master Mode is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

The switch can operate as both an NTPv4 client and an NTPv4 server. You can configure the NTPv4 server by enabling the master mode. When the master mode is configured, peers can synchronize themselves with the local clock when the NTPv4 server loses synchronization or if an external NTPv4 source is not reachable. For information about configuring NTPv4 server master mode, see [Configuring NTP Master Mode](#) on page 2376 and [Configure NTP Globally](#) on page 2381.

### *NTP Restrict*

**Note**

DEMO FEATURE - NTPv4 Restrict is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

The switch offers the restrict capability on the NTPv4 server. When the NTPv4 server master mode is disabled, the restrict capabilities are disabled by default. All IPv4 or IPv6 addresses or networks except for those addresses configured as servers are ignored. For addresses configured as servers, traffic is allowed but there are some default restriction values.

When the NTPv4 server master mode is enabled, there are no restrict rules configured, which means all connections are allowed or there are one or multiple rules configured and only those addresses or networks with the configured rules are allowed. For more information about creating NTP restrict entries, see [Creating NTP Restrict Entries](#) on page 2377.

## NTP authentication

You can authenticate time synchronization to ensure that the local time server obtains its time services only from known sources. NTP authentication adds a level of security to your NTP configuration. By default, network time synchronization is not authenticated.

If you select authentication, the switch uses the Message Digest 5 (MD5) or the Secure Hash Algorithm 1 (SHA1) algorithm to produce a message digest of the key. The message digest is created using the key and the message, but the key itself is not sent. Depending on which algorithm you select, the MD5 or SHA1 algorithm verifies the integrity of the communication, authenticates the origin, and checks for timeliness.

To authenticate the message, the client authentication key must match that of the time server. Therefore, you must securely distribute the authentication key in advance (the client administrator must obtain the key from the server administrator and configure it on the client).

While a server can know many keys (identified by many key IDs), it is possible to declare only a subset of these as trusted. The time server uses this feature to share keys with a client that requires authenticated time and that trusts the server, but that is not trusted by the time server.

## Configuring NTP Using CLI

---

This section describes how to configure the Network Time Protocol (NTP) using Command Line Interface (CLI).

Before you configure NTP, you must perform the following tasks:

- NTPv3 does not use the Segmented Management Instance. For NTPv3, configure a traditional IP interface on the switch and ensure that the NTP server is reachable through this interface.

### Note

NTPv3 is only supported on VSP 8600 Series.

- For NTPv4, you must create a Segmented Management Instance and configure routing for that instance.

### Important

NTP server MD5 authentication or SHA1 authentication does not support passwords (keys) that start with a special character or that contain a space between characters.

The following task flow diagram shows the sequence of procedures you perform to configure NTP.

Figure 198: NTP Configuration Procedures

## Configure the NTP Version

### Note

This procedure only applies to VSP 8600 Series.

Configure the switch to use NTPv3 or NTPv4. The default is NTPv3.

### Before You Begin

You must globally disable NTP before you change the version.

### About This Task

NTPv3 supports IPv4 addresses. NTPv4 supports both IPv4 and IPv6 addresses.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the version:  
`ntp version <3 | 4>`

## Enable NTP Globally

Enable NTP globally. Default values are in effect for most parameters. You can customize NTP by modifying parameters.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. (Optional) Configure the NTP interval time (between successive NTP updates):  
`ntp interval <1-2185>`

OR

- `ntp interval <4-17>`
3. Enable NTP globally:  
`ntp`
4. Confirm the global configuration:  
`show ntp`

### Example

Specify the time interval between NTP updates, and then enable NTP globally.

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#ntp interval 10
Switch:1(config)#ntp
```

Confirm the configuration:

```
Switch:1(config)#show ntp
```

```
=====
 NTP Master
=====
Version Enabled Stratum

### Variable Definitions

The following table defines parameters for the **ntp** command.

| Variable                                                                                                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>authentication-key &lt;1-65534&gt;<br/>WORD&lt;0-20&gt;</code>                                                                              | Creates an authentication key for MD5 or SHA1 authentication. To configure this option to the default value, use the <b>default</b> operator with the command. The default configuration is to delete the authentication key. NTP server MD5 or SHA1 authentication does not support passwords (keys) that start with a special character or contain a space between characters. <code>WORD&lt;0-20&gt;</code> specifies the secret key.                                                                                                |
| <code>type &lt;md5   sha1&gt;</code>                                                                                                              | Specifies the type of authentication as MD5 or SHA1. The default is MD5 authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>interval&lt;1-2185&gt; OR &lt;4-17&gt;</code><br><br><b>Note:</b><br>Exception: interval range 1-2185 is supported on VSP 8600 Series only. | <b>VSP 8600 Series:</b><br>Specifies the time interval between successive NTP updates in minutes. The default for NTPv3 is 15 minutes. The default for NTPv4 is 6 minutes.<br><b>VOSS switches:</b><br>Specifies the time interval between successive NTP updates as a power of 2 in seconds. The default for NTPv4 is 2 to the power of 8 seconds.<br><br><b>Note:</b><br>Exception: NTPv3 is supported on VSP 8600 Series only.<br><br>To restore the NTP interval to the default value, use the <b>default ntp interval</b> command. |

## Add an NTP Server

Add a remote NTP server to the configuration by specifying its IP address. NTP adds this IP address to a list of servers, which the local NTP client uses to query remote time servers for time information. The list of qualified servers called to is a peer list.

### About This Task

For NTPv3, you can configure a maximum of 10 IPv4 NTP servers.

#### Note

NTPv3 is only supported on VSP 8600 Series.

For NTPv4, this procedure adds the NTP server information to the switch that is acting as an NTP client. You can configure a maximum of 10 IPv4 NTP servers and 10 IPv6 NTP servers.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add an NTP server:

```
ntp server WORD<0-255>
```

3. Configure additional options for the NTP server:

```
ntp server WORD<0-255> [auth-enable] [authentication-key <0-65534>]
[enable] [source-ip WORD<0-46>]
```

#### Note

The *source-ip* parameter applies only to NTPv3 on VSP 8600 Series.

The NTP server is automatically enabled by default.

4. Confirm the configuration:

```
show ntp server
```

### Example

```
Switch:>enable
Switch:1configure terminal
Switch:1(config)#ntp server 192.0.2.187
```

The output for the **show ntp server** command includes different information for NTPv3 and NTPv4.

For NTPv3:

```
Switch:1(config)#show ntp server
```

```
=====
 NTP Server
=====
Server Ip Enabled Auth Key Id Source IP Auth Type

192.0.2.187 true false 0 0.0.0.0 N/A
```

For NTPv4:

```
Switch:1(config)#show ntp server
```

```
=====
 NTP Server
=====
Server Ip Enabled Auth Key Id Auth Type

192.0.2.187 true false 0 N/A
```

### Variable Definitions

The following table defines parameters for the **ntp server** command.

| Variable                            | Value                                                                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>auth-enable</i>                  | Activates MD5 or SHA1 authentication on this NTP server. Without this option, the NTP server will not have any authentication by default.                            |
| <i>authentication-key</i> <0-65534> | Specifies the key ID value used to generate the MD5 or SHA1 digest for the NTP server. The default authentication key is 0, which indicates disabled authentication. |

| Variable                                                                                                 | Value                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code>                                                                                      | Activates the NTP server. To set this option to the default value, use the default operator with the command.                                                                                                                                               |
| <code>source-ip WORD&lt;0-46&gt;</code><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Specifies the source IP for the server. If you do not configure this parameter, by default, the source IP entry is initialized to 0.0.0.0. The IP address specified can be any local interface. The <code>source-ip</code> parameter applies only to NTPv3. |
| <code>WORD&lt;0-255&gt;</code>                                                                           | Specifies the IPv4 or IPv6 address of the NTP server.                                                                                                                                                                                                       |

## View NTP Statistics

### About This Task

Use the **show ntp statistics** command to view the output for each NTP stratum regardless of whether authentication is enabled.

#### Note

NTPv3 is only supported on VSP 8600 Series.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View NTP statistics:  
`show ntp statistics`

### Examples

The output for the **show ntp statistics** command includes different information for NTPv3 and NTPv4.

For NTPv3:

```
Switch:1#show ntp statistics

 NTP Server : 192.0.2.187

 Stratum : unknown
 Version : unknown
 Sync Status : not synchronized
 Reachability : unreachable
 Root Delay : unknown
 Precision : unknown
 Access Attempts : 2
 Server Synch : 0
 Server Fail : 2
 Fail Reason : Server unreachable
```

For NTPv4:

```
Switch:1#show ntp statistics

 NTP Server : 192.0.2.187
```

```

 Stratum : 16
 Version : NTPv4
 Broadcast : No
Auth Enabled : Disabled
Auth Status : Not-Auth
Sync Status : Rejected
Reachability : Unreachable
Root Delay : 0.000
Root Disp : 0.000
 Delay : 0.000
Dispersion : 15937.500
 Offset : 0.000
Precision : -23
 Jitter : 0.000
Last Event : Mobilize

NTP Server : 192.0.2.201

```

```

 Stratum : 4
 Version : NTPv4
 Broadcast : No
Auth Enabled : Enabled
Auth Status : Ok
Sync Status : Candidate
Reachability : Reachable
Root Delay : 18.448
Root Disp : 128.677
 Delay : 18.448
Dispersion : 0.366
 Offset : 0.202
Precision : -24
 Jitter : 1.041
Last Event : Popcorn

```

## Configuring Authentication Keys

### About This Task

Configure up to 10 NTP authentication keys to use MD5 or SHA1 authentication.

### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Create an authentication key:  

```
ntp authentication-key <1-65534> WORD<0-20> [type <md5|sha1>]
```
3. Enable MD5 or SHA1 authentication for the server:  

```
ntp server WORD<0-255> auth-enable
```

4. Assign an authentication key to the server:

```
ntp server WORD<0-46> authentication-key <0-65534>
```

#### Note

If you must disable authentication on the server, you must also disable authentication on the switch for example: `no ntp server WORD<0-255> auth-enable`

5. Confirm the configuration:

```
show ntp key
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ntp authentication-key 5 SecretKey type md5
Switch:1(config)#ntp server 192.0.2.187 auth-enable
Switch:1(config)#ntp server 192.0.2.187 authentication-key 5
Switch:1(config)#show ntp key
```

| NTP Key |                 |      |
|---------|-----------------|------|
| Key_Id  | Key             | Type |
| 5       | SecretKey       | MD5  |
| 10      | a               | SHA1 |
| 20      | abcdef&^%#1112  | MD5  |
| 30      | 1234567abcdtest | SHA1 |
| 100     | b               | MD5  |

#### Variable Definitions

The following table defines parameters for the **ntp** and **ntp server** commands.

| Variable                                                                         | Value                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auth-enable</code>                                                         | Activates MD5 or SHA1 authentication on this NTP server. The default is no authentication. To set this option to the default value, use the <b>default</b> operator with the command.                                                                |
| <code>authentication-key &lt;1-65534&gt;</code><br><code>WORD&lt;0-20&gt;</code> | Creates an authentication key for MD5 or SHA1 authentication. To set this option to the default value, use the <b>default</b> operator with the command. The default configuration is to delete the authentication key.                              |
| <code>authentication-key &lt;0-65534&gt;</code>                                  | Specifies the key ID value used to generate the MD5 or SHA1 digest for the NTPv4 server. The default value is 0, which indicates disabled authentication. To set this option to the default value, use the <b>default</b> operator with the command. |
| <code>type &lt;md5 sha1&gt;</code>                                               | Specifies the type of authentication, whether MD5 or SHA1. The default is MD5 authentication.                                                                                                                                                        |
| <code>WORD&lt;0-255&gt;</code>                                                   | Specifies the IPv4 or IPv6 address of the server.                                                                                                                                                                                                    |

## Configuring NTP Master Mode

### About This Task

#### Note

DEMO FEATURE - NTPv4 Master Mode is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Perform the following procedure to set the switch to act as the Network Time Protocol (NTP) server, which means it will run in the master mode. The default value is disabled. You can also enable NTP master mode for a specific stratum.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable NTP master:  

```
ntp master
```
3. (Optional) Configure NTP master for a specific stratum:  

```
ntp master <1-16>
```
4. Verify the configuration:  

```
show ntp
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ntp master
Switch:1(config)#show ntp
```

#### NTP Master

| Version | Enabled | Stratum |
|---------|---------|---------|
| 4       | True    | 11      |

#### NTP Client

| Version | Enabled | Interval | Last Update Time | Synchronized To |
|---------|---------|----------|------------------|-----------------|
| 3       | False   | 60       |                  |                 |

## Variable Definitions

The following table defines parameters for the **ntp master** command:

| Variable | Value                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-16>   | Specifies a stratum value. The default value is 10.<br><br><b>Note:</b><br>If there is a better stratum available, it is preferred than what is configured. |

## Creating NTP Restrict Entries

### Note

DEMO FEATURE - NTPv4 Restrict is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Perform the following procedure to configure the NTP restrict capability for a specific IPv4 or IPv6 address(es), which means the switch permits NTP traffic flow from the specified IP addresses only. By default the NTP restrict capability is disabled.

### Note

- You can configure a maximum of 128 NTP Restrict entries (IPv4 or IPv6 addresses).
- 0.0.0.0/0 or ::/0 NTP restrict entries are equivalent to no NTP restrict rules configured.

## Procedure

- Enter Global Configuration mode:
 

```
enable
configure terminal
```
- Configure a specific NTP restrict IP address:
 

```
ntp restrict WORD<0-255>
```
- Verify the restricted IP address:
 

```
show ntp restrict
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ntp restrict 192.0.0.0
Switch:1(config)#show ntp restrict
=====
 NTP Restrict Information
=====
TYPE ADDRESS MASK/PREFIX LEN
=====
```

|      |           |    |
|------|-----------|----|
| IPv4 | 192.0.0.0 | 23 |
|------|-----------|----|

### Variable Definitions

The following table defines parameters for the **ntp restrict** command:

| Variable            | Value                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-255> | Specifies the IPv4 or IPv6 address.<br><br><b>Note:</b><br>You can configure a maximum of 128 IPv4 and IPv6 addresses in the NTP restrict list. |

## Example of NTPv3 Configuration to NTPv4 Migration

### Note

This procedure only applies to VSP 8600 Series.

### Procedure

1. Configure a Segmented Management Instance.

```
Switch:1(config)#mgmt vlan 10
Switch:1(mgmt:vlan)#ip address 192.0.2.1/24
Switch:1(mgmt:vlan)# enable
```

OR

```
Switch:1(config)#mgmt clip
Switch:1(mgmt:clip)#ip address 198.51.100.1/32
Switch:1(mgmt:clip)#enable
```

2. Configure routing for the Management Instance.

For the VLAN interface, create a static route to reach the NTP server:

```
Switch:1(config)#mgmt vlan
Switch:1(mgmt:vlan)#ip route 203.0.113.1/24 next-hop 192.0.2.2
```

OR for the CLIP interface:

```
Switch:1(config)#router ospf
Switch:1(config-ospf)#redistribute direct
Switch:1(config-ospf)#redistribute direct enable
Switch:1(config-ospf)#exit
Switch:1(config)#ip ospf apply redistribute direct
```

3. Verify connectivity between the Management Instance and the NTPv4 server.

```
Switch:1(config)#ping 203.0.113.1 mgmt
```

4. Disable NTP globally.

```
Switch:1(config)#no ntp
```

5. Change the NTP version.

```
Switch:1(config)#ntp version 4
```

6. Enable NTP globally.

```
Switch:1(config)#ntp
```

7. Enable NTP master.

```
Switch:1(config)#ntp master
```

## Configuring NTP Using EDM

This section describes how to configure the Network Time Protocol (NTP) using Enterprise Device Manager (EDM).

Before you configure NTP, you must perform the following tasks:

- NTPv3 does not use the Segmented Management Instance. For NTPv3, configure a traditional IP interface on the switch and ensure that the NTP server is reachable through this interface.

### Note

NTPv3 is only supported on VSP 8600 Series.

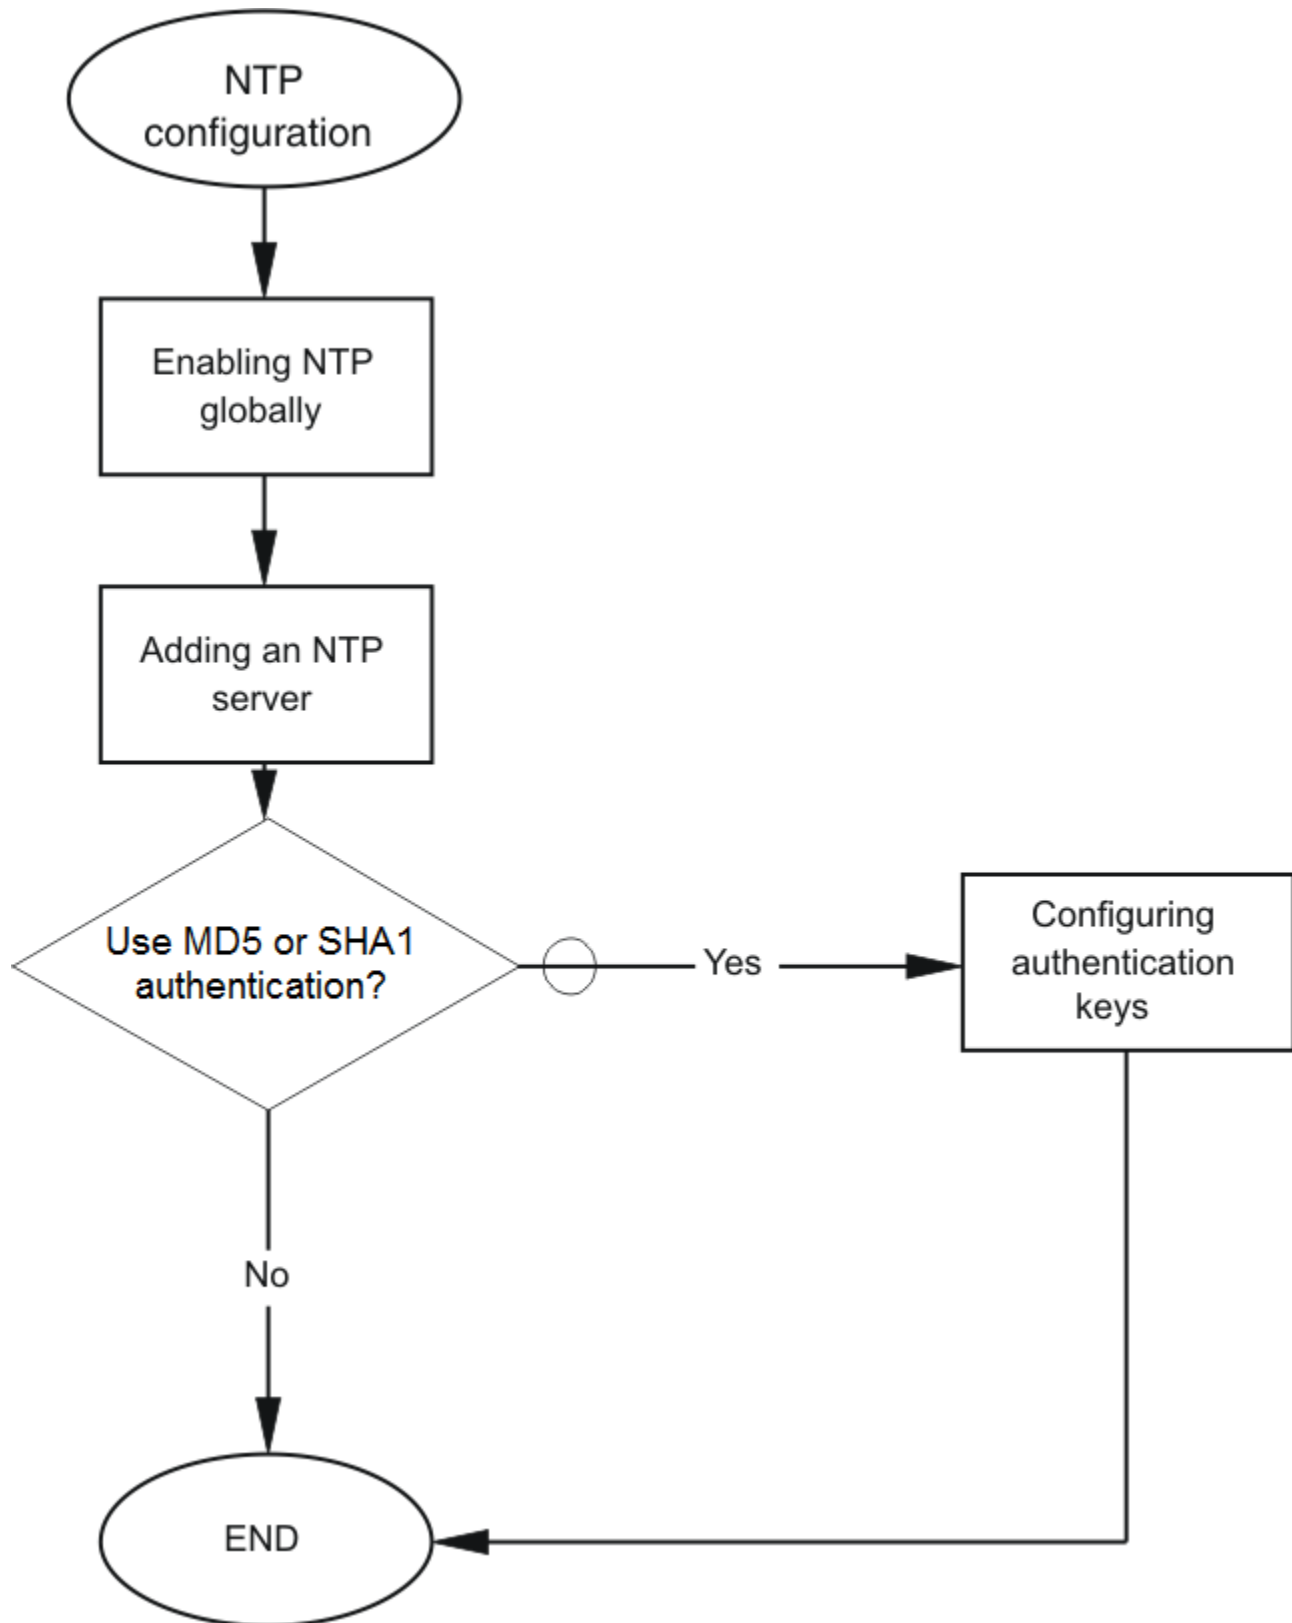

- For NTPv4, you must create a Segmented Management Instance and configure routing for that instance.

### Important

NTP server MD5 authentication or SHA1 authentication does not support passwords (keys) that start with a special character or that contain a space between characters.

This task flow shows you the sequence of procedures you perform to configure NTP.

**Figure 199: NTP Configuration Procedures**

## Configure NTP Globally

### Note

DEMO FEATURE - NTPv4 Master Mode is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

You can use the following procedure to globally enable NTP. For the VSP 8600 Series, you can configure the NTP version.

You can also enable master mode on the NTP server configured on the switch. When the master mode is configured, peers can synchronize themselves with the local clock when the NTP server loses synchronization or if an external NTP source is not reachable.

### Before You Begin

You must globally disable NTP before you change the version.

### About This Task

NTPv3 supports IPv4 addresses. NTPv4 supports both IPv4 and IPv6 addresses.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > NTP**.
2. Select **General**.
3. Select the **Globals** tab.
4. Select **Enable**.
5. Enter a time interval.

6.  **Note**  
This step only applies to VSP 8600 Series.

Select the NTP version.

7. (Optional) To configure the switch as an NTP server, in the **NTP Master** section, select **Enable**.
8. In the **Stratum** field, enter a value.
9. Select **Apply**.

### **Globals** Field Descriptions

Use data in the following table to use the **Globals** tab.

**NTP Client** section:

| Name                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>                                                                                 | Enables the client NTP server. By default, NTP is disabled.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Interval</b><br><br><b>Note:</b><br>Exception: NTPv3 is only supported on VSP 8600 Series. | <b>VSP 8600 Series:</b><br>Specifies the time interval between successive NTP updates in minutes.<br>The default values are: <ul style="list-style-type: none"> <li>• NTPv3: 15 minutes</li> <li>• NTPv4: 6 minutes</li> </ul> <b>VOSS switches:</b><br>Specifies the time interval between successive NTP updates as a power of 2 in seconds.<br>The default value for NTPv4 is 2 to the power of 8 seconds. |
| <b>Note:</b><br>Exception: only supported on VSP 8600 Series.<br><br><b>Version</b>           | Configures the NTP version. The default is NTPv3.                                                                                                                                                                                                                                                                                                                                                             |

**NTP Master** section:

| Name           | Description                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>  | Enables master mode for the configured NTP server. The default value is disabled.                                                                                              |
| <b>Stratum</b> | Specifies the stratum for the master NTP server.<br>The default value is 10.<br><br><b>Note:</b><br>If a better stratum is available, it is preferred over what is configured. |

## Add an NTPv3 Server

Add a remote NTP server to the configuration by specifying its IP address. NTP adds this IP address to a list of servers, which the local NTP client uses to query remote time servers for time information. The list of qualified servers called to is a peer list.

**Note**

This procedure is only supported on VSP 8600 Series.

**About This Task**

For NTPv3, you can configure a maximum of 10 IPv4 NTP servers.

## Procedure

1. In the navigation pane, expand **Configuration > Edit > NTP**.
2. Select **NTPv3**.
3. Select the **Server** tab.
4. Select **Insert**.
5. Specify the IP address of the NTP server.
6. Select **Insert**.

### *Server Field Descriptions*

Use the data in the following table to use the **Server** tab.

| Name                                                                                     | Description                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServerAddressType</b>                                                                 | Specifies the IP address of the remote NTP server.                                                                                                                                                                                                                        |
| <b>Enable</b>                                                                            | Activates or disables the remote NTP server. The default is enabled.                                                                                                                                                                                                      |
| <b>Authentication</b>                                                                    | Activates or disables MD5 or SHA1 authentication on this NTP server. MD5 or SHA1 produces a message digest of the key. MD5 or SHA1 verifies the integrity of the communication, authenticates the origin, and checks for timeliness.<br>The default is no authentication. |
| <b>KeyId</b>                                                                             | Specifies the key ID used to generate the MD5 or SHA1 digest for this NTP server. The default is 0, which indicates that authentication is disabled.                                                                                                                      |
| <b>AccessAttempts</b>                                                                    | Specifies the number of NTP requests sent to this NTP server.                                                                                                                                                                                                             |
| <b>Success</b>                                                                           | Specifies the number of times this NTP server updated the time.                                                                                                                                                                                                           |
| <b>Failure</b>                                                                           | Specifies the number of times the client rejected this NTP server while it attempted to update the time.                                                                                                                                                                  |
| <b>Stratum</b>                                                                           | This variable is the stratum of the server.                                                                                                                                                                                                                               |
| <b>Version</b>                                                                           | This variable is the NTP version of the server.                                                                                                                                                                                                                           |
| <b>RootDelay</b>                                                                         | This variable is the root delay of the server.                                                                                                                                                                                                                            |
| <b>Precision</b>                                                                         | This variable is the NTP precision of the server in seconds.                                                                                                                                                                                                              |
| <b>Reachable</b>                                                                         | This variable is the NTP reachability of the server.                                                                                                                                                                                                                      |
| <b>Synchronized</b>                                                                      | This variable is the status of synchronization with the server.                                                                                                                                                                                                           |
| <b>SourceIpAddr</b><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Specifies the source IP for the server. If you do not configure a source IP, by default, the entry is initialized to 0.0.0.0. The IP address specified can be any local interface.                                                                                        |

## Configure Authentication Keys for NTPv3

Assign an NTP key to use MD5 or SHA1 authentication on the server.

### Note

This procedure is only supported on VSP 8600 Series.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > NTP**.
2. Select **NTPv3**.
3. Select the **Key** tab.
4. Select **Insert**.
5. Specify the secret key.
6. Select **Insert**.

### Key field descriptions

Use the data in the following table to use the **Key** tab.

| Name             | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| <b>KeyId</b>     | Specifies the key ID that generates the MD5 or SHA1 digest.                                                   |
| <b>KeySecret</b> | Specifies the MD5 or SHA1 key that generates the MD5 or SHA1 digest. You must specify an alphanumeric string. |
| <b>KeyType</b>   | Specifies the type of authentication, whether MD5 or SHA1. The default is MD5 authentication.                 |

## Add an NTPv4 Server

Add a remote NTP server to the configuration by first specifying its IP address. NTP adds this IP address to a list of servers, which the local NTP client uses to query remote time servers for time information. The list of qualified servers called to is a peer list.

### About This Task

For NTPv4, this procedure adds the NTP server information to the switch that is acting as an NTP client. You can configure a maximum of 10 IPv4 NTP servers and 10 IPv6 NTP servers.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > NTP**.
2. Click **NTPv4**.
3. Click the **Server** tab.
4. Click **Insert**.
5. Specify if the IP address is IPv4 or IPv6.
6. Specify the IP address of the NTP server.
7. Click **Insert**.

**Server** field descriptions

Use the data in the following table to use the **Server** tab.

| Name                     | Description                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServerAddressType</b> | Specifies the address type as IPv4 or IPv6.                                                                                                                                                                                                                               |
| <b>ServerAddress</b>     | Specifies the IP address of the remote NTP server.                                                                                                                                                                                                                        |
| <b>Enable</b>            | Activates or disables the remote NTP server. The default is enabled.                                                                                                                                                                                                      |
| <b>Authentication</b>    | Activates or disables MD5 or SHA1 authentication on this NTP server. MD5 or SHA1 produces a message digest of the key. MD5 or SHA1 verifies the integrity of the communication, authenticates the origin, and checks for timeliness.<br>The default is no authentication. |
| <b>KeyId</b>             | Specifies the key ID used to generate the MD5 or SHA1 digest for this NTP server. The default is 0, which indicates that authentication is disabled.                                                                                                                      |
| <b>Stratum</b>           | Shows the stratum of the server.                                                                                                                                                                                                                                          |
| <b>Version</b>           | Shows the NTP version of the server.                                                                                                                                                                                                                                      |
| <b>Broadcast</b>         | Shows if broadcast is enabled or disabled                                                                                                                                                                                                                                 |
| <b>AuthEnabled</b>       | Shows if authentication is enabled or disabled                                                                                                                                                                                                                            |
| <b>AuthStatus</b>        | Shows the authentication status.                                                                                                                                                                                                                                          |
| <b>Synchronized</b>      | Shows the status of synchronization with the server.                                                                                                                                                                                                                      |
| <b>Reachable</b>         | Shows the NTP reachability status of the server.                                                                                                                                                                                                                          |
| <b>RootDelay</b>         | Shows the root delay of the server.                                                                                                                                                                                                                                       |
| <b>RootDisp</b>          | Shows the root dispersion of the server.                                                                                                                                                                                                                                  |
| <b>ServerDelay</b>       | Shows the delay of the server.                                                                                                                                                                                                                                            |
| <b>Dispersion</b>        | Shows the dispersion of the server.                                                                                                                                                                                                                                       |
| <b>Offset</b>            | Shows the offset of the server.                                                                                                                                                                                                                                           |
| <b>Precision</b>         | Shows the NTP precision of the server in seconds.                                                                                                                                                                                                                         |
| <b>Jitter</b>            | Shows the jitter of the server                                                                                                                                                                                                                                            |
| <b>LastEvent</b>         | Shows the last event of the server.                                                                                                                                                                                                                                       |

## Configure Authentication Keys for NTPv4

Assign an NTP key to use MD5 or SHA1 authentication on the server.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > NTP**.
2. Click **NTPv4**.
3. Click the **Key** tab.
4. Click **Insert**.
5. Complete the fields.
6. Click **Insert**.

**Key** field descriptions

Use the data in the following table to use the **Key** tab.

| Name             | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| <b>KeyId</b>     | Specifies the key ID that generates the MD5 or SHA1 digest.                                                   |
| <b>KeySecret</b> | Specifies the MD5 or SHA1 key that generates the MD5 or SHA1 digest. You must specify an alphanumeric string. |
| <b>KeyType</b>   | Specifies the type of authentication as MD5 or SHA1. The default is MD5 authentication.                       |

## Creating NTPv4 Restrict Entries

**Note**

DEMO FEATURE - NTPv4 Restrict is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Perform the following procedure to configure the NTP restrict capability for a specific IPv4 or IPv6 address(es), which means the switch permits traffic flow from the specified IP address only. By default the NTP restrict capability is disabled.

**Note**

- You can configure a maximum of 128 NTP Restrict entries (IPv4 or IPv6 addresses).
- 0.0.0.0/0 or ::/0 NTP restrict entries are equivalent to no NTP restrict rules configured.

**Before You Begin**

You must enable NTPv4 server master mode. For more information, see [Configure NTP Globally](#) on page 2381.

**Procedure**

1. In the Navigation pane, expand **Configuration > Edit > NTP**.
2. Click **Restrict**.
3. Click the **Restrict Info** tab.
4. Click **Insert**.
5. In the **RowIndex** field, enter a value.
6. Select the IP address type.
7. Enter the IPv4 or IPv6 address.
8. Enter the restrict mask value.
9. Click **Insert**.

**Restrict Info** Field Descriptions

Use data in the following table to use the **Restrict Info** tab.

| Name                   | Description                                                                   |
|------------------------|-------------------------------------------------------------------------------|
| <b>RowIndex</b>        | Specifies the NTP Restrict entry.                                             |
| <b>AddressType</b>     | Specifies the NTP Restrict address type.                                      |
| <b>RestrictAddress</b> | Specifies the NTP address to be restricted.                                   |
| <b>RestrictMask</b>    | Specifies the prefix length of the IPv4 or IPv6 NTP address to be restricted. |

## OSPF fundamentals

Use the information in these sections to help you understand Open Shortest Path First (OSPF).

OSPF is an Interior Gateway Protocol (IGP) that distributes routing information between routers that belong to a single autonomous system (AS). Intended for use in large networks, OSPF is a link-state protocol that supports IP subnets, Type of Service (TOS)-based routing, and tagging of externally-derived routing information.

For information about the Border Gateway Protocol (BGP), see [BGP](#) on page 377.

## OSPF overview

In an OSPF network, each router maintains a link-state database that describes the topology of the AS. The database contains the local state for each router in the AS, including its usable interfaces and reachable neighbors. Each router periodically checks for changes in its local state and shares detected changes by flooding link-state advertisements (LSA) throughout the AS. Routers synchronize their topological databases based on the sharing of information from LSAs.

From the topological database, each router constructs a shortest-path tree, with itself as the root. The shortest-path tree provides the optimal route to each destination in the AS. Routing information from outside the system displays the AS on the tree as leaves.

OSPF routes IP traffic based on the destination IP address, subnet mask, and IP TOS.

In large networks, OSPF offers the following benefits:

- fast convergence

After network topology changes, OSPF recalculates routes quickly.

- minimal routing protocol traffic

Unlike distance vector routing protocols, such as Routing Information Protocol (RIP), OSPF generates a minimum of routing protocol traffic.

- load sharing

OSPF provides support for Equal Cost Multipath (ECMP) routing. If several equal-cost routes to a destination exist, ECMP distributes traffic equally among them.

- type of service

OSPF can calculate separate routes for each IP TOS.

## OSPFv3

The Open Shortest Path First Protocol (OSPF) for IPv6, defined in RFC 2740 and RFC 5340, is an Interior Gateway Protocol used to distribute IPv6 routing information within a single Autonomous System (AS).

The IPv4 terms subnet and network are replaced in IPv6 by link. An IPv6 link is a communication medium between nodes at the link layer. You can assign multiple IP subnets (prefixes) to a link. Two IPv6 nodes with common or different prefixes can communicate over a single link.

OSPF for IPv6 operates on each link rather than each subnet as in IPv4. IPv6 makes the following changes to how packets are received and to the contents of network LSAs and hello packets:

- The OSPF packet contains no IPv6 addresses. LSA payloads carried in link state update packets contain IPv6 addresses.
- The following IDs remain at 32-bits and are not assigned IPv6 addresses: area IDs, LSA link state IDs, and OSPF router IDs.
- IPv6 OSPF neighbors use Router IDs to identify neighboring routers on broadcast and nonbroadcast multiaccess (NBMA) networks and for other communication media, point to point.

### *Flooding scope*

LSA flooding scope is generalized in OSPFv3 and coded in the LS type field of the LSA. The following three flooding scopes are available for LSAs:

- Link scope: The LSA is not flooded beyond the local link.
- Area scope: The LSA is flooded in a single OSPF area. Area scope is used in router LSAs, network LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router LSAs, and Intra-Area-Prefix- LSAs.
- AS scope: The LSA is flooded through the routing domain. AS scope is used for ASexternal- LSAs.

### *Link-local addresses*

IPv6 uses link-local addresses on a single link. Link-local addresses facilitate features such as neighbor discovery and autoconfiguration. Datagrams with link-local sources are not forwarded. Instead, routers assign link-local unicast addresses from the IPv6 address range.

OSPF for IPv6 does not assign link-local unicast addresses to physical segments attached to a router, it assumes that each router already has link-local unicast addresses assigned. The source for all OSPF packets sent on OSPF physical interfaces is the associated link-local unicast address. Routers learn link-local addresses for all other nodes on links. The nexthop information during packet forwarding includes the learned addresses.

OSPFv3 packets always use link-local addresses as the source and destination, except on a virtual link. All OSPFv3 packets sent over a virtual link use global addresses.

Link LSA is the only OSPF LSA type that includes link-local addresses. Link-local addresses must not be advertised in other LSA types.

### *Authentication*

OSPFv3 for IPv6 requires the IP authentication header and the IP encapsulating security payload for authentication and security. OSPFv3 does not support the authentication feature from OSPFv2.

### *Packet format*

OSPFv3 runs directly over IPv6. All other addressing information is absent in OSPF packet headers. OSPFv3 is network-protocol-independent. LSA types contain addressing information.

OSPFv3 implements the following packet changes from OSPFv2:

- The hello packet and database description packet operations fields are expanded to 24 bits.
- The packet header does not include Authentication and AuType fields.
- The interface ID replaces the address information in the hello packet. The Interface ID becomes the network LSA link-state ID, if the router becomes the designated router on the link.
- Router-bit (R-bit) and V6-bit in the options field process router LSAs during Shortest Path First (SPF) calculation. R-bits and V6-bits determine participation in topology distribution. The V6-bit specializes the R-bit. If the V6-bit is clear, the OSPF speaker can participate in the OSPF topology distribution without forwarding IPv6 datagrams. If the R-bit is set and the V6-bit is clear, the OSPF speaker still does not forward IPv6 datagrams, but it can forward IPv4 datagrams.
- The packet header includes the instance ID, which allows multiple OSPF protocol instances on the same link.

### *R-bit*

Unlike OSPF for IPv4, OSPFv3 for IPv6 supports the R-bit. The R-bit indicates whether the originating node is an active router. If the R-bit is cleared, routes that transit the advertising node cannot be calculated.

For example, if a multi-homed host participates in routing without forwarding non-locally-addressed packets, the R-bit is cleared.

An IPv6-enabled switch can continue to operate as an OSPFv3 neighbor even if you disable IPv6 forwarding on the switch. This behavior differs from IPv4 OSPF, in which the switch drops a neighbor, if IP forwarding on the neighbor is disabled.

### *LSAs*

OSPFv3 includes link LSAs and Intra-Area-Prefix LSAs.

#### **Link LSA**

The link LSA uses link flooding scope, not flooded beyond the associated link.

Link LSAs have three purposes:

- to provide the link-local address of the router to all other nodes on the link
- to provide the list of IPv6 prefixes associated with the link
- to allow the router to associate options bits with the network LSA for the link

#### **Intra-Area-Prefix LSA**

The Intra-Area-Prefix-LSA carries all IPv6 prefix information. In IPv4, this information is in router LSAs and network LSAs.

#### **Unknown LSA types**

In OSPFv3, unknown LSA types are either stored and flooded as though understood or given link flooding scope. Specific behavior is coded in the LS type field of the header.

### *Link LSA Suppression*

To decrease unnecessary link LSA generation and flooding for non-broadcast and non-NBMA interfaces, the Link LSA Suppression interface configuration parameter has been added in RFC 5340. If Link LSA Suppression is configured for an interface, and the interface type is not broadcast or NBMA, the originated link LSA may be suppressed. Link LSA suppression is disabled, by default. For more information on configuration see, [Configuring OSPF on a port or VLAN](#) on page 2467.

### *Stub area*

OSPFv3 retains the concept of stub areas, which minimize link-state databases and routing table sizes.

IPv6 stub areas carry only router LSAs, network LSAs, Inter-Area-Prefix-LSAs, link LSAs, and Intra-Area-Prefix-LSAs.

Unlike IPv4, IPv6 can store LSAs with unrecognized link-state (LS) types or flood them as though they are understood. Rules applied to the stub area prevent the excessive growth of the link-state database.

An LSA with an unrecognized link state can be flooded only if the LSA uses area- or link-flooding scope, and the LSA U-bit is 1 throughout stub and NSSA areas.

#### *Stub area*

OSPFv3 retains the concept of stub areas, which minimize link-state databases and routing table sizes.

IPv6 stub areas carry only router LSAs, network LSAs, Inter-Area-Prefix-LSAs, link LSAs, and Intra-Area-Prefix-LSAs.

Unlike IPv4, IPv6 can store LSAs with unrecognized link-state (LS) types or flood them as though they are understood. Rules applied to the stub area prevent the excessive growth of the link-state database. An LSA with an unrecognized link state can be flooded only if the LSA uses area- or link-flooding scope, and the LSA U-bit is 0.

#### *Deprecation of MOSPF for IPV6*

OSPFv3 in RFC 5340 deprecates Multicast Extensions to OSPF (MOSPF) support, and its attendant protocol fields.

#### *NSSA Specification*

RFC 2740 partially specifies this protocol feature, the level of specification was insufficient to implement it. However, RFC 5340 includes an NSSA specification unique to OSPFv3. This specification coupled with NSSA provide sufficient specification for implementation. Current Infinity IPv6 OSPF has full support for NSSA feature and is consistent with the additional specifications in RFC 5340.

#### *Stub Area Unknown LSA Flooding Restriction Deprecated*

In RFC 2740, flooding of unknown LSA was restricted within stub and NSSA areas. Following were the restrictions:

- Unlike IPv4, in IPv6 you can label unrecognized LS types as "Store and flood the LSA, as if type understood". Uncontrolled introduction of such LSAs could cause a stub area's link-state database to grow larger than its component router's capacities
- To guard the above situation, the following rule regarding stub areas has been established:

An LSA whose LS type is unrecognized can be flooded only into a stub area, if both the LSAs have area or link-local flooding scope, and the LSA has U-bit set to 0

Now the above restrictions have been deprecated. OSPFv3 routers flood link and area scope LSAs whose LS type is unrecognized and U-bit is set to 1 throughout stub and NSSA areas. The only backward compatibility issue is that the OSPFv3 routers still supporting the restrictions may not propagate newly defined LSA types.

#### *LSA Options and Prefix Options Updates*

The LSA Options and Prefix Options fields have been updated to reflect recent protocol additions. Specifically, bits related to MOSPF have been deprecated, Options field bits common with OSPFv2 have been reserved, and the DN-bit has been added to the prefix- options.

#### *IPv6 Site-Local Address*

All references to IPv6 site-local addresses have been removed in RFC 5340. Infinity IPv6 OSPF does not contain any reference to IPv6 site-local addresses and is already compliant with RFC 5340 for this.

## Dijkstras algorithm

A separate copy of the OSPF routing algorithm (Dijkstra's algorithm) runs in each area. Routers that connect to multiple areas run multiple copies of the algorithm. The sequence of processes governed by the routing algorithm is as follows:

1. After a router starts, it initializes the OSPF data structures, and then waits for indications from lower-level protocols that the router interfaces are functional.
2. A router then uses the Hello protocol to discover neighbors. On point-to-point and broadcast networks the router dynamically detects neighbors by sending hello packets to the multicast address AllSPFRouters. On Non-Broadcast Multiple Access (NBMA) networks, you must provide some configuration information to discover neighbors.
3. On all multiaccess networks (broadcast or nonbroadcast), the Hello protocol elects a designated router (DR) for the network.
4. The router attempts to form adjacencies with some of its neighbors. On multiaccess networks, the DR determines which routers become adjacent. This behavior does not occur if you configure a router as a passive interface because passive interfaces do not form adjacencies.
5. Adjacent neighbors synchronize their topological databases.
6. The router periodically advertises its link state, and does so after its local state changes. LSAs include information about adjacencies, enabling quick detection of dead routers on the network.
7. LSAs flood throughout the area to ensure that all routers in an area have an identical topological database.
8. From this database each router calculates a shortest-path tree, with itself as the root. This shortest-path tree in turn yields a routing table for the protocol.

## Autonomous system and areas

The AS subdivides into areas that group contiguous networks, routers that connect to these networks, and attached hosts. Each area has a topological database, which is invisible from outside the area. Routers within an area know nothing of the detailed topology of other areas. Subdividing the AS into areas significantly reduces the amount of routing protocol traffic compared to treating the entire AS like a single link-state domain.

You can attach a router to more than one area. When you perform this action, you can maintain a separate topological database for each connected area. Two routers within the same area maintain an identical topological database for that area. Each area uses a unique area ID and the area ID 0.0.0.0 is reserved for the backbone area.

The router routes packets in the AS based on their source and destination addresses. If the source and destination of a packet reside in the same area, the router uses intra-area routing. If the source and destination of a packet reside in different areas, the router uses inter-area routing. Intra-area routing protects the area from bad routing information because it does not use routing information obtained from outside the area. Inter-area routing must pass through the backbone area. For more information about the backbone area, see [Backbone area](#) on page 2395.

In large networks with many routers and networks, the link-state database (LSDB) and routing table can become excessively large. Large route tables and LSDBs consume memory. The processing of link-state advertisements results in additional CPU cycles to make forwarding decisions. To reduce these undesired effects, you can divide an OSPF network into subdomains called areas.

An area comprises a number of OSPF routers that have the same area identification (ID).

By dividing a network into multiple areas, the router maintains a separate LSDB, which consists of router LSAs and network LSAs, for each area. Each router within an area maintains an LSDB only for the area to which it belongs. Area router LSAs and network LSAs do not flood beyond the area borders.

The impact of a topology change is localized to the area in which it occurs. The only exception is for the area border router (ABR), which must maintain an LSDB for each area to which they belong. The area border routers advertise changes in topology to the remainder of the network by advertising summary LSAs.

A 32-bit area ID, expressed in IP address format (x.x.x.x), identifies areas. Area 0 is the backbone area and distributes routing information to all other areas.

If you use multiple areas, they must all attach to the backbone through an ABR, which connects area 0.0.0.0 to the nonbackbone areas. If you cannot physically and directly connect an area through an ABR to area 0, you must configure a virtual link to logically connect the area to the backbone area.

### *Backbone area*

The backbone area consists of the following network types:

- networks and attached routers that do not exist in other areas
- routers that belong to multiple areas

The backbone is usually contiguous but you can create a noncontiguous area by configuring virtual links.

You can configure virtual links between two backbone routers that have an interface to a nonbackbone area. Virtual links belong to the backbone and use intra-area routing only.

The backbone distributes routing information between areas. The topology of the backbone area is invisible to other areas, while it knows nothing of the topology of those areas.

In inter-area routing, a packet travels along three contiguous paths in a point-to-multipoint configuration:

- an intra-area path from the source to an ABR
- a backbone path between the source and destination areas
- another intra-area path to the destination

The OSPF routing algorithm finds the set of paths that has the smallest cost. The topology of the backbone dictates the backbone paths used between areas. OSPF selects inter-area paths by examining the routing table summaries for each connected ABR. The router cannot learn OSPF routes through an ABR unless it connects to the backbone or through a virtual link.

### *Stub area*

Configure a stub area at the edge of the OSPF routing domain. A stub area has only one ABR. A stub area does not receive LSAs for routes outside its area, which reduces the size of its link-state database. A packet destined outside the stub area is routed to the ABR, which examines it before forwarding the packet to the destination. The network behind a passive interface is treated as a stub area and does not form adjacencies. The network is advertised into the OSPF area as an internal route.

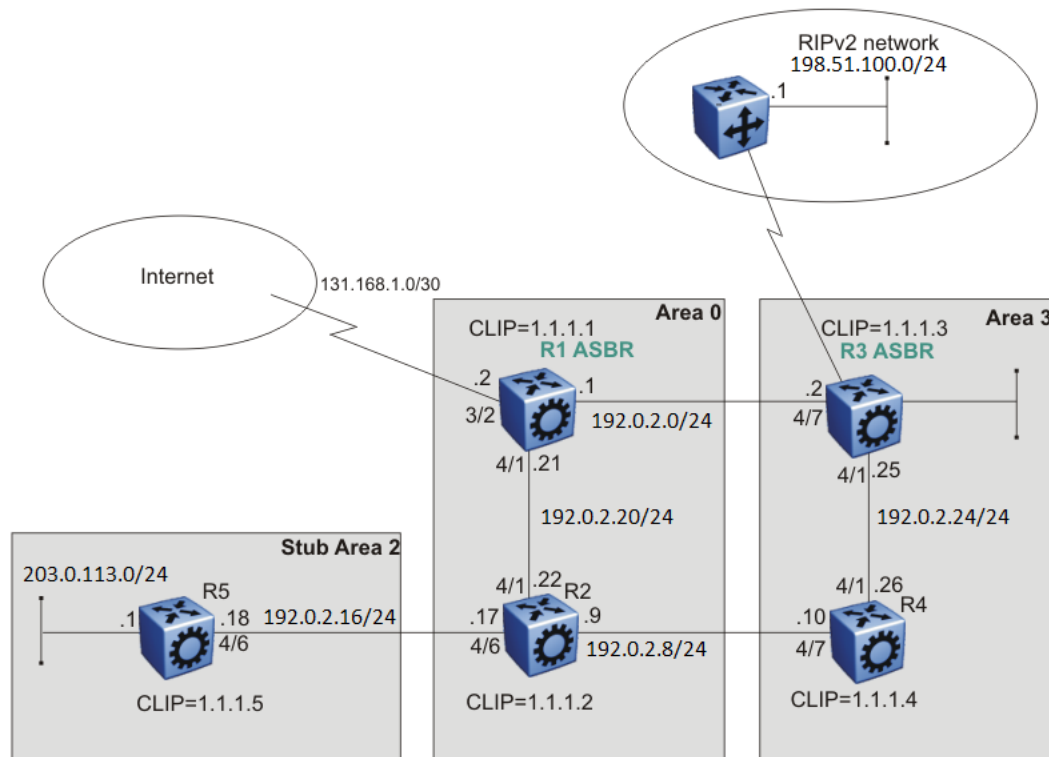

### Not so stubby area

A not-so-stubby area (NSSA) prevents the flooding of external LSAs into the area by replacing them with a default route. An NSSA can import small stub (non-OSPF) routing domains into OSPF. Like stub areas, NSSAs are at the edge of an OSPF routing domain. Non-OSPF routing domains attach to the NSSAs to form NSSA transit areas. Accessing the addressing scheme of small stub domains permits the NSSA border router to also perform manual aggregation.

In an OSPF NSSA, the NSSA N/P bit notifies the ABR which external routes to advertise to other areas. If the NSSA N/P bit is set (the value is 1), the ABR exports the external route. This configuration is the default. When the NSSA N/P bit is not set (the value is 0), the ABR drops the external route. You can create a route policy to manipulate the N/P bit.

### Multiarea OSPF configuration

The following figure shows five devices (R1 to R5) in a multi-area configuration.

**Figure 200: Multiarea configuration example**

The following list explains the configuration for devices R1 through R5:

- R1 is an OSPF AS boundary router (ASBR) that is associated with OSPF Area 0 and OSPF Area 3. R1 distributes a default route for Internet traffic.
- R2 is an OSPF stub ABR for OSPF Area 2 and ABR to OSPF Area 3.
- R3 is an OSPF ASBR and distributes OSPF to RIP and RIP to OSPF.
- R4 is an OSPF internal router in Area 3.
- R5 is an internal OSPF subrouter in Area 2.
- All OSPF interfaces are brouter ports except R5.

Network 203.0.113.0/24 on R5 uses a VLAN configuration instead of a brouter port. This example uses brouter ports rather than VLANs because the spanning tree algorithm is disabled by default if you use brouter interfaces.

- All interfaces are Ethernet; therefore, the OSPF interfaces are broadcast, except the circuitless IP (CLIP) interfaces, which are passive.
- The interface priority on R5 is 0; therefore, R5 cannot become a DR.
- Configure the OSPF router priority so that R1 becomes the DR (priority 100) and R2 becomes the backup designated router (BDR) with a priority value of 50.

Use stub or NSSA areas to reduce the LSDB size by excluding external LSAs. The stub ABR advertises a default route into the stub area for all external routes.

## OSPF neighbors

In an OSPF network, two routers that have an interface to the same network are neighbors. Routers use the Hello protocol to discover their neighbors and to maintain neighbor relationships. On a broadcast or point-to-point network, the Hello protocol dynamically discovers neighbors. On an NBMA network, you must manually configure neighbors for the network.

The Hello protocol provides bidirectional communication between neighbors. Periodically, OSPF routers send hello packets over all interfaces. Included in these hello packets is the following information:

- router priority
- router hello timer and dead timer values
- list of routers that sent the router hello packet on this interface
- router choice for DR and backup designated router (BDR)

Bidirectional communication is determined after one router discovers itself listed in the hello packet of its neighbor.

NBMA interfaces whose router priority is a positive, nonzero value are eligible to become DRs for the NBMA network and are configured with a list of all attached routers. The neighbors list includes each neighbor IP address and router priority. In an NBMA network, a router with a priority other than zero is eligible to become the DR for the NBMA network. You must manually configure the IP address, mask, and router priority of neighbors on routers that are eligible to become the DR or BDR for the network.

Log messages indicate when an OSPF neighbor state change occurs. Each log message indicates the previous state and the new state of the OSPF neighbor. The log message generated for system traps also indicates the previous state and the current state of the OSPF neighbor.

Neighbors can form an adjacency to exchange routing information. After two routers form an adjacency, they perform a database exchange process to synchronize their topological databases. After the databases synchronize, the routers are fully adjacent. Adjacency conserves bandwidth because, from this point, the adjacent routers pass only routing change information.

All routers connected by a point-to-point network or a virtual link always form an adjacency. All routers on a broadcast or NBMA network form an adjacency with the DR and the BDR.

In an NBMA network, before the routers elect a DR, the router sends hello packets only to those neighbors eligible to become a DR. The NBMA DR forms adjacencies only with its configured neighbors

and drops all packets from other sources. The neighbor configuration also notifies the router of the expected hello behavior for each neighbor.

If a router receives a hello packet from a neighbor with a priority different from that which is already configured for the neighbor, the router can automatically change the configured priority to match the dynamically learned priority.

## Router types

To limit the amount of routing protocol traffic, the Hello protocol elects a DR and a BDR on each multiaccess network. Instead of neighboring routers forming adjacencies and swapping link-state information, which on a large network can mean significant routing protocol traffic, all routers on the network form adjacencies with the DR and the BDR only, and send link-state information to them. The DR redistributes this information to every other adjacent router.

If the BDR operates in backup mode, it receives link-state information from all routers on the network and listens for acknowledgements. If the DR fails, the BDR can transition quickly to the role of DR because its routing tables are up-to-date.

Routers in an OSPF network can have various roles depending on how you configure them. The following table describes the router types you can configure in an OSPF network.

**Table 173: Router types in an OSPF network**

| Router type              | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AS boundary router       | A router that attaches at the edge of an OSPF network is an ASBR. An ASBR generally has one or more interfaces that run an interdomain routing protocol such as Border Gateway Protocol. In addition, a router that distributes static routes or RIP routes into OSPF is an ASBR. The ASBR forwards external routes into the OSPF domain. In this way, routers inside the OSPF network learn about destinations outside their domain. |
| Area border router       | A router that attaches to two or more areas inside an OSPF network is an ABR. ABRs play an important role in OSPF networks by condensing the amount of disseminated OSPF information.                                                                                                                                                                                                                                                 |
| Internal router (IR)     | A router that has interfaces only within a single area inside an OSPF network is an IR. Unlike ABRs, IRs have topological information only about the area in which they reside.                                                                                                                                                                                                                                                       |
| Designated router        | In a broadcast or NBMA network, the routers elect a single router as the DR for that network. A DR makes sure that all routers on the network synchronize and advertises the network to the rest of the AS.                                                                                                                                                                                                                           |
| Backup designated router | A BDR is elected in addition to the DR and, if the DR fails, can assume the DR role quickly.                                                                                                                                                                                                                                                                                                                                          |

## OSPF Interfaces

Configure an OSPF interface, or link, on an IP interface. An IP interface can be either a single link (brouter port) or a logical interface configured on a VLAN (multiple ports). The state information

associated with the interface is obtained from the underlying lower-level protocols and the routing protocol itself.

#### Important

To change the interface type of an enabled OSPF interface, you must first disable it, change the type, and then reenable it. For an NBMA interface, you must first delete manually configured neighbors.

OSPF network types allow OSPF-neighboring between routers over various types of network infrastructures. You can configure each interface to support various network types. The following table describes the supported OSPF network interface types:

**Table 174: OSPF Network Types**

| Network interface type                                                | Description                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Broadcast Interfaces</a> on page 2399                     | Broadcast interfaces automatically discover every OSPF router on the network by sending OSPF hello packets to the multicast group AllOSPF Routers (224.0.0.5). Neighboring is automatic and requires no configuration.                                                                                |
| <a href="#">Non-Broadcast Multiple Access Interfaces</a> on page 2399 | The NBMA network type models network environments that do not have native Layer 2 broadcast or multicast capabilities, such as Frame Relay and X.25. OSPF hello packets are unicast to manually configured neighbors.                                                                                 |
| <a href="#">Passive Interfaces</a> on page 2403                       | A passive interface is an interfacing network in OSPF that does not generate LSAs or form adjacencies. Use a passive interface on an access network or on an interface used for BGP peering. Using passive interfaces limits the amount of CPU cycles required to perform the OSPF routing algorithm. |

#### *Broadcast Interfaces*

Broadcast interfaces support many attached routers and can address a single physical message to all attached broadcast routers (sent to AllOSPF Routers and AllDRouters).

Broadcast interfaces dynamically discover neighboring routers using the OSPF Hello protocol. Each pair of routers on a broadcast network, such as an Ethernet, communicate directly.

#### *Non-Broadcast Multiple Access Interfaces*

An NBMA network interconnects multiple devices through point-to-point links. NBMA does not use broadcast and multicast data transmission.

NBMA interfaces support many routers, but cannot broadcast. NBMA networks perform the following activities:

- statically establish OSPF neighbor relationships

You must establish neighbor relationships because hub-and-spoke Wide Area Network (WAN) topologies do not support any-to-any broadcasting.

- control meshed WAN connections

In contrast to a broadcast network, where some OSPF protocol packets are multicast (sent to AllSPFRouters and AllDRouters), OSPF packets on an NBMA interface are replicated and sent in turn to each neighboring router as unicast. NBMA networks drop all OSPF packets with destination address AllSPFRouters and AllDRouters.

The following figure shows an example of four routers attached to an NBMA subnet. The NBMA segment uses a single IP subnet and each router uses an IP address within the subnet.

**Figure 201: NBMA Subnet**

#### *NBMA Interface Operations and Parameters*

OSPF treats an NBMA network much like it treats a broadcast network. Because many routers attach to the network, the Hello protocol elects a DR to generate the network link-state advertisements.

Because the NBMA network does not broadcast, you must manually configure neighbors for each router eligible to become DR (those networks with a positive, nonzero router priority value). You must also configure a poll interval for the network.

NBMA interfaces with a positive, nonzero router priority can become DR for the NBMA network and contain a list of all attached routers, or neighbors. This neighbors list includes each neighbor IP address and router priority.

The router uses neighbor information both during and after the DR election process. After an interface to a nonbroadcast network with a nonzero priority initializes, and before the Hello protocol elects a DR,

the router sends hello packets only to those neighbors eligible to become DR. After the Hello protocol elects a DR, it forms adjacencies only with its configured neighbors and drops all packets from other sources. This neighbor configuration also notifies the router of the expected hello behavior of each neighbor.

If a router eligible to become the DR receives a hello packet from a neighbor that shows a different priority from that which is already configured for this neighbor, the DR changes the configured priority to match the dynamically learned priority.

Configure an NBMA interface with a poll interval. The poll interval designates the interval at which the router sends hello packets to inactive neighboring routers. The router typically sends hello packets at the Hello interval, for example, every 10 seconds. If a neighboring router becomes inactive, or if the router does not receive hello packets for the established RouterDeadInterval period, the router sends hello packets at the specified poll interval, for example, every 120 seconds.

You must configure a neighbors list for the DR to allow an NBMA network to send hello packets. If the router is eligible to become a DR, it periodically sends hello packets to all neighbors that are also eligible. The effect of this action is that two eligible routers always exchange hello packets, which is necessary for the correct DR election. You can minimize the number of hello packets by minimizing the number of eligible routers on a nonbroadcast network.

After the Hello protocol elects a DR, it sends hello packets to all manually configured neighbors to synchronize their link-state databases, establish itself as the DR, and identify the BDR.

If a router is not eligible to become DR, it periodically sends hello packets to both the DR and the BDR. The router also sends a hello packet in reply to a hello packet received from an eligible neighbor (other than the current DR and BDR). This process establishes an initial bidirectional relationship with a potential DR.

When a router sends hello packets to a neighbor, the neighbor state determines the interval between hello packets. If the neighbor is in the down state, the router sends hello packets at the designated poll interval, for example, every 120 seconds. Otherwise, the router sends hello packets at the designated hello interval, for example, every 10 seconds.

#### *OSPF and NBMA Example: Adjacency Formation*

In an NBMA network, as in a broadcast network, all routers become adjacent to the DR and the BDR. The adjacencies form after you assign the router priorities, configure the neighbors, and the Hello protocol elects the network DR.

The following figure shows an NBMA subnet with router priorities and manually configured neighbors.

**Figure 202: NBMA Subnet Configuration Example**

Because R1 and R2 have a router priority of 0, they are not eligible to become the DR. Also, R1 and R2 do not require configuration of a neighbors list; R1 and R2 discover neighbors dynamically through the Hello protocol.

R3 and R4 both have a positive, nonzero priority and are eligible to become the DR. Manually configure neighbor lists on R3 and R4.

To create this NBMA network, configure the following parameters:

1. On each router: NBMA interface type, poll interval, router priority
2. On R3: R1, R2, and R4 as neighbors
3. On R4: R1, R2, and R3 as neighbors

If all routers start at the same time, the routers perform the following steps:

1. R3 and R4 send each other a hello packet to elect a DR.
2. The Hello protocol elects R3 as the DR, and R4 as the BDR.
3. R3 (DR) and R4 (BDR) send hello packets to all other routers on the NBMA subnet to synchronize their link-state databases and establish themselves as DR and BDR.

4. R1 and R2 reply to R3 and R4.
5. R3 and R4 each form three adjacencies (one with each router on the NBMA subnet).
6. R1 and R2 each form two adjacencies (one with the DR and one with the BDR).

### *Passive Interfaces*

Use a passive interface to enable an interface to advertise into an OSPF domain while limiting its adjacencies.

After you change the interface type to passive, the router advertises the interface into the OSPF domain as an internal stub network with the following behaviors:

- does not send hello packets to the OSPF domain
- does not receive hello packets from the OSPF domain
- does not form adjacencies in the OSPF domain

If you configure an interface as passive, the router advertises it as an OSPF internal route. If the interface is not a passive interface, to advertise a network into OSPF and not form OSPF adjacencies, you must configure the interface as nonOSPF, and the router must redistribute the local network as an autonomous system external (ASE) LSA.

## OSPF and IP

OSPF runs over IP, which means that an OSPF packet transmits with an IP data packet header. The protocol field in the IP header is 89, which identifies it as an OSPF packet and distinguishes it from other packets that use an IP header.

An OSPF route advertisement expresses a destination as an IP address and a variable-length mask. Together, the address and the mask indicate the range of destinations to which the advertisement applies.

Because OSPF can specify a range of networks, it can send one summary advertisement that represents multiple destinations. For example, a summary advertisement for the destination 192.0.2.0 with a mask of 255.255.0.0 describes a single route to destinations 192.0.2.0 to 192.0.2.255.

## OSPF Packets

All OSPF packets start with a 24-octet header that contains information about the OSPF version, the packet type and length, the ID of the router that transmits the packet, and the ID of the OSPF area that sends the packet. An OSPF packet is one of the following types:

- The router transmitted hello packets between neighbors and never forwards them. The Hello protocol requires routers to send hello packets to neighbors at predefined hello intervals. A neighbor router that does not receive a hello packet declares the other router dead.
- The router exchanges DD packets after neighboring routers establish a link, which synchronizes their LSDBs.
- Link-state request packets describe one or more link-state advertisements that a router requests from its neighbor. Routers send link-state requests if the information received in DD packets from a neighbor is not consistent with its own link-state database.

- Link-state update packets contain one or more LSAs and the router sends them following a change in network conditions.
- The router sends link-state acknowledgement packets to acknowledge receipt of link-state updates. Link-state acknowledgement packets contain the headers of the received LSAs.

## Intra-area Link-state Advertisements

OSPF does not require each router to send its entire routing table to its neighbors. Instead, each OSPF router floods only link-state change information in the form of LSAs throughout the area or AS. LSAs in OSPF are one of the following five types:

- A router link advertisement is flooded only within the area and contains information about neighbor routers and the LANs to which the router attaches. A backbone router can flood router link advertisements within the backbone area.
- A DR on a LAN generates network links advertisement to list all routers on that LAN, and floods network links advertisements only within the area. A backbone DR can flood network links advertisements within the backbone area.
- An ABR floods a network summary link advertisement into an area and describes networks that are reachable outside the area. An ABR attached to two areas generates a different network summary link advertisement for each area. ABRs also generate area summary link advertisements that contain information about destinations within an area that are flooded to the backbone area.
- An ASBR summary link advertisement describes the cost of the path to an ASBR from the router that generates the advertisement.
- An ASBR sends an ASE link advertisement to describe the cost of the path to a destination outside the AS from the ASBR that generates the advertisement. This information is flooded to all routers in the AS.

## ASE routes

OSPF considers the following routes as ASE routes:

- a route to a destination outside the AS
- a static route
- a default route
- a route derived by RIP
- a directly connected network that does not run OSPF

## OSPF virtual links

On an OSPF network, a switch that acts as an ABR must connect directly to the backbone. If no physical connection is available, you can automatically or manually configure a virtual link.

An automatic virtual link can provide redundancy support for critical network connections. Automatic virtual linking creates virtual paths for vital traffic paths in your OSPF network. If a connection fails on the network, such as after an interface cable that provides connection to the backbone (either directly or indirectly) disconnects from the switch, the virtual link is available to maintain connectivity.

Use automatic virtual linking to ensure that a link is created to another router. If automatic virtual linking uses more resources than you want to expend, creating a manual virtual link can be the better solution. Use this approach to conserve resources and control virtual links in the OSPF configuration.

On the switch, OSPF behavior follows OSPF standards; the router cannot learn OSPF routes through an ABR unless the ABR connects to the backbone or through a virtual link.

The following figure shows how to configure a virtual link between the ABR in area 2.2.2 and the ABR in area 0.0.0.0.

**Figure 203: Virtual link between ABRs through a transit area**

To configure a virtual link between the ABRs in area 1 and area 3, define area 2 as the transit area between the other two areas, and identify R2 as the neighbor router through which R2 must send information to reach the backbone through R1.

## OSPF ASBRs

ASBRs advertise nonOSPF routes into OSPF domains so that they can pass through the OSPF routing domain. A router can function as an ASBR if one or more interfaces connects to a nonOSPF network, for example, RIP, BGP, or Exterior Gateway Protocol (EGP).

An ASBR imports external routes into the OSPF domain by using ASE LSAs (LSA type 5) originated by the ASBR.

ASE LSAs flood across area borders. When an ASBR imports external routes, it imports OSPF route information using external type 1 or type 2 metrics. The result is a four-level routing hierarchy, as shown in the following table, according to routing preference.

**Table 175: ASBR routing hierarchy**

| Level | Description             |
|-------|-------------------------|
| 1     | Intra-area routing      |
| 2     | Inter-area routing      |
| 3     | External type 1 metrics |
| 4     | External type 2 metrics |

The use of these metrics results in a routing preference from most preferred to least preferred of

- routing within an OSPF area
- routing within the OSPF domain
- routing within the OSPF domain and external routes with external type 1 metrics
- routing within the OSPF domain and external routes with external type 2 metrics

For example, an ASBR can import RIP routes into OSPF with external type 1 metrics. Another ASBR can import Internet routes and advertise a default route with an external type 2 metric. This results in RIP-imported routes that have a higher preference than the Internet-imported default routes. In reality, BGP Internet routes must use external type 2 metrics, whereas RIP imported routes must use external type 1 metrics.

Routes imported into OSPF as external type 1 are from IGP's whose external metric is comparable to OSPF metrics. With external type 1 metrics, OSPF adds the internal cost of the ASBR to the external metric. EGP's, whose metric is not comparable to OSPF metrics, use external type 2 metrics. External type 2 metrics use only the internal OSPF cost to the ASBR in the routing decision.

To conserve resources, you can limit the number of ASBRs in your network or specifically control which routers perform as ASBRs to control traffic flow.

#### *Area link-state advertisements*

The following table explains the seven LSA types exchanged between areas. LSAs share link-state information among routers. LSAs typically contain information about the router and its neighbors. OSPF generates LSAs periodically to ensure connectivity or after a change in state of a router or link (that is, up or down).

**Table 176: OSPF LSA types**

| LSA type | Description                                                                                                                                                                      | Area of distribution             |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| 1        | A router originates type 1 LSAs (router LSAs) to describe its set of active interfaces and neighbors.                                                                            | Passed only within the same area |
| 2        | Type 2 LSAs (network LSAs) describe a network segment such as broadcast or NBMA. In a broadcast network, the DR originates network LSAs.                                         | Passed only within the same area |
| 3        | The ABR originates type 3 LSAs (network-summary LSAs) to describe the networks within an area.                                                                                   | Passed between areas             |
| 4        | Type 4 LSAs (ASBR-summary LSAs) advertise the location of the ASBRs from area to area.                                                                                           | Passed between areas             |
| 5        | Type 5 LSAs (ASE LSAs) describe networks outside of the OSPF domain. The ASBR originates type 5 LSAs. In stub and NSSA areas, a single default route replaces type 5 LSA routes. | Passed between areas             |
| 6        | Type 6 LSAs (group membership LSAs) identify the location of multicast group members in multicast OSPF.                                                                          | Passed between areas             |
| 7        | Type 7 LSAs import external routes in OSPF NSSAs.                                                                                                                                | Translated between areas         |

## OSPF metrics

For OSPF, the best path to a destination is the path that offers the least-cost metric (least-cost delay). You can configure OSPF cost metrics to specify preferred paths. You can configure metric speed globally or for specific ports and interfaces on the network. In addition, you can control redistribution options between nonOSPF interfaces and OSPF interfaces.

Assign default metric speeds for different port types, such as 10 Mb/s or 1 Mb/s ports. You can specify a new metric speed for an IP interface. An IP interface can be a brouter port or a VLAN.

RFC1583 states the following:

"OSPF supports two types of external metrics. Type 1 external metrics are equivalent to the link state metric. Type 2 external metrics are greater than the cost of path internal to the Autonomous System. Use of Type 2 external metrics assumes that routing between Autonomous Systems is the major cost of routing a packet, and eliminates the need for conversion of external costs to internal link state metrics."

"Both Type 1 and Type 2 external metrics can be present in the Autonomous System at the same time. In that event, Type 1 external metrics always take precedence."

## OSPF security mechanisms

The switch implementation of OSPF includes security mechanisms to prevent unauthorized routers from attacking the OSPF routing domain. These security mechanisms prevent a malicious person from joining an OSPF domain and advertising false information in the OSPF LSAs. Likewise, security prevents a misconfigured router from joining an OSPF domain.

### *Simple password*

The simple password security mechanism is a simple-text password; only routers that contain the same authentication ID in their LSA headers can communicate with each other.

Do not use this security mechanism because the system stores the password in plain text. A user or system can read the password from the configuration file or from the LSA packet.

### *Message Digest 5*

Message Digest 5 (MD5) for OSPF security provides standards-based (RFC1321) authentication using 128-bit encryption, usually expressed as a 32-digit hexadecimal number. When you use MD5 for OSPF security, it is almost impossible for a malicious user to compute or extrapolate the decrypting codes from the OSPF packets.

If you use MD5, each OSPF packet has a message digest appended to it. The digest must match between the sending and receiving routers. Both the sending and receiving routers calculate the message digest based on the MD5 key and padding, and then compare the results. If the message digest computed at the sender and receiver does not match, the receiver rejects the packet.

### *Secure hash algorithm 1*

The secure hash algorithm 1 (SHA-1) is a cryptographic hash function that uses 160-bit encryption, usually given in a 40 digit hexadecimal number. SHA-1 is one of the most widely used of the existing SHA hash functions and is more secure than MD5.

SHA-1 takes a variable length input message and SHA-1 creates a fixed length output message referred to as the hash, or message digest, of the original message. If you use SHA-1 with OSPF, each OSPF packet has a message digest appended to it.

The message digest or hash must match between the sending and receiving routers. If the message digest computed at the sender and receiver does not match, the receiver rejects the packet. The hash functions produce a type of checksum or summary of the input.

It is almost impossible to determine the original input message based on the output hash message.

A cryptographic hash function is fully defined and uses no secret key.

#### *Secure hash algorithm 2*

Secure hash algorithm 2 (SHA-2) is also a cryptographic hash function. SHA-2 updates SHA-1 and offers six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits message digest size values. Output size depends on the hash function, so, for instance, SHA-256 is 256 bits.

SHA-2 is more secure than SHA-1 and MD5.

SHA-2 works similarly to SHA-1, in that SHA-2 takes a variable length input message and creates a fixed length output message referred to as the hash, or message digest, of the original message. If you use SHA-2 with OSPF, each OSPF packet has a message digest appended to it. Among the differences in SHA-2 from SHA-1 are an increased bit encryption length.

Similarly with other hash functions, for SHA-2, the message digest or hash must match between the sending and receiving routers. If the message digest computed at the sender and receiver does not match, the receiver rejects the packet. The hash functions produce a type of checksum or summary of the input.

## IPsec Support with OSPFv3

You can use Internet Protocol Security (IPsec) with OSPFv3 virtual link for the security protection of communication between the end points. You can also use IPsec with OSPFv3 on a brouter port or VLAN interface, for example, if you want to encrypt OSPFv3 control traffic on a broadcast network.

OSPF virtual link provides connectivity to the OSPF backbone area for redundancy or to provide a virtual link if a physical connection is not possible.

Because the device does not know the IPv6 addresses of the OSPFv3 virtual link end points at the time of configuration, you cannot manually configure the security policy ahead of time. The system must self-manage its security policy dynamically. The device also dynamically manages the IPsec enable flag, which the virtual link uses on a Layer 2 interface, either a VLAN or brouter port interface.

The following events can trigger an IPsec policy activation:

1. An OSPFv3 routing module detects the establishment of a virtual link.
2. IPsec is enabled on the already established virtual link.

On the other hand, the following two events can dynamically trigger an IPsec policy deactivation:

1. The virtual link is turn down.

2. IPsec is disabled on the virtual link.

IPsec policies can also change dynamically if a neighbor address or a local address changes.

You can enable IPsec support for IPv6 OSPF virtual link at the system level through CLI. You must disable IPsec before you can perform virtual link policy configuration changes.

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You can configure the direction you want IPsec to protect, either, ingress, egress, or both. In addition, you can permit or drop communication for the OSPF virtual link.

You can also use IPsec with OSPFv3 on a brouter port or VLAN interface. For a full configuration example, see [OSPFv3 IPsec configuration example](#) on page 1765 and [OSPFv3 virtual link IPsec configuration example](#) on page 1772.

## OSPF and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPF routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPF routes through BGP. This configuration sends OSPF routes to a router that uses BGP.

You can redistribute routes

- on an interface basis
- on a global basis between protocols on a single VRF instance (intraVRF)
- between the same or different protocols on different VRF instances (interVRF)

To configure interface-based redistribution, configure a route policy, and then apply it to the interface. Configure the match parameter to the protocol from which to learn routes.

Use the **ip ospf redistribute** command to accomplish the (intraVRF) redistribution of routes through OSPF, so that OSPF redistribution occurs globally on all OSPF-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### *OSPF route redistribution and DvR*

DvR Controllers redistribute routes (direct routes, static routes and the default route) into the DvR domain. You can configure redistribution of DvR host routes into OSPF.

## ECMP with OSPFv3

The ECMP feature supports and complements OSPFv3 protocol.

With Equal Cost Multipath (ECMP), you can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

#### Note

To add OSPFv3 equal cost paths in the routing table, you must first enable IPv6 ECMP feature globally.

For scaling information on the ECMP paths supported per destination prefix, see [VOSS Release Notes](#).

## OSPFv3 and Route Redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if OSPFv3 routes exist in a router and they must travel through a BGP network, then configure redistribution of OSPFv3 routes through BGP. This configuration sends OSPFv3 routes to a router that uses BGP.

You can redistribute routes on a global basis between protocols on a single VRF instance (intraVRF).

Use the **ipv6 ospf redistribute** command to accomplish the (intraVRF) redistribution of routes through OSPF, so that OSPF redistribution occurs globally on all OSPF-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

#### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For a redistribute policy (OSPFv3) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

## OSPF configuration considerations

This section describes considerations to keep in mind as you configure OSPF.

## OSPF host route advertisements and nonbackbone areas

The switch does not associate a host route with a specific area. Therefore, if you create a host route in a nonbackbone area, nonbackbone (nonOSPF core) areas do not advertise it.

For example, in an OSPF network with multiple areas, including areas not adjacent to the core, which use virtual links, a host route on a router that belongs to a nonOSPF core area is not advertised on noncore routers.

To ensure host route advertisement, disable and enable OSPF on the noncore routers.

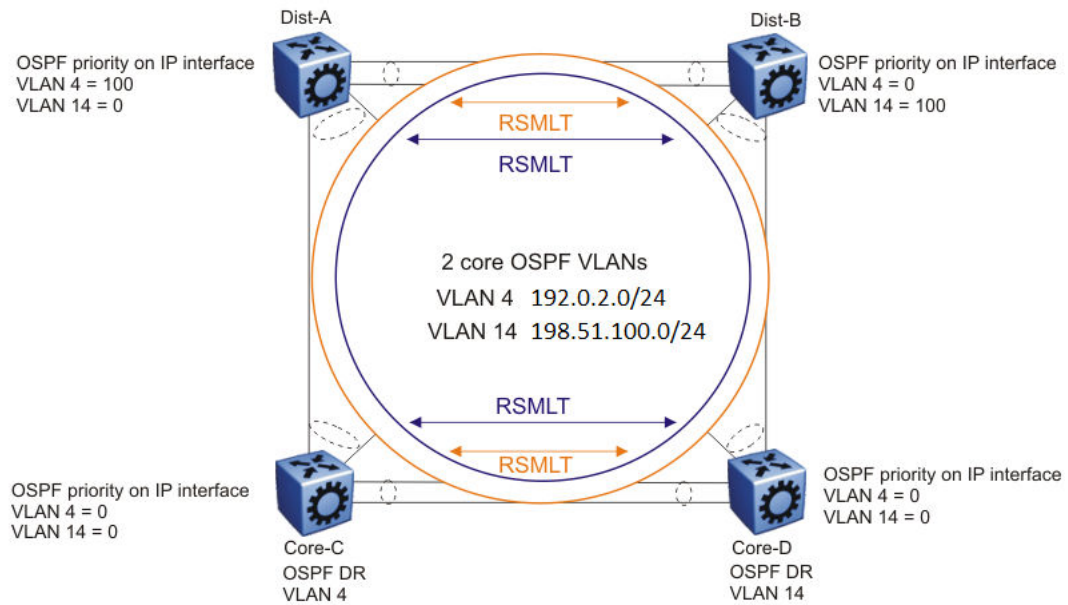

## OSPF with switch clustering

If the network loses the DR, the BDR immediately becomes the new DR on the broadcast segment. After OSPF elects the new DR, all routers perform an SPF run and issue new LSAs for the segment. The new DR generates a new network LSA for the segment and every router on the segment must refresh the router LSA.

Each router performs the SPF run as soon as it detects a new DR. Depending on the speed of the router, the router can perform the SPF run before it receives the new LSAs for the segments, which requires a second SPF run to update and continue routing across the segment. The OSPF hold-down timer does not permit two consecutive SPF runs within the value of the timer. This limitation can lead to traffic interruption of up to 10 seconds.

In a classical OSPF routed design, this situation never causes a problem because OSPF runs over multiple segments so even if a segment is not usable, routes are recalculated over alternative segments. Typical Routed Split MultiLink Trunking (RSMLT) designs only deploy a single OSPF routed vlan, which constitutes a single segment.

You can use RSMLT in a configuration with dual core VLANs to minimize traffic interruption when the network loses the DR. This configuration creates a second OSPF core VLAN, forcing different nodes to become the DR for each VLAN. Each OSPF core VLAN has a DR (priority of 100) and no BDRs. This configuration does not require a BDR because the two VLANs provide backup for each other from a routing perspective. See the following figure for a network example.

**Figure 204: RSMLT with dual core VLANs**

## OSPF Graceful Restart

In many OSPF networks, OSPF routers remove a restarting OSPF router from the network topology, if the router is restarted. This action causes all OSPF routers to re-converge and route around the restarting router. The OSPF Graceful Restart feature is an OSPF enhancement to allow an OSPF router to stay on the forwarding path when the software is restarting.

This feature is documented under RFC 3623 for OSPFv2 (IPv4) and RFC 5187 for OSPFv3 (IPv6). The switch software supports only helper mode for both OSPFv2 and OSPFv3 protocols.

### Helper Mode

Helper mode is a part of the OSPF Graceful restart feature. Helper mode uses the OSPF routers to help other OSPF routers on the network stay on the forwarding path while the software is restarting. The OSPF router sends a type of LSA called a GRACE-LSA to inform the other OSPF routers that it is restarting the software. When an OSPF router receives a GRACE-LSA from a neighbor OSPF Router, it enters the Helper mode for that neighbor on that network. An OSPF router supports Helper mode by default.

### Operations of Helper Mode

The following section describes the operations in the Helper mode:

- Entering Helper mode — An OSPF router enters the Helper mode provided the following conditions are true:
  - The router is fully adjacent with the neighbor already.
  - No changes have been made in the LSDB since the neighbor router started.
  - The grace period has not expired.

- Local policy configured parameters allow it to help the neighbor.
- The router is not in the process of restarting itself.

The OSPF router will not help the neighbor if any of the above conditions are not met.

If the OSPF router is already helping a neighbor, and receives another GRACE-LSA from the neighbor, it accepts the latest GRACE-LSA, and updates the grace period accordingly. The OSPF router in Helper mode continues to advertise its LSAs like the neighbor it is helping is still full, until any changes are made on the network during the grace period.

- Exiting Helper mode — An OSPF router exits the Helper mode, under the following conditions:
  - The GRACE-LSA is flushed. It means graceful restart has successfully terminated.
  - The GRACE-LSA's grace period expires.
  - There is a network topology change.

When an OSPF router exits Helper mode, the following actions occur:

- It recalculates the DR for the network.
- It re-originates its router LSA.
- If it is the DR, it re-originates the network LSA for the network.
- If it is a virtual link, it re-originates the router LSA for the virtual link transit area.

## Open Shortest Path First guidelines

Use OSPF to ensure that the switch can communicate with other OSPF routers. This section describes some general design considerations and presents a number of design scenarios for OSPF.

### *OSPF LSA limits*

To determine OSPF link-state advertisement (LSA) limits:

1. Use the command **show ip ospf area** to determine the LSA\_CNT and to obtain the number of LSAs for a given area.
2. Use the following formula to determine the number of areas. Ensure the total is less than 16,000 (16K):

$$\sum Adj_N * LSA\_CNT_N < 16k$$

N = 1 to the number of areas for each switch

Adj<sub>N</sub> = number of adjacencies for each Area N

LSA\_CNT<sub>N</sub> = number of LSAs for each Area N

For example, assume that a switch has a configuration of three areas with a total of 18 adjacencies and 1000 routes. This includes:

- 3 adjacencies with an LSA\_CNT of 500 (Area 1)
- 10 adjacencies with an LSA\_CNT of 1000 (Area 2)
- 5 adjacencies with an LSA\_CNT of 200 (Area 3)

Calculate the number as follows:

$$3*500+10*1000+5*200=12.5K < 16K$$

This configuration ensures that the switch operates within accepted scalability limits.

### *OSPF design guidelines*

Follow these additional OSPF guidelines:

- OSPF timers must be consistent across the entire network.
- Use OSPF area summarization to reduce routing table sizes.
- Use OSPF passive interfaces to reduce the number of active neighbor adjacencies.
- Use OSPF active interfaces only on intended route paths.

Configure wiring-closet subnets as OSPF passive interfaces unless they form a legitimate routing path for other routes.

- Minimize the number of OSPF areas for each switch to avoid excessive shortest-path calculations.

The switch executes the Dijkstra algorithm for each area separately.

- Ensure that the OSPF dead interval is at least four times the OSPF hello-interval.
- Use MD5 authentication on untrusted OSPF links.
- Use stub or NSSAs as much as possible to reduce CPU overhead.

### *OSPF and CPU utilization*

After you create an OSPF area route summary on an area border router, the summary route can attract traffic to the area border router for which the router does not have a specific destination route. Enabling ICMP unreachable-message generation on the switch can result in a high CPU utilization rate.

To avoid high CPU utilization, use a black-hole static route configuration. The black-hole static route is a route (equal to the OSPF summary route) with a next hop of 255.255.255.255. This configuration ensures that all traffic that does not have a specific next-hop destination route is dropped.

### *OSPF network design examples*

You can use OSPF routing in the core of a network.

The following figure describes a simple implementation of an OSPF network: enabling OSPF on two switches (S1 and S2) that are in the same subnet in one OSPF area.

**Figure 205: Example 1: OSPF on one subnet in one area**

The routers in the preceding figure use the following configuration:

- S1 has an OSPF router ID of 1.1.1.1, and the OSPF port uses an IP address of 192.0.2.1.
- S2 has an OSPF router ID of 1.1.1.2, and the OSPF port uses an IP address of 192.0.2.2.

The general method to configure OSPF on each routing switch is:

1. Enable OSPF globally.
2. Enable IP forwarding on the switch.
3. Configure the IP address, subnet mask, and VLAN ID for the port.
4. Disable RIP on the port, if you do not need it.
5. Enable OSPF for the port.

After you configure S2, the two switches elect a designated router and a backup designated router. They exchange hello packets to synchronize their link state databases.

The following figure shows a configuration in which OSPF operates on three switches. OSPF performs routing on two subnets in one OSPF area. In this example, S1 directly connects to S2, and S3 directly connects to S2, but traffic between S1 and S3 is indirect, and passes through S2.

**Figure 206: Example 2: OSPF on two subnets in one area**

The routers in example 2 use the following configuration:

- S1 has an OSPF router ID of 1.1.1.1, and the OSPF port uses an IP address of 192.0.2.1.
- S2 has an OSPF router ID of 1.1.1.2, and two OSPF ports use IP addresses of 192.0.2.2 and 198.51.100.1.
- S3 has an OSPF router ID of 1.1.1.3, and the OSPF port uses an IP address of 198.51.100.2.

The general method to configure OSPF on each routing switch is:

1. Enable OSPF globally.
2. Insert IP addresses, subnet masks, and VLAN IDs for the OSPF ports on S1 and S3, and for the two OSPF ports on S2. The two ports on S2 enable routing and establish the IP addresses related to the two networks.

3. Enable OSPF for each OSPF port allocated with an IP address.

After you configure all three switches for OSPF, they elect a designated router and a backup designated router for each subnet and exchange hello packets to synchronize their link-state databases.

The following figure shows an example where OSPF operates on two subnets in two OSPF areas. S2 becomes the area border router for both networks.

**Figure 207: Example 3: OSPF on two subnets in two areas**

The routers in scenario 3 use the following configuration:

- S1 has an OSPF router ID of 1.1.1.1. The OSPF port uses an IP address of 192.0.2.1, which is in OSPF area 1.
- S2 has an OSPF router ID of 1.1.1.2. One port uses an IP address of 192.0.2.2, which is in OSPF area 1. The second OSPF port on S2 uses an IP address of 198.51.100.1, which is in OSPF area 2.
- S3 has an OSPF router ID of 1.1.1.3. The OSPF port uses an IP address of 198.51.100.2, which is in OSPF area 2.

The general method to configure OSPF for this three-switch network is:

1. On all three switches, enable OSPF globally.
2. Configure OSPF on one network.

On S1, insert the IP address, subnet mask, and VLAN ID for the OSPF port. Enable OSPF on the port. On S2, insert the IP address, subnet mask, and VLAN ID for the OSPF port in area 1, and enable OSPF on the port. Both routable ports belong to the same network. Therefore, by default, both ports are in the same area.

3. Configure three OSPF areas for the network.
4. Configure OSPF on two additional ports in a second subnet.

Configure additional ports and verify that IP forwarding is enabled for each switch to ensure that routing can occur. On S2, insert the IP address, subnet mask, and VLAN ID for the OSPF port in area 2, and enable OSPF on the port. On S3, insert the IP address, subnet mask, and VLAN ID for the OSPF port, and enable OSPF on the port.

The three switches exchange hello packets.

In an environment with a mix of switches and routers from different vendors, you may need to manually modify the OSPF parameter `RtrDeadInterval` to 40 seconds.

## OSPF configuration using CLI

Configure Open Shortest Path First (OSPF) so that the switch can use OSPF routing to communicate with other OSPF routers and to participate in OSPF routing.

### Configuring OSPF globally

Configure OSPF parameters on the switch so that you can control OSPF behavior on the system. The switch uses global parameters to communicate with other OSPF routers. Globally configure OSPF before you configure OSPF for an interface, port, or VLAN.

#### Before You Begin

- Ensure that the switch has an IP interface.
- You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix `ip ospf` to commands. Not all parameters are configurable on non0 VRFs.

#### Procedure

1. Enter OSPF Router Configuration mode:  
`enable`  
  
`configure terminal`  
  
`router ospf`
2. Configure the OSPF router ID:  
`router-id {A.B.C.D}`
3. Configure the router as an autonomous system boundary router (ASBR):  
`as-boundary-router enable`

#### Note

Configure the following steps as and when needed.

4. Enable the automatic creation of OSPF virtual links:  
`auto-vlink`
5. Configure the OSPF default metrics:  
`default-cost {ethernet|fast-ethernet|forty-gig-ethernet|gig-ethernet|  
hundred-gig-ethernet|ten-gig-ethernet|twentyfive-gig-ethernet}  
<1-65535>]`  
  
`default-cost vlan <1-65535>]`
6. Configure the OSPF hold-down timer value:  
`timers basic holddown <3-60>`
7. Enable the RFC1583 compatibility mode:  
`rfc1583-compatibility enable`

8. Enable the router to issue OSPF traps:

```
trap enable
```

9. Verify the OSPF configuration:

```
show ip ospf [vrf WORD<1-16>] [vrfs WORD<0-512>]
```

10. Exit OSPF Router Configuration mode:

```
exit
```

You return to Global Configuration mode.

11. Enable OSPF for the switch:

```
router ospf enable
```

## Example

Configure the OSPF router ID to 192.0.2.2, enable the automatic creation of OSPF virtual links, and enable traps. Configure the default cost metric for Ethernet to 101, for fast Ethernet to 110, and for gig-Ethernet, ten-gig-Ethernet, twentyfive-gig-ethernet, forty-gig-Ethernet, and hundred-gig-ethernet to 20, and vlan to 1. Configure the basic holdown to 10. Enable OSPF for the switch, and review the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#router-id 192.0.2.2
Switch:1(config-ospf)#auto-vlink
Switch:1(config-ospf)#default-cost ethernet 101
Switch:1(config-ospf)#default-cost fast-ethernet 110
Switch:1(config-ospf)#default-cost gig-ethernet 20
Switch:1(config-ospf)#default-cost ten-gig-ethernet 20
Switch:1(config-ospf)#default-cost twentyfive-gig-ethernet 20
Switch:1(config-ospf)#default-cost Forty-gig-ethernet 20
Switch:1(config-ospf)#default-cost hundred-gig-ethernet 20
Switch:1(config-ospf)#default-cost vlan 2
Switch:1(config-ospf)#timers basic holddown 10
Switch:1(config-ospf)#trap enable
Switch:1(config-ospf)#exit
Switch:1(config)#router ospf enable
Switch:1(config)#show ip ospf

### Variable definitions

The following table defines parameters for the **router-id** command.

| Variable                     | Value                                                                      |
|------------------------------|----------------------------------------------------------------------------|
| <code>&lt;A.B.C.D&gt;</code> | Configures the OSPF router ID IP address, where A.B.C.D is the IP address. |

The following table defines parameters for the **default-cost** command.

| Variable                                             | Value                                                                                                                                                                                                          |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ethernet &lt;1-65535&gt;</code>                | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>ethernet</i> is for 10 Mb/s Ethernet (default is 100).                       |
| <code>fast-ethernet &lt;1-65535&gt;</code>           | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>fast-ethernet</i> is for 100 Mb/s (Fast) Ethernet (default is 10).           |
| <code>forty-gig-ethernet &lt;1-65535&gt;</code>      | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>forty-gig-ethernet</i> is for 40 Gigabit Ethernet (default is 1).            |
| <code>gig-ethernet &lt;1-65535&gt;</code>            | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>gig-ethernet</i> is for Gigabit Ethernet (default is 1).                     |
| <code>hundred-gig-ethernet &lt;1-65535&gt;</code>    | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>hundred-gig-ethernet</i> is for 100 Gigabit Ethernet (default is 1).         |
| <code>ten-gig-ethernet &lt;1-65535&gt;</code>        | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. <i>ten-gig-ethernet</i> is for 10 Gigabit Ethernet (default is 1).              |
| <code>twentyfive-gig-ethernet &lt;1-65535&gt;</code> | Configures the OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet. On a channelized 100 Gbps port, the default-cost for each 25 Gbps channel is 1. |
| <code>vlan &lt;1-65535&gt;</code>                    | Configures the OSPF default metrics. <i>vlan</i> is for Vlan interfaces (default is 10).                                                                                                                       |

The following table defines parameters for the **timers basic holddown** command.

| Variable | Value                                                                    |
|----------|--------------------------------------------------------------------------|
| <3-60>   | Configures the OSPF hold-down timer value in seconds. The default is 10. |

The following table defines parameters for the **show ip ospf** command.

| Variable                  | Value                         |
|---------------------------|-------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.      |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs. |

## Configure OSPF for a Port or VLAN

Configure OSPF parameters on a port or VLAN so you can control OSPF behavior on the port or VLAN.

### Before You Begin

- Enable OSPF globally.
- Ensure IP interfaces exist and are enabled.

### About This Task

To configure OSPF on a VRF instance for a port or VLAN, you configure OSPF on the port or VLAN, and then associate the port or VLAN with the VRF.

#### Important

When you enable OSPF on a VLAN or a port, the switch automatically creates an area 0.0.0.0, and advertises it on the specific VLAN or port, by default. To avoid this behavior, you must manually configure the VLAN or port into a properly configured area on the switch.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the OSPF interface area ID:

```
ip ospf area {A.B.C.D}
```

3. Enable OSPF routing:

```
ip ospf enable
```

- Choose the OSPF update authentication method:

```
ip ospf authentication-type <message-digest|none|sha-1|sha-2|simple>
```

Both sides of an OSPF connection must use the same authentication type and key.

- If you choose simple, you must configure the password.

```
ip ospf authentication-key WORD<0-8>
```

- If you choose an authentication key other than simple such as MD5, Sha-1 or Sha-2, you must configure the digest key first and then assign it to the authentication type.

- Create the digest-key:

```
ip ospf digest-key <1-255> key WORD<0-16>
```

- Assign the newly created digest key to the authentication type:

```
ip ospf authentication-type <message-digest|none|sha-1|sha-2|simple>
primary-digest-key <1-255>
```

- Specify the interface type:

```
ip ospf network <broadcast|nbma|passive>
```

- Configure the remaining parameters as required, or accept their default values. View the following variable definitions table for more information.

### Example

Configure the OSPF interface area ID to 192.0.2.2, enable OSPF routing, choose the OSPF update authentication method as message-digest, and specify the interface type as broadcast.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#ip ospf area 192.0.2.2
Switch:1(config-if)#ip ospf enable
Switch:1(config-if)#ip ospf authentication-type message-digest
Switch:1(config-if)#ip ospf network broadcast
```

### Variable Definitions

The following table defines parameters for the **ip ospf** commands.

| Variable                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>advertise-when-down</i><br><i>enable</i>         | Enables or disables AdvertiseWhenDown. If enabled, OSPF advertises the network on this interface as up, even if the port is down. The default is disabled.<br>After you configure a port with no link and enable advertise-when-down, OSPF does not advertise the route until the port is active. OSPF advertises the route even when the link is down. To disable advertising based on link status, you must disable this parameter. |
| <i>area {A.B.C.D}</i>                               | Configures the OSPF identification number for the area, typically formatted as an IP address.                                                                                                                                                                                                                                                                                                                                         |
| <i>authentication-key</i><br><i>WORD&lt;0-8&gt;</i> | Configures the eight-character simple password authentication key for the port or VLAN.                                                                                                                                                                                                                                                                                                                                               |

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authentication-type</i><br><message-digest none <br>sha-1 sha-2 simple> | <p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha-1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>SHA-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <i>bfd</i>                                                                 | Enable Bidirectional Forwarding Detection (BFD) at the OSPF application level. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>cost</i> <0-65535>                                                      | Configures the OSPF cost associated with this interface and advertised in router link advertisements. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>dead-interval</i><br><0-2147483647>                                     | Configures the router OSPF dead interval, which is the number of seconds the OSPF neighbors of a switch must wait before they assume the OSPF router is down. The default is 40. The value must be at least four times the hello interval.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>enable</i>                                                              | Enables OSPF on the port or VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>hello-interval</i><br><1-65535>                                         | Configures the OSPF hello interval, which is the number of seconds between hello packets sent on this interface. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>message-digest-key</i><br><1-255> md5 WORD<0-16>                        | <p>Configures the MD5 key. You can configure a maximum of two MD5 keys for an interface.</p> <p>If you configure two keys, the interface uses only the first key. To transition to the second key, configure a <i>primary-md5-key</i> to use the ID of the second configured key, and then delete the first key.</p> <p><b>Important:</b><br/>Use the correct key id when two keys are configured. The key id and md5 password must match with the other OSPF routers, to form the OSPF adjacencies.</p> <p>&lt;1-255&gt; is the ID for the MD5 key<br/>WORD&lt;0-16&gt; is an alphanumeric password of up to 16 bytes {string length 0-16}</p>                                                                                                                                                                                                                                                                                                                                                                   |
| <i>primary-digest-key</i><br><1-255>                                       | Use this parameter to transition to a new MD5 key. The new MD5 key changes the primary key used to encrypt outgoing packets. <1-255> is the ID for the new MD5 key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Variable                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mtu-ignore enable</code>                      | Enables maximum transmission unit (MTU) ignore. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable <code>mtu-ignore</code> . The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.                                                                                                                                                                                                                                 |
| <code>network &lt;broadcast nbma passive&gt;</code> | Specifies the type of OSPF interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>poll-interval &lt;0-2147483647&gt;</code>     | Configures the OSPF poll interval in seconds. The default is 120.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>priority &lt;0-255&gt;</code>                 | Configures the OSPF priority for the port during the election process for the designated router. The port with the highest priority number is the best candidate for the designated router. If you configure the priority to 0, the port cannot become either the designated router or a backup designated router. The default is 1.                                                                                                                                                                   |
| <code>retransmit-interval &lt;0-3600&gt;</code>     | Configures the retransmit interval for the virtual interface, which is the number of seconds between link-state advertisement retransmissions.                                                                                                                                                                                                                                                                                                                                                         |
| <code>transit-delay &lt;0-3600&gt;</code>           | Configures the transit delay for the virtual interface, which is the estimated number of seconds required to transmit a link-state update over the interface.                                                                                                                                                                                                                                                                                                                                          |
| <code>&lt;1-4059&gt;</code>                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br>This variable applies only to VLAN interfaces, not to ports. |

## Viewing OSPF errors on a port

Check OSPF errors for administrative and troubleshooting purposes.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display extended information about OSPF errors for the specified port or for all ports:

```
show ip ospf port-error [port {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable definitions

The following table defines parameters for the **show ip ospf port-error** command.

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]<br/>[-slot/port[/sub-port]]<br/>[,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>vrf WORD&lt;1-16&gt;</code>                                          | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <code>vrfids WORD&lt;0-512&gt;</code>                                      | Specifies a range of VRFs by ID number.                                                                                                                                                                                                                                                                                                                       |

## Configuring OSPF areas on the router

Import information from other areas to learn their OSPF relationships. Perform this procedure to create normal, stubby, or not-so-stubby areas (NSSA).

### Before You Begin

- Ensure that the VLAN exists if you configure OSPF on a VLAN.
- You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

### About This Task

Place stubby or NSSAs at the edge of an OSPF routing domain. Ensure that you configure all routers in a stubby or NSSA as stubby or NSSA, respectively.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create an OSPF area:
 

```
area {A.B.C.D}
```
3. Specify the area type:
 

```
area {A.B.C.D} import <external|noexternal|nssa>
```
4. Configure other OSPF area parameters as required.
5. Ensure that the configuration is correct:
 

```
show ip ospf area [vrf WORD<1-16>] [vrfids WORD<0-255>]
```

### Example

Create the OSPF area 192.0.2.10, and specify the area type as NSSA. Configure the area support to import summary advertisements into a stub area and configure the import external option for this area as stub. Ensure the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#area 192.0.2.10
Switch:1(config-ospf)#area 192.0.2.10 import nssa
Switch:1(config-ospf)#area 192.0.2.10 import stub
Switch:1(config-ospf)#area 192.0.2.10 import-summaries enable
Switch:1(config-ospf)#show ip ospf area
```

```

### Variable Definitions

The following table defines parameters for the **area {A.B.C.D}** command.

| Variable                                 | Value                                                                                                                                                                                                                |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>default-cost</i><br><0-16777215>      | Specifies the stub area default metric for this stub area, which is the cost from 0-16777215. This metric value applies at the indicated type of service.                                                            |
| <i>import</i> <external noexternal nssa> | Specifies the type of area: <ul style="list-style-type: none"> <li>external—stub and NSSA are both false</li> <li>noexternal—configures the area as stub area.</li> <li>nssa—configures the area as NSSA.</li> </ul> |
| <i>import-summaries enable</i>           | Configures the area support to import summary advertisements into a stub area. Use this variable only if the area is a stub area.                                                                                    |
| <i>stub</i>                              | Configures the import external option for this area as stub. A stub area has only one exit point (router interface) from the area.                                                                                   |

The following table defines parameters for the **show ip ospf area** command.

| Variable                  | Value                         |
|---------------------------|-------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies a VRF.              |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs. |

## Viewing the OSPF area information

View the OSPF area information.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF area information:  
show ip ospf area [vrf WORD<1-16>] [vrfids WORD<0-512>]

**Example**

View the OSPF area information:

```
Switch:1>enable
Switch:1#show ip ospf area

=====

```

*Variable definitions*

The following table defines parameters for the **show ip ospf area** command.

| Variable           | Value                         |
|--------------------|-------------------------------|
| vrf WORD<1-16>     | Specifies a VRF by name.      |
| vrfids WORD<0-512> | Specifies a range of VRF IDs. |

**Configuring OSPF aggregate area ranges on the router**

Use aggregate area ranges to reduce the number of link-state advertisements required within the area. You can also control advertisements.

**Before You Begin**

- Enable OSPF globally.
- Ensure that an area exists.
- You configure OSPF area ranges on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

**Procedure**

1. Enter OSPF Router Configuration mode:  
enable  
  
configure terminal  
  
router ospf

2. Configure an OSPF area range:
 

```
area range {A.B.C.D} {A.B.C.D/X} <summary-link|nssa-extlink>
```
3. Configure the advertised metric cost:
 

```
area range {A.B.C.D} {A.B.C.D/X} <summary-link|nssa-extlink>
advertise-metric <0-65535>
```
4. Configure the advertisement mode:
 

```
area range {A.B.C.D} {A.B.C.D/X} <summary-link|nssa-extlink>
advertise-mode <summarize|suppress|no-summarize>
```
5. Ensure that the configuration is correct:
 

```
show ip ospf area-range [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Configure an OSPF area range to 192.0.2.2, configure the advertised metric cost to 10, and the advertisement mode to summarize.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)# area range 192.0.2.2 255.255.255.0/32 summary-link
Switch:1(config-ospf)# area range 192.0.2.2 255.255.255.0/32 summary-link advertise-
metric 10
Switch:1(config-ospf)# area range 192.0.2.2 255.255.255.0/32 summary-link advertise-mode
summarize
```

### Variable definitions

The following table defines parameters for the **area range** command.

| Variable                                                                | Value                                                                                                                                          |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D} {A.B.C.D/X}</i>                                            | <i>{A.B.C.D}</i> identifies an OSPF area and <i>{A.B.C.D/X}</i> is the IP address and subnet mask of the range, respectively.                  |
| <i>advertise-metric</i><br><i>&lt;0-65535&gt;</i>                       | Changes the advertised metric cost of the OSPF area range.                                                                                     |
| <i>advertise-mode</i><br><i>&lt;summarize suppress no-summarize&gt;</i> | Changes the advertisement mode of the range.                                                                                                   |
| <i>&lt;summary-link nssa-extlink&gt;</i>                                | Specifies the link-state advertisement (LSA) type. If you configure the range as type nssa-extlink, you cannot configure the advertise-metric. |

The following table defines parameters for the **show ip ospf area-range** command.

| Variable                        | Value                         |
|---------------------------------|-------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF by name.      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRF IDs. |

## Viewing the OSPF area range information

View the OSPF area range information.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF area range information:  
show ip ospf area-range [vrf WORD<1-16>] [vrfids WORD<0-512>]

*Variable definitions*

The following table defines parameters for the **ip ospf area-range** command.

| Variable           | Value                         |
|--------------------|-------------------------------|
| vrf WORD<1-16>     | Specifies a VRF by name.      |
| vrfids WORD<0-512> | Specifies a range of VRF IDs. |

**Enabling automatic virtual links**

Use automatic virtual links to provide an automatic, dynamic backup link for vital OSPF traffic. Automatic virtual links require more system resources than manually configured virtual links.

**Before You Begin**

- You configure automatic virtual links on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

**Procedure**

1. Enter OSPF Router Configuration mode:  
enable  
  
configure terminal  
  
router ospf
2. Enable the automatic virtual links feature for the router:  
auto-vlink

**Configuring an OSPF area virtual interface**

Use manual virtual interfaces to provide a backup link for vital OSPF traffic with a minimum of resource use.

**Before You Begin**

- Enable OSPF globally.
- You configure an OSPF area virtual interface on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

**About This Task**

Both sides of the OSPF connection must use the same authentication type and key.

You cannot configure a virtual link using a stub area or an NSSA.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create an OSPF area virtual interface:
 

```
area virtual-link {A.B.C.D} {A.B.C.D}
```
3. Choose the OSPF update authentication method:
 

```
area virtual-link {A.B.C.D} {A.B.C.D} authentication-type <message-
digest|none|sha-1|sha-2|simple>
```

Both sides of an OSPF connection must use the same authentication type and key.

4. If required, configure an MD5 key for the virtual interface:
 

```
area virtual-link message-digest-key {A.B.C.D} {A.B.C.D} <1-255> md5-
key WORD<1-16>
```
5. Configure optional parameters, as required.
6. Ensure that the configuration is correct:
 

```
show ip ospf virtual-link {A.B.C.D} {A.B.C.D} [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

### Example

Create an OSPF area virtual interface with an area ID of 192.0.2.12 and the virtual interface ID of 198.51.100.2, choose the OSPF update authentication method to simple, and the hello-interval to 100.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#area virtual-link 192.0.2.12 198.51.100.2 198.51.100.2
Switch:1(config-ospf)#area virtual-link 192.0.2.12 198.51.100.2 198.51.100.2
authentication-type simple
Switch:1(config-ospf)#area virtual-link 192.0.2.12 198.51.100.2 198.51.100.2 hello-
interval 100
```

### Variable Definitions

The following table defines parameters for the **area virtual-link** command.

| Variable                                            | Value                                                        |
|-----------------------------------------------------|--------------------------------------------------------------|
| <i>{A.B.C.D} {A.B.C.D}</i>                          | Specifies the area ID and the virtual interface ID.          |
| <i>authentication-key</i><br><i>WORD&lt;0-8&gt;</i> | Configures the authentication key of up to eight characters. |

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authentication-type</i><br><message-digest none <br>sha-1 sha-2 simple> | <p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha-1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <i>dead-interval</i><br><0-2147483647>                                     | Configures the number of seconds between router hello packets before neighbors declare the router down. This value must be at least four times the hello interval value. The default is 60.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>hello-interval</i> <1-65535>                                            | Configures the hello interval, in seconds, on the virtual interface for the length of time (in seconds) between the hello packets that the router sends on the interface. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>primary-digest-key</i><br><1-255>                                       | Use this parameter to transition to a new MD5 key; It changes the primary key used to encrypt outgoing packets. <1-255> is the ID for the MD5 key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>retransmit-interval</i><br><0-3600>                                     | Configures the retransmit interval for the virtual interface, the number of seconds between LSA retransmissions. The range is from 1-3600.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>transit-delay</i> <0-3600>                                              | Configures the transit delay for the virtual interface, the estimated number of seconds required to transmit a link-state update over the interface. The range is from 1-3600.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The following table defines parameters for the **area virtual-link message-digest-key** command.

| Variable                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i> <i>{A.B.C.D}</i> | Specifies the area ID and the virtual interface ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>&lt;1-255&gt;</i>              | Specifies the ID for the message digest key                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>md5-key WORD&lt;1-16&gt;</i>   | <p>Configures the MD5 key, you can configure a maximum of two MD5 keys for an interface. If you configure two keys, the interface uses only the first key. To transition to the second key, configure a primary-md5-key to use the ID of the second configured key, and then delete the first key.</p> <p><b>Important:</b><br/>Use the correct key id when two keys are configured. The key id and md5 password must match with the other OSPF routers, to form the OSPF adjacencies.</p> <p><i>WORD&lt;1-16&gt;</i> is an alphanumeric password of up to 16 characters.</p> |

The following table defines parameters for the **show ip ospf virtual-link** command.

| Variable                                      | Value                                               |
|-----------------------------------------------|-----------------------------------------------------|
| <i>&lt;A.B.C.D&gt;</i> <i>&lt;A.B.C.D&gt;</i> | Specifies the area ID and the virtual interface ID. |
| <i>vrf WORD&lt;1-16&gt;</i>                   | Specifies a VRF.                                    |
| <i>vrfids WORD&lt;0-512&gt;</i>               | Specifies a range of VRF IDs.                       |

## Configuring an OSPF area on a VLAN or port

Import information from other areas to learn their OSPF relationships. Perform this procedure to create normal, stubby, or NSSA. Place stubby or NSSAs at the edge of an OSPF routing domain.

### Before You Begin

- Enable OSPF globally.
- Ensure that the VLAN exists.

### About This Task

Ensure that you configure all routers in a stubby or NSSA as stubby or NSSA, respectively.

To configure OSPF areas on a VRF instance for a port or VLAN, you configure OSPF on the port or VLAN, and then associate the port or VLAN with the VRF.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an OSPF area on the VLAN or port:

```
ip ospf area {A.B.C.D}
```

3. Specify the type of network:

```
ip ospf network <broadcast|nbma|passive>
```

4. Configure other OSPF area parameters as required.

## Example

Create an OSPF area 192.0.2.2 on VLAN 1, and specify the type of network as broadcast.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#ip ospf area 192.0.2.2
Switch:1(config-if)#ip ospf network broadcast
```

### Variable Definitions

The following table defines parameters for the **ip ospf** command.

| Variable                               | Value                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------|
| {A.B.C.D}                              | Specifies the area ID.                                                                  |
| <i>authentication-key</i><br>WORD<0-8> | Configures the eight-character simple password authentication key for the port or VLAN. |

| Variable                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <i>authentication-type</i><br><message-digest none <br>sha-1 sha-2 simple> | Specifies the type of authentication required for the interface. <ul style="list-style-type: none"> <li>• none—Specifies that no authentication required.</li> <li>• simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter.</li> <li>• MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key.</li> <li>• sha-1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long.</li> <li>• sha-2—Specifies SHA-2, which offers the hash function SHA-256.</li> </ul> <p><b>Note:</b><br/>sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p> |
| <i>cost</i> <0-65535>                                                      | Configures the OSPF cost associated with this interface and advertised in router link advertisements. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>dead-interval</i><br><0-2147483647>                                     | Configures the the number of seconds between router hello packets before neighbors declare the router down. This value must be at least four times the hello interval value. The default is 60.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>hello-interval</i> <1-65535>                                            | Configures the hello interval, in seconds, on the virtual interface for the length of time (in seconds) between the hello packets that the router sends on the interface. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>mtu-ignore enable</i>                                                   | Enables MTU ignore. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable mtu-ignore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>network</i> <broadcast nbma <br>passive>                                | Specifies the type of OSPF interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>poll-interval</i><br><0-2147483647>                                     | Configures the OSPF poll interval in seconds. The default is 120.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>primary-digest-key</i><br><1-255>                                       | Use this parameter to transition to a new MD5 key; it changes the primary key used to encrypt outgoing packets. <1-255> is the ID for the message digest key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>priority</i> <0-255>                                                    | Configures the OSPF priority for the port during the election process for the designated router. The port with the highest priority number is the best candidate for the designated router. If you set the priority to 0, the port cannot become either the designated router or a backup designated router. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>retransmit-interval</i><br><0-3600>                                     | Configures the retransmit interval: the number of seconds between LSA retransmissions.<br>The range is from 1-3600.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>transit-delay</i> <0-3600>                                              | Configures the transit delay: the estimated number of seconds it takes to transmit a link-state update over the interface.<br>The range is from 1-3600.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Configuring an OSPF host route

Configure host routes when the switch resides in a network that uses routing protocols other than OSPF. A host route is a more-specific route and is used even if it is higher cost than a network route.

### Before You Begin

- Globally enable OSPF.
- You configure an OSPF host route on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

### About This Task

Use a host route to create a custom route to a specific host to control network traffic.

You can specify which hosts directly attach to the router, and the metrics and types of service to advertise for the hosts.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create a host route:
 

```
host-route {A.B.C.D} [metric <0-65535>]
```
3. Ensure that the configuration is correct:
 

```
show ip ospf host-route [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Create a host route on IP address 192.0.2.20 with a metric of 20.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#host-route 192.0.2.20 metric 20
Switch:1(config-ospf)#show ip ospf host-route
Switch:1(config-ospf)#show ip ospf host-route
```

```
=====
 OSPF Host Route - GlobalRouter
=====
HOSTIPADDR TOS METRIC

192.0.2.20 - 20
```

### Variable definitions

The following table defines parameters for the **host-route** command.

| Variable                      | Value                                                          |
|-------------------------------|----------------------------------------------------------------|
| <i>{A.B.C.D}</i>              | Specifies the IP address of the host router in a.b.c.d format. |
| <i>metric &lt;0-65535&gt;</i> | Configures the metric (cost) for the host route.               |

The following table defines parameters for the **show ip ospf host-route** command.

| Variable                        | Value                         |
|---------------------------------|-------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF by name.      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRF IDs. |

## Configuring OSPF NBMA neighbors

Configure NBMA neighbors so that the interface can participate in designated router election. All OSPF neighbors that you manually configure are NBMA neighbors.

### Before You Begin

- Enable OSPF globally.
- Ensure that the interface uses an IP address.
- Ensure that the interface is NBMA.
- You configure OSPF NBMA neighbors on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on non0 VRFs.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create an NBMA OSPF neighbor:
 

```
neighbor {A.B.C.D} priority <0-255>
```
3. Ensure that the configuration is correct:
 

```
show ip ospf neighbor [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Create an NBMA OSPF neighbor.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#neighbor 198.51.100.2 priority 10
```

*Variable definitions*

The following table defines parameters for the **neighbor** command.

| Variable                      | Value                                                 |
|-------------------------------|-------------------------------------------------------|
| <i>{A.B.C.D}</i>              | Identifies an OSPF area in IP address format a.b.c.d. |
| <i>priority &lt;0-255&gt;</i> | Changes the priority level of the neighbor.           |

The following table defines parameters for the **show ip ospf neighbors** command.

| Variable                        | Value                         |
|---------------------------------|-------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies a VRF by name.      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies a range of VRF IDs. |

## Enabling or disabling Helper mode for OSPFv2

### About This Task

By default, OSPF Helper mode is enabled when OSPF is configured. You can disable helper mode by the following command and re-enable it again by using **no** or **default** operators.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Enter the following command to disable Helper mode:
 

```
helper-mode-disable
```
3. Enter the following command to enable Helper mode:
 

```
no helper-mode-disable
```

Or

```
default helper-mode disable
```

### Example

Disable Helper mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#helper-mode-disable
```

Enable Helper mode:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router ospf
Switch:1(config-ospf)#no helper-mode-disable
```

## Apply OSPF Route Acceptance Policies

Use a route policy to define how the switch redistributes external routes from a specified source into an OSPF domain. The policy defines which route types the switch accepts and redistributes.

### Before You Begin

- Enable OSPF globally.
- Ensure that a route policy exists.
- Ensure that the area exists.
- You apply OSPF route acceptance policies on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip ospf**. The VRF must have an RP Trigger of OSPF. Not all parameters are configurable on nonO VRFs.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```
2. Create an acceptance policy instance:

```
accept adv-rtr {A.B.C.D}
```
3. Configure the type of metric to accept:

```
accept adv-rtr {A.B.C.D} metric-type <type1|type2|any>
```
4. Indicate the route policy:

```
accept adv-rtr {A.B.C.D} route-map WORD<0-64>
```
5. Enable a configured OSPF route acceptance instance:

```
accept adv-rtr {A.B.C.D} enable
```
6. Ensure that the configuration is correct:

```
show ip ospf accept [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

Create an acceptance policy instance, configure the type of metric to accept, indicate the route policy and enable the OSPF route acceptance instance. Ensure the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#router ospf
Switch:1(config-ospf)#accept adv-rtr 192.0.2.11
Switch:1(config-ospf)#accept adv-rtr 192.0.2.11 metric-type type1
Switch:1(config-ospf)#accept adv-rtr 192.0.2.11 route-map test1
Switch:1(config-ospf)#accept adv-rtr 192.0.2.11 enable
Switch:1#show ip ospf accept
=====
 Ospf Accept - GlobalRouter
=====
ADV_RTR MET_TYPE ENABLE POLICY

192.0.2.11 type1 true test1
```

### Variable definitions

The following table defines parameters for the **accept adv-rtr** command.

| Variable                             | Value                                                 |
|--------------------------------------|-------------------------------------------------------|
| <A.B.C.D>                            | Specifies the IP address.                             |
| <i>enable</i>                        | Enables an OSPF acceptance policy.                    |
| <i>metric-type</i> <type1 type2 any> | Configures the metric type as type 1, type 2, or any. |
| <i>route-map</i> WORD<0-64>          | Configures the route policy by name.                  |

The following table defines parameters for the **ip ospf accept** command.

| Variable                  | Value                         |
|---------------------------|-------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.      |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs. |

## View the OSPF Configuration Information

View the OSPF configuration information.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF configuration information:  
show ip ospf accept [vrf WORD<1-16>] [vrfids WORD<0-512>]

### Example

```
Switch:1#show ip ospf accept
=====
 Ospf Accept - GlobalRouter
```

```

=====
ADV_RTR MET_TYPE ENABLE POLICY

192.0.2.11 type1 true test1

```

### Variable definitions

The following table defines parameters for the **show ip ospf accept** command.

| Variable                              | Value                         |
|---------------------------------------|-------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF by name.      |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRF IDs. |

## Viewing the OSPF link-state database

View the area advertisements and other information in the LSDB to ensure correct OSPF operations.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF link-state database:  
show ip ospf lsdb [adv\_rtr {A.B.C.D}] [area {A.B.C.D}>] [lsa-type <0-7>] [lsid {A.B.C.D}] [vrf WORD<1-16>] [vrfids WORD<0-512>] [detail]

### Example

```

Switch(config-ospf)#show ip ospf lsdb
=====
 OSPF LSDB - GlobalRouter
=====

### Variable definitions

The following table defines parameters for the **show ip ospf lsdb** command.

| Variable                  | Value                                                            |
|---------------------------|------------------------------------------------------------------|
| <i>adv_rtr</i> {A.B.C.D}  | Specifies the advertising router.                                |
| <i>area</i> {A.B.C.D}     | Specifies the OSPF area.                                         |
| <i>detail</i>             | Provides detailed output.                                        |
| <i>lsa-type</i> <0-7>     | Specifies the link-state advertisement type in the range of 0-7. |
| <i>lsid</i> {A.B.C.D}     | Specifies the link-state ID.                                     |
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.                                         |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs.                                    |

## Viewing the OSPF external link-state database

View the LSDB to determine externally learned routing information. The system displays the information for all metric types or for the type you specify.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View the OSPF autonomous system external (ASE) link-state advertisements:
 

```
show ip ospf ase [metric-type <1-2>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

```

Switch:1#show ip ospf ase

=====
 OSPF AsExternal Lsas - GlobalRouter
=====

LSTYPE LINKSTATEID ADV_ROUTER ETYPE METRIC ASE_FWD_ADDR AGE SEQ_NBR
CSUM

```

### Variable definitions

The following table defines parameters for the **show ip ospf ase** command.

| Variable                  | Value                       |
|---------------------------|-----------------------------|
| <i>metric-type</i> <1-2>  | Specifies the metric type.  |
| <i>vrf</i> WORD<1-16>     | Identifies the VRF by name. |
| <i>vrfids</i> WORD<0-512> | Specifies a VRF by ID.      |

## Configuring route redistribution to OSPF

Configure a redistribute entry to announce certain routes into the OSPF domain, including DvR host routes, static routes, direct routes, Routing Information Protocol (RIP) routes, OSPF routes, IS-IS routes or Border Gateway Protocol (BGP) routes. Optionally, use a route policy to control the redistribution of routes.

### Before You Begin

- Enable OSPF globally.
- Ensure that a route policy exists.
- Ensure that you set OSPF as the boundary router.

#### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create the redistribution instance:
 

```
redistribute <bgp|direct|isis|ospf|rip|static|dvr> [vrf-src
WORD<1-16>]
```
3. Apply a route policy if required:
 

```
redistribute <bgp|direct|isis|ospf|rip|static|dvr> route-map
WORD<0-64> [vrf-src WORD<1-16>]
```

4. Configure other parameters, as required.

5. Enable the redistribution.

```
redistribute <bgp|direct|isis|ospf|rip|static|dvr> enable [vrf-src
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip ospf redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution.

```
ip ospf apply redistribute <bgp|direct|isis|ospf|rip|static|dvr> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

Changes do not take effect until you apply them.

9. View all routes (including DvR host routes) that are redistributed into OSPF:

a. View the routes that are redistributed from the GRT to OSPF:

```
show ip ospf lsdb
```

b. View the routes that are redistributed to OSPF for a specific VRF instance:

```
show ip ospf lsdb [vrf WORD<1-64>] [vrfids WORD<0-512>]
```

## Example

### Example 1:

Redistribute static routes from the GRT to OSPF.

Create the redistribution instance, apply a route policy, enable redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#redistribute static

WARNING: Routes will not be injected until apply command is issued after enable command
Switch:1(config-ospf)#redistribute static route-map policy1
Switch:1(config-ospf)#redistribute static enable
Switch:1(config-ospf)#exit
Switch:1(config)#ip ospf apply redistribute static
Switch:1(config)#show ip ospf redistribute

=====
 OSPF Redistribute List - GlobalRouter
=====
```

| SRC-VRF      | SRC  | MET | MTYPE | SUBNET | ENABLE | RPOLICY |
|--------------|------|-----|-------|--------|--------|---------|
| GlobalRouter | STAT | 0   | type2 | allow  | TRUE   | policy1 |
| GlobalRouter | DVR  | 0   | type2 | allow  | FALSE  |         |

### Example 2:

Redistribute DvR host routes from the GRT to OSPF:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#router ospf
Switch:1(config-ospf)#redistribute dvr
Switch:1(config-ospf)#redistribute dvr enable
Switch:1(config-ospf)#exit
Switch:1(config)#ip ospf apply redistribute dvr
Switch:1(config)#show ip ospf redistribute
```

```
=====
 OSPF Redistribute List - GlobalRouter
=====

SRC-VRF SRC MET MTYPE SUBNET ENABLE RPOLICY

GlobalRouter DVR 0 type2 allow TRUE test1
```

### Example 3:

Redistribute DvR host routes to OSPF for a specific VRF `vrf1`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrf1
Switch:1(router-vrf)#ip ospf redistribute dvr
Switch:1(router-vrf)#ip ospf redistribute dvr enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip ospf apply redistribute dvr vrf vrf1
```

View the DvR host routes that are distributed into OSPF:

```
Switch:1(config)#show ip ospf lsdb vrf vrf1

### Variable definitions

The following table defines parameters for the **redistribute** command.

| Variable                              | Value                                                                                                                                                                                                                                              |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                         | Enables the OSPF route redistribution instance.                                                                                                                                                                                                    |
| <i>metric</i> <0-65535>               | Configures the metric to apply to redistributed routes.                                                                                                                                                                                            |
| <i>metric-type</i> <type1 type2>      | Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. |
| <i>route-map</i> WORD<0-64>           | Configures the route policy to apply to redistributed routes.                                                                                                                                                                                      |
| <i>subnets</i> <allow suppress>       | Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.                                                                                                                                       |
| <i>vrf-src</i> WORD<1-16>             | Specifies the optional source VRF instance. You can use this variable with the other command variables.                                                                                                                                            |
| <bgp direct isis ospf rip static dvr> | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, dvr or static.                                                                                                                 |

The following table defines parameters for the **ip ospf apply redistribute** command.

| Variable                        | Value                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF instance.                                                                                                    |
| <i>vrf-src WORD&lt;1-16&gt;</i> | Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.         |
| <i>WORD&lt;0-32&gt;</i>         | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static. |

## Viewing the OSPF redistribution configuration information

Displays the OSPF redistribution configuration information.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF redistribution configuration information:  
show ip ospf redistribute [vrf WORD<1-16>] [vrffids WORD<0-512>]

### Example

```
Switch:1#show ip ospf redistribute
```

```
=====
 OSPF Redistribute List - GlobalRouter
=====
SRC-VRF SRC MET MTYPE SUBNET ENABLE RPOLICY

GlobalRouter STAT 0 type2 allow TRUE
```

### Variable definitions

The following table defines parameters for the **show ip ospf redistribute** command.

| Variable                              | Value                         |
|---------------------------------------|-------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF by name.      |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRF IDs. |

## Configuring interVRF route redistribution for OSPF

Use route redistribution so that a VRF interface can announce routes learned by other protocols, for example, OSPF or BGP. The switch supports interVRF route redistribution. Use a route policy to control the redistribution of routes.

You can also redistribute inter-VRF DvR routes to OSPF.

### Before You Begin

- Enable OSPF globally.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.

#### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip ospf redistribute <bgp|direct|isis|ospf|rip|static|dvr>
```

3. Apply a route policy if required:

```
ip ospf redistribute <bgp|direct|isis|ospf|rip|static|dvr> route-map
WORD<0-64> [vrf-src WORD<1-16>]
```

4. Configure other parameters, as required.

5. Enable the redistribution:

```
ip ospf redistribute <bgp|direct|isis|ospf|rip|static|dvr> enable
[vrf-src WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip ospf redistribute [vrf WORD<1-16>] [vrffids WORD<0-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip ospf apply redistribute <bgp|direct|isis|ospf|rip|static|dvr> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

## Example

### Example 1:

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ip ospf redistribute isis
Switch:1(router-vrf)#ip ospf redistribute isis route-map test2
Switch:1(router-vrf)#ip ospf redistribute isis enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip ospf apply redistribute isis
```

### Example 2:

This example demonstrates redistribution of inter-VRF routes (both direct and DvR routes) to OSPF, with a route policy configured.

Redistribute inter-VRF DvR routes between VRFs (with VRF IDs 10 and 30), to OSPF.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf 10
Switch:1(router-vrf)#ip prefix-list "test10" 192.0.2.0/24 ge 25 le 32
Switch:1(router-vrf)#route-map "test10" 1
Switch:1(router-vrf)#permit
Switch:1(router-vrf)#enable
Switch:1(router-vrf)#match network "test10"
Switch:1(router-vrf)#set metric 99
Switch:1(router-vrf)#exit

Switch:1(config)#router vrf 30
Switch:1(router-vrf)#ip ospf redistribute direct vrf-src 10
Switch:1(router-vrf)#ip ospf redistribute direct enable vrf-src 10
Switch:1(router-vrf)#ip ospf redistribute dvr vrf-src 10
Switch:1(router-vrf)#ip ospf redistribute dvr route-map "test10" vrf-src 10
Switch:1(router-vrf)#ip ospf redistribute dvr enable vrf-src 10
Switch:1(router-vrf)#exit

Switch:1(config)#ip ospf apply redistribute direct vrf 30 vrf-src 10
Switch:1(config)#ip ospf apply redistribute dvr vrf 30 vrf-src 10
```

### Variable definitions

The following table defines parameters for the **ip ospf redistribute** command.

| Variable                              | Value                                                                                                                                                                                                                           |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                         | Enables the OSPF route redistribution instance.                                                                                                                                                                                 |
| <i>metric</i> <0-65535>               | Configures the metric to apply to redistributed routes.                                                                                                                                                                         |
| <i>metric-type</i> <type1 type2>      | Specifies a metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. |
| <i>route-map</i> WORD<0-64>           | Configures the route policy to apply to redistributed routes.                                                                                                                                                                   |
| <i>subnets</i> <allow suppress>       | Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.                                                                                                                    |
| <i>vrf-src</i> WORD<1-16>             | Specifies the optional source VRF instance. You can use this variable with the other command variables.                                                                                                                         |
| <bgp direct isis ospf rip static dvr> | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, static or dvr.                                                                                              |

The following table defines parameters for the **ip ospf apply redistribute** command.

| Variable                  | Value                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF instance.                                                                                                    |
| <i>vrf-src</i> WORD<1-16> | Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.         |
| WORD<0-32>                | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static. |

## Forcing shortest-path calculation updates

Force the switch to update its shortest-path calculations so that the switch uses the latest OSPF routing information. Manually initiate a shortest path first (SPF) run, or calculation, to immediately update the OSPF LSDB. This action is useful in the following circumstances:

- when you need to immediately restore a deleted OSPF-learned route
- when the routing table entries and the LSDB do not synchronize

### Before You Begin

- You can perform this procedure in one of the following CLI modes: User EXEC, Privileged EXEC, or Global Configuration.

### About This Task

This process is computationally intensive. Use this command only if required.

### Procedure

1. To enter User EXEC mode, log on to the switch.

- Force the router to update its shortest-path calculations:

```
ip ospf spf-run [vrf WORD<1-16>]
```

### Example

Force the router to update its shortest-path calculations:

```
Switch:1>ip ospf spf-run
```

### Variable definitions

The following table defines parameters for the **ip ospf spf-run** command.

| Variable                          | Value                             |
|-----------------------------------|-----------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies a VRF instance by name. |

## Viewing the OSPF default cost information

View the OSPF default cost information to ensure accuracy.

### Procedure

- Enter Privileged EXEC mode:

```
enable
```

- View the OSPF cost information:

```
show ip ospf default-cost [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

View the OSPF cost information on the switch:

```
Switch:1#show ip ospf default-cost vrf 3
```

```
=====
 OSPF Default Metric - VRF 3
=====
10MbpsPortDefaultMetric: 100
100MbpsPortDefaultMetric: 10
1000MbpsPortDefaultMetric: 1
10000MbpsPortDefaultMetric: 1
25000MbpsPortDefaultMetric: 1
40000MbpsPortDefaultMetric: 1
100000MbpsPortDefaultMetric: 1
```

### Variable definitions

The following table defines parameters for the **show ip ospf default-cost** command.

| Variable                              | Value                         |
|---------------------------------------|-------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF by name.      |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRF IDs. |

## Viewing the OSPF timer information

Display OSPF timers information to ensure accuracy.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF timers information:  
show ip ospf int-timers [vrf WORD<1-16>] [vrfids WORD<0-512>]

### Example

```
Switch:1#show ip ospf int-timers
```

```
=====
 OSPF Interface Timer - GlobalRouter
=====
```

| INTERFACE  | AREAID  | TRANSIT<br>DELAY | RETRANS<br>INTERVAL | HELLO<br>INTERVAL | DEAD<br>INTERVAL | POLL<br>INTERVAL |

### Variable definitions

The following table defines parameters for the **show ip ospf int-timers** command.

| Variable           | Value                         |
|--------------------|-------------------------------|
| vrf WORD<1-16>     | Specifies a VRF by name.      |
| vrfids WORD<0-512> | Specifies a range of VRF IDs. |

## Viewing the OSPF neighbor information

Displays OSPF neighbor information.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF neighbor information:  
show ip ospf neighbor [vrf WORD<1-16>] [vrfids WORD<0-512>]

### Example

View OSPF neighbor information:

```
Switch:1#show ip ospf neighbor
```

```

=====
 OSPF Neighbors - GlobalRouter
=====

Total ospf neighbors: 2

H = Helping a Restarting neighbor

```

*Variable definitions*

The following table defines parameters for the **show ip ospf neighbor** command.

| Variable                  | Value                         |
|---------------------------|-------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.      |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs. |

### Viewing the OSPF authentication information

Display OSPF authentication information to ensure accuracy.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF authentication information:  
show ip ospf int-auth [*vrf* WORD<1-16>] [*vrfids* WORD<0-512>]

**Example**

View the OSPF authentication information:

```

Switch:1#show ip ospf int-auth

=====
 OSPF Interface AuthKey - GlobalRouter
=====
INTERFACE AUTHTYPE AUTHKEY

192.0.2.1 none
192.0.2.11 none
192.0.2.3 none

```

*Variable definitions*

The following table defines parameters for the **show ip ospf int-auth** command.

| Variable                  | Value                         |
|---------------------------|-------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.      |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs. |

## View the OSPF Interface Statistics

Use statistics to help you monitor OSPF performance.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the OSPF interface statistics:

```
show ip ospf ifstats [detail vrf WORD<1-16> vrfids WORD<0-512>]
[mismatch vrf WORD<1-16> vrfids WORD<0-512>] [vlan <1-4059>] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

View the OSPF interface statistics:

```
Switch:1#show ip ospf ifstats
=====
 OSPF Interface Statistics - GlobalRouter
=====
---HELLOS--- ---DBS--- -LS REQ-- --LS UPD--- --LS ACK---
INTERFACE RX TX RX TX RX TX RX TX RX Tx

192.0.2.8 76038 76349 0 0 0 0 0 0 0 0
```

### Variable definitions

The following table defines parameters for the **show ip ospf ifstats** command.

| Variable                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>detail</i>             | Displays the details of the OSPF.                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>mismatch</i>           | Specifies the number of times the area ID is not matched.                                                                                                                                                                                                                                                                                                                                                                  |
| <i>vrf</i> WORD<1-16>     | Specifies a VRF by name.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>vrfids</i> WORD<0-512> | Specifies a range of VRF IDs.                                                                                                                                                                                                                                                                                                                                                                                              |

## View OSPF Range Statistics

Use statistics to help you monitor Open Shortest Path First (OSPF) performance. You can also use statistics in troubleshooting procedures. OSPF range statistics include area ID, range network address, range subnet mask, range flag, and LSDB type.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the OSPF range statistics:

```
show ip ospf stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

```
Switch:1#show ip ospf stats

=====
 OSPF Statistics - GlobalRouter

NumEnabledOspfAreas:0
```

*Variable Definitions*

Use the data in the following table to use the **show ip ospf stats** command.

| Variable                 | Value                                   |
|--------------------------|-----------------------------------------|
| <i>vrf</i> WORD<1-16>    | Specifies a VRF instance by VRF name.   |
| <i>vrfids</i> WORD<0-16> | Specifies a VRF or range of VRFs by ID. |

**Clearing IP OSPF Statistics**

Use the following procedure to clear all IPv4 OSPF statistics.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear IPv4 OSPF statistics:

```
clear ip ospf stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

Use the data in the following table to use the **clear ip ospf stats** command.

| Variable           | Value                                 |
|--------------------|---------------------------------------|
| vrf WORD<1-16>     | Specifies a VRF instance by VRF name. |
| vrfids WORD<0-512> | Specifies the ID of the VRF.          |

## Showing OSPF Error Statistics on a Port

Use statistics to help you monitor Open Shortest Path First (OSPF) performance. You can also use statistics in troubleshooting procedures.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display extended information about OSPF errors for the specified port or for all ports:
 

```
show interfaces GigabitEthernet error ospf [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Variable Definitions

Use the following table to help you use the **show interfaces GigabitEthernet error ospf** command.

| Variable                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port]}[-slot/port[/sub-port]][,...] | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing Basic OSPF Statistics for a Port

Use statistics to help you monitor Open Shortest Path First (OSPF) performance. You can also use statistics in troubleshooting procedures.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View basic OSPF statistics:
 

```
show ports statistics ospf main [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Example

View basic OSPF statistics:

```
Switch:1>enable
Switch:1#show ports statistics ospf main

=====
Port Stats Ospf
=====
PORT_NUM RX_HELLO TX_HELLO RXDB_DESCR TXDB_DESCR RXLS_UPDATE TXLS_UPDATE

1/3 0 0 0 0 0 0
```

### Variable Definitions

Use the data in the following table to use the **show ports statistics ospf main** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Showing Extended OSPF Statistics

Use statistics to help you monitor Open Shortest Path First (OSPF) performance. You can also use statistics in troubleshooting procedures.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display extended OSPF information about the specified port or for all ports:
 

```
show ports statistics ospf extended [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

### Example

Display extended OSPF information:

```
Switch:1>enable
Switch:1#show ports statistics ospf extended

=====
Port Stats Ospf Extended
=====
PORT_NUM RXLS_REQS TXLS_REQS RXLS_ACKS TXLS_ACKS

1/3 0 0 0 0
```

### Variable Definitions

Use the data in the following table to use the **show ports statistics ospf extended** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing the OSPF virtual link information

Displays the OSPF virtual link information to ensure accuracy.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the OSPF virtual link information:

```
show ip ospf virtual-link {A.B.C.D} {A.B.C.D} [vrf WORD<1-16>] [vrfs
WORD<0-512>]
```

### Example

View the OSPF virtual link information:

```
Switch:1#show ip ospf virtual-link

=====
 OSPF Interface AuthKey - GlobalRouter
=====
INTERFACE AUTHTYPE AUTHKEY

192.0.2.11 none
```

### Variable definitions

The following table defines parameters for the **show ip ospf virtual-link** command.

| Variable                                                | Value                                                                                                                                             |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{A.B.C.D} {A.B.C.D} vrf WORD&lt;1-16&gt;</code>   | Specifies the area ID and the virtual interface ID. The first IP address specifies the area ID and the second specifies the virtual interface ID. |
| <code>{A.B.C.D} {A.B.C.D} vrfs WORD&lt;0-512&gt;</code> | Displays OSPF configuration for a particular VRF. Specifies a VRF by name.                                                                        |
| <code>{A.B.C.D} {A.B.C.D}</code>                        | Specifies a range of VRF IDs.                                                                                                                     |

## Viewing the VRF configurations

Use the following command to view VRF configurations.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the VRF configuration:  
show ip ospf vrf WORD<1-16>

### Example

View the VRF configuration:

```
Switch:1#show ip ospf vrf virtualrandf1

=====
 OSPF General - VRF virtualrandf1

```

### Variable definitions

The following table defines parameters for the **show ip ospf vrf** command.

| Variable       | Value                    |
|----------------|--------------------------|
| vrf WORD<1-16> | Specifies a VRF by name. |

## Viewing the VRFIDS

Use the following command to view VRFIDS.

### Procedure

1. Enter Privileged EXEC mode:  
enable

2. View the VRF IDs:

```
show ip ospf vrfids WORD<0-512>
```

### Example

View the VRF IDs:

```
Switch:1#show ip ospf vrfids 1

=====
 OSPF General - VRF virtualrandf1
=====

 RouterId: 192.0.2.1
 AdminStat: disabled
 VersionNumber: 2
 AreaBdrRtrStatus: false
 ASBdrRtrStatus: false
 Bad-Lsa-Ignore: false
 ExternLsaCount: 0
 ExternLsaCksumSum: 0(0x0)
 TOSSupport: 0
 OriginateNewLsas: 0
 RxNewLsas: 0
 TrapEnable: false
 AutoVirtLinkEnable: false
 SpfHoldDownTime: 10
 Rfc1583Compatibility: disable

 default-metric :
 ethernet - 100

--More-- (q = quit)
```

#### Variable definitions

The following table defines parameters for the **show ip ospf vrfid** command.

| Variable                              | Value                         |
|---------------------------------------|-------------------------------|
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a range of VRF IDs. |

## OSPFv3 Configuration using CLI

Use the procedures in this section to configure OSPFv3 using CLI.

### Configuring OSPF globally

Configure OSPFv3 globally to enable it on the system and to configure the router ID.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Enable OSPFv3 for IPv6:

```
router ospf ipv6-enable
```

The default is disabled.

3. Log on to OSPF Router Configuration mode:

```
router ospf
```

4. Specify the router ID:

```
ipv6 router-id {A.B.C.D}
```

5. Optionally, make the router an autonomous system (AS) boundary router (BR):

```
ipv6 as-boundary-router enable
```

Enable the ASBR if the router attaches at the edge of the OSPF network, and has one or more interfaces that run an interdomain routing protocol. The default is disabled.

## Example

Enable OSPFv3 for IPv6:

```
Switch:1(config)#router ospf ipv6-enable
```

Log on to OSPF Router Configuration mode:

```
Switch:1(config)#router ospf
```

Specify the router ID:

```
Switch:1(config-ospf)#ipv6 router-id 1.1.1.1
```

### Variable definitions

Use the data in the following table to use the **ipv6 router-id** command.

| Variable         | Value                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i> | Specifies a 32-bit integer that identifies the router in the autonomous system. This value must be unique. The default value will be one of the IPv4 interface addresses. |

## Creating an OSPF area

Create an area to subdivide the autonomous system (AS) into areas that group contiguous networks, routers that connect to these networks, and attached hosts. Subdividing the AS into areas significantly reduces the amount of routing protocol traffic compared to treating the entire AS like a single link-state domain.

## About This Task

A stub area does not receive advertisements for external routes, which reduces the size of the link-state database (LSDB). A stub area uses only one area border router (ABR). Any packets destined for outside the area are routed to the area border exit point, examined by the ABR, and forwarded to a destination.

A not so stubby area (NSSA) prevents the flooding of AS-External link-state advertisements into the area by replacing them with a default route. NSSAs also import small stub (non- OSPF) routing domains into OSPF.

## Before You Begin

You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

## Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```
2. Specify the area ID:

```
ipv6 area {A.B.C.D}
```
3. Configure optional area parameters if the default values do not meet your requirements:
  - a. Configure the area type if you need a stub or NSSA area:

```
ipv6 area {A.B.C.D} type <nssa|stub>
```

By default, the area is a normal area; neither a stub nor NSSA area.
  - b. Configure the default cost:

```
ipv6 area {A.B.C.D} default-cost <0-16777215>
```

You do not need to configure this parameter if the area is a normal area.
  - c. Configure the area support for importing advertisements:

```
ipv6 area {A.B.C.D} import <external|noexternal|nssa>
```

The default is external.
  - d. Disable the importation of summary advertisements into a stub area:

```
no ipv6 area {A.B.C.D} import-summaries enable
```

The default is enabled.
  - e. Configure translation of Type 7 LSAs into Type 5 LSAs:

```
ipv6 area {A.B.C.D} translator-role <1-2>
```

The default value is 2-candidate.

## Example

Specify the area ID:

```
Switch:1(config-ospf)#ipv6 area 0.0.0.1
```

### Variable definitions

Use the data in the following table to use the **ipv6 area** command.

| Variable                                         | Value                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>                                 | Specifies a 32-bit integer to uniquely identify an area. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                                                                                                                                       |
| <i>default-cost</i><br><i>&lt;0-16777215&gt;</i> | Configures the metric value advertised for the default route to stub and NSSA areas.                                                                                                                                                                                                                                                                |
| <i>import &lt;external noexternal nssa&gt;</i>   | Configures area support for importing AS-external LSAs: <ul style="list-style-type: none"> <li>external—normal area</li> <li>noexternal—stub area</li> <li>nssa—not-so-stubby area</li> </ul> AS-scope LSAs are not imported into stub areas or NSSAs. NSSAs import AS-External data at Type 7 LSAs, which use area scope. The default is external. |
| <i>import-summaries</i><br><i>enable</i>         | Controls the import of inter-area LSAs into a stub area. If you disable this parameter, the router does not originate nor propagate inter-area LSAs into the stub area. If you enable this parameter (the default), the router both summarizes and propagates inter-area LSAs.                                                                      |
| <i>&lt;nssa stub&gt;</i>                         | Configures the type of area. By default, the area is neither a stub area or an NSSA.                                                                                                                                                                                                                                                                |
| <i>translator-role</i><br><i>&lt;1-2&gt;</i>     | Indicates if the NSSA border router can perform NSSA translation of Type 7 LSAs to Type 6 LSAs. The possible values are always (1) or candidate (2). The default is candidate (2).                                                                                                                                                                  |

## Creating OSPF area ranges

Create an area address range on the OSPF router to reduce the number of area border router (ABR) advertisements into other OSPF areas. An area address range is an implied contiguous range of area network addresses for which the ABR advertises a single summary route.

### Before You Begin

- You must create the OSPF area.
- You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

### About This Task

If you create two ranges, and one range is a subset of the other, the router uses the most specific match.

## Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable

configure terminal

router ospf
```
2. Create an area range:
 

```
ipv6 area range {A.B.C.D} WORD<0-255> [inter-area-prefix-link|nssa-
extlink] advertise-mode <advertise|not-advertise> [advertise-metric
<0-65535>]
```

## Example

Create an area range:

```
Switch:1(config-ospf)#ipv6 area range 0.0.0.1 3000::0/16 advertise-mode
advertise
```

### Variable definitions

Use the data in the following table to use the **ipv6 area range** command.

| Variable                                                             | Value                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>                                                     | Specifies the area in which the address aggregate exists. Use dotted decimal notation to specify the area name.                                                                                                                                       |
| <i>advertise-metric</i><br><i>&lt;0-65535&gt;</i>                    | Specifies a cost value to advertise for the OSPF area range. This value applies to summary LSAs (Type 3). If the value is 0, OSPF uses the cost to the farthest point in the network that is summarized.                                              |
| <i>advertise-mode</i><br><i>&lt;advertise not-<br/>advertise&gt;</i> | Specifies the advertisement mode for prefixes in the range. <i>advertise</i> advertises the aggregate summary LSA with the same link-state ID. <i>not-advertise</i> does not advertise networks that fall within the range. The default is advertise. |
| <i>&lt;inter-area-<br/>prefix-link nssa-<br/>extlink&gt;</i>         | Specifies the area LSDB type to which the address aggregate applies. <i>inter-area-prefix-link</i> generates an aggregated summary. <i>nssa-extlink</i> generates an NSSA link summary.                                                               |
| <i>WORD&lt;0-255&gt;</i>                                             | Specifies the IPv6 address and prefix.                                                                                                                                                                                                                |

## Creating an OSPF virtual link

Create a virtual link if the switch does not connect directly to the backbone. The switch can create automatic virtual links or you can perform this procedure to create virtual links manually. Manual virtual links conserve resources and provide specific control over virtual link placement in your OSPF configuration.

### Before You Begin

- The router must be an ABR to create a virtual router interface.
- You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

## About This Task

Virtual linking is similar to backup redundancy. The switch creates a virtual link for vital traffic paths in your OSPF configuration if traffic is interrupted, such as when an interface cable that provides a connection to the backbone (either directly or indirectly) is disconnected from the switch. Automatic virtual linking ensures that a link is created by using another switch.

OSPF routes cannot be learned through an ABR unless it connects to the backbone directly or through a virtual link.

## Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```

2. Create a virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D}
```

3. Configure optional parameters for the virtual link if the default values do not meet your requirements:

- a. Configure the router dead interval:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} dead-interval <1-65535>
```

The default is 60 seconds.

- b. Configure the hello interval:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} hello-interval <1-65535>
```

The default is 10 seconds.

- c. Configure the retransmit interval:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} retransmit-interval
<1-1800>
```

The default is 5 seconds.

- d. Configure the transit delay:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} transit-delay <1-1800>
```

The default is 1 second.

## Example

Create a virtual link:

```
Switch:1(config-ospf)#ipv6 area virtual-link 0.0.0.1 2.2.2.2
```

Configure optional parameters for a virtual link:

```
Switch:1(config-ospf)#ipv6 area virtual-link 0.0.0.1 4.4.4.4 dead-
interval 90 retransmit-interval 10
```

*Variable definitions*

Use the data in the following table to use the **ipv6 area virtual-link** command.

| Variable                                            | Value                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i><br><i>{A.B.C.D}</i>                | Specifies the ID for the transit area that the virtual link traverses and the router ID of the virtual neighbor. Do not use 0.0.0.0 for the transit area.                                                                                                               |
| <i>dead-interval</i><br><i>&lt;1-65535&gt;</i>      | Specifies the number of seconds after which the neighbor declares the router down if it does not receive hello packets. Configure this value as a multiple of the hello interval. You must configure the same value on the virtual neighbor. The default is 60 seconds. |
| <i>hello-interval</i><br><i>&lt;1-65535&gt;</i>     | Specifies the number of seconds between hello packets that the router sends on this interface. Configure the same value on the virtual neighbor. The default is 10 seconds.                                                                                             |
| <i>retransmit-interval</i><br><i>&lt;1-1800&gt;</i> | Specifies the number of seconds between link-state advertisement retransmissions for adjacencies that belong to this interface. This value also applies to the retransmissions of database description and link-state request packets. The default is 5 seconds.        |
| <i>transit-delay</i><br><i>&lt;1-1800&gt;</i>       | Specifies the estimated number of seconds to transmit a link-state update packet over this interface. The default is 1 second.                                                                                                                                          |

## Configure IPsec for the OSPF Virtual Link

Use the following procedure to configure and enable IPsec for the OSPF virtual link.

IPsec is disabled by default.

### Before You Begin

- Configure the OSPF virtual link.
- Create the IPsec security association.

### About This Task

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You must disable IPsec before you can perform virtual link policy configuration changes.

For configuration examples of IPsec used with OSPFv3 virtual link, see [OSPFv3 virtual link IPsec configuration example](#) on page 1772.

### Procedure

1. Enter OSPF Router Configuration mode:
 

```
enable
configure terminal
router ospf
```

2. Create the IPsec policy under the OSPF virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} ipsec
```

3. Configure the action of the IPsec policy under the OSPF virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} ipsec action <drop|permit>
```

4. Configure the direction of the IPsec policy under the OSPF virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} ipsec direction <both|in|out>
```

5. Link the security association to the OSPF virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} ipsec security-association WORD<0-32>
```

6. Enable the IPsec policy created under the OSPF virtual link:

```
ipv6 area virtual-link {A.B.C.D} {A.B.C.D} ipsec enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#(config)router ospf
Switch:1(config-ospf)#ipv6 area virtual-link 1.1.1.1 2.2.2.2 ipsec
Switch:1(config-ospf)#ipv6 area virtual-link 1.1.1.1 2.2.2.2 ipsec action permit
Switch:1(config-ospf)#ipv6 area virtual-link 1.1.1.1 2.2.2.2 ipsec direction both
Switch:1(config-ospf)#ipv6 area virtual-link 1.1.1.1 2.2.2.2 ipsec security-association test1
Switch:1(config-ospf)#ipv6 area virtual-link 1.1.1.1 2.2.2.2 ipsec enable
```

### Variable definitions

Use the data in the following table to use the **ipv6 area virtual link {A.B.C.D} {A.B.C.D} ipsec** command.

| Variable                                     | Value                                                                                                                                                                                                                                                              |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D} {A.B.C.D}</i>                   | The first IP address specifies the area IP address, and the second IP address specifies the virtual-link IP address.                                                                                                                                               |
| <i>action &lt;drop permit&gt;</i>            | Configures the action of the IPsec policy under the OSPF virtual tunnel to one of the following: <ul style="list-style-type: none"> <li>• drop—Drops the IP packets.</li> <li>• permit—Permits the IP packets.</li> </ul> The default is permit.                   |
| <i>direction &lt;both in out&gt;</i>         | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>• in—Specifies ingress traffic.</li> <li>• out—Specifies egress traffic.</li> <li>• both—Specifies both ingress and egress traffic.</li> </ul> The default is both. |
| <i>enable</i>                                | Enables the IPsec policy under the OSPF virtual link.                                                                                                                                                                                                              |
| <i>security-association WORD&lt;0-32&gt;</i> | Links the security association to the OSPF virtual link.                                                                                                                                                                                                           |

## Configuring OSPF default metrics

### Before You Begin

You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

### About This Task

Use the following procedure to configure global OSPF default metrics.

### Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```

2. Configure OSPF default-cost:

```
ipv6 default-cost {ethernet|fast-ethernet|forty-gig-ethernet|hundred-
gig-ethernet|gig-ethernet|ten-gig-ethernet|twentyfive-gig-ethernet|
vlan} <1-65535>
```

#### Note

Different hardware platforms support different port speeds. For more information, see your hardware documentation.

### Example

Configure IPv6 default cost metric for Ethernet to 100, for fast Ethernet to 20, for gig-ethernet, twentyfive-gig-ethernet, forty-gig-Ethernet, and hundred-gig-ethernet to 2, and VLAN to 1.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#ipv6 default-cost ethernet 100
Switch:1(config-ospf)#ipv6 default-cost fast-ethernet 20
Switch:1(config-ospf)#ipv6 default-cost gig-ethernet 2
Switch:1(config-ospf)#ipv6 default-cost ten-gig-ethernet 2
Switch:1(config-ospf)#ipv6 default-cost Forty-gig-ethernet 2
Switch:1(config-ospf)#ipv6 default-cost twentyfive-gig-ethernet 2
Switch:1(config-ospf)#ipv6 default-cost hundred-gig-ethernet 2
Switch:1(config-ospf)#ipv6 default-cost vlan 1
```

### Variable definitions

Use the data in the following table to use the **ipv6 default-cost** command.

#### Note

Different hardware platforms support different port speeds. For more information, see your hardware documentation.

| Variable                                    | Value                                                                                                                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ethernet</i><br><1-65535>                | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>ethernet</i> is for 10 Mb/s Ethernet (default is 100).                       |
| <i>fast-ethernet</i><br><1-65535>           | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>fast-ethernet</i> is for 100 Mb/s Fast-Ethernet (default is 10).             |
| <i>forty-gig-ethernet</i><br><1-65535>      | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>forty-gig-ethernet</i> is for 10 Mb/s Forty-Gigabit-Ethernet (default is 1). |
| <i>gigabit-ethernet</i><br><1-65535>        | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>gigabit-ethernet</i> is for 10 Mb/s Gigabit-Ethernet (default is 1).         |
| <i>hundred-gig-ethernet</i><br><1-65535>    | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>hundred-gig-ethernet</i> is for 100 Gigabit Ethernet (default is 1).         |
| <i>ten-gig-ethernet</i><br><1-65535>        | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>ten-gig-ethernet</i> is for 10 Mb/s Ten-Gigabit-Ethernet (default is 1).     |
| <i>twentyfive-gig-ethernet</i><br><1-65535> | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br>On a channelized 100 Gbps port, the default-cost for each 25 Gbps channel is 1. |
| <i>vlan</i> <1-65535>                       | Configures the IPv6 OSPF default metrics. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.<br><i>vlan</i> is for Vlan interfaces (default is 10).                             |

## Configuring OSPF on a port or VLAN

Configure the OSPF protocol on IPv6 interface to support dynamic routing on the interface.

### Before You Begin

- The IPv6 interface must exist.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an OSPF area on the interface:

```
ipv6 ospf area {A.B.C.D}
```

3. Enable OSPFv3 on the interface:

```
ipv6 ospf enable
```

The default is disabled.

4. Configure optional parameters to meet your requirements:

- a. Configure the interface metric:

```
ipv6 ospf cost <0-65535>
```

The default for a brouter port or VLAN is 1.

### Note

If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.

- b. Configure the router dead interval:

```
ipv6 ospf dead-interval <1-65535>
```

The default is 40 seconds.

- c. Configure the hello interval:

```
ipv6 ospf hello-interval <1-65535>
```

The default is 10 seconds.

- d. Configure the link LSA suppression:

```
ipv6 ospf link-lsa-suppression
```

### Note

Before configuring Link LSA suppression for OSPF, configure Link LSA suppression for OSPF area for point to point (p2p) or point to multipoint interfaces (p2mp), otherwise it defaults to a broadcast interface type where you cannot use Link LSA suppression.

- e. Configure the poll interval:

```
ipv6 ospf poll-interval <0-65535>
```

The default is 120 seconds.

- f. Configure the interface priority:

```
ipv6 ospf priority <0-255>
```

The default is 1.

- g. Configure the retransmit interval:

```
ipv6 ospf retransmit-interval <1-1800>
```

The default is 5 seconds.

- h. Configure the transit delay:

```
ipv6 ospf transit-delay <1-1800>
```

The default is 1 second.

### Example

Create an OSPF area on the interface:

```
Switch:1(config-if)#ipv6 ospf area 0.0.0.0
```

Enable OSPFv3 on the interface:

```
Switch:1(config-if)#ipv6 ospf enable
```

### Variable Definitions

Use the data in the following table to use the **ipv6 ospf** command.

| Variable                              | Value                                                                                                                                                                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>area {A.B.C.D}</i>                 | Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                                                            |
| <i>cost &lt;0-65535&gt;</i>           | Specifies the cost for the interface.<br>The default for a brouter port or VLAN is 1.                                                                                                                                                                                       |
| <i>dead-interval &lt;1-65535&gt;</i>  | Specifies the number of seconds after which the neighbor declares the router down, if it does not receive hello packets. Configure this value as a multiple of the hello interval. You must configure the same value on the virtual neighbor.<br>The default is 40 seconds. |
| <i>enable</i>                         | Specifies the administrative status for the OSPFv3 interface.<br>If you enable the status, it is advertised as an internal route to some areas.<br>If you disable the status, the interface is external to OSPFv3.<br>The default is disabled.                              |
| <i>hello-interval &lt;1-65535&gt;</i> | Specifies the number of seconds between hello packets that the router sends on this interface. Configure the same value on the virtual neighbor.<br>The default is 10 seconds.                                                                                              |
| <i>link-lsa-suppression</i>           | Configures link LSA suppression on the specified port or VLAN. It is only used for point to point or point to multipoint interfaces. By default, it is disabled.                                                                                                            |

| Variable                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>poll-interval</code><br><0-65535>      | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor.<br>The default is 120.                                                                                                                                                                                                                                                                                                                       |
| <code>priority</code> <0-255>                | Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router.<br>The default is 1. |
| <code>retransmit-interval</code><br><1-1800> | Specifies the number of seconds between link-state advertisement retransmissions for adjacencies that belong to this interface. This value also applies to the retransmissions of database description and link-state request packets. The default is 5 seconds.                                                                                                                                                                      |
| <code>transit-delay</code><br><1-1800>       | Specifies the estimated number of seconds to transmit a link-state update packet over this interface.<br>The default is 1 second.                                                                                                                                                                                                                                                                                                     |

Use the data in the following table to use the **interface** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |

## Configuring OSPF on a tunnel

Configure the OSPF protocol on IPv6 interface to support dynamic routing on the interface.

### Before You Begin

- The IPv6 interface must exist.

### Procedure

- Enter OSPF Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router ospf
```

2. Create an OSPF area on the interface:  
`ipv6 tunnel <1-2000> area {A.B.C.D}`
3. Enable OSPFv3 on the interface:  
`ipv6 tunnel <1-2000> enable`
4. Configure optional parameters to meet your requirements:
  - a. Configure the router dead interval:  
`ipv6 tunnel <1-2000> dead-interval <1-65535>`  
  
The default is 40 seconds.
  - b. Configure the hello interval:  
`ipv6 tunnel <1-2000> hello-interval <1-65535>`  
  
The default is 10 seconds.
  - c. Configure the interface metric:  
`ipv6 tunnel <1-2000> metric <0-65535>`
  - d. Configure the poll interval:  
`ipv6 tunnel <1-2000> poll-interval <0-65535>`  
  
The default is 120 seconds.
  - e. Configure the interface priority:  
`ipv6 tunnel <1-2000> priority <0-255>`  
  
The default is 1.
  - f. Configure the retransmit interval:  
`ipv6 tunnel <1-2000> retransmit-interval <1-1800>`  
  
The default is 5 seconds.
  - g. Configure the transit delay:  
`ipv6 tunnel <1-2000> transit-delay <1-1800>`  
  
The default is 1 second.

### Example

Create an OSPF area on the interface:

```
Switch:1(config-if)#ipv6 tunnel 4 area 0.0.0.0
```

Enable OSPFv3 on the interface:

```
Switch:1(config-if)#ipv6 tunnel 4 enable
```

## Variable definitions

Use the data in the following table to use the **ipv6 tunnel** command.

| Variable                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-2000>                               | Specifies the tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>area</i> {A.B.C.D}                  | Specifies the area ID to which the IPv6 interface connects.<br>Use 0.0.0.0 for the OSPFv3 backbone.                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>dead-interval</i><br><1-65535>      | Specifies the number of seconds after which the neighbor declares the router down if it does not receive hello packets.<br>Configure this value as a multiple of the hello interval.<br><br><b>Tip:</b><br>You must configure the same value on the virtual neighbor.<br><br>The default is 40 seconds.                                                                                                                                                                                        |
| <i>enable</i>                          | Specifies the administrative status for the OSPFv3 interface.<br>If you enable the status, it is advertised as an internal route to some areas.<br>If you disable the status, the interface is external to OSPFv3.<br>The default is enabled.                                                                                                                                                                                                                                                  |
| <i>hello-interval</i><br><1-65535>     | Specifies the number of seconds between hello packets that the router sends on this interface.<br><br><b>Tip:</b><br>You must configure the same value on the virtual neighbor.<br><br>The default is 10 seconds.                                                                                                                                                                                                                                                                              |
| <i>metric</i> <0-65535>                | Specifies the cost for the interface.<br>The default for a tunnel is 100.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>poll-interval</i><br><0-65535>      | Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor.<br>The default is 120.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>priority</i> <0-255>                | Specifies the priority of this interface.<br>Multiaccess networks use the priority in the designated router election.<br>A higher priority value increases the likelihood that the router becomes the designated router.<br>A value of zero (0) indicates the router cannot become the designated router for the network.<br>If more than one router uses the same priority value, the system uses the router ID to determine which router becomes the designated router.<br>The default is 1. |
| <i>retransmit-interval</i><br><1-1800> | Specifies the number of seconds between link-state advertisement retransmissions for adjacencies that belong to this interface.<br>The retransmit-interval value also applies to the retransmissions of database description and link-state request packets.<br>The default is 5 seconds.                                                                                                                                                                                                      |
| <i>transit-delay</i><br><1-1800>       | Specifies the estimated number of seconds required to transmit a link-state update packet over this interface.<br>The default is 1 second.                                                                                                                                                                                                                                                                                                                                                     |

## View OSPFv3 Information

View information about OSPF to view the current configuration.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View OSPF global information:  
show ipv6 ospf [vrf WORD <1-16>] [vrfids WORD <0-512>]
3. View OSPF areas:  
show ipv6 ospf area [vrf WORD <1-16>] [vrfids WORD <0-512>]
4. View OSPF interface information  
show ipv6 ospf interface [gigabitEthernet {slot/port[sub-port]}|vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]
5. View OSPF interface timers:  
show ipv6 ospf int-timers [vrf WORD <1-16>] [vrfids WORD <0-512>]
6. View the link-state database (LSDB) table:  
show ipv6 ospf lsdb [adv-rtr <A.B.C.D>] [area <A.B.C.D>] [interface gigabitEthernet {slot/port[sub-port]}|vlan <1-4059> ] [lsa-type <1-11>] [lsid <0-4294967295>] [scope <1-3>] [tunnel <1-2000>] [detail] [vrf WORD <1-16>] [vrfids WORD <0-512>]
7. View OSPF neighbors to see routers with interfaces to a common network, including neighbors on the virtual link to the OSPF backbone:  
show ipv6 ospf neighbor [vrf WORD <1-16>] [vrfids WORD <0-512>]

### Examples

```
Switch:1#show ipv6 ospf

*Variable Definitions*

Use the data in the following table to use the **show ipv6 ospf** commands.

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>adv-rtr</i> <A.B.C.D>      | Shows information for the specified advertising router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>area</i> <A.B.C.D>         | Shows information for the specified area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>detail</i>                 | Shows information beyond the basic information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>{slot/port[/sub-port]}</i> | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>lsa-type</i> <1-11>        | Shows information for the specified LSA type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>lsid</i> <0-4294967295>    | Shows information for the specified link-state ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>scope</i> <1-3>            | Shows information for the specified scope: <ol style="list-style-type: none"> <li>link-scope LSAs-View the link-scope LSDB to view the LSAs that are not flooded beyond the local link.</li> <li>area-scope LSAs-View the area-scope LSDB to see the LSAs that are flooded in a single OSPF area. Area scope is used in router LSAs, network LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router LSAs, and Intra-Area-Prefix-LSAs.</li> <li>AS-scope LSAs-View the AS-scope LSDB to see the LSAs that are flooded through the routing domain. The AS scope is used for ASexternal- LSAs.</li> </ol> |
| <i>tunnel</i> <1-2000>        | Specifies the ID number of the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vlan &lt;1-4059&gt;</code>      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies VRF IDs.                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Viewing OSPFv3 Default Cost Information

### About This Task

Use the following procedure to view the OSPF default cost information, to ensure accuracy.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the OSPF cost information:  
show ipv6 ospf default-cost [vrf WORD <1-16>] [vrfids WORD <0-512>]

### Example

```
Switch:1#show ipv6 ospf default-cost
=====
 IPv6 OSPF Default Metric - GlobalRouter
=====
 10MbpsPortDefaultMetric: 100
 100MbpsPortDefaultMetric: 10
 1000MbpsPortDefaultMetric: 1
10000MbpsPortDefaultMetric: 1
25000MbpsPortDefaultMetric: 1
40000MbpsPortDefaultMetric: 1
100000MbpsPortDefaultMetric: 1
 VlanDefaultMetric: 10
```

## Adding an NBMA neighbor

Add an NBMA neighbor for each interface that is eligible to become the DR.

An NBMA interface with a positive nonzero router priority is eligible to become the DR for the NBMA network and is configured with the identification of all attached routers, IPv6 addresses, and router priorities.

### Before You Begin

- Identify the following information:
  - specific interfaces to include in the NBMA network
  - the IPv6 address for each interface

- the router priority for each interface
- the hello interval for the network
- the router dead interval for the network
- the poll interval for the network

### About This Task

In contrast to a broadcast network where switches multicast (send to AllSPFRouters and AllDRouters) certain OSPF protocol packets, switches replicate and send NBMA packets to each neighboring router as unicast. NBMA networks drop all OSPF packets with destination addresses AllSPFRouters and AllDRouters. Because the NBMA network does not broadcast, you must manually configure a list of neighbors and priorities for all routers in the network that can become the DR. Potential DRs use a positive nonzero router priority.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a new NBMA neighbor:

```
ipv6 ospf nbma-nbr WORD<0-43> <0-255>
```

3. Change the priority of an existing NBMA neighbor:

```
ipv6 ospf nbma-nbr WORD<0-43> priority <0-255>
```

### Example

Create an NBMA neighbor that will not become the DR:

```
Switch:1(config-if)#ipv6 ospf nbma-nbr fe80:0:0:0:8217:7dff:fe76:8a03 0
```

#### Variable definitions

Use the data in the following table to use the **ipv6 ospf nbma-nbr** command.

| Variable                | Value                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>priority</i> <0-255> | Specifies the priority to use for this neighbor in the designated router election process. A value of 0 indicates the neighbor cannot become the designated router. The higher the priority value, the higher chance the switch will win the election process. The default is 1. |
| <i>WORD</i> <0-43>      | Specifies the IPv6 address of the neighbor.                                                                                                                                                                                                                                      |

## Configuring link LSA suppression

### About This Task

Use the following procedure to configure link LSA suppression on a port or a VLAN, to decrease unnecessary link LSA generation and flooding for non-broadcast and non-NBMA interface.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ipv6 ospf area {A.B.C.D} network {p2p | p2mp} link-lsa-suppression
```

### Example

#### Variable definitions

Following table describes the variables to the **ipv6 ospf area {A.B.C.D} network p2p link-lsa-suppression** command.

| Variable                           | Description                      |
|------------------------------------|----------------------------------|
| <i>area {A.B.C.D}</i>              | Create an IPv6 OSPF area.        |
| <i>network</i>                     | Sets the type of interface.      |
| <i>[eth NBMA p2mp p2p passive]</i> | Specifies the type of interface. |
| <i>link-lsa-suppression</i>        | Enables link LSA suppression.    |

## Configuring Route Redistribution to OSPFv3 in GRT mode

Configure a redistribute entry to announce certain routes into the OSPFv3 domain, including static routes, direct routes, RIPng, OSPF routes, IS-IS routes, or Border Gateway Protocol (BGP) routes. Optionally, use a route policy to control the redistribution of routes.

#### Note

RIPng is not virtualized, therefore RIPng redistribution in OSPFv3 works only in GRT.

### Before You Begin

- Enable OSPFv3 globally.
- Ensure that a route policy exists.
- Ensure that you set OSPFv3 as the boundary router.

#### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For a redistribute policy (OSPFv3) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where the last sequence permits all routes that are not explicitly permitted or denied.
- You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

### Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```

2. Create the redistribution instance:

```
ipv6 redistribute <bgp|direct|isis|rip|static>
```

#### Note

The switch loads the existing configuration when you upgrade to the current release. Once you have the configuration file saved using the current release, only the new configuration will be loaded.

3. Apply a route policy if required:

```
ipv6 redistribute <bgp|direct|isis|rip|static> route-map WORD<0-64>
```

#### Note

No inter-vrf Route Redistribution is supported for IPv6.

4. Configure other parameters, as required.
5. Enable the redistribution.

```
ipv6 redistribute <bgp|direct|isis|rip|static> enable
```

6. Ensure that the configuration is correct:

```
show ipv6 ospf redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution.

```
ipv6 ospf apply redistribute <bgp|direct|isis|rip|static> [vrf WORD<1-16>]
```

Changes do not take effect until you apply them.

9. View all routes that are redistributed into OSPFv3:

- a. View the routes that are redistributed from the GRT to OSPFv3:

```
show ipv6 ospf redistribute
```

- b. View the routes that are redistributed to OSPFv3 for a specific VRF instance:

```
show ipv6 ospf redistribute [vrf WORD<1-64>] [vrfs WORD<0-512>]
```

### Example

Redistribute static routes from the GRT to OSPF.

Create the redistribution instance, apply a route policy, enable redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#ipv6 redistribute static

WARNING: Routes will not be injected until apply command is issued after enable command
Switch:1(config-ospf)#ipv6 redistribute static route-map policy1
Switch:1(config-ospf)#ipv6 redistribute static enable
Switch:1(config-ospf)#exit
Switch:1(config)#ipv6 ospf apply redistribute static
Switch:1(config)#show ipv6 ospf redistribute

=====
 OSPFv3 Redistribute List - GlobalRouter
=====

STAT 0 type2 TRUE policy1
```

### Variable Definitions

Use the data in the following table to use the **ipv6 redistribute** command.

| Variable                                  | Value                                                                                                                                                                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                             | Enables the OSPF route redistribution instance.                                                                                                                                                                                                    |
| <i>metric &lt;0-65535&gt;</i>             | Configures the metric to apply to redistributed routes.                                                                                                                                                                                            |
| <i>metric-type &lt;type1 type2&gt;</i>    | Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. |
| <i>route-map WORD&lt;0-64&gt;</i>         | Configures the route policy to apply to redistributed routes.                                                                                                                                                                                      |
| <i>&lt;bgp direct isis rip static&gt;</i> | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, or static.                                                                                                                           |

Use the data in the following table to use the **ipv6 ospf apply redistribute** command.

| Variable                                                                  | Value                                                                                                                    |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>vrf</i> <i>WORD</i> <1-16>                                             | Specifies the VRF instance.                                                                                              |
| < <i>bgp</i>   <i>direct</i>   <i>isis</i>   <i>rip</i>   <i>static</i> > | Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, or static. |

## Viewing the Status of OSPFv3 Redistribution

View the status of OSPFv3 route redistribution to verify the current configuration. You can redistribute directly connected routes and IPv6 static routes into OSPFv3.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the current configuration:  
show ipv6 ospf redistribute [*vrf* *WORD* <1-16>] [*vrfids* *WORD* <0-512>]

### Example

```
Switch:1#show ipv6 ospf redistribute

=====
 OSPFv3 Redistribute List - GlobalRouter
=====
SOURCE MET MTYPE ENABLE RPOLICY

Static 0 external TRUE

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 ospf redistribute** command.

| Variable                          | Value                   |
|-----------------------------------|-------------------------|
| <i>vrf</i> <i>WORD</i> <1-16>     | Specifies the VRF name. |
| <i>vrfids</i> <i>WORD</i> <0-512> | Specifies VRF IDs.      |

## View OSPFv3 Statistics

View OSPFv3 statistics to analyze trends.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:  
show ipv6 ospf statistics [*vrf* *WORD* <1-16>] [*vrfids* *WORD* <0-512>]

## Example

View IPv6 OSPF statistics:

```
Switch:1>enable
Switch:1#show ipv6 ospf statistics

=====
 OSPFv3 Statistics - GlobalRouter
=====

 NumTxPkt: 9958
 NumRxPkt: 8982
NumTxDropPkt: 33
NumRxDropPkt: 0
 NumRxBadPkt: 0
 NumSpfRun: 42
 LastSpfRun: 0 day(s), 02:44:32
 LsdbTblSize: 45
 NumBadLsReq: 0
 NumSeqMismatch: 0
NumOspfAdjacencies: 7
```

### Variable Definitions

Use the data in the following table to use the **show ipv6 ospf stats** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies VRF IDs.      |

## Clear OSPFv3 Statistics

### About This Task

Use the following procedure to clear all OSPFv3 statistics.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Clear the statistics:
 

```
clear ipv6 ospf stats [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Variable Definitions

Use the data in the following table to use the **clear ipv6 ospf stats** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies VRF IDs.      |

## Disabling Helper mode for OSPFv3

### Before You Begin

You configure OSPF on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router configuration mode and replace *ipv6* with *ipv6 ospf*.

### About This Task

By default, OSPF Helper mode is enabled when OSPF is configured. You can disable helper mode by the following command and re-enable it again by using “no” or “default” commands.

### Procedure

1. Enter OSPF Router Configuration mode:  
`enable`  
  
`configure terminal`  
  
`router ospf`
  2. Enter the following command to disable Helper mode:  
`ipv6 helper-mode-disable`
  3. Enter the following command to enable Helper mode:  
`no ipv6 helper-mode-disable`
- Or
- ```
default ipv6 helper-mode disable
```

Example

Disabling Helper mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#ipv6 helper-mode-disable
```

Enabling Helper mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
Switch:1(config-ospf)#no ipv6 helper-mode-disable
```

OSPF configuration using EDM

Configure Open Shortest Path First (OSPF) parameters so that the switch can participate in OSPF routing operations. The following section describes procedures that you use while you configure OSPF using Enterprise Device Manager (EDM).

Configuring OSPF globally

Configure OSPF parameters, such as automatic virtual links and OSPF metrics, so you can control OSPF behavior on the system.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.
- Assign an IP address to the switch.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **General** tab.
4. Specify the OSPF router ID.
5. In AdminStart, select **enabled**.
6. (Optional) If required, configure the metrics that OSPF uses for different link speeds.
The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.
7. (Optional) To enable the switch to use OSPF SNMP traps, select the **TrapEnable** check box.
8. (Optional) To enable the automatic creation of virtual links, select the **AutoVirtLinkEnable** check box.
9. (Optional) Configure the OSPF holddown timer as required.
10. Click **Apply**.

General field descriptions

Use the data in the following table to use the **General** tab.

Name	Description
RouterId	Specifies the OSPF router ID. This variable has the same format as an IP address but distinguishes this router from other routers in the OSPF domain.
AdminStat	Shows the administrative status of OSPF for the router. Enabled denotes that the OSPF process is active on at least one interface; disabled disables it for all interfaces. The default is disabled.
VersionNumber	Specifies the OSPF version.
AreaBdrRtrStatus	Denotes if this router is an area border router (ABR). AreaBdrRtrStatus value must be true to create a virtual router interface.
ASBdrRtrStatus	Specifies ASBR status. If you select the ASBdrRtrStatus check box, the router is an autonomous system boundary router (ASBR).
ExternLsaCount	Shows the number of external (LS type 5) link-state advertisements in the link-state database.
ExternLsaChecksumSum	Shows the 32-bit unsigned sum of the link-state checksums of the external link-state advertisements in the link-state database. This sum determines if a change occurred in a router link-state database and compares the link-state databases of two routers.
OriginateNewLsas	Shows the number of new link-state advertisements originated from this router. This number increments each time the router originates a new link-state advertisement (LSA).

Name	Description
RxNewLsas	Shows the number of received link-state advertisements that are new instances. This number does not include new instances of self-originated link-state advertisements.
10MbpsPortDefaultMetric	Indicates the default cost applied to 10 Mbps interfaces (ports). The default is 100.
100MbpsPortDefaultMetric	Indicates the default cost applied to 100 Mbps interfaces (ports). The default is 10.
1000MbpsPortDefaultMetric	Indicates the default cost applied to 1 Gbps interfaces (ports). The default is 1.
10000MbpsPortDefaultMetric	Indicates the default cost applied to 10 Gbps interfaces (ports). The default is 1.
25000MbpsPortDefaultMetric	Indicates the default cost applied to 25 Gbps interfaces (channelized 100 Gbps ports). The default is 1.
40000MbpsPortDefaultMetric	Indicates the default cost applied to 40 Gbps interfaces (ports). The default is 1.
100000MbpsPortDefaultMetric	Indicates the default cost applied to 100 Gbps interfaces (ports). The default is 1.
VlanDefaultMetric	Configures the VLAN interfaces default metric. The default is 10.
TrapEnable	Indicates whether to enable traps for OSPF. The default is false.
AutoVirtLinkEnable	Enables or disables the automatic creation of virtual links. The default is false.
SpfHoldDownTime	Specifies the OSPF holddown timer (3–60 seconds). The default is 10 seconds. The holddown timer delays a metric change due to a routing table update by x seconds. If you configure the timer to 0, OSPF accepts a new metric change immediately.
OspfAction	Initiates a new Shortest Path First (SPF) run to update the routing table. The default is none.
Rfc1583Compatability	Controls the preference rules used when the router chooses among multiple autonomous system external (ASE) LSAs which advertise the same destination. If enabled, the preference rule is the same as that specified by RFC 1583. If disabled, the preference rule is as described in RFC 2328, which can prevent routing loops when ASE LSAs for the same destination originate from different areas. The default is disable.
LastSpfRun	Indicates the time since the last SPF calculation made by OSPF.
HelperModeDisable	Disables the helper mode. It is enabled by default.

Enabling OSPF globally

Enable OSPF globally enabled to use the protocol on the router. If you disable OSPF globally, all OSPF actions cease.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **General** tab.
4. For **AdminStat**, select the **enabled** or **disabled** option button, as required.
5. Click **Apply**.

Configuring global default metrics

Configure the metrics that OSPF uses for different link speeds. The lower the metric, the more likely that OSPF chooses the link to route an OSPF packet.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **General** tab.
4. Change the metric for one or all of the following:
 - 10MbpsPortDefaultMetric
 - 100MbpsPortDefaultMetric
 - 1000MbpsPortDefaultMetric
 - 10000MbpsPortDefaultMetric
 - 25000MbpsPortDefaultMetric
 - 40000MbpsPortDefaultMetric
 - 100000MbpsPortDefaultMetric
5. Click **Apply**.

Configuring an OSPF interface

Configure OSPF parameters, such as authentication and priority, so you can control OSPF interface behavior. You can specify the interface as passive, broadcast, or Non-Broadcast Multiple Access (NBMA).

Before You Begin

- Enable OSPF globally.
- Ensure that the interface exists (the port or VLAN has an IP address).

- You must know the network OSPF password to use password authentication.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Interfaces** tab.
4. Click **Insert**.
5. Select the IP address for the interface from the IP Address list.
6. To designate a router priority, in the **RtrPriority** box, type a new value.
7. In the **Type** area, select the type of OSPF interface you want to create.
8. Select the authentication type you want in the **AuthType** field.
9. If you chose **simplePassword**, in the **AuthKey** box, type a password of up to eight characters.
10. To change their values, select the current value in the **HelloInterval**, **RtrDeadInterval**, or **PollInterval** boxes, and then type new values.
11. Click **Insert**.
12. On the **Interfaces** tab, click **Apply**.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IP Address	Specifies the IP address of the current OSPF interface
AddressLessIf	Designates whether an interface has an IP address: Interfaces with an IP address = 0 Interfaces without IP address = ifIndex
AreaId	Specifies the OSPF area name in dotted-decimal format. For VLANs, keeping the default area setting on the interface causes link-state database (LSDB) inconsistencies. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).
AdminStat	Specifies the current administrative status of the OSPF interface (enabled or disabled).
State	Specifies the current state of the OSPF interface. The value can be one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter

Name	Description
RtrPriority	Specifies the OSPF priority to use during the election process for the designated router. The interface with the highest priority becomes the designated router. The interface with the second-highest priority becomes the backup designated router. If the priority is 0, the interface cannot become the designated router or the backup. The range is 0–255. The default is 1.
DesignatedRouter	Specifies the IP address of the designated router.
BackupDesignatedRouter	Specifies the IP address of the backup designated router.
Type	<p>Specifies the type of OSPF interface (broadcast or NBMA).</p> <p>Note: To make it passive, first create the interface. After interface creation, click VLAN > VLANs to select the VLAN that is created with the OSPF interface. Click the IP tab and select the IP interface that is created with the OSPF interface. Lastly, click the OSPF tab and select Passive for the IfType.</p>
AuthType	<p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. <p>Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p>
AuthKey	Specifies the key (up to 8 characters) required when you specify simple password authentication in the AuthType parameter.
HelloInterval	<p>Specifies the length of time, in seconds, between hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds.</p> <p>After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.</p>
TransitDelay	Specifies the length of time, in seconds, required to transmit an LSA update packet over the interface. The default is 1.
RetransInterval	Specifies the length of time, in seconds, required between LSA retransmissions. The default is 5.

Name	Description
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the Hello interval. To avoid interpretability issues, the RtrDeadInterval value for the OSPF interface must match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. The default is 120.
Events	Indicates the number of times this OSPF interface has changed state, or an error has occurred.

Changing an OSPF non-passive interface type

Change the interface type to designate the interface as either passive, NBMA, or broadcast.

Before You Begin

- Enable OSPF globally.
- Ensure that the interface uses an IP address.
- If the interface is currently an NBMA interface with manually configured neighbors, you must first delete all manually configured neighbors.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Interfaces** tab.
4. To disable the interface, double-click the **AdminStat** cell, and then select **disabled**.
5. Click **Apply**.
6. To change the interface type, double-click the **Type** cell, and then choose the new interface type.
7. Click **Apply**.
8. To enable the interface, double-click the **AdminStat** cell, and then select **enabled**.
9. Click **Apply**.

Changing an OSPF passive interface type

Change the interface type to designate the interface as either passive, NBMA, or broadcast.

Before You Begin

- Enable OSPF globally.
- Ensure that the interface uses an IP address.

- If the interface is currently an NBMA interface with manually configured neighbors, you must first delete all manually configured neighbors.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click on the VLAN where the OSPF interface is created.
4. Click **IP**.
5. Select the IP Address where the OSPF interface is created.
6. Click the **OSPF** tab.
7. Clear the **Enable** check box to disable the OSPF interface.
8. Click **Apply**.
9. Modify the interface type to passive.
10. Select the **Enable** check box.
11. Click **Apply**.

Viewing the OSPF advanced interface

View the OSPF advanced interface.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Interface Advanced** tab.

Interface Advanced field description

Use the data in the following table to use the OSPF Interface Advanced tab.

Name	Description
Index	Indicates the Index of the OSPF interface.
Metric	Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is $(10^9 / \text{interface speed})$. The default is 1. <ul style="list-style-type: none"> • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.

Name	Description
AdvertiseWhenDown	Advertises the network on this port as up, even if the port is down. The default is false. After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on linkstates, disable AdvertiseWhenDown.
IfMtuIgnore	Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.

Configuring NBMA interface neighbors

Configure NBMA neighbors so that the interface can participate in designated router election. All neighbors that you manually insert on the Neighbors tab are NBMA neighbors.

Before You Begin

- Enable OSPF globally.
- Ensure that the interface uses an IP address.
- Ensure that the interface type is NBMA.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Neighbors** tab.
4. Click **Insert**.
5. Enter the IP address and priority for the first neighbor.
6. Click **Insert**.
7. Add all required neighbors.
8. Click **Apply**.

Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
NbrIpAddr	Specifies the neighbor IP address.
AddressLessIndex	Indicates addressed and addressless interfaces. This value is 0 on an interface with an IP address. On addressless interfaces, the corresponding value of ifIndex in the Internet standard management information base (MIB).
NbrRtrId	Specifies the router ID of the neighboring router. The router ID has the same format as an IP address but identifies the router independent of its IP address.

Name	Description
Options	Specifies the bit mask that corresponds to the neighbor options parameter.
Priority	Specifies the priority.
State	Specifies the OSPF interface state.
Events	Specifies the number of state changes or error events that occur between the OSPF router and the neighbor router.
Retransmission Queue Length	Specifies the number of elapsed seconds between advertising retransmissions of the same packet to a neighbor.
ospfNbmaNbrPermanence	Indicates whether the neighbor is a manually configured NBMA neighbor; permanent indicates it is an NBMA neighbor.
HelloSuppressed	Indicates whether hello packets to a neighbor are suppressed.

Configuring OSPF interface metrics

Configure the metrics associated with the peer layer interface to control OSPF behavior. For finer control over port-specific metric speed, you can specify the metric speed when you configure OSPF on a port.

Before You Begin

- Enable OSPF globally.
- Ensure that the interface uses an IP address.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **If Metrics** tab.
4. Double-click the value cell, and type a new value.
5. Click **Apply**.

When you enable a port for OSPF routing, the default metric in the port tab is 0. A value of 0 means that the port uses the default metrics for port types that you specify on the OSPF General tab.

If Metrics field descriptions

Use the data in the following table to use the **If Metrics** tab.

Name	Description
IP Address	Specifies the IP address of the device used to represent a point of attachment in a TCP/IP internetwork.
AddressLessIf	Indicates addressed and addressless interfaces. This variable is 0 on interfaces with IP addresses and equals ifIndex for interfaces that have no IP address.

Name	Description
TOS	Specifies the type of service (TOS). The TOS is a mapping to the IP type of service flags as defined in the IP forwarding table management information base (MIB).
Value	Indicates the metric from the OSPF router to a network in the range.
Status	Specifies the status of the interface as active or not active. This variable is read-only.

Viewing all OSPF-enabled interfaces

View all OSPF-enabled interfaces to determine which interfaces use OSPF routing.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Interfaces** tab.
4. To ensure the system displays the latest information, click **Refresh**.

Configure OSPF on a Port

Configure OSPF parameters on a port so you can control OSPF behavior on the port.

Important

When you enable OSPF on a port, the switch automatically creates an area 0.0.0.0, and advertises it on the specific port, by default. To avoid this behavior, you must manually configure the port into a properly configured area on the switch.

Before You Begin

- Enable OSPF globally .
- Ensure that the port uses an IP address.
- Ensure that the ospf_md5key.txt file is on the switch to use MD5 authentication.
- You must know the network OSPF password to use password authentication.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **OSPF** tab.
5. Select **Enable**.
6. Specify the hello interval.
7. Specify the router dead interval.
8. Designate a router priority.
9. Configure a metric.

10. If you want, select an authentication type.
11. If you select **simplePassword** authentication, type a password in the **AuthKey** box.
12. Configure the area ID.
13. If desired, select the **AdvertiseWhenDown** check box.
14. Select an interface type.
15. Type a value in the **PollInterval** box.
16. For **IfMtuIgnore**, select either **enable** or **disable**.
- 17.
18. For **BfdEnable**, select **enable**.
19. Select **Apply**.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified port. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet, and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this port in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.
Metric	Specifies the metric for the type of service (TOS) on this port. The value of the TOS metric is $(10^9 / \text{interface speed})$. The default is 1. <ul style="list-style-type: none"> • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.

Name	Description
AuthType	<p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. <p>Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p>
AuthKey	Specifies the key (up to 8 characters) when you specify simple password authentication in the port AuthType variable.
AreaId	Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).
AdvertiseWhenDown	<p>Advertises the network on this port as up, even if the port is down. The default is false.</p> <p>After you configure a port with no link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even if the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.</p>
IfType	<p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must have the same poll interval.
IfMtuIgnore	Specifies whether the interface ignores the global maximum transmission unit (MTU) configuration. To allow the switch to accept OSPF database description (DD) packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enable Bidirectional Forwarding Detection (BFD) for OSPF.

Viewing Port OSPF Statistics

View port OSPF statistics to manage network performance.

Procedure

1. On the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **OSPF** tab.

OSPF Field Descriptions

The following table describes parameters on the **OSPF** tab.

Name	Description
VersionMismatches	Specifies the number of version mismatches received by this interface.
AreaMismatches	Specifies the number of area mismatches received by this interface.
AuthTypeMismatches	Specifies the number of authentication type mismatches received by this interface.
AuthFailures	Specifies the number of authentication failures.
NetmaskMismatches	Specifies the number of net mask mismatches received by this interface.
HelloIntervalMismatches	Specifies the number of hello interval mismatches received by this interface.
DeadIntervalMismatches	Specifies the number of dead interval mismatches received by this interface.
OptionMismatches	Specifies the number of option mismatches in the hello interval or dead interval fields received by this interface.
RxHellos	Specifies the number of hello packets received by this interface.
RxDBDescrs	Specifies the number of database descriptor packets received by this interface.
RxLSUpdates	Specifies the number of link state update packets received by this interface.
RxLSReqs	Specifies the number of link state request packets received by this interface.
RxLSAcks	Specifies the number of link state acknowledge packets received by this interface.
TxHellos	Specifies the number of hello packets transmitted by this interface.
TxDBDescrs	Specifies the number of database descriptor packets transmitted by this interface.
TxLSUpdates	Specifies the number of link state update packets transmitted by this interface.

Name	Description
TxLSReqs	Specifies the number of link state request packets transmitted by this interface.
TxLSAcks	Specifies the number of link state acknowledge packets transmitted by this interface.

Graphing OSPF Statistics for a Port

Use statistics to help you monitor OSPF performance on a VLAN. You can also graph statistics for all OSPF packets.

Procedure

1. On the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IP**.
4. Click the **OSPF** tab.
5. Click **Graph**.
6. Select one or more values.
7. Click the type of graph.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
VersionMismatches	Indicates the number of version mismatches received by this interface.
AreaMismatches	Indicates the number of area mismatches received by this interface.
AuthTypeMismatches	Indicates the number of AuthType mismatches received by this interface.
AuthFailures	Indicates the number of authentication failures.
NetMaskMistmatches	Indicates the number of net mask mismatches received by this interface.
HelloIntervalMismatches	Indicates the number of hello interval mismatches received by this interface.
DeadIntervalMismatches	Indicates the number of dead interval mismatches received by this interface.
OptionMismatches	Indicates the number of options mismatches received by this interface.
RxHellos	Indicates the number of hello packets received by this interface.
RxDBDescrs	Indicates the number of database descriptor packets received by this interface.

Name	Description
RxLSUpdates	Indicate the number of Link state update packets received by this interface.
RxLsReqs	Indicates the number of Link state request packets received by this interface.
RxLSAcks	Indicates the number of Link state acknowledge packets received by this interface.
TxHellos	Indicates the number of hello packets transmitted by this interface.
TxDBDescrs	Indicates the number of database descriptor packets transmitted by this interface.
TxLSUpdates	Indicate the number of Link state update packets transmitted by this interface.
TxLSReqs	Indicates the number of Link state request packets transmitted by this interface.
TxLSAcks	Indicates the number of Link state acknowledge packets transmitted by this interface.

Configuring OSPF on a VLAN

Configure OSPF parameters on a VLAN to control OSPF behavior on the VLAN.

Important

When you enable OSPF on a VLAN, the switch automatically creates an area 0.0.0.0, and advertises it on the specific VLAN, by default. To avoid this behavior, you must manually configure the VLAN into a properly configured area on the switch.

Before You Begin

- Enable OSPF globally.
- Ensure that the VLAN uses an IP address.
- Ensure that the `ospf_md5key.txt` file is on the switch to use MD5 authentication.
- Ensure that you know the network OSPF to use password authentication.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **OSPF** tab.

The information on the OSPF tab applies only to a routed port or VLAN, which means the VLAN uses an IP address.

7. To enable OSPF on the VLAN interface, select the **Enable** check box.
8. To change their values, select the current value in the **HelloInterval**, **RtrDeadInterval**, or **PollInterval** boxes, and then type new values.
9. To designate a router priority, in the **DesigRtrPriority** box, type the new value.
10. Select the authentication type in the **AuthType** field.
11. If you chose **simplePassword**, in the **AuthKey** box, type a password of up to eight characters.
12. Select the interface type you want to create.
13. Click **Apply**.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
Enable	Enables or disables OSPF routing on the specified VLAN. The default is false.
HelloInterval	Specifies the length of time, in seconds, between the transmission of hello packets. This value must be the same for all routers attached to a common network. The default is 10 seconds. After you change the hello interval values, you must save the configuration file, and then restart the switch. After the switch restarts, it restores the values and checks for consistency.
RtrDeadInterval	Specifies the interval used by adjacent routers to determine if the router was removed from the network. This interval must be identical on all routers on the subnet and a minimum of four times the hello interval. To avoid interoperability issues, the RtrDeadInterval value for the OSPF interface needs to match with the RtrDeadInterval value for the OSPF virtual interface. The default is 40 seconds.
DesigRtrPriority	Specifies the priority of this VLAN in multiaccess networks to use in the designated router election algorithm. The value 0 indicates the router is not eligible to become the designated router on this particular network. If a tie occurs, routers use their router ID as a tie breaker. The default is 1.
Metric	Specifies the metric for this TOS on this VLAN. The value of the TOS metric is $(10^9 / \text{interface speed})$. The default is 1. <ul style="list-style-type: none"> • FFFF—No route exists for this TOS. • IPCP links—Defaults to 0. • 0—Use the interface speed as the metric value when the state of the interface is up.

Name	Description
AuthType	<p>Specifies the type of authentication required for the interface.</p> <ul style="list-style-type: none"> • none—Specifies that no authentication required. • simple password—Specifies that all OSPF updates received by the interface must contain the authentication key specified in the interface AuthKey parameter. • MD5 authentication—Specifies that all OSPF updates received by the interface must contain the MD5 key. • sha1—Specifies secure hash algorithm 1 (SHA-1), which is a cryptographic hash function that produces a 160-bit hash value, usually given in a hexadecimal number, 40 digits long. You can only access and enable the SHA-1 authentication type after you enable enhanced secure mode. • sha-2—Specifies SHA-2, which offers the hash function SHA-256. <p>Note: sha-2, an update of SHA-1, can offer six hash functions that include SHA-224, SHA-256, SHA-384, SHA-512, SHA-512/224, SHA 512/256, with hash values that are 224, 256, 384, or 512 bits. However, the current release supports only SHA-256.</p>
AuthKey	Specifies the key (up to eight characters) when you specify simple password authentication in the VLAN AuthType variable.
AreaId	Specifies the OSPF area name in dotted-decimal format. The area name is not related to an IP address. You can use a suitable value for the OSPF area name (for example, 1.1.1.1 or 200.200.200.200).
AdvertiseWhenDown	<p>Advertises the network even if the port is down. If true, OSPF advertises the network on this VLAN as up, even if the port is down. The default is false.</p> <p>After you configure a port without a link and enable AdvertiseWhenDown, it does not advertise the route until the port is active. Then, OSPF advertises the route even when the link is down. To disable advertising based on link states, disable AdvertiseWhenDown.</p>
IfType	<p>Specifies the type of OSPF interface (broadcast, NBMA, or passive).</p> <p>Before you change an OSPF interface type, you must first disable the interface. If the interface is an NBMA interface, you must also delete all configured neighbors.</p>
PollInterval	Specifies the length of time, in seconds, between hello packets sent to an inactive OSPF router. Neighbors must use the same poll interval.
IfMtuIgnore	Specifies whether the VLAN ignores the MTU configuration. To allow the switch to accept OSPF DD packets with a different MTU size, enable MtuIgnore. The interface drops incoming OSPF DD packets if their MTU is greater than 1500 bytes.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Graphing OSPF Statistics for a VLAN

Use statistics to help you monitor OSPF performance on a VLAN. You can also graph statistics for all OSPF packets.

Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Select a **VLAN**.
4. Click **IP**.
5. Click the **OSPF** tab.
6. Click **Graph**.
7. Select one or more values.
8. Click the type of graph.

OSPF Field Descriptions

Use the data in the following table to use the **OSPF** tab.

Name	Description
VersionMismatches	Indicates the number of version mismatches received by this interface.
AreaMismatches	Indicates the number of area mismatches received by this interface.
AuthTypeMismatches	Indicates the number of AuthType mismatches received by this interface.
AuthFailures	Indicates the number of authentication failures.
NetMaskMistmatches	Indicates the number of net mask mismatches received by this interface.
HelloIntervalMismatches	Indicates the number of hello interval mismatches received by this interface.
DeadIntervalMismatches	Indicates the number of dead interval mismatches received by this interface.
OptionMismatches	Indicates the number of options mismatches received by this interface.
RxHellos	Indicates the number of hello packets received by this interface.
RxDBDescrs	Indicates the number of database descriptor packets received by this interface.
RxLSUpdates	Indicate the number of Link state update packets received by this interface.
RxLsReqs	Indicates the number of Link state request packets received by this interface.
RxLSAcks	Indicates the number of Link state acknowledge packets received by this interface.

Name	Description
TxHellos	Indicates the number of hello packets transmitted by this interface.
TxDBDescrs	Indicates the number of database descriptor packets transmitted by this interface.
TxLSUpdates	Indicate the number of Link state update packets transmitted by this interface.
TxLSReqs	Indicates the number of Link state request packets transmitted by this interface.
TxLSAcks	Indicates the number of Link state acknowledge packets transmitted by this interface.

Viewing graphs for OSPF on a VLAN

View graphs for OSPF on a VLAN. The graph formats available are: line chart, area chart, bar chart, and pie chart.

Before You Begin

- OSPF must be enabled.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN, and then click **IP**.
5. Click the **OSPF** tab.
6. Click **Graph**.
7. (Optional) To refresh the values in the table, click **Clear Counters**.
8. To specify the polling interval, from the **Poll Interval** drop down menu, select a value. The options are:

Choice Option	Choice Description
5s	The polling interval is 5 seconds.
10s	The polling interval is 10 seconds.
30s	The polling interval is 30 seconds.
1m	The polling interval is 1 minute.
5m	The polling interval is 5 minutes.
30m	The polling interval is 30 minutes.
1h	The polling interval is 1 hour.

9. Select one or two values.

To select two values, for example, AbsoluteValue and Cumulative. Select the first value, and then press the **Control** key to select the second value. You cannot select more than two values.

10. From the toolbar, click a chart icon. The options are:

Choice Option Choice Description

Line Chart	Displays a line chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Area Chart	Displays an area chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Bar Chart	Displays a bar chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Pie Chart	Displays a pie chart for the values you selected against the polling interval.

The Chart Legend uses different colors to identify the values you selected that are plotted on the graph.

11. To switch the horizontal and vertical axes values, on the chart toolbar, click **Horizontal**.
12. To switch views of the log scale from high to low values, or low to high values, on the chart toolbar, click **Log Scale**.
13. To switch to another chart using the same values, on the chart toolbar, click a chart icon.

OSPF graph field descriptions

Use the data in the following table to use the OSPF graph tab.

Name	Description
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the OSPF-Graph tab.
Average/sec	Displays the average value for each second.
Minimum/sec	Displays the minimum value for each second.
Maximum/sec	Displays the maximum value for each second.
LastVal/sec	Displays the last value for each second.
VersionMismatches	Displays the number version mismatches received by this interface.
AreaMismatches	Displays the number area mismatches received by this interface.
AuthTypeMismatches	Displays the number AuthType mismatches received by this interface.
AuthFailures	Displays the number Authentication failures.
NetMaskMismatches	Displays the number net mask mismatches received by this interface.
HelloIntervalMismatches	Displays the number hello interval mismatches received by this interface.
DeadIntervalMismatches	Displays the number dead interval mismatches received by this interface.
OptionMismatches	Displays the number options mismatches received by this interface.

Name	Description
RxHellos	Displays the number hello packets received by this interface.
RxDBDescrs	Displays the number database descriptor packets received by this interface.
RxLSUpdates	Displays the number Link state update packets received by this interface.
RxLSReqs	Displays the number Link state request packets received by this interface.
RxLSAcks	Displays the number Link state acknowledge packets received by this interface.
TxHellos	Displays the number hello packets transmitted by this interface.
TxDBDescrs	Displays the number database descriptor packets transmitted by this interface.
TxLSUpdates	Displays the number Link state update packets transmitted by this interface.
TxLSReqs	Displays the number Link state request packets transmitted by this interface.
TxLSAcks	Displays the number Link state acknowledge packets transmitted by this interface.

Creating stubby or not-so-stubby OSPF areas

Import information from other areas to learn their OSPF relationships. Perform this procedure to create normal, stubby, or not-so-stubby areas (NSSA).

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

Place stubby areas or NSSAs at the edge of an OSPF routing domain. Ensure that you configure all routers in the stubby or NSSA as stubby or NSSA, respectively.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Areas** tab.

The backbone ID has an area ID of 0.0.0.0.

4. Click **Insert**.
5. Configure the area ID.
6. Select an option in the ImportAsExtern area.

To add a not-so-stubby (NSSA) area, select **importNssa**. To import external LSAs (create a normal OSPF area), select **importExternal**. To not import external LSAs (create a stubby area), select **importNoExternal**.
7. Click **Apply**.

Areas field descriptions

Use the data in the following table to use the **Areas** tab.

Name	Description
AreaId	Specifies a 32-bit integer that uniquely identifies an area. Area ID 0.0.0.0 is the OSPF backbone. For VLANs, using the default area on the interface causes LSDB inconsistencies.
ImportAsExtern	Specifies the method to import ASE link-state advertisements. The value can be importExternal (default), importNoExternal, or importNssa.
SpfRuns	Specifies the number of SPF calculations performed by OSPF.
AreaBdrRtrCount	Specifies the number of area border routers reachable within this area. Each SPF pass calculates this value, initially zero.
AsBdrRtrCount	Specifies the number of autonomous system border routers reachable within this area. Each SPF pass calculates this value, initially zero.
AreaLsaCount	Specifies the total number of link state advertisements in this area LSDB, excluding AS-external LSAs.
AreaLsaCksumSum	Specifies the number of link-state advertisements. This sum excludes external (LS type 5) link-state advertisements. The sum determines if a change occurred in a router LSDB and compares the LSDB of two routers.
AreaSummary	Specifies whether to send summary advertisements in a stub area.
ActiveifCount	Specifies the number of active interfaces in this area.

Configuring stub area metrics advertised by an ABR

Configure metrics to control the use of routes in a routing domain.

Before You Begin

- Enable OSPF globally.
- Ensure that the port uses an IP address.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Stub Area Metrics** tab.
4. Double-click the metric value to edit it and specify a new metric speed for the required stub areas.
5. Click **Apply**.

Stub Area Metrics *field descriptions*

Use the data in the following table to use the **Stub Area Metrics** tab.

Name	Description
AreaID	Specifies the 32-bit identifier for the stub area.
TOS	Specifies the type of service associated with the metric.
Metric	Specifies the metric value applied at the indicated type of service. By default, the value equals the lowest metric value at the type of service among the interfaces to other areas.
Status	Specifies the status of the stub area. This variable is read-only.

Inserting OSPF area aggregate ranges

Use aggregate area ranges to reduce the number of link-state advertisements required within the area. You can also control advertisements.

Before You Begin

- Enable OSPF globally.
- Ensure that the port uses an IP address.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Area Aggregate** tab.
4. Click **Insert**.
5. Type the area ID.
6. Select the type of link-state database.
7. Type the IP address of the network.
8. Type the subnet mask.
9. Select the effect.
10. In the **AdvertiseMetric** box, type a cost to advertise for the OSPF area range.
11. Click **Insert**.

Area Aggregate *Field Descriptions*

Use the data in the following table to use the **Area Aggregate** tab.

Name	Description
AreaID	Specifies the area in which the address exists.
LsdbType	Specifies the LSDB type: <ul style="list-style-type: none"> • summaryLink—aggregated summary link • nssaExternalLink—not so stubby area link

Name	Description
IP Address	Specifies the IP address of the network or subnetwork indicated by the range.
Mask	Specifies the network mask for the area range.
Effect	Specifies advertisement methods: <ul style="list-style-type: none"> • advertiseMatching means advertise the aggregate summary LSA with the same LSID. • doNotAdvertiseMatching means suppress all networks that fall within the entire range. • advertiseDoNotAggregate means advertise individual networks.
AdvertiseMetric	Changes the advertised metric cost for the OSPF area range.

Enabling automatic virtual links

Use automatic virtual links to provide an automatic, dynamic backup link for vital OSPF traffic.

Before You Begin

- Enable OSPF globally.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **General** tab.
4. Select the **AutoVirtLinkEnable** check box.
5. Click **Apply**.

Configuring a manual virtual interface

Use manual virtual links (interfaces) to provide a backup link for vital OSPF traffic with a minimum of resource use.

Before You Begin

- Enable OSPF globally.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Virtual If** tab.
4. Click **Insert**.

5. Specify the area ID of the transit area.
The transit area is the common area between two ABRs.
6. Specify the neighbor ID.
The neighbor ID is the IP router ID of the ABR that the other ABR needs to reach the backbone.
7. Click **Insert**.
8. To verify that the virtual link is active, click **Refresh** and check the **State** column.
If the state is point-to-point, the virtual link is active. If the state is down, the virtual link configuration is incorrect.

Virtual If field descriptions

Use the data in the following table to use the **Virtual If** tab.

Name	Description
AreaId	Specifies the transit area ID that the virtual link traverses.
Neighbor	Specifies the router ID of the virtual neighbor.
TransitDelay	Specifies the estimated number of seconds required to transmit a link-state update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between link-state advertisement, and retransmissions for adjacencies that belong to this interface. This variable also applies to DD and link-state request packets. This value must exceed the expected round-trip time. The default is 5.
HelloInterval	Specifies the length of time, in seconds, between the hello packets that the router sends on the interface. This value must be the same for the virtual neighbor. The default is 10.
RtrDeadInterval	Specifies the number of seconds that expires before neighbors declare the router down. This value must be a multiple of the hello interval. This value must be the same for the virtual neighbor. The default is 60.
State	Specifies the OSPF virtual interface state.
Events	Specifies the number of state changes or error events on this virtual Link.
AuthType	Specifies the authentication type specified for a virtual interface. You can locally assign additional authentication types. The default is none.
AuthKey	Specifies the authentication password. If AuthType is a simple password, the device adjusts and zeros fill the eight octets. Unauthenticated interfaces need no authentication key, and simple password authentication cannot use a key with more than eight octets.

Viewing virtual neighbors

View virtual neighbors to view the area and virtual link configuration for the neighboring device.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Virtual Neighbors** tab.

Virtual Neighbors field descriptions

Use the data in the following table to use the **Virtual Neighbors** tab.

Name	Description
Area	Specifies the subnetwork in which the virtual neighbor resides.
RtrId	Specifies the 32-bit integer (represented as an IP address) that uniquely identifies the neighbor router in the autonomous system.
IP Address	Specifies the IP address of the virtual neighboring router.
Options	Specifies the bit mask that corresponds to the neighbor options parameter.
State	Specifies the OSPF interface state.
Events	Specifies the number of state changes or error events that occurred between the OSPF router and the neighbor router.
LsRetransQLen	Specifies the number of elapsed seconds between advertising retransmissions of the same packet to a neighbor.
HelloSuppressed	Specifies whether hello packets from the neighbor are suppressed.

Configuring host routes

Configure host routes when the switch resides in a network that uses routing protocols other than OSPF. A host route is a more-specific route and is used even if it is higher cost than a network route.

Before You Begin

- Enable OSPF globally.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

You can specify which hosts directly connect to the router and the metrics and types of service to advertise for the hosts.

Use a host route to create a custom route to a specific host to control network traffic.

Procedure

1. In the navigation pane, expand **Configuration > IP**.

2. Click **OSPF**.
3. Click the **Hosts** tab.
4. To insert a new host, click **Insert**.
5. In the **IP Address** box , type the area IP address of the new host.
6. In the **Metric** box, type the metric to advertise.
7. Click **Insert**.
8. Click **Apply**.

Hosts field descriptions

Use the data in the following table to use the **Hosts** tab.

Name	Description
IpAddress	Specifies the IP address of the host that represents a point of attachment in a TCP/IP internetwork.
TOS	Specifies the type of service of the route.
Metric	Specifies the metric advertised to other areas. The value indicates the distance from the OSPF router to a network in the range.
AreaID	Specifies the area where the host is found. By default, the area that submits the OSPF interface is in 0.0.0.0.

Enabling ASBR status

Enable the ASBR status to make the switch an autonomous system boundary router (ASBR). Use ASBRs to advertise nonOSPF routes into OSPF domains so that the routes pass through the domain. A router can function as an ASBR if one or more of its interfaces connects to a non-OSPF network, for example, Routing Information Protocol (RIP), BGP, or Exterior Gateway Protocol (EGP).

Before You Begin

- Enable OSPF globally.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

To conserve resources, you can limit the number of ASBRs on your network or specifically control which routers perform as ASBRs to control traffic flow.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **General** tab.
4. Select the **ASBdrRtrStatus** check box.
5. Click **Apply**.

Managing OSPF neighbors

View or delete OSPF neighbors to control OSPF operations.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

The OSPF Hello protocol initiates and maintains neighbor relationships. The exception is that, in an NBMA network, you must manually configure permanent neighbors on each router eligible to become the DR. You can add neighbors for NBMA interfaces, but all other neighbors are dynamically learned.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Neighbors** tab.
4. To delete a manually configured neighbor, select the neighbors with a value of **permanent** in the **ospfNbmaNbrPermanence** column.
5. Click **Delete**.
6. Click **Apply**.

Viewing the link-state database

View the area advertisements and other information in the LSDB to ensure correct OSPF operations.

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **OSPF**.
3. Click the **Link State Database** tab.

Link State Database field descriptions

Use the data in the following table to use the **Link State Database** tab.

Name	Description
Areald	Identifies the area. The OSPF backbone uses the area ID 0.0.0.0.
Type	Specifies the OSPF interface type. Broadcast LANs, such as Ethernet and IEEE 802.5, use broadcast; X.25 and similar technologies use NBMA; and links that are point-to-point use pointToPoint.
Lsid	Identifies the piece of the routing domain that the advertisement describes.

Name	Description
RouterId	Identifies the router in the autonomous system.
Sequence	Identifies old and duplicate link-state advertisements.
Age	Specifies the age, in seconds, of the link-state advertisement.
Checksum	Contains the checksum of the complete contents of the advertisement, except for the age parameter. The checksum does not include the age parameter so that advertisement age increments without updating the checksum.

Configure Route Redistribution to OSPF

Configure a redistribute entry to announce routes of a certain source protocol type into the OSPF domain, for example, static, RIP, or direct. Optionally, use a route policy to control the redistribution of routes.

Before You Begin

- Enable OSPF globally.
- Ensure that a route policy exists.
- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

Important

Changing the OSPF redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform this procedure. As a best practice, if you want to change default preferences for an OSPF redistribute context, do so before you enable the protocols.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **OSPF**.
3. Select the **Redistribute** tab.
4. Select **Insert**.
5. Select an option for the route source.
6. Select **enable**.
7. Select a route policy.
8. Configure the metric type.
9. Configure the subnet.
10. Select **Insert**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination virtual router forwarding instance. You cannot configure this variable.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.
SrcVrfId	Specifies the source VRF instance. You cannot configure this variable.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) an OSPF redistribute entry for a specified source type.
RoutePolicy	Configures the route policy (by name) to use for detailed redistribution of external routes from a specified source into an OSPF domain. Click the ellipsis (...) button and choose from the list in the dialog box.
Metric	Configures the OSPF route redistribution metric for basic redistribution. The value can be a range from 0–65535. A value of 0 indicates to use the original cost of the route.
MetricType	Configures the OSPF route redistribution metric type. The default is type 2. The cost of a type 2 route is the external cost, regardless of the interior cost. A type 1 cost is the sum of both the internal and external costs.
Subnets	Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.

View OSPF Statistics

View OSPF statistics.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **OSPF**.
3. Select the **Stats** tab.

Graph OSPF Statistics

Graph OSPF statistics. The graph formats available are: line chart, area chart, bar chart, and pie chart.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **OSPF**.
3. Select the **Stats** tab.
4. (Optional) To refresh the values in the table, select **Clear Counters**.

5. To specify the polling interval, from the **Poll Interval** drop down menu, select a value. The options are:

Option	Description
5s	The polling interval is 5 seconds.
10s	The polling interval is 10 seconds.
30s	The polling interval is 30 seconds.
1m	The polling interval is 1 minute.
5m	The polling interval is 5 minutes.
30m	The polling interval is 30 minutes.
1h	The polling interval is 1 hour.

6. Select one value; for example, AbsoluteValue or Cumulative.

- Or, select two values; for example, AbsoluteValue and Cumulative.

To select a second value, press the **Ctrl** key, then select the second value. You cannot select more than two values.

7. From the toolbar, select a chart icon. The options are:

Option	Description
Line Chart	Displays a line chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Area Chart	Displays an area chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Bar Chart	Displays a bar chart for the values you selected against the polling interval. The X axis represents time. The vertical axis represents the logging scale.
Pie Chart	Displays a pie chart for the values you selected against the polling interval.

The Chart Legend uses different colors to identify the values you selected that are plotted on the graph.

8. To switch the horizontal and vertical axes values, on the chart toolbar, select **Horizontal**.
9. To switch views of the log scale from high to low values, or low to high values, on the chart toolbar, select **Log Scale**.
10. To switch to another chart using the same values, on the chart toolbar, select a chart icon.

Stats Field Descriptions

Use the data in the following table to use the OSPF **Stats** tab.

Name	Description
AbsoluteValue	Displays the counter value.
Cumulative	Displays the total value since you opened the Stats tab.
Average/sec	Displays the average value for each second.
Minimum/sec	Displays the minimum value for each second.
Maximum/sec	Displays the maximum value for each second.
LastVal/sec	Displays the last value for each second.
LsdbTblSize	Displays the number of entries in the link state database table.
TxPackets	Displays the number of packets transmitted by OSPF.
RxPackets	Displays the number of packets received by OSPF.
TxDropPackets	Displays the number of packets dropped before transmitted by OSPF.
RxDropPackets	Displays the number of packets dropped before received by OSPF.
RxBadPackets	Displays the number of packets received by OSPF that are bad.
SpfRuns	Displays the total number of SPF calculations performed by OSPF, which includes the number of partial route table calculation for incremental updates.
BuffersAllocated	Displays the number of buffers allocated for OSPF.
BuffersFreed	Displays the number of buffers that are freed by the OSPF.
BufferAllocFailures	Displays the number of times that OSPF has failed to allocate buffers.
BufferFreeFailures	Displays the number of times that OSPF has failed to free buffers.
Routes	Displays the number of OSPF routes added to RTM.
Adjacencies	Displays how many adjacencies are learned through the interface.
Areas	Displays the number of areas configured.
Nbrs	Indicates the number of OSPF neighbors.
BadLsReqs	Indicates the number of bad link state requests.
SeqMismatches	Indicates the number of sequence mismatched packets.
NumAllocDDP	Indicates the number of database description (DD) packet buffers allocated for OSPF.
NumFreeDDP	Indicates the number of DD packet buffers that are freed by the OSPF.

Forcing shortest-path calculation updates

Manually initiate an SPF run, or calculation, to immediately update the OSPF LSDB. This configuration is useful if

- you need to immediately restore a deleted OSPF-learned route
- the routing table entries and the LSDBs do not synchronize

Before You Begin

- Change the VRF instance as required to configure OSPF on a specific VRF instance. The VRF must have an RP trigger of OSPF. Not all parameters are configurable on non-default VRFs.

About This Task

This process is computationally intensive. Use this command only if required.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Double-click **OSPF**.
3. Click the **General** tab.
4. In the **OspfAction** area, select the **runSpf** option button.
5. Click **Apply**.
6. Click **Yes** to force an SPF run.

After you initiate an SPF run, wait at least 10 seconds before you initiate another SPF run.

OSPFv3 Configuration using EDM

Use the procedures in this section to configure OSPFv3 using EDM.

Configuring OSPFv3 globally

Configure OSPFv3 globally to enable it on the system and to configure the router ID.

Before You Begin

- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPsec on OSPFv3 virtual link interfaces

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Globals** tab.
4. Type the router ID, in the format of an IPv4 address.
5. Select **enabled**.
6. Optionally, select **ASBdrRtrStatus** to make the router an AS boundary router.

Enable the ASBR if the router attaches at the edge of the OSPF network, and has one or more interfaces that run an interdomain routing protocol. The default is disabled.

7. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

**Note**

Different hardware platforms support different port speeds. For more information, see your hardware documentation.

Name	Description
RouterId	Specifies a 32-bit integer that identifies the router in the autonomous system. This value must be unique. The default value will be one of the IPv4 interface addresses.
AdminStat	Enables or disables OSPFv3 on the router. If you disable OSPFv3 globally, you disable it on all interfaces. The default is disabled.
VersionNumber	Shows the OSPF version number, which for IPv6 is version 3.
AreaBdrRtrStatus	Shows if the router is an area border router.
ASBdrRtrStatus	Configures the router as an autonomous system boundary router. The default is disabled (clear).
HelperModeDisable	Disables Graceful Restart Helper Mode feature.
AsScopeLsaCount	Shows the number of AS-external link-state advertisements in the LSDB.
AsScopeLsaCksumSum	Shows the sum of the checksums for the link-scope LSAs in the LSDB. Use the sum to determine if a change in the LSDB occurs, and to compare the LSDBs of the two routers.
OriginateNewLsas	Shows the number of new link-state advertisements. The number increases each time the router originates a new LSA.
RxNewLsas	Shows the number of new link-state advertisements received. This number does not include new instances of self-originated link-state advertisements.
ExtLsaCount	Shows the number of external (LS type 0x4005) LSAs in the LSDB.
10MbpsPortDefaultMetric	Indicates the default cost applied to 10 Mbps interfaces (ports). The default is 100.
100MbpsPortDefaultMetric	Indicates the default cost applied to 100 Mbps interfaces (ports). The default is 10.
1000MbpsPortDefaultMetric	Indicates the default cost applied to 1 Gbps interfaces (ports). The default is 1.
10000MbpsPortDefaultMetric	Indicates the default cost applied to 10 Gbps interfaces (ports). The default is 1.

Name	Description
25000MbpsPortDefaultMetric	Indicates the default cost applied to 25 Gbps interfaces (channelized 100 Gbps ports). The default is 1.
40000MbpsPortDefaultMetric	Indicates the default cost applied to 40 Gbps interfaces (ports). The default is 1.
100000MbpsPortDefaultMetric	Indicates the default cost applied to 100 Gbps interfaces (ports). The default is 1.
vlanDefaultMetric	Indicates the default cost applied to VLAN interfaces. The default is 10.

Creating an OSPFv3 Area

Create an area to subdivide the autonomous system (AS) into areas that group contiguous networks, routers that connect to these networks, and attached hosts. Subdividing the AS into areas significantly reduces the amount of routing protocol traffic compared to treating the entire AS like a single link-state domain.

About This Task

A stub area does not receive advertisements for external routes, which reduces the size of the link-state database (LSDB). A stub area uses only one area border router (ABR). Any packets destined for outside the area are routed to the area border exit point, examined by the ABR, and forwarded to a destination.

A not so stubby area (NSSA) prevents the flooding of AS-External link-state advertisements into the area by replacing them with a default route. NSSAs also import small stub (non- OSPF) routing domains into OSPF.

Before You Begin

- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPSec on OSPFv3 virtual link interfaces

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Areas** tab.
4. Click **Insert**.
5. Type the area ID.
6. Click **Insert**.

Areas field descriptions

Use the data in the following table to use the **Areas** tab.

Name	Description
Id	Specifies a 32-bit integer to uniquely identify an area. Use 0.0.0.0 for the OSPFv3 backbone.
ImportasExtern	<p>Indicates the support for importing AS-external LSAs::</p> <ul style="list-style-type: none"> • importExternal—normal area • importNoExternal—stub area • importNssa—not-so-stubby-area <p>AS-scope LSAs are not imported into stub areas or NSSAs. NSSAs import AS-External data at Type 7 LSAs, which use area scope. importExternal is the default.</p>
SpfRuns	Shows the number of times the intra-area route table was calculated using the LSDB of this area.
BdrRtrCount	Shows the number of reachable ABRs in this area. The value starts at zero (0). The system calculates this value in each SPF run.
AsBdrRtrCount	Shows the number of reachable ASBRs in this area. The value starts at zero (0). The system calculates this value in each SPF run.
ScopeLsaCount	Shows the number of area-scope LSAs in the LSDB for this area.
ScopeLsaChecksumSum	Shows the sum of the checksums for the area-scope LSAs in the LSDB. Use the sum to determine if a change in the LSDB occurs, and to compare the LSDBs of the two routers.
Summary	Controls the import of inter-area LSAs into a stub area. If the value is noAreaSummary , the router does not originate nor propagate inter-area LSAs into the stub area. If the value is sendAreaSummary (the default), the router both summarizes and propagates inter-area LSAs.
StubMetric	Configures the metric value advertised for the default route to stub and NSSA areas.
NssaTranslatorRole	Indicates if the NSSA border router can perform NSSA translation of Type 7 LSAs to Type 6 LSAs. The possible values are always or candidate. The default is candidate.

Name	Description
NssaTranslatorState	<p>Indicates if and how an NSSA border router translates Type 7 LSAs to Type 5 LSAs. The possible values are</p> <ul style="list-style-type: none"> • enabled—The border router always translates the LSAs. • elected—A candidate border router translates the LSAs. • disabled—A candidate border router does not translate the LSAs.
StubMetricType	<p>Specifies the type of metric advertised as a default route. The possible values are:</p> <ul style="list-style-type: none"> • ospfv3Metric—OSPF metric • comparableCost—external Type 1 • nonComparable—external Type 2 <p>The default is ospfv3Metric.</p>

Create OSPFv3 Area Ranges

Create an area address range on the OSPFv3 router to reduce the number of area border router (ABR) advertisements into other OSPF areas. An area address range is an implied contiguous range of area network addresses for which the ABR advertises a single summary route.

Before You Begin

- You must create the OSPF area.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPsec on OSPFv3 virtual link interfaces

About This Task

If you create two ranges, and one range is a subset of the other, the router uses the most specific match.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Select **OSPFv3**.
3. Select the **Area Aggregate** tab.
4. Select **Insert**.
5. Select the area ID.
6. Select the type of area.

interAreaPrefixLsa generates an aggregated summary.

nssaExternalLsa generates an NSSA link summary.

7. Type the prefix for the IPv6 area address.
8. Type the number of bits from the IPv6 address that you want to advertise.
9. Select **Insert**.

Area Aggregate Field Descriptions

Use the data in the following table to use the **Area Aggregate** tab.

Name	Description
AreaID	Specifies the area in which the address aggregate exists. Use dotted decimal notation to specify the area name.
AreaLsdbType	Specifies the area LSDB type to which the address aggregate applies. interAreaPrefixLsa generates an aggregated summary. nssaExternalLsa generates an NSSA link summary.
Prefix	Specifies the IPv6 prefix. The prefix and prefix length define the range.
PrefixLength	Specifies the length of the prefix, in bits. The prefix cannot be shorter than 3 bits. The prefix and prefix length define the range.
Effect	Specifies the advertisement mode for prefixes in the range. advertiseMatching advertises the aggregate summary LSA with the same link-state ID. doNotAdvertiseMatching does not advertise networks that fall within the range.
AdvertiseMetric	Specifies a cost value to advertise for the OSPF area range. This value applies to summary LSAs (Type 3). If the value is 0, OSPF uses the cost to the farthest point in the network that is summarized.

Creating an OSPFv3 Virtual Link

Create a virtual link if the switch does not connect directly to the backbone. The switch can create automatic virtual links or you can perform this procedure to create virtual links manually. Manual virtual links conserve resources and provide specific control over virtual link placement in your OSPFv3 configuration.

Before You Begin

- The router must be an ABR to create a virtual router interface.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPSec on OSPFv3 virtual link interfaces

About This Task

Virtual linking is similar to backup redundancy. The switch creates a virtual link for vital traffic paths in your OSPFv3 configuration if traffic is interrupted, such as when an interface cable that provides a connection to the backbone (either directly or indirectly) is disconnected from the switch. Automatic virtual linking ensures that a link is created by using another switch.

OSPF routes cannot be learned through an ABR unless it connects to the backbone directly or through a virtual link.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Virtual If** tab.
4. Click **Insert**.
5. Specify the ID for the transit area.

The transit area is the common area between two ABRs.

6. Specify the router ID for the virtual neighbor.

The neighbor ID is the IP router ID of the ABR through which the other ABR must route traffic destined for the backbone.

7. Click **Insert**.
8. Click **Refresh** to verify that the virtual link is active.

If the state is point-to-point, the virtual link is active. If the state is down, the virtual link is configured incorrectly.

Virtual If field descriptions

Use the data in the following table to use the **Virtual If** tab.

Name	Description
AreaId	Specifies the ID for the transit area that the virtual link traverses. Do not use 0.0.0.0.
Neighbor	Specifies the router ID of the virtual neighbor.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state update packet over this interface. The default is 1 second.
RetransInterval	Specifies the number of seconds between link-state advertisement retransmissions for adjacencies that belong to this interface. This value also applies to the retransmissions of database description and link-state request packets. The default is 5 seconds.
HelloInterval	Specifies the number of seconds between hello packets that the router sends on this interface. Configure the same value on the virtual neighbor. The default is 10 seconds.

Name	Description
RtrDeadInterval	Specifies the number of seconds after which the neighbor declares the router down if it does not receive hello packets. Configure this value as a multiple of the hello interval. You must configure the same value on the virtual neighbor. The default is 60 seconds.
State	Shows the state of the virtual interface: either down or pointToPoint.
Events	Shows the number of state changes or error events on the virtual link.
LinkScopeLsaCount	Shows the number of link-scope LSAs in the LSDB for the virtual link.
LinkLsaCksumSum	Shows the sum of the checksums for the link-scope LSAs in the LSDB. Use the sum to determine if a change in the LSDB occurs, and to compare the LSDBs of the two routers.

Create an OSPF Interface on a Brouter Port

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPF interface on a brouter port.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2535. To configure OSPFv3 on an IPv6 VLAN, see [Create an OSPF VLAN Interface](#) on page 2525.

Before You Begin

- The IPv6 interface must exist.

Procedure

- In the Device Physical view, select a port.
- In the navigation pane, expand the **Configuration > Edit > Port** folders.
- Select **IPv6**.
- Select the **IPv6 OSPF Interface** tab.
- Select **Insert**.
- Select the area ID.
- Select **enabled**.
- Select **Insert**.

IPv6 OSPF Interface Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
Areald	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint • passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.

Name	Description
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enable Bidirectional Forwarding Detection (BFD) for OSPF.

Create an OSPF VLAN Interface

Configure the OSPF protocol on an IPv6 VLAN to support dynamic routing on the interface.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2535.

Before You Begin

- The IPv6 interface must exist.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **Basic** tab.
4. Select a **VLAN**.
5. Select **IPv6**.
6. Select the **IPv6 OSPF Interface** tab.
7. Select **Insert**.
8. Select the area ID.

9. Select **enabled**.
10. Select **Insert**.

IPv6 OSPF Interface Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
AreaId	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint • passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an interal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.

Name	Description
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesignatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

Create an OSPF Interface on a Tunnel

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPF interface on a tunnel.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2535. To configure OSPFv3 on an IPv6 VLAN, see [Create an OSPF VLAN Interface](#) on page 2525.

Before You Begin

- The IPv6 interface must exist.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **Tunnel**.
3. Select the **Tunnel Config** tab.
4. Select a configured tunnel.
5. Select **IPv6 OSPF**.
6. Select **Insert**.
7. Select the area ID.
8. Select **enabled**.
9. Select **Insert**.

OSPF Interface Field Descriptions

Use the data in the following table to use the **OSPF Interface** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
Areald	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> • broadcast • NBMA • point-to-point • point-to-multipoint
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an interal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.

Name	Description
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.

Viewing the AS-scope link-state database

View the AS-scope link-state database (LSDB) to see the LSAs that are flooded through the routing domain. The AS scope is used for AS external-LSAs.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **AS-scope LSDB** tab.

AS-scope LSDB field descriptions

Use the data in the following table to use the **AS-scope LSDB** tab.

Name	Description
Type	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. AS-scope LSAs not recognized by the router may be stored in the database.
RouterId	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is being described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Viewing the area-scope LSDB

View the area-scope LSDB to see the LSAs that are flooded in a single OSPFv3 area. Area scope is used in router LSAs, network LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router LSAs, and Intra-Area-Prefix-LSAs.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Area-scope LSDB** tab.

Area-scope LSDB field descriptions

Use the data in the following table to use the **Area-scope LSDB** tab.

Name	Description
AreaId	Identifies the area ID from which the LSA is received. Area ID 0.0.0.0 is the OSPF backbone.
Type	Identifies the type of the link-state advertisement. Each link-state type has a separate advertisement format. Area-scope LSAs unrecognized by the router are also stored in this database.
RouterId	Identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Viewing the link-scope LSDB

View the link-scope LSDB to view the LSAs that are not flooded beyond the local link.

Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Link-scope LSDB** tab.

Link-scope LSDB field descriptions

Use the data in the following table to use the **Link-scope LSDB** tab.

Name	Description
IfIndex	Shows the identifier of the link from which the LSA was received.
Type	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. Link-scope LSAs not recognized by the router may be stored in the database.
RouterId	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is being described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

Adding an NBMA neighbor

Add an NBMA neighbor for each interface that is eligible to become the DR.

An NBMA interface with a positive nonzero router priority is eligible to become the DR for the NBMA network and is configured with the identification of all attached routers, IPv6 addresses, and router priorities.

Before You Begin

- Identify the following information:
 - specific interfaces to include in the NBMA network
 - the IPv6 address for each interface
 - the router priority for each interface
 - the hello interval for the network
 - the router dead interval for the network
 - the poll interval for the network
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

About This Task

In contrast to a broadcast network where switches multicast (send to AllSPFRouters and AllDRouters) certain OSPF protocol packets, switches replicate and send NBMA packets to each neighboring router as unicast. NBMA networks drop all OSPF packets with destination addresses AllSPFRouters and AllDRouters. Because the NBMA network does not broadcast, you must manually configure a list of

neighbors and priorities for all routers in the network that can become the DR. Potential DRs use a positive nonzero router priority.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **NBMA Neighbors** tab.
4. Click **Insert**.
5. Select the IPv6 port or VLAN interface.
6. Specify the IPv6 address for the neighbor.
7. Specify the priority for the neighbor.
8. Click **Insert**.

NBMA Neighbors field descriptions

Use the data in the following table to use the **NBMA Neighbors** tab.

Name	Description
IfIndex	Specifies the link ID for the link over which the switch reaches the neighbor.
Address	Specifies the IPv6 address of the neighbor.
Priority	Specifies the priority to use for this neighbor in the designated router election process. A value of 0 indicates the neighbor cannot become the designated router. The higher the priority value, the higher chance the switch will win the election process. The default is 1.
RtrId	Identifies the neighboring router in the autonomous system. The value is 0.0.0.0 until the switch receives a hello message from the neighbor.
State	Identifies the state of the relationship with the neighbor. The state can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full

Configuring Route Redistribution to OSPFv3

Configure a redistribute entry to announce routes of a certain source protocol into the OSPFv3 domain. Optionally, use a route policy to control the redistribution of routes.

About This Task

Important

Changing the OSPFv3 redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform this procedure. As a best practice, change the default preferences for an OSPFv3 redistribute context, you must do so before you enable the protocols.

Before You Begin

- Enable OSPFv3 globally.
- Ensure that a route policy exists if you intend to use a route policy.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance. The VRF must have an RP trigger of OSPFv3. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Select an option for the route source.
6. Select the **enable** option button.
7. Select a route policy.
8. Configure the metric type.
9. Click **Insert**.

Redistribute Field Descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination virtual router forwarding instance. You cannot configure this variable.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.
SrcVrfId	Specifies the source VRF instance. You cannot configure this variable.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) an OSPF redistribute entry for a specified source type.
RoutePolicy	Configures the route policy (by name) to use for detailed redistribution of external routes from a specified source into an OSPF domain. Click the ellipsis (...) button and choose from the list in the dialog box.

Name	Description
Metric	Configures the OSPF route redistribution metric for basic redistribution. The value can be a range from 0–65535. A value of 0 indicates to use the original cost of the route.
MetricType	Configures the OSPF route redistribution metric type. The default is type 2. The cost of a type 2 route is the external cost, regardless of the interior cost. A type 1 cost is the sum of both the internal and external costs.

Modify an OSPFv3 Interface

Configure the OSPF protocol on IPv6 interface to support dynamic routing on the interface. An IPv6 interface can be a tunnel, port or VLAN.

Before You Begin

- The OSPFv3 interface must exist.

Procedure

- In the navigation pane, expand **Configuration > IPv6**.
- Select **OSPFv3**.
- Select the **Interfaces** tab.
- Double-click a cell to edit the value.
- Select **Apply**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Index	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
Areald	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
Type	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> broadcast NBMA point-to-point point-to-multipoint passive
AdminStat	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.

Name	Description
RtrPriority	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
TransitDelay	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
RetransInterval	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
HelloInterval	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
RtrDeadInterval	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
PollInterval	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
State	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> • down • loopback • waiting • pointToPoint • designatedRouter • backupDesginatedRouter • otherDesignatedRouter
DesignatedRouter	Shows the router ID for the designated router.
BackupDesignatedRouter	Shows the router ID for the backup designated router.

Name	Description
MetricValue	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100. Note: If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
LinkLsaSuppression	Specifies whether Link LSA suppression is enabled.
BfdEnable	Enable Bidirectional Forwarding Detection (BFD) for OSPF.

Viewing OSPFv3 neighbors

View OSPFv3 neighbors to see routers with interfaces to a common network.

The OSPFv3 hello protocol maintains and dynamically discovers neighbor relationships.

The exception is an NBMA network; you manually configure permanent neighbors on each router eligible to become the designated router (DR).

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Neighbors** tab.

Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
IfIndex	Displays the local-link ID of the link over which the neighbor can be reached.
RtrId	Identifies the neighboring router in the Autonomous System. The value is the router ID of the neighboring router, which in OSPF uses the same format as an IPv6 address but identifies the router independent of IPv6 address.
Address	Displays the IPv6 address for the neighbor associated with the local link.
Options	Displays the bit mask that corresponds to the options field on the neighbor.

Name	Description
State	Displays the state of the relationship with the neighbor. The value can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full
NbrIfId	Displays the interface ID that the neighbor advertises in its hello packets on this link.
DeadIntCnt	Displays the Dead interval Count or TTL (time to live) field that indicates how many seconds remain before the system declares the Neighbor down. The starting value is the Router Dead Interval value and it decrements to 0 if no Hello is received for that neighbor within the interval. If no Hello is received within the interval, then the system declares the neighbor down. When a hello is received for the neighbor, the system resets the value to the Router Dead Interval value.

Viewing virtual neighbors

View information about the neighbors on the virtual link to the OSPFv3 backbone.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Virtual Neighbors** tab.

Virtual Neighbors field descriptions

Use the data in the following table to use the **Virtual Neighbors** tab.

Name	Description
Area	Shows the ID for the transit area.
RtrId	Shows the ID for the neighboring router in the autonomous system.
LocalIfIndex	Shows the local interface ID for the virtual link over which the switch can reach the neighbor.

Name	Description
AddressType	Shows the type of address as one of the following: <ul style="list-style-type: none"> • ipv4 • ipv6 • ipv4z • ipv6z • dns ipv4z and ipv6z indicate a scope zone.
Address	Shows the IPv6 address that this virtual neighbor advertises. This value must be a global scope address.
Options	Shows a bit mask that corresponds to the OSPF options field of the neighbor.
State	Shows the state of the virtual neighbor relationship. The value can be one of the following: <ul style="list-style-type: none"> • down • attempt • init • twoWay • exchangeStart • exchange • loading • full

View OSPFv3 Statistics

View OSPF statistics to analyze trends. You can also graph statistics for all OSPF packets transmitted by the switch.

Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **OSPFv3**.
3. Select **Stats**.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
TxPackets	Shows the count of sent packets.
RxPackets	Shows the count of received packets.
TxDropPackets	Shows the count of sent, dropped packets.
RxDropPackets	Shows the count of received, dropped packets.
RxBadPackets	Shows the count of received, bad packets.

Name	Description
SpfRuns	Shows the count of intra-area route table updates with calculations using this area link-state database.
LastSpfRun	Shows the count of the most recent SPF run.
LsdbTblSize	Shows the size of the link state database table.
BadLsReqs	Shows the count of bad link requests.
SeqMismatches	Shows the count of sequence mismatched packets.
Routes	Shows the number of OSPF routes added to the routing table.
Adjacencies	Shows the number of existing adjacencies.
Areas	Shows the number of configured areas.
Nbrs	Shows the number of OSPF neighbors.

OSPFv3 Configuration Example

This section shows an example of OSPFv3 configuration. The following figure shows the network.

Figure 208: OSPFv3 configuration

To complete the configuration, you must perform the following actions:

- Configure an IPv6 VLAN (VLAN 2) with port member 1/1.
- Configure an IPv6 brouter port (1/2).
- Use IPv6 address 2001:100:102::/64.

Configure VLAN 2 and add port members.

```
vlan create 2 type port-mstprstp 0
vlan mlt 2 4
vlan members 2 1/1 portmember
interface vlan 2
ipv6 interface
ipv6 interface enable
ipv6 interface address 2001:100:102:202:0:0:0:1/64
exit
```

Enable OSPFv3 on VLAN 2.

```
# IPV6 OSPF VLAN CONFIGURATION
interface vlan 2
ipv6 ospf area 0.0.0.0
```

```

ipv6 ospf poll-interval 0
ipv6 ospf enable
exit
    
```

Create router port 1/2 with IPv6 and OSPFv3.

```

interface gigabitethernet 1/2
ipv6 interface vlan 3999
ipv6 interface enable
ipv6 interface address 2001:100:102:201:0:0:0:1/64
ipv6 ospf area 0.0.0.0
ipv6 ospf enable
exit
    
```

Verification

The following example shows the Global Router example for OSPFv3 Area configuration:

```

Switch:1#show ipv6 ospf area

=====
                        OSPF Area - GlobalRouter
=====
AREA_ID          STUB_AREA  NSSA   IMPORT_SUM  TRANS_ROLE  TRANS_STATE
-----

Port Performance Management

[Digital Diagnostic Monitoring](#) on page 2543

[Port Performance Management Using CLI](#) on page 2543

[Port Performance Management using EDM](#) on page 2548

Digital Diagnostic Monitoring

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works at any time during active laser operation without affecting data traffic.

The following optical transceivers support DDM:

- 1 Gbps Small Form Factor Pluggable (SFP)
- 10 Gbps Small Form Factor Pluggable plus (SFP+)
- 25 Gbps Small Form Factor Pluggable 28 (SFP28)
- 40 Gbps Quad Small Form Factor Pluggable plus (QSFP+)
- 100 Gbps Quad Small Form Factor Pluggable 28 (QSFP28)

Digital Diagnostic Interface (DDI) is an interface that supports DDM. These devices provide real-time monitoring of individual DDI transceivers. The DDM software provides warnings or alarms after the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about optical transceivers, see [Extreme Optics](#) website

Port Performance Management Using CLI

This section contains procedures to monitor individual DDI transceivers using the CLI.

Configure DDM

Configure Digital Diagnostic Monitoring to get information concerning the status of the transmitted and received signals to allow better fault isolation and error detection.

About This Task

When you enable DDM, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.

For information about how to reset a transceiver for troubleshooting purposes, see [Reset a QSFP+ or QSFP28 Transceiver](#) on page 3592.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. (Optional) Configure an alarm to occur if the port goes down:

```
pluggable-optical-module ddm-alarm-portdown
```
3. (Optional) Configure the DDM interval:

```
pluggable-optical-module ddm-monitor-interval <5-60>
```
4. (Optional) Enable the sending of trap messages when an alarm occurs:

```
pluggable-optical-module ddm-traps-send
```
5. Enable DDM:

```
pluggable-optical-module ddm-monitor
```

Example

Configure the interval to 10 seconds and enable DDM.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#pluggable-optical-module ddm-monitor-interval 10
Switch:1(config)#pluggable-optical-module ddm-monitor
```

Variable Definitions

Use the data in the following table to use the **pluggable-optical-module** command

Variable	Value
<i>ddm-alarm-portdown</i>	When enabled, the port goes down when any alarm occurs. The default is disabled.
<i>ddm-monitor</i>	Enables DDM. When enabled, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.
<i>ddm-monitor-interval</i> <5-60>	Configures the DDM monitor interval. If an alarm occurs, the log message is received within the specific interval. The default value is 5 seconds.
<i>ddm-traps-send</i>	Enables or disables the sending of trap messages. When enabled, the trap message is sent to the device manager any time the alarm occurs. The default is enabled.

View DDI Port Information

Perform this procedure to view basic manufacturing information and characteristics, and the current configuration.

About This Task

This command displays information for DDI transceivers.

Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View basic manufacturing information and characteristics:
show pluggable-optical-modules basic [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
3. View configuration information:
show pluggable-optical-modules config
4. View detailed manufacturing information and characteristics:
show pluggable-optical-modules detail [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

Examples

```
Switch:1#show pluggable-optical-modules config
=====
Pluggable Optical Module Global Configuration
=====
          ddm-monitor : disabled
dgm-monitor-interval : 5
          ddm-traps-send : enabled
dgm-alarm-portdown   : disabled
```

The following example includes Extreme extended diagnostic information. Not all parts support this information. A value of 254 indicates the part has not been initialized.

```
Switch:1#show pluggable-optical-modules detail 1/29

Variable Definitions

Use the data in the following table to use the **show pluggable-optical-modules basic** and **show pluggable-optical-modules detail** commands.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View DDI Temperature Information

About This Task

This command displays information for DDI transceivers.

Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View temperatures:

```
show pluggable-optical-modules temperature [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1#show pluggable-optical-modules temperature

Port Performance Management using EDM

This section contains procedures to monitor individual DDI transceivers using EDM.

View DDI Information

About This Task

You can view DDI information, for example, port information, temperature, and voltages for DDI transceivers.

Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

Procedure

1. On the Physical Device view, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **DDI/SFP** tab.

DDI/SFP Field Descriptions

Use the data in the following table to use the **DDI/SFP** tab.

Name	Description
ConnectorType	Indicates the type of connector.
SupportsDDM	Indicates if the transceiver supports DDM.
DdmStatusMask	Indicates the DDM status. A value other than ddm-ok represents a specific error.
CLEI	Indicates the Telcordia register assignment CLEI code.
VendorName	Indicates the name of the manufacturer.
VendorPartNumber	Indicates the part number for the transceiver.
VendorRevNumber	Indicates the manufacturer revision level for the transceiver.
VendorSN	Indicates the manufacturer serial number for the transceiver.
VendorDateCode	Indicates the manufacturer date code for the transceiver.
Wavelength	Indicates the wavelength in nm. This field is valid for optical transceivers only.
Calibration	Indicates if the calibration is internal or external.
PowerMeasure	Indicates Rx power measurement as average or OMA.
Aux1Monitoring	Indicates if auxiliary monitoring is implemented for the transceiver.
Aux2Monitoring	Indicates if auxiliary monitoring is implemented for the transceiver.
TemperatureLowAlarmThreshold	Indicates the low alarm threshold in degrees Celsius.
TemperatureLowWarningThreshold	Indicates the low warning threshold in degrees Celsius.
Temperature	Indicates the current temperature in degrees Celsius of the transceiver.
TemperatureHighWarningThreshold	Indicates the high warning threshold in degrees Celsius.
TemperatureHighAlarmThreshold	Indicates the high alarm threshold in degrees Celsius.
TemperatureStatus	Indicates if any temperature thresholds were exceeded.
VoltageLowAlarmThreshold	Indicates the low alarm threshold in volts.
VoltageLowWarningThreshold	Indicates the low warning threshold in volts.
Voltage	Indicates the current voltage in volts.

Name	Description
VoltageHighWarningThreshold	Indicates the high warning threshold in volts.
VoltageHighAlarmThreshold	Indicates the high alarm threshold in volts.
VoltageStatus	Indicates if any voltage thresholds were exceeded.
BiasLowAlarmThreshold	Indicates the bias current low alarm threshold in mA.
BiasLowWarningThreshold	Indicates the bias current low warning threshold in mA.
Bias	Indicates the laser bias current in mA.
BiasHighWarningThreshold	Indicates the bias current high warning threshold in mA.
BiasHighAlarmThreshold	Indicates the bias current high alarm threshold in mA.
BiasStatus	Indicates if any bias thresholds were exceeded.
TxPowerLowAlarmThreshold	Indicates the low alarm threshold in dBm for the Tx power.
TxPowerLowWarningThreshold	Indicates the low warning threshold in dBm for the Tx power.
TxPower	Indicates the current Tx power in dBm.
TxPowerHighWarningThreshold	Indicates the high warning threshold in dBm for the Tx power.
TxPowerHighAlarmThreshold	Indicates the high alarm threshold in dBm for the Tx power.
TxPowerStatus	Indicates if any Tx power thresholds were exceeded.
RxPowerLowAlarmThreshold	Indicates the low alarm threshold in dBm for the Rx power.
RxPowerLowWarningThreshold	Indicates the low warning threshold in dBm for the Rx power.
RxPower	Indicates the current Rx power in dBm.
RxPowerHighWarningThreshold	Indicates the high warning threshold in dBm for the Rx power.
RxPowerHighAlarmThreshold	Indicates the high alarm threshold in dBm for the Rx power.
RxPowerStatus	Indicates if any Rx power thresholds were exceeded.
Aux1LowAlarmThreshold	Indicates the low alarm threshold auxiliary 1 reading.
Aux1LowWarningThreshold	Indicates the low warning threshold auxiliary 1 reading.
Aux1	Indicates the current auxiliary 1 reading.
Aux1HighWarningThreshold	Indicates the high warning threshold auxiliary 1 reading.
Aux1HighAlarmThreshold	Indicates the high alarm threshold auxiliary 1 reading.
Aux1Status	Indicates if any auxiliary 1 thresholds were exceeded.
Aux2LowAlarmThreshold	Indicates the low alarm threshold auxiliary 2 reading.
Aux2LowWarningThreshold	Indicates the low warning threshold auxiliary 2 reading.
Aux2	Indicates the current auxiliary 2 reading.

Name	Description
Aux2HighWarningThreshold	Indicates the high warning threshold auxiliary 2 reading.
Aux2HighAlarmThreshold	Indicates the high alarm threshold auxiliary 2 reading.
Aux2Status	Indicates if any auxiliary 2 thresholds were exceeded.
PowerOnCounter	Tracks the power-on-life of the part. This value increments by 1 every 48 hours of consecutive power. This value is never decremented or cleared. If you remove or reinsert the part, reset or reboot the chassis, reset the slot, or channelize or dechannelize the port, then the 48-hour time period restarts.
TxDdmInitial	Indicates the Tx dB from low alarm, which is the difference between the TxPower dBm and the TxPower low alarm. The host provides the value after the first 48 consecutive hours of operation.
TxDdmLastGasp	Indicates the last gasp of Tx dB from low alarm. The host updates this value every 48 hours.
RxDdmInitial	Indicates the Rx dB from low alarm, which is the difference between the RxPower dBm and the RxPower low alarm. The host provides the value after the first 48 consecutive hours of operation after a power cycle.
RxDdmLastGasp	Indicates the last gasp of Rx dB from low alarm. The host updates this value every 48 hours.
ExtremeExtraFeatures	Indicates if the device supports the extra Extreme features.

Note

1. Threshold and actual values for TxBias, TxPower, and RxPower are provided for all 4 channels in QSFP+ and QSFP28 optical transceivers.
2. Auxiliary monitoring does not apply to QSFP+s or QSFP28s.

Power over Ethernet (PoE) is the implementation of IEEE 802.3af, IEEE 802.3at, and IEEE 802.3bt (Type 3 and Type 4), which allows for both data and power to pass over a copper Ethernet LAN cable. Typical power devices include wireless Access Points and VoIP telephones.

Depending on the technology and application requirements, PoE is classified into classes. Depending on the power requirements, the PoE devices are categorized by type. Classes range from Class 0 to 8 whereas types range from Type 1 to 4. Each type associates with an IEEE 802.3 PoE standard. These standards provide signalling between the power sourcing equipment (PSE) and the powered device (PD). PSE devices, such as switches, provide power on the network cable. The devices that PSE provides power to are called PDs, such as VoIP phones, wireless access points, and IP surveillance cameras.

To know which ports support PoE, see the following documents:

- [ExtremeSwitching 5520 Series Hardware Installation Guide](#)
- [Installing the Virtual Services Platform 4450GSX-PWR+](#) or [Installing the Virtual Services Platform 4450GTX-HT-PWR+](#)
- [VSP 4900 Series Switches: Hardware Installation Guide](#)

The switch uses the Dynamic Power Allocation scheme when supplying power to devices. Only the power being consumed by the device is allocated, improving efficiency and enabling support for more number of devices.

You can configure PoE from CLI and Enterprise Device Manager (EDM).

PoE Overview

You can plug any IEEE 802.3af-compliant, 802.3at-compliant, or 802.3bt-compliant (Type 3 and Type 4) for PWR+ powered device into a front-panel port and receive power in that port. Data also can pass simultaneously on that port. This capability is called PoE.

For more information about PoE and power supplies, see your hardware documentation.

The IEEE 802.3af draft standard regulates a maximum of 15.4 W of power for each port; that is, a power device cannot request more than 15.4 W of power. As different network devices require different levels of power, the overall available power budget of the switch depends on your power configuration and the particular connected network devices. If you connect an IP device that requires more than 16 W of power, you see an error on that port notifying you of an overload.

The switch automatically detects each IEEE 802.3af-compliant powered device attached to each front-panel port and immediately sends power to that appliance. The switch also automatically detects how much power each device requires and supply the required DC voltage at a set current based on the load conditions and current availability. The switch supports both PoE and standard LAN devices.

Similarly, the switch automatically detects any IEEE 802.3at-compliant (maximum 25.5 W) or IEEE 802.3bt-compliant (maximum 60W for Type 3, maximum 90W for Type 4) powered device attached to any PoE front panel port and immediately sends power to that appliance.

The power detection function of the switch operates independently of the data link status. A device that is already operating the link for data or a device that is not yet operational can request power. That is, the switch provides power to a requesting device even if the data link for that port is disabled. The switch monitors the connection and automatically disconnects power from a port when you remove or change the device, as well as when a short occurs.

The switch automatically detects devices that require no power connections from them, such as laptop computers or other switching devices, and sends no power to those devices. You control the supply of power to specific ports by setting the maximum allowed power to each port in 1 W increments, from 3 W to 98W.

Important

Wait for 30 seconds between unplugging and replugging an IP device to the switch to enable the IP device to discharge. If you attempt to connect earlier, the switch cannot detect the IP device.

The switch provides the capability to set a PoE power threshold, which lets you set a percentage of the total PoE power usage at which the switch sends a warning message. If the power consumption is below the threshold, the switch logs an information message.

Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings (for example, power limits, or port power priority), you must resave the running configuration file.

PoE Detection Types

The following table identifies product support for the different PoE types.

Table 178: PoE type support

Product	Highest PoE Standard
5420F-48P-4XE	802.3at Type 2 PoE (30W)
5420F-48P-4XL	802.3at Type 2 PoE (30W)
5420F-24P-4XE	802.3at Type 2 PoE (30W)
5420F-8W-16P-4XE	802.3bt Type 4 PoE (90W) on 8 ports 802.3at Type 2 PoE (30W) on 16 ports
5420F-16W-32P-4XE	802.3bt Type 4 PoE (90W) on 16 ports 802.3at Type 2 PoE (30W) on 32 ports
5420F-16MW-32P-4XE	802.3bt Type 4 PoE (90W) on 16 ports 802.3at Type 2 PoE (30W) on 32 ports
5420M-24W-4YE	802.3bt Type 4 PoE (90W)
5420M-48W-4YE	802.3bt Type 4 PoE (90W)
5420M-16MW-32P-4YE	802.3bt Type 4 PoE (90W) on 16 ports 802.3at Type 2 PoE (30W) on 32 ports
5520-12MW-36W	802.3bt Type 4 PoE (90W)
5520-24W	802.3bt Type 4 PoE (90W)
5520-48W	802.3bt Type 4 PoE (90W)
VSP 4450GSX-PWR+	802.3at Type 2 PoE (30W)
VSP 4450GTX-HT-PWR+	802.3at Type 2 PoE (30W)
VSP4900-12MXU-12XE	802.3bt Type 3 PoE (60W)
VSP4900-48P	802.3at Type 2 PoE (30W)

The global configured detection type specifies the following versions of the IEEE standard to support. Standards are arranged from oldest (top) to newest (bottom).

Detection Type	Power Mode
802.3af	Normal
802.3af and legacy	Normal
802.3at	High
802.3at and legacy	High
802.3bt type 3	Normal
802.3bt type 4	Normal
802.3bt and legacy	Normal

By default, 802.3at (including legacy) is the POE PD detection type. In this high power mode, Class 4 PDs receive up to 32 watts of power.

Note

802.3at is backwards compatible with 802.3af. Therefore, both normal power and high power devices are supported in this mode.

802.3af (maximum 15.4 W) and 802.3at (maximum 25.5W) are the older standards.

Note

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

Power usage threshold

The power usage threshold is a chassis configurable percent of the total power available on the switch. When the POE power consumption exceeds this threshold, a log message is generated to warn such an event. When power consumption transitions below the threshold, an informational log message is logged. The default threshold is 80%.

Port Power Limit

Each PoE port has a configurable power limit. This configuration attribute limits the amount of power supplied on a particular port and varies across different hardware platforms. If a PD requires more than the configured limit, the device will not connect properly or is forced to run at a lower limit.

The following table lists the power limit for different hardware platforms:

Table 179: Power Limits

Platform	Power Limit
5420 Series	32 watts <ul style="list-style-type: none"> • 5420F-24P-4XE • 5420F-48P-4XE • 5420F-48P-4XL 98 watts <ul style="list-style-type: none"> • 5420F-8W-16P-4XE • 5420F-16W-32P-4XE • 5420M-24W-4YE • 5420M-48W-4YE • 5420M-16MW-32P-4YE
5520 Series	98 watts
VSP 4450 Series	32 watts
VSP4900-48P	32 watts
VSP4900-12MXU-12XE	64 watts

Port Power Priority

You can configure the power priority of each port by choosing low, high, or critical power priority settings.

The switch automatically drops low-priority ports when the power requirements exceed the available power budget. When the power requirements become lower than the switch power budget, the power returns to the dropped port. When several ports have the same priority and the power budget is exceeded, the ports with the highest interface number are dropped until the consumption is within the power budget.

The priority methods are:

1. Port configured PoE priority

- Low: (default) standard priority for standard devices
- High: higher priority than low for important devices
- Critical: highest priority for critical devices like wireless APs

2. Port number priority where the lower port numbers have a higher priority.

PD Classification

The PDs are classified during initial connection establishment as defined in IEEE 802.3 standards. The classification defines the amount of power a device is expected to consume.

Table 180: Classification Chart for Various Standards

Name	Standard	Class	Type	PSE Min Output Power (in W)	PD Min Input Power (in W)	Example of Supported PDs
PoE	IEEE 802.3af	0	1	15.4	12.95	Static surveillance camera, VoIP phones, wireless access points
		1	1	4	3.84	IP phones
		2	1	7	6.49	IP camera

PoE/PoE+ Allocation Using LLDP

Power over Ethernet/Power over Ethernet Plus allocation using Link Layer Discovery Protocol (LLDP) supports Ethernet switches, which do not support hardware-level power negotiation. With this feature, these switches support IEEE-based PoE and play the role of power sourcing equipment (PSE).

The devices that are powered using PoE, such as IP Phone and Video Surveillance Cameras, are classified as Powered Devices (PD). The maximum allowed continuous output power per cable for each standard is:

- IEEE 802.3af: 15.4 W
- IEEE 802.3at: 25.5 W
- IEEE 802.3bt Type 3: 60 W
- IEEE 802.3bt Type 4: 90 W

The negotiation of actual power supply and demand between a PSE and a PD can be executed at either the physical layer or at the data link layer. After the link is established at the physical layer, the PSE can use the IEEE 802.1AB LLDP protocol to repeatedly query the PD to discover its power needs.

Communication using LLDP allows for a finer control of power allocation, making it possible for the PSE

to dynamically supply the exact power levels needed by individual PDs, and globally for all PDs that are attached. Using LLDP is optional for the PSE, however, it is mandatory for a Type 2 PD that requires more than 12.95 watts of power.

**Important**

LLDP supports PoE discovery and power allocation because some switches do not support hardware-level power negotiation. This allows Type 2 PDs such as PTZ (pan-tilt-zoom) Video Surveillance Cameras to be fully functional when connected to one of these switches. This functionality is enabled by default and is not configurable.

**Note**

Some switches feature a hardware design that supports hardware-level detection. Therefore, they do not require LLDP.

Fast PoE and Perpetual PoE

Fast PoE minimizes the PoE controller recovery time in case of a power failure. With Fast PoE, the PoE controller initializes the moment the switch powers on, which results in a faster recovery period.

Perpetual PoE provides uninterrupted power to all connected devices during a switch reboot.

**Important**

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

View PoE Ports using EDM

The front panel view of Enterprise Device Manager (EDM) provides additional information for Power over Ethernet (PoE) ports for the following PoE switches:

- 5420F-24P-4XE
- 5420F-8W-16P-4XE
- 5420M-24W-4YE
- 5420M-48W-4YE
- 5420F-48P-4XE
- 5420F-16W-32P-4XE
- 5420F-48P-4XL
- 5420F-16MW-32P-4XE
- 5420M-16MW-32P-4YE
- 5520-12MW-36W
- 5520-24W
- 5520-48W
- VSP4900-48P

- VSP4900-12MXU-12XE
- VSP 4450 Series

This additional information is in the form of a colored **P** that displays inside the graphic representation of the port. This colored P represents the current power aspect of the PoE port.

Table 181: Power Aspect color codes

Color	Description
Green	The port is currently delivering power.
Red	The power and detection mechanism for the port is disabled.
Orange	The power and detection mechanism for the port is enabled. The port is not currently delivering power.
White/Gray	The power and detection mechanism for the port is unknown.

Important

The data and power aspect coloring schemes are independent of each other. You can view the initial status for both data and power aspect for the port. To refresh the power status, right-click the unit, and select **Refresh Port Tooltips** from the shortcut menu.

Power over Ethernet Configuration using CLI

This section provides details to configure PoE settings using CLI.

Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Disabling PoE on a port

About This Task

Perform the following procedure to disable PoE on a port. The Ethernet connected device does not receive any power over Ethernet if you shutdown PoE on the port.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable PoE on the port:

```
poe poe-shutdown [port <portlist>]
```

<portlist> is the port on which you want to disable PoE. The default is enable.

What to Do Next

To return power to the port, enter `no poe-shutdown [port <portlist>]`.

Configure PoE Detection Type

Perform the following procedure to configure the PoE powered device (PD) detection type. You can enable either 802.3af and Legacy compliant PD detection methods, or 802.3at and Legacy compliant PD detection methods. The default detection type is 802.3at and legacy.

- 802.3af : normal power mode
- 802.3af and legacy
- 802.3at : high power mode
- 802.3at and legacy
- 802.3bt Type 3 : normal power mode
- 802.3bt Type 4 : normal power mode

802.3at is backwards compatible with 802.3af. Therefore, normal power and high power devices are supported in 802.3at.

Important

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure PoE detection type:

```

poe poe-pd-detect-type {802dot3af | 802dot3af_and_legacy | 802dot3at |
802dot3at_and_legacy | 802dot3bt_type3 | 802dot3bt_type4}

```

Variable Definitions

The following table defines parameters for the **poe-pd-detect-type** command.

Variable	Value
<code>{802dot3af 802dot3af_and_legacy 802dot3at 802dot3at_and_legacy 802dot3bt_type3 802dot3bt_type4}</code>	<p>Configures the detection type to one of the following values:</p> <ul style="list-style-type: none"> • 802dot3af: Set PD detection mode in 802.3af • 802dot3af_and_legacy: Set PD detection mode in 802.3af and legacy • 802dot3at: Set PD detection mode in 802.3at • 802dot3at_and_legacy: Set PD detection mode in 802.3at and legacy • 802dot3bt_type3: Set PD detection mode in 802dot3bt Type3 • 802dot3bt_type4: Set PD detection mode in 802dot3bt Type4

Configuring PoE Power Usage Threshold

About This Task

Perform the following procedure to configure the PoE power usage threshold limit globally as a percentage on the switch. The switch logs a warning message when a PoE PD power usage exceeds the configured threshold. The switch logs an informational message when a PoE PD power usage is below the configured threshold.

Procedure

1. Enter Global Configuration mode:

```

enable

configure terminal

```
2. Configure the power usage threshold:

```

poe poe-power-usage-threshold <1-99>.

```

Variable Definitions

The following table defines parameters for the **poe-power-usage-threshold** command.

Variable	Value
<code><1-99></code>	Specifies the PoE usage threshold in the range of 1–99 percent.

Configure Power Limits for Channels

About This Task

Perform the following procedure to configure the PoE power limit for specific ports or channels. You can limit the PoE wattage available from an individual port or list of ports.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure PoE channel limits:

```
po e poe-limit [port <portlist>] <power_limit>
```

Variable definitions

The following table defines parameters for the **poe-limit** command.

Variable	Value
<i><portlist></i>	Identifies the ports on which the limit is set.
<i><power_limit></i>	Specifies the configurable power limit, in watts on a particular port. To see the available range for the switch, use the CLI Help.

Configuring Port Power Priority

About This Task

Perform the following procedure to configure the PoE power priority for a port or list of ports. You can configure the PoE power priority of ports to manage availability of the connected PDs. If the switch needs to shut down PDs because PoE exceeds the power limit threshold, low priority devices are shut down before high priority, and high priority are shut down before critical.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port power priority:

```
poe poe-priority [port <portlist>] {critical| high| low}
```

Variable Definitions

The following table defines parameters for the **poe-priority** command.

Variable	Value
<portlist>	Identifies the ports to set priority for.
{low high critical}	Identifies the PoE priority.

Enable Fast PoE Globally

About This Task

Perform this procedure to enable Fast PoE on the switch. After you enable Fast PoE, you must save the running configuration file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable Fast PoE:

```
poe fast-poe-enable
```

3. Save the configuration file:

```
save config
```

Enable Perpetual PoE Globally

About This Task

Perform this procedure to enable Perpetual PoE on the switch. After you enable Perpetual PoE, you must save the running configuration file.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable Perpetual PoE:

```
poe perpetual-poe-enable
```
3. Save the configuration file:

```
save config
```

Enable Fast PoE on a Port

About This Task

Perform this procedure to enable Fast PoE on a specific copper port of the switch. After you enable Fast PoE, you must save the running configuration file.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]}
```
2. Enable Fast PoE on the copper port:

```
poe fast-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]]
```
3. Save the configuration file:

```
save config
```

Variable Definitions

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

Enable Perpetual PoE on a Port

About This Task

Perform this procedure to enable Perpetual PoE on a specific copper port of the switch. After you enable Perpetual PoE, you must save the running configuration file.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```
2. Enable Fast PoE on the copper port:

```
poe perpetual-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}]
```
3. Save the configuration file:

```
save config
```

Variable Definitions

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

Display Global PoE Configuration**About This Task**

Perform the following procedure to display the global PoE configuration. You can view the global PoE status, power consumption, power limit threshold, and more.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the global configuration:

```
show poe-main-status
```

Example

```
Switch:1#show poe-main-status
=====
                        PoE Main Status - Stand-alone
=====
Available DTE Power      : 1855 Watts
DTE Power Status         : NORMAL
DTE Power Consumption    : 92 Watts
DTE Power Usage Threshold : 80
PD Detect Type           : 802.3at and Legacy
Power Source Present     : AC Only
Primary Power Status     : Present and operational
Redundant Power Status   : Present and Operational
Fast POE Status          : Enabled
```

```
Perpetual POE Status      : Enabled
POE Firmware Version:    : 3.0.0.6
```

Displaying PoE Port Status

About This Task

Perform the following procedure to display the PoE status for each port. You can use this information to view the status, classification, watts, and priority for each PoE port.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View the port status:
show poe-port-status

Example

```
Switch:1#show poe-port-status
=====
                        POE Port Status
=====
      ADMIN  CURRENT          LIMIT          FAST PERPETUAL
PORT  STATUS  STATUS          CLASSIFICATION (Watts)  PRIORITY POE      POE
-----
Port mgmt does not support DTE power
-----
1/1   Enable  DeliveringPower Class0          98      Low    Disable  Disable
1/2   Enable  DeliveringPower Class0          98      Low    Disable  Disable
1/3   Enable  DeliveringPower Class0          98      High   Disable  Disable
1/4   Enable  Searching        Class0          98      Low    Disable  Disable
1/5   Enable  Searching        Class0          98      Low    Disable  Disable
1/6   Enable  Searching        Class0          98      Low    Disable  Disable
1/7   Enable  Searching        Class0          98      Low    Disable  Disable
1/8   Enable  Searching        Class0          98      Low    Disable  Disable
1/9   Enable  Searching        Class0          98      Low    Disable  Disable
1/10  Enable  Searching        Class0          98      Low    Disable  Disable
```

Note

The PoE status of all ports is displayed. The preceding output is a sample of the full output.

Displaying Port Power Measurement

About This Task

Perform the following procedure to display the PoE power measurement. You can view the voltage, amperage, and wattage for every PoE port. PoE ports without a PD in use are measured as zeros.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View measurement information:
show poe-power-measurement

Example

```
Switch:1#show poe-power-measurement
=====
                                POE Port Measurement
=====
PORT  Volt (V)  CURRENT (mA)  POWER (Watt)
-----
1/1   34.0      117           6.200
1/2   34.0      94            5.000
1/3   34.0      535           28.500
1/4   0.0       0             0.000
1/5   0.0       0             0.000
1/6   34.0      525           27.900
1/7   34.0      152           8.100
1/8   34.0      49            2.600
```

**Note**

The PoE port measurement for all ports is displayed. The preceding output is a sample of the full output.

Power over Ethernet configuration using EDM

This section provides details to configure PoE settings using EDM.

Configure PoE Globally

About This Task

Configure PoE usage threshold and device type settings, and enable Fast PoE and Perpetual PoE globally on a switch.

**Important**

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **PoE** tab.
4. Configure the fields as required.
5. Select **Apply**.

PoE Field Descriptions

Use the data in the following table to use the PoE tab.

Name	Description
Power(watts)	Specifies the nominal power of the Power Sourcing Entity expressed in Watts.
OperStatus	Specifies the operational status of the main Power Sourcing Entity.
ConsumptionPower(watts)	Specifies the measured usage power expressed in Watts.
UsageThreshold%	Configures the usage threshold in percent for comparing the measured power and initiating an alarm if the threshold is exceeded.
PoweredDeviceDetectType	Configures the mechanism used to detect powered ethernet devices attached to a powered ethernet port. The options are: <ul style="list-style-type: none"> • 802.3af • 802.3afAndLegacySupport • 802.3at • 802.3atAndLegacySupport • 802.3bt Type 3 • 802.3bt Type 4
PowerPresent	Specifies the current power source present on the switch. Available power sources are AC and DC. A value of acOnly indicates that the only power supply is AC. A value of dcOnly indicates that the only power supply is DC. A value of acDc indicates that the two power supplies, AC and DC are supplying power.
FastPoeEnable Note: Exception: only supported on 5420 Series, 5520 Series and VSP 4900 Series.	Enables Fast PoE on the switch. The default is disabled.
PerpetualPoeEnable Note: Exception: only supported on 5420 Series, 5520 Series and VSP 4900 Series.	Enables Perpetual PoE on the switch. The default is disabled.

Configure PoE on Ports

About This Task

Enable or disable PoE on a port, and configure PoE priority and power limit settings.

Important

If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

Procedure

1. In the Device Physical View, select one or more ports that support PoE. For information about which ports support PoE, see your hardware documentation.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **PoE** tab.
5. Configure the fields as required.
6. Click **Apply**.

PoE Field Descriptions

Use the data in the following table to configure PoE settings for specific ports.

Name	Description
AdminEnable	Enabled or disables PoE on this port.
FastPoeEnable Note: Exception: only supported on 5420 Series, 5520 Series, and VSP 4900 Series.	Enables or disables Fast PoE on this port. The default is disabled.
PerpetualPoeEnable Note: Exception: only supported on 5420 Series, 5520 Series, and VSP 4900 Series.	Enables or disables Perpetual PoE on this port. The default is disabled.
DetectionStatus	Specifies the operational status of the power device detecting mode on this port: <ul style="list-style-type: none"> • Disabled—detecting function disabled • Searching—detecting function is enabled and the system is searching for a valid powered device on this port • DeliveringPower—detection found a valid powered device and the port is delivering power • Fault (OtherFault)—a power-specific fault has been detected on the port • Test—detecting device is in test mode

Name	Description
PowerClassifications	Specifies the power classification of the device connected to this port. Power classification tags different terminals on the Power over LAN network according to their power consumption. Devices such as IP telephones, WLAN access points, and others can be classified according to their power requirements.
PowerPriority	Configures the power priority for this port: <ul style="list-style-type: none">• critical• high• low
PowerLimit(Watts)	Configures the maximum power that the switch can supply to a port.
Voltage(volts)	Specifies the power measured in volts.
Current(amps)	Specifies the power measured in amps.
Power(Watts)	Specifies the power measured in watts.

Power Savings

[Power Savings Fundamentals](#) on page 2575

[Power Savings Configuration Using CLI](#) on page 2579

[Power Savings Configuration Using EDM](#) on page 2587

Power savings allow you to reduce network infrastructure power consumption during periods of low data activity without impacting network connectivity.

Depending on the power saving option you choose, you can implement power savings on a switch-wide, or on a per-port basis. The following power saving options are supported:

- Energy Saver (switch-wide or per-port)
- Energy Efficient Ethernet (EEE) (per-port only)

You must choose either Energy Saver, or Energy Efficient Ethernet (EEE)—you cannot use both options together.

The following sections describe the Energy Saver and Energy Efficient Ethernet (EEE) features, and how to configure them.

Power Savings Fundamentals

Energy Saver

Table 182: Energy Saver product support

Feature	Product	Release introduced
Energy Saver	5420 Series	VOSS 8.4 Switch models: 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16W-32P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W
	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1 VSP4900-48P and ports 1/1 to 1/12 on VSP4900-12MXU-12XE only
	VSP 7200 Series	VOSS 7.0 VSP 7254XTQ only
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

To reduce direct power consumption by up to 40%, Energy Saver uses intelligent-switching capacity reduction in off-peak mode by controlling port link speeds and optionally powering off low priority PoE devices during off-peak periods. You can schedule Energy Saver to activate during multiple specific time periods. These time periods can be as short as one minute, or can last a week, a weekend, or individual days.

**Note**

- Energy Saver is supported only on copper ports that have auto-negotiation enabled on them.
- If auto-negotiation is disabled on a port and a custom port speed is configured, Energy Saver will not change the speed of that port.

**Important**

- Configuring the port link speed to a low value impacts the overall network performance. The best practice is to use the Energy Saver feature during the hours when the network is not overburdened.
- If a switch is reset while Energy Saver is activated, the PoE power-saving calculation might not accurately reflect the power saving, and in some cases might display zero savings. This problem occurs because the switch did not have sufficient time to record PoE usage between the reset of the switch and the reactivation of Energy Saver. When Energy Saver is next activated, the PoE power saving calculation is correctly updated.
- When Energy Saver is active and you replace a unit, that unit will not be in Energy Saver mode. You must configure Energy Saver directly after replacing a unit.

Interaction with PoE

Energy Saver can use Power over Ethernet (PoE) port-power priority levels to shut down low-priority PoE ports and provide power savings. The power consumption savings of each switch is determined by the number of ports with Energy Saver enabled, and by the power consumption of PoE ports that are powered off. If Energy Saver is disabled on a port, the port is not powered off, irrespective of the PoE configuration. Energy Saver turns off the power to a port only when PoE is enabled globally, the port Energy Saver is enabled, and the PoE priority for the port is configured to Low.

Configuration Fundamentals

To fully configure and use Energy Saver, you must first enable Energy Saver on ports, create a schedule, and then enable Energy Saver globally.

Alternatively, you can configure Energy Saver using the Efficiency Mode quick configuration method, which enables Energy Saver on all ports, creates a default schedule, and enables Energy Saver globally.

You can manually deactivate and reactivate Energy Saver at any time, without affecting the port configurations.

**Note**

- Energy Saver is supported only on copper ports that have auto-negotiation enabled.
- Network Time Protocol (NTP) must be enabled and configured to use Energy Saver.

Energy Efficient Ethernet

Table 183: Energy Efficient Ethernet product support

Feature	Product	Release introduced
Energy Efficient Ethernet (EEE)	5420 Series	VOSS 8.4 All fixed ports on 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W
	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.1 All fixed ports on VSP4900-48P and ports 1/1-1/12 on VSP4900-12MXU-12XE
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 8.1 8424GT
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Energy Efficient Ethernet (EEE) supports the IEEE 802.3az standard for power savings in Ethernet networks for a select group of physical layer devices. A physical device that can support low power idle (LPI) mode is considered EEE-capable. Legacy devices that do not support EEE can be made EEE-compliant with an EEE-compliant PHY and an SDK version that allows the MAC device to interact with the PHY EEE functionality.

In a typical configuration, the EEE protocol communicates with the switch and the physical device to determine when to enter LPI mode during a period of inactivity, and to exit LPI mode when data transmission resumes.

**Note**

EEE is supported only on copper ports that have auto-negotiation enabled on them.

Power Savings Configuration Using CLI

Configure Energy Saver or Energy Efficient Ethernet using the command line interface (CLI).

Enable Energy Saver on Ports

About This Task

Perform this procedure to enable Energy Saver on a specific port or range of ports.

Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before enabling Energy Saver on individual ports.
- If you have previously enabled Efficiency Mode, you must disable it before enabling Energy Saver on individual ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Saver on the specified port:

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port).

```
energy-saver port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} enable
```

Example

Enable energy savings on slot 1 port 2:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface GigabitEthernet 1/2  
Switch:1(config-if)#energy-saver port 1/2 enable
```

What to Do Next

Configure an Energy Saver schedule.

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<code>enable</code>	Enables energy savings on ports. The default is disabled.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Create an Energy Saver Schedule

About This Task

Perform this procedure to configure scheduled time intervals during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

Note

You can configure a maximum of 84 entries in the Energy Saver schedule.

Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before creating a schedule.
- If you have previously enabled Efficiency Mode, you must disable it before creating a schedule. You cannot change the default Efficiency Mode schedule entries when Efficiency Mode is enabled.
- You must enable Energy Saver on every port affected by the schedule.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the Energy Saver schedule:

```
energy-saver schedule {friday | monday | saturday | sunday | thursday
| tuesday | wednesday | weekday | weekend} <hhmm> {activate |
deactivate}
```

Example

Configure an Energy Saver schedule:

```
Switch:1>enable
Switch:1# configure terminal
Switch:1(config)#energy-saver schedule weekend 0735 activate
Switch:1(config)#energy-saver schedule monday 0600 deactivate
```

What to Do Next

Enable Energy Saver globally.

Variable Definitions

The following table defines parameters for the **energy-saver schedule** command.

Variable	Value
<code>{activate deactivate}</code>	Activates or deactivates the scheduled event.
<code><hhmm></code>	Specifies the hour and minutes to enable Energy Saver feature on the switch.
<code>{friday monday saturday sunday thursday tuesday wednesday weekday weekend}</code>	Specifies the day(s) to enable Energy Saver feature on the switch.

Enable Energy Saver Globally

About This Task

Perform this procedure to enable Energy Saver globally on the switch. You can optionally configure PoE power savings, to power off low priority PoE devices during off-peak times.

Before You Begin

- You must enable Energy Saver on individual ports.
- You must create an Energy Saver schedule.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. (Optional) Configure PoE power savings:

```
energy-saver poe-power-saving
```

Note

You must configure PoE power savings before you enable Energy Saver globally.

3. Enable Energy Saver:

```
energy-saver enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver poe-power-saving
Switch:1(config)#energy-saver enable
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>enable</i>	Enables Energy Saver feature. The default is disabled.
<i>poe-power-saving</i>	Enables PoE power saving. The default is disabled.

Enable and Configure Energy Saver using Quick Configuration

About This Task

Perform this procedure to enable and configure Energy Saver globally using the quick configuration Efficiency Mode. Efficiency Mode automatically configures the following:

- enables Energy Saver on all ports.
- creates a default schedule with a weekday schedule of Energy Saver activated from 6:00 p.m. to 7:30 a.m., and during weekends. You cannot change this default schedule while Efficiency Mode is enabled.
- enables Energy Saver globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable efficiency mode:

```
energy-saver efficiency-mode
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver efficiency-mode
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>efficiency-mode</i>	Enables efficiency mode. The default is disabled.

Activate or Deactivate Energy Saver Manually

About This Task

Perform this procedure to activate or deactivate Energy Saver on the switch at any time. Energy Saver is deactivated by default.

Activating Energy Saver reduces the port speed to the minimum value supported by the switch and enables PoE power saving, even if PoE is globally disabled. Deactivating Energy Saver restores the previous configuration.

Before You Begin

Before you can change any previously saved Energy Saver settings, you must disable Energy Saver globally.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Activate or deactivate Energy Saver:
`energy-saver {activate | deactivate}`

Example

```
Switch:1 enable
```

Activate Energy Saver:

```
Switch:1# energy-saver activate
```

Deactivate Energy Saver:

```
Switch:1# energy-saver deactivate
```

Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>activate</i>	Activates Energy Saver manually.
<i>deactivate</i>	Deactivates Energy Saver manually.

Energy Saver Show Commands

Use the procedures in this section to display specific information about Energy Saver configuration on the switch.

Display Energy Saver Global Information

About This Task

Perform this procedure to display information about Energy Saver global configuration.

Procedure

1. Enter Privileged EXEC mode:
`enable`

2. Display global configuration:

```
show energy-saver global
```

Example

```
Switch:1#show energy-saver global
Energy Saver: Disabled
Energy Saver PoE Power Saving Mode: Disabled
Energy Saver Efficiency-Mode Mode: Disabled
Day/Time: Wednesday 02:31:12
Current Energy Saver state: Energy Saver is Inactive
```

Display Energy Saver Interface Information

About This Task

Perform this procedure to display information about Energy Saver configuration on the ports.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about all ports or specify a particular port:

```
show energy-saver interface [{slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

Example

```
Switch:1>enable
Switch:1#show energy-saver interface
Port ES State PoE Savings PoE Priority
-----
1/1      Enabled Enabled Enabled Low
1/2      Enabled Enabled Enabled Low
1/3      Enabled Enabled Enabled Low
1/4      Enabled Enabled Enabled Low
1/5      Enabled Enabled Enabled Low
1/6      Enabled Enabled Enabled Low
1/7      Enabled Enabled Enabled Low
1/8      Enabled Enabled Enabled Low
1/9      Enabled Enabled Enabled Low
1/10     Enabled Enabled Enabled Low
1/11     Enabled Enabled Enabled Low
1/12     Enabled Enabled Enabled Low
1/13     Disabled N/A      N/A
1/14     Disabled N/A      N/A
1/15     Disabled N/A      N/A
```

Display Energy Saver Power Savings Information

About This Task

Perform this procedure to display information about Energy Saver power savings on the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about energy savings:

```
show energy-saver savings
```

Example

```
Switch:1#show energy-saver savings
-----
Unit Model          Switch Capacity      Saving PoE Saving
-----
8404C                0.0 watts           N/A
=====
```

Display Energy Saver Schedule Information

About This Task

Perform this procedure to display information about Energy Saver schedules configured on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about Energy Saver schedules:
show energy-saver schedule

Example

```
Switch:1#show energy-saver schedule
-----
Day      Time  Action
-----
Monday   18:00 Activate
Monday   07:00 Deactivate
```

Enable Energy Efficient Ethernet (EEE)

About This Task

Perform this procedure to enable Energy Efficient Ethernet (EEE) on a port. The default is disabled.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Efficient Ethernet:
energy-saver eee enable

Display Energy Efficient Ethernet (EEE) Statistics

About This Task

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all ports or specify a particular port:

```
show energy-saver eee statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1>show energy-saver eee statistics
```

EEE Port Status					
PortId	EEE Status	Tx LPI Events	Tx Idle Duration (micro seconds)	Rx LPI Events	Rx Idle Duration (micro seconds)
1/1	enabled	847	963657920	115	965100020

Variable Definitions

Use the data in following table to use the `show energy-saver eee statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Clear Energy Efficient Ethernet (EEE) Statistics

About This Task

Perform this procedure to clear information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. Enter Privileged EXEC mode:
2. Clear Energy Efficient Ethernet statistics on all ports or specify a particular port:

```
enable
clear energy-saver eee stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Variable Definitions

Use the data in following table to use the `clear energy-saver eee stats` command.

Variable	Value
<code>port</code>	Specifies one or more ports.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Power Savings Configuration Using EDM

Use the following procedures to configure either Energy Saver or Energy Efficient Ethernet EEE using Enterprise Device Manager (EDM).

Enable Energy Saver Globally

About This Task

Perform this procedure to enable Energy Saver globally.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Globals** tab.
4. Configure the fields as required.
5. Click **Apply**.

Energy Saver Globals Field Descriptions

Name	Description
EnergySaverEnabled	Enables Energy Saver globally on the switch. The default is disabled.
PoePowerSavingEnabled	Enables Energy Saver PoE power saving. The default is disabled.
EfficiencyModeEnabled	Enables Energy Saver efficiency mode. The default is disabled. Efficiency mode enables Energy Saver globally and on all ports, it also enables PoE power saving. It also creates a weekday schedule that starts at 6:00 p.m. and ends at 7:30 a.m., and during the weekend Energy Saver is always activated.
EnergySaverActive	Activates Energy Saver on the switch. Energy Saver is deactivated by default.

Configure Energy Saver Schedule

About This Task

Perform this procedure to configure a scheduled time interval during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

Note

- You can configure maximum 84 entries in the Energy Saver schedule.
- If efficiency mode is enabled, you cannot configure any other entries in the Energy Saver schedule.

Before You Begin

- You must disable Energy Saver globally.
- You must enable Energy Saver on every port affected by the schedule.
- You must deactivate Energy Saver efficiency-mode.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Schedules** tab.
4. Click **Insert**.
5. Configure the fields as required.
6. Click **Insert**.
7. Click **Apply**.

Energy Saver Schedules Field Descriptions

Name	Description
ScheduleDay	Specifies the day on which Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> • monday • tuesday • wednesday • thursday • friday • saturday • sunday • weekdays • weekend
ScheduleHour	Specifies the hour at which Energy Saver is activated or deactivated. The range is 0 to 23. Note: 0 is equivalent to 12 a.m., and 12 is equivalent to 12 p.m.

Name	Description
ScheduleMinute	Specifies the minute at which Energy Saver is activated or deactivated. The range is 0 to 59.
ScheduleAction	Specifies if Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> • activate • deactivate

Enable Energy Saver or EEE on Ports

You can enable Energy Saver or EEE using the Energy Saver tab accessed by the Edit navigation path, or the Power Management navigation path. Use one of the following procedures to enable either Energy Saver or EEE on ports.

Enable Energy Saver or EEE on Ports

About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Edit > Port**.
3. Select **General**.
4. Select the **Energy Saver** tab.
5. Enable either Energy Saver or EEE:
 - To enable Energy Saver, select **EnergySaverEnabled**.
 - To enable EEE, select **EnergySaverEEEEnable**.
6. Select **Apply**.

Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
Port	Specifies the port number.
EnergySaverEnabled	Configures whether Energy Saver is enabled on the specific port.
EnergySavedPoeStatus	Specifies the Energy Saver PoE status for the specific port.
EnergySaverEEEEnable	Configures whether EEE is enabled on the specific port.

Enable Energy Saver or EEE on Ports

About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Select **Energy Saver**.
3. Select the **Ports** tab.
4. Enable either Energy Saver or EEE:
 - To enable Energy Saver, in the **EnergySaverEnabled** column, double-click the field associated with the specific ports, and then select **true**.
 - To enable EEE, in the **EnergySaverEEEEEnable** column, double-click the field associated with the specific ports, and then select **true**.
5. Select **Apply**.

Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
Port	Specifies the port number.
EnergySaverEnabled	Configures whether Energy Saver is enabled on the specific port.
EnergySaverPoEStatus	Specifies Energy Saver PoE status for the specific port.
EnergySaverEEEEEnable	Configures whether EEE is enabled on the specific port.

View Energy Savings

About This Task

Perform this procedure to view the amount of switch capacity and PoE power being saved on the units.

Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Savings** tab.

Energy Savings field descriptions

Name	Description
UnitIndex	Specifies the unit number.
UnitSavings(1/10 watts)	Specifies the amount of switch capacity power being saved on the specific unit.
PoeSavings(1/10 watts)	Specifies the amount of PoE power being saved on the specific unit.

Display Energy Efficient Ethernet Statistics

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

Procedure

1. In the navigation pane, expand **Configuration** > **Power Management**.
2. Select **Energy Saver**.
3. Select the **EEE Statistics** tab.
4. (Optional) Select **Clear Stats** to clear information about EEE statistics.

EEE Statistics Field Descriptions

The following table describes parameters on the **EEE Statistics** tab.

Name	Description
Port	Shows the port number.
State	Shows the state of Energy Efficient Ethernet (EEE) on the port.
TxEvents	Shows the EEE Tx event count for the port.
TxDuration	Shows the EEE Tx durations for the port.
RxEvents	Shows the EEE Rx event count for the port.
RxDuration	Shows the EEE Rx durations for the port.

Quality of Service

[QoS fundamentals on page 2592](#)

[Basic DiffServ configuration using CLI on page 2624](#)

[Basic DiffServ configuration using EDM on page 2628](#)

[QoS configuration using CLI on page 2630](#)

[QoS configuration using EDM on page 2653](#)

QoS fundamentals

Use the information in this section to help you understand Quality of Service (QoS).

This section describes a range of features that you can use on the switch to manage traffic flowing through your network. You can configure your network to prioritize specific types of traffic to ensure that the traffic receives the appropriate QoS level. For those cases where traffic levels are so high that congestion occurs despite management, the switch provides additional congestions handling features that are described in this section.

QoS refers to the ability to control network flows either by prioritizing traffic or by guaranteeing performance levels. QoS does not refer to a specifically achieved service quality. To provide QoS, you can use some combination of the switch's traffic management tools to help deliver provisioned network QoS. It is up to the network administrator to accurately analyze a given situation and select the proper tool(s) for the task.

Introduction to QoS

The switch comes with a set of traffic management tools that you can use to provide QoS for Layer 2 (bridged) or Layer 3 (routed) traffic flows. Many of these flows are multiplexed across a set of network switches and compete for network resources at convergence points. Without traffic management, the congested data flows compete for resources and the result is unpredictable. The resulting QoS can only be described as best-effort. The opposite is also true, without congestion there are sufficient network resources for all traffic to pass without competition. Without congestion, traffic management is not required. In this sense, you cannot separate discussions about QoS and traffic management from those on congestion. The switch provides a set of tools that you can use to provide network services that are far superior to best-effort thereby enabling the delivery of provisioned QoS.

To deliver QoS, the switch uses two types of traffic management tools:

- Congestion management
- Congestion handling

Congestion management acts to prevent congestion by prioritizing traffic flows through priority queuing and priority-aware servicing methods. Other functions, such as policing, are also considered congestion management. Policing indirectly prioritizes some traffic by limiting the rates of other traffic.

Congestion handling alleviates existing congestion by dropping lower priority traffic before higher priority traffic. The switch handles the congestion by queue-specific tail dropping. The basic QoS architecture of the switch identifies three primary functional areas:

- Ingress QoS identification and classification
- the switch's internals and queuing architecture
- QoS marking/remarking for downstream use

Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter.

The QoS architecture is coherent end-to-end across a network. The QoS at any particular network element can be marked in the relevant Layer 2 or Layer 3 protocol fields and provided to the next hop. The receiving next hop can then use this information to classify its own ingress traffic, apply its specific internal traffic management features, and remark the results for subsequent hops.

Depending on the product, the QoS implementation on the switch can support the following options:

1. Ingress priority mappings including: DSCP to internal QoS, 802.1p-bits to internal QoS, and port-level QoS configuration.
2. Egress priority mappings including: internal QoS to DSCP and internal QoS to 802.1p-bits.
3. Automatic QoS
4. Port-based rate limiting or ingress policers
5. Port-based broadcast and multicast rate limiting
6. Port-based egress shaping
7. Egress queue rate limiting

Note

The VSP 7400 Series does not support port-based rate limiting or ingress policers.

Traffic management

Prioritized traffic handling requires QoS classification first. The switch typically classifies traffic by using the endpoint switch configuration in conjunction with the protocol elements of the incoming frame such as *priority*. You can add additional classification by using access control lists (ACLs) and other filtering functionality.

The switch's internal traffic management functions use the results of classification to determine the prioritization of traffic. Examples of internal functions that prioritize traffic would be both strict and weighted round robin (WRR) queue scheduling. These mechanisms prioritize data by favorable scheduling or weighting.

The disposition of a particular data frame is not necessarily fully determined as a result of classification. You can apply additional traffic management functions such as Ingress Port Rate Limiting or Policing depending on your switch features. Ingress Port Rate Limiting is a congestion management mechanism

to limit the traffic rate accepted by the specified ingress port. Policing is a congestion management method that limits incoming traffic at the ingress that could cause congestion at the egress. While queuing strategies affect prioritization by favoring some traffic; policing is essentially the opposite. Policing works not by favoring some traffic, but by penalizing the bursty traffic. Queue scheduling and policing are only two of the available tools for congestion management. Additional details are presented in subsequent sections of this document.

In addition to the traffic management tools which aid in the prevention of congestion, tools are also provided to handle congestion as it occurs. Congestion handling tools monitor congestion levels at convergence points in the switch and selectively discard frames if congestion begins to increase. Per queue tail dropping is the primary congestion handling function of the switch. You can also use ACLs and filtering as congestion handling tools.

Differentiated Services (DiffServ)

Table 184: Differentiated Services product support

Feature	Product	Release introduced
Differentiated Services (DiffServ) including Per-Hop Behavior	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

Differentiated Services (DiffServ) is a traffic management tool that classifies network traffic into eight traffic classes, and then gives each class differentiated treatment. DiffServ networks map the traffic's class into a set of packet forwarding behavior, referred to as a *Per-Hop Behavior (PHB)*. A PHB could specify which egress queue to use. For example, a switch may classify a packet by determining its protocol to be IPv4, subsequently extract the DSCP value, and apply a PHB by directing the packet to a specific queue. DiffServ does not prescribe a set of traffic classes and does not predetermine which types of traffic should be handled by a given class. DiffServ simply provides a generic means of classifying packets so they may be treated differently.

DiffServ applies to IP packets only.

DiffServ Access and DiffServ Core

A fundamental characteristic of DiffServ networks is the distinction made between switches at the network edges and those residing in the network interior. The switch refers to this distinction as DiffServ Access (edge) and DiffServ Core (interior), respectively.

It is important to note that the switch operates simultaneously as both a DiffServ Access switch and a DiffServ Core switch. The architectural premise is that the edge or access nodes perform the bulk of the

work (classification, policing, etc.) and mark the packet for downstream processing. In theory this would permit the interior or core switches to bypass much of the edge processing as they would “trust” the classification and marking performed by the access switch. The notion of trust is key to the access/core switch distinction.

- If you configure a port as an access port, the system does not trust packet markings.
- If you configure a port as a core port, the system trusts packet markings.

On the access side, malicious users can send packets into a network with intent to cause serious harm (e.g., denial of service attacks). However, on core switches, the only traffic sources are one’s own upstream switches. As such, a core switch has the opportunity to trust the classification, markings (and implied PHB) determined by the previous hop.

The following figure shows DiffServ network operations. The devices are on the network edge where they perform classification, marking, policing, and shaping functions.

Figure 209: DiffServ network core and edge devices

Use a DiffServ Access port at the edge of a DiffServ network. The access port classifies traffic according to port QoS. Outgoing packet DSCP and 802.1p values are derived from port QoS and QoS maps. The system strips Dot1Q headers at ingress, and adds them back at egress only if you configure the egress port as a tagged or trunk port.

A DiffServ Core port does not change packet classification or markings; the port trusts the incoming traffic markings. A core port preserves the DSCP marking of all incoming packets, and uses these markings to assign the packet to an internal QoS level. For tagged packets, the port honors the 802.1p bits within a Dot1Q header, and uses these bits to classify ingress traffic. You can control the honoring (or not) of 802.1p bits by configuring the 802.1p override in CLI or Enterprise Device Manager (EDM).

Per-Hop Behavior (PHB)

Traffic entering the DiffServ network enter a queue according to their marking, which determines the PHB of the packets. For example, if the system marks a video stream to receive the highest priority, it enters a high-priority queue. As these packets traverse the DiffServ network, the system forwards the video stream before other packets.

As a standard, DiffServ is described in the context of Layer 3. Classification is accomplished by mapping a packet priority field from the packet and then applying a per-hop behavior. DiffServ standards define the IPv4 header’s Differentiated Services Code Point (DSCP) field to determine classification and subsequent per-hop behavior.

The RFC2598 standard provides only the following four fundamental per-hop behaviors:

- Default (DF) — This PHB provides best-effort forwarding behavior.
- Expedited Forwarding (EF) — This PHB provides performance-critical forwarding.
- Assured Forwarding (AF) — This PHB classifies traffic based upon **class** (priority) only.

Important

The switch never classifies nor takes action based upon drop precedence. In response to congestion, the only drops available for a given traffic class are tail drops.

- Class Selector (CS) — This PHB provides a simple mapping of a DSCP to one of eight traffic classes. While the switch provides all four PHBs, the CS PHB is most analogous to the switch's internal processing – classification occurs to derive priority, which subsequently determine the per-hop behavior (e.g., queuing).

DiffServ and filters

QoS (DiffServ) and filters operate independently; you do not have to use filters to provide QoS. However, filters can override QoS operations. For more information, see [Traffic filtering fundamentals](#) on page 3344.

DiffServ and VXLAN Gateway

DSCP bits in the outer IP header of VXLAN-encapsulated packets are always derived from the internal QoS, irrespective of the ingress port DiffServ configuration. Customer packet IP DSCP bits are not modified as part of VXLAN encapsulation. For more information about VXLAN, see [VXLAN Gateway](#) on page 3858.

Traffic traversing the switch

The switch's traffic management capabilities are best understood by examining the functionality that is invoked as packets flow from ingress ports, through the switch, to egress ports. The following list includes the set of features and processing that the switch performs as flows traverse the switch:

- Classification and ingress mapping
- Filtering
- Rate Limiting or Policing
- Queueing
- Remarking
- Shaping

The switch classifies packets to determine their priority. While DiffServ is traditionally defined as Layer 3 functionality, the switch extends the logical concept to Layer 2. The switch can, based upon user configuration, determine a packet's priority from either its Layer 2 (p-bits) or Layer 3 (DSCP) information.

- If the packet arrives on an untrusted port (DiffServ Access), then the packet's priority comes from user-configured parameters such as port priority.
- If the packet arrives on a trusted port, priority comes from information contained in the packet's header (p-bits or DSCP).

After the switch determines the packet's configured or marked priority, it maps that value to be used internally. The QoS level used by the switch is referred to as the **Internal QoS Level (IQL)**. The IQL is the

internal numerical value that the switch uses to determine the packets per-hop behaviors such as queue selection and bandwidth guarantee.

The following list identifies the order of DiffServ operations for a packet:

- Packet classification: IEEE 802.1p and DSCP markings classify (map) the packet to its appropriate PHB and QoS level.
- Remarking: The switch can remark packets according to QoS actions you configure on the switch (internal QoS mappings).
- Shaping: The switch provides port-based shaping. Port-based shaping shapes all outgoing traffic to a specific rate.

Classification and mapping

Traffic classification includes functions that examine a packet to determine further actions according to defined rules. Classification involves identifying flows so that the router can modify the packet contents or Per-Hop Behavior (PHB), apply conditioning treatments to the packet, and determine how to forward the packet to the egress interface. Packet classification depends on the service type of the packet and the point in the traffic management process where the classification occurs.

The device classifies traffic as it enters the DiffServ network, and assigns appropriate PHB based on the classification. To differentiate between classes of service, the device marks the DiffServ (DS) parameter in the IP packet header, as defined in RFC2474 and RFC2475. The DSCP marking defines the forwarding treatment of the packet at each network hop. This marking (or classification) occurs at the edge of the DiffServ domain, and is based on the policy (or filter) associated with the particular microflow or aggregate flow.

You can configure the mapping of DSCP-to-forwarding behaviors and DSCP re-markings. Re-marking the DSCP resets the treatment of packets based on new network specifications or desired levels of service.

Layer 3 marking uses the DSCP parameter. Layer 2 (Ethernet) marking involves the 802.1p-bits parameter.

For Layer 2 packets, priority bits (or 802.1p bits) define the traffic priority of the Ethernet packet. You can configure an interface to map DSCP or 802.1p bits to internal QoS levels on ingress. You can configure an interface to map internal QoS levels to DSCP or 802.1p bits at egress. 802.1p bit mapping provides the Ethernet VLAN QoS requirements.

Within the network, a packet PHB associated with the DSCP determines how a device forwards the packet to the next hop—if at all. Consequently, nodes can allocate buffer and bandwidth resources to each competing traffic stream. The initial DSCP value is based on network policies for the type of service required. The objective of DSCP-to-Service Class mapping is to translate the QoS characteristics defined by the packet DSCP marker to a Service Class. The DSCP-to-Service Class mapping occurs at ingress. For each received packet, the mapping function assigns a Service Class.

The switch maintains four mapping tables. These tables translate the ingress 802.1p-bits or DSCP markings to an internal QoS level, and then retranslate the internal QoS level to an egress DSCP or 802.1p-bits marking as follows:

- ingress 802.1p-bits to QoS level
- ingress DSCP to QoS level
- QoS level to egress 802.1p-bits
- QoS level to egress DSCP

Service classes

Service classes define a standard architecture to provide end-to-end QoS on a broad range of Ethernet switching and voice products. They function as default QoS policies built into the product. They incorporate the various QoS technologies to provide a complete end-to-end QoS behavioral treatment. The switch includes a built-in QoS implementation for service classes.

The switch includes eight preconfigured queues (corresponding to the eight service classes) on each port of an interface module.

A service class domain classifies traffic as one of the following:

- Network control traffic (Critical/Network)
- Subscriber traffic (Premium, Metal, or Standard)

Queue 7 — Critical/Network Service Class (PHB of CS6/CS7)

The switch uses the Critical/Network Service Class for traffic within a single administrative network domain. If such traffic does not get through, the network cannot function.

Queue 6 — Premium Service Class (PHB of CS5/EF)

The switch uses the Premium Service Class for IP telephony services, and provides the low latency and low jitter required to support such services. IP telephony services include Voice over IP (VoIP), voice signaling, Fax over IP (FoIP), and voice-band data services over IP (for example, analog modem). The switch can also use the Premium Service Class for Circuit Emulation Services over IP (CESoIP).

Metal Service Classes

The Platinum, Gold, Silver, and Bronze Service Classes are collectively referred to as the metal classes. The metal Service Classes provide a minimum bandwidth guarantee and are for variable bit rate or bursty types of traffic. Applications that use the metal Service Class support mechanisms that dynamically adjust their transmit rate and burst size based on congestion (packet loss) detected in the network. The following list describes the individual metal classes:

- Queue 5 — Platinum Service Class (PHB of CS4/AF41)

The switch uses the Platinum Service Class for applications that require low latency, for example, real-time services such as video conferencing and interactive gaming. Platinum Service Class traffic provides the low latency required for interhuman (interactive) communications. The Platinum Service Class provides a minimum bandwidth assurance for Assured Forwarding (AF) 41 and Class Selector (CS) 4-marked flows.

- Queue 4 — Gold Service Class (PHB of CS3/AF31)

The switch uses the Gold Service Class for applications that require near-real-time service and are not as delay-sensitive as applications that use the Platinum service. Such applications include streaming audio and video, video on demand, and surveillance video.

The Gold Service Class assumes that traffic buffers at the source and destination and, therefore, the traffic is less sensitive to delay and jitter. By default, the Gold Service Class provides a minimum bandwidth assurance for AF31, AF32, AF33 and CS3-marked flows.

- Queue 3— Silver Service Class (PHB of CS2/AF21)

The switch uses the Silver Service Class for responsive (typically client- and server-based) applications. Such applications include Systems Network Architecture (SNA) terminals (for example, a PC or Automatic Teller Machine) to mainframe (host) transactions that use Data Link Switching (SNA over IP), Telnet sessions, web-based ordering and credit card processing, financial wire transfers, and Enterprise Resource Planning applications.

Silver Service Class applications require a fast response and have asymmetrical bandwidth needs. The client sends a short message to the server and the server responds with a much larger data flow back to the client. For example, after a user clicks a hyperlink (that sends a few dozen bytes) on a webpage, a new webpage opens (that downloads kilobytes of data). The Silver Service Class provides a minimum bandwidth assurance for AF21 and CS2-marked flows.

The Silver Service Class favors short-lived, low-bandwidth TCP-based flows.

- Queue 2 — Bronze Service Class (PHB of CS1/AF11)

The switch uses the Bronze Service Class for longer-lived TCP-based flows, such as file transfers, e-mail, or noncritical Operation, Administration, and Maintenance (OAM) traffic. The Bronze Service Class provides a minimum bandwidth assurance for AF11 and CS1-marked flows. As a best practice, use the Bronze Service Class for noncritical OAM traffic with the CS1 DSCP marking.

Queue 1 and 0 — Standard (PHB of CS0/DF) and Custom Service Classes

The switch uses the Standard and Custom Service Classes for best-effort services. Delays, loss, or jitter guarantees for these service classes are not specified. However, the Standard Service Class has more forwarding resources than the custom service classes.

Internal QoS level

The internal QoS level or effective QoS level is a key element in the switch QoS architecture. The internal QoS level specifies the kind of treatment a packet receives. The switch classifies every packet that enters and assigns it an internal QoS level.

Internal QoS levels map to the queues on a port. For example, for an access port the internal QoS level is derived from the port QoS level. For Layer 3 trusted (core) ports, the system honors incoming DSCP or type of service (TOS) bits. The system assigns the internal QoS level using the ingress DSCP to QoS level map.

Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter. For more information, see [Internal QoS Level and Remarking](#) on page 3358.

Ingress mappings

The system uses ingress maps to translate incoming packet QoS markings to the internal QoS level. The system uses the internal QoS level to classify packets.

Ingress mappings include

- 802.1p to (internal) QoS level
- DSCP to (internal) QoS level

The following logical table shows how the system performs ingress mappings for data packets and for control packets not destined for the Control Processor (CP).

Table 185: Data packet ingress mapping

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	No	x	No	x	x	Use port QoS
x	Yes	x	No	x	No	Use port QoS
x	Yes	x	No	x	Yes	Use ingress p-bits mapping
0x1B	x	x	Yes	x	x	4
0x23	x	x	Yes	x	x	5
0x29	x	x	Yes	x	x	5
0x2F	x	x	Yes	x	x	6
x	No	No	x	x	x	Use port QoS
x	No	Yes	Yes	x	x	Use ingress DSCP mapping
x	Yes	No	Yes	x	No	Use port QoS
x	Yes	No	Yes	x	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	No	No	Use ingress DSCP mapping

Table 185: Data packet ingress mapping (continued)

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	Yes	Yes	Yes	No	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	Yes	Yes	Use ingress DSCP mapping

**Important**

On a tagged port that is Layer-2 trusted, Layer-3 trusted and DiffServ enabled, all multicast packets honor the ingress DSCP value.

The QoS level for control packets destined for the CPU is assigned internally to ensure timely packet processing and scaling numbers. You cannot configure the QoS level for these control packets. The system assigns the highest QoS-level to time-critical protocols.

The following table shows ingress IEEE 802.1p to QoS level mappings.

Table 186: Default ingress 802.1p to QoS mappings

Ingress IEEE 802.1p	PHB	QoS Level	Network Service Class (NSC)
0	CS0/DF	1	Standard
1	Custom	0	Custom
2	CS1/AF11	2	Bronze
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold
5	CS4/AF41	5	Platinum
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows DSCP to internal QoS level mappings.

Table 187: Default ingress DSCP to QoS mapping

Ingress				Internal QoS level	PHB level
DSCP (decimal)	DSCP (binary)	DSCP (hexadecimal)	TOS (hexadecimal)

63	111111	3F	FC	1	CS0

Egress mappings

Egress mappings include:

- QoS level to IEEE 802.1p mappings
- QoS level to DSCP mappings

When a packet is forwarded by the switch, the software does the following:

- Always performs 802.1p remarking before the packet egresses.
- If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the IP packet is DSCP remarked before the packet egresses.

If the ingress port is not configured this way, the packets are not DSCP remarked.

The following table shows egress QoS level to IEEE 802.1p mappings.

Table 188: Default egress QoS level to IEEE 802.1p mappings

QoS level	PHB	Default 1p remarking on egress	Network Service Class (NSC)
0	Custom	1	Custom
1	CS0/DF	0	Standard
2	CS1/AF11	2	Bronze
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold
5	CS4/AF41	5	Platinum
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows QoS level to DSCP mappings.

Table 189: Default egress QoS level to DSCP mappings

Egress

The switch QoS implementation supports the following two features for bandwidth management and traffic control:

- ingress port-rate limiting—a mechanism to limit the traffic rate accepted by the specified ingress port
- egress port-rate shaping—the process by which the system delays and transmits packets to produce an even and predictable flow rate

Each port has eight unicast and multicast queues, Class of Service (CoS) 0 to CoS 7. Traffic shaping exists on the egress CoS 6 and CoS 7, but you cannot change the configuration. CoS 6 and CoS 7 are strict priority queues, with traffic shaping for CoS 6 at 50 percent and CoS 7 to five percent of line rate.

Some VOSS hardware platforms allow you to configure an egress shaping rate for each port manually. For XA1400 Series, the egress shaping rate for each front panel port dynamically adjusts to the auto-negotiated link speed, up to the maximum link speed of the port.

The VSP 4450 Series switch QoS implementation supports the following two features for bandwidth management and traffic control:

- ingress traffic policing—a mechanism to limit the number of packets in a stream that matches a particular classification
- egress traffic shaping—the process by which the system delays (or drops) and transmits packets to produce an even and predictable flow rate

Each feature is important to deliver DiffServ within a QoS network domain.

Token buckets

Tokens are a key concept in traffic control. A port-rate limiter, policer, or shaper calculates the number of packets that passed, and at what data rate. Each packet corresponds to a token, and the port-rate limiter, policer, or shaper transmits or passes the packet if the token is available. For more information, see [Figure 210](#).

The token container is like a bucket. In this view, the bucket represents both the number of tokens that a port-rate limiter, policer, or shaper can use instantaneously (the depth of the bucket) and the rate at which the tokens replenish (how fast the bucket refills).

Each policer has two token buckets: one for the peak rate and the other for the service rate. The following figure shows the flow of tokens.

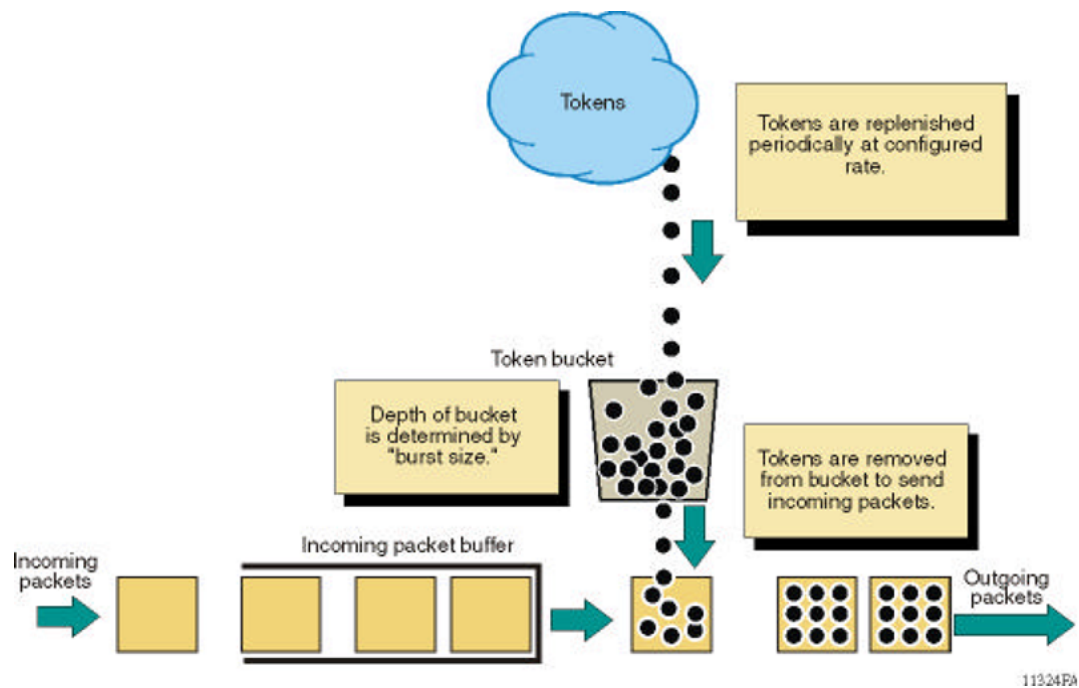

Figure 210: Token flow

Ingress port-rate limiter

Ingress port-rate limiter limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be set.

For more information on ingress port-rate limiter, see:

- [View the Ingress Port-Rate Limit Information](#) on page 2636
- [Configuring the ingress port-rate limiter](#) on page 2635

Queuing

Queuing is a congestion-avoidance function that prioritizes packet delivery. Queuing ensures discriminate packet discard during network congestion, and can delay a packet in memory until the scheduled transmission.

You can use queuing to manage congestion. Congestion management involves the creation of queues, assignment of packets to the queues based on the classification of the packet, and scheduling of the packets in a queue for transmission.

The system schedules packets for transmission according to their assigned priority and the queuing mechanism configured for the interface. The scheduler determines the order of packet transmission by controlling how the system services queues with respect to each other. The switch uses 16 CPU queues

(used by traffic destined to the CPU), and eight unicast and eight multicast queues for each port. The deepest queue does not go beyond 60,000 packets.

A scheduler services the eight queues for each port, using a combination of strict priority and round-robin. Queue zero through five use round robin, and queues six and seven drain completely, or up to certain rate limits.

There are eight priorities on each egress port. Each Weighted Round Robin (WRR) queue has a minimum guaranteed weight to ensure fair bandwidth allocation for each queue in case all QoS queues are utilized and there is congestion. With the default profile, Class of Service (CoS) 0 to CoS 5 are WRR, and the default weights are 10, 20, 30, 40, 50, and 50 respectively. CoS 6 and CoS 7 are strict priority queues. The switch subjects CoS 6 and CoS 7 to traffic shaping at 50 per cent and five per cent of line rate respectively.

Note

VSP 4450 Series switches use Weighted Deficit Round Robin (WDRR). The priorities and default weights are the same as WRR.

For the VSP 8600 Series, 8 CPU queues are implemented. The highest priority packets, such as VLACP, are routed to the highest priority CPU queue (COS 7). The least time critical packets are routed to the lowest CPU queue (COS 0). Statistics for the CPU port are displayed using the CLI command **show qos cosq-stats cpu-port**.

All packets destined for the CPU are sent as unicast packets.

Front panel ports also have 8 queues. When a front panel port is oversubscribed with both unicast and multicast packets, the bandwidth is divided so that the unicast packets receive 80% of the bandwidth and multicast packets 20% of the bandwidth.

If there are no multicast packets using the reserved 20%, the bandwidth is evenly distributed between COS levels 0 to 6. This results in approximately 3.3% more bandwidth for each level. If a specific COS level is not oversubscribed, the unused bandwidth is evenly distributed between the other COS levels. The CLI provides commands to map ingress packets to specific COS levels.

Note

Unicast packets will be tail dropped on the ingress card. Multicast packets will be dropped at egress card.

Among the WRR queues, the approximate bandwidth percentage is relative to the remaining bandwidth after subtracting the Strict Priority queues. The following tables provide the approximate bandwidth percentage based on queue congestion.

Table 191: Bandwidth for Queue 0 to 5 congestion

Queue	Approximate bandwidth percentage*
0	5%
1	10%
2	15%
3	20%

Table 191: Bandwidth for Queue 0 to 5 congestion (continued)

Queue	Approximate bandwidth percentage*
4	25%
5	25%
* The approximate value assumes that all queues 0 to 5 are congested and similar packet sizes. Any queue that does not require bandwidth results in adding more bandwidth to the WRR queues. Percentage is relative to the total bandwidth minus the bandwidth consumed by Cos 6 and 7 (strict queues).	

Table 192: Bandwidth for Queue 0 to 7 congestion

Queue	Approximate bandwidth percentage*
0	2.25%
1	4.5%
2	6.75%
3	9%
4	11.25%
5	11.25%
6	50%
7	5%
* The approximate value assumes that all queues 0 to 7 are congested and similar packet sizes.	

CPU Queues

This section provides information about CPU traffic and queues for different hardware platforms.

Note

To view the CPU traffic and queue information for the VSP 8600 Series use the command `show qos cosq-stats cpu-port`.

The following table outlines the CPU traffic, and which queue it uses, for the VSP 4450 Series.

Queue description	Queue ID	Queue pps, burst size	Traffic type

Low latency	13	256 pps, 32 kbps	SLPP
Low latency	14	100 pps, 32 kbps	BPDU
Low latency	15	250 pps, 32 kbps	LACP, VLACP, TUNI-extract

The XA1400 Series uses filters to rate limit packets to the CPU.

Packet Type	Rate (PPS)	Packet Size (Bytes)
CFM, VLACP, RIPv2, SONMP, RIPv1, VRRP, ARP.	100	64
DHCP	50	1400
ISIS, OSPF	100	1400
Other Packets	Not rate limited	Not Applicable

Queue profiles

Table 193: Queue Profiles product support

Feature	Product	Release introduced
QoS per queue rate limiting	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.1
	VSP 8400 Series	VOSS 5.1.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

This section identifies optional ways to customize the egress queues and scheduling depending on your need to override the default configuration. You can also enable egress queue rate limiting, if desired.

Use a queue profile to apply configured egress queue parameters and modify each queue individually. You can use the queue profile to configure a minimum weight for the queue and to enable rate limiting for the queue. The queue profile applies to all ports in the switch.

Note

If you enable rate limiting for all queues, the scheduler treats all queues as strict priority queues. If all queues are strict priority, the scheduler services the highest priority queue first until the maximum bandwidth is met, and then it services the next highest priority queue. Queue 0 is the lowest priority queue, which means that when over-subscribed, the lower priority queues are serviced last, or not at all.

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Note

The egress queues with rate limiting enabled must be contiguous. For example, you can configure queues 3–6, but you cannot configure 3 and 6.

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

Configuration considerations

If you modify the QoS configuration for a port that is a member of MultiLink Trunking (MLT), all ports in the MLT inherit the same configuration. If you remove the port from the MLT, it keeps the QoS configuration it inherited from the MLT.

QoS support for 10 GbE interface in 1GbE mode

If you use QoS with a 10 gigabit Ethernet (GbE) interface and re-purpose the interface as a 1 GbE interface, you must make the necessary configuration changes to accommodate the new link speed.

Check your rate limiting and shaping settings, if you choose to change the port link speed from 10 GbE to 1 GbE.

Review the following commands to ensure proper configuration for the port speed you use.

Command	Description
<code>qos if-rate-limiting [port {slot/port}] rate <1000-40000000></code>	Configures ingress port rate limiting in kbps. Note: The range can vary depending on your hardware platform.
<code>rate-limit broadcast {<1-65535> <50-65000000>}</code>	Configures ingress port broadcast rate limiting in packets/second. Note: The range can vary depending on your hardware platform.

Command	Description
<code>rate-limit multicast {<1-65535> <50-65000000>}</code>	Configures ingress port multicast rate limiting in packets/second. Note: The range can vary depending on your hardware platform.
<code>qos if-shaper [port {slot/ port[/sub-port] [-slot/ port[/sub-port]] [, ...] }] shape-rate <shape-rate></code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: <code>Error: port slot/port, The QoS Egress shaper rate can not exceed the port capability.</code>

802.1p and 802.1Q Best Practices

In a network, to map the 802.1p user priority bits, use 802.1Q-tagged encapsulation on customer-premises equipment (CPE). You require encapsulation because the switch does not provide classification when it operates in bridging mode.

To ensure consistent Layer 2 QoS boundaries within the service provider network, you must use 802.1Q encapsulation to connect a CPE directly to the switch access node. If you do not require packet classification, use Ethernet Routing Switch 5600 to connect to the access node. In this case, configure the traffic classification functions in the Ethernet Routing Switch 5600.

At the egress access node, packets are examined to determine if their IEEE 802.1p or DSCP values must be re-marked before leaving the network. Upon examination, if the packet is a tagged packet, the IEEE 802.1p tag is configured based on the QoS level-to-IEEE 802.1p-bit mapping. For bridged packets, the DSCP is re-marked based on the QoS level.

Network congestion and QoS design

When you provide QoS in a network, one of the major elements you must consider is congestion, and the traffic management behavior during congestion. Congestion in a network is caused by many different conditions and events, including node failures, link outages, broadcast storms, and user traffic bursts.

At a high level, three main types or stages of congestion exist:

1. No congestion
2. Bursty congestion
3. Severe congestion

In a noncongested network, QoS actions ensure that delay-sensitive applications, such as real-time voice and video traffic, are sent before lower-priority traffic. The prioritization of delay-sensitive traffic is essential to minimize delay and reduce or eliminate jitter, which has a detrimental impact on these applications.

A network can experience momentary bursts of congestion for various reasons, such as network failures, rerouting, and broadcast storms. The switch has sufficient capacity to handle bursts of congestion in a seamless and transparent manner. If the burst is not sustained, the traffic management and buffering process on the switch allows all the traffic to pass without loss.

Severe congestion is defined as a condition where the network or certain elements of the network experience a prolonged period of sustained congestion. Under such congestion conditions, congestion thresholds are reached, buffers overflow, and a substantial amount of traffic is lost.

When you perform traffic engineering and link capacity analysis for a network, the standard design rule is to design the network links and trunks for a maximum average-peak utilization of no more than 80%. This value means that the network peaks to up to 100% capacity, but the average-peak utilization does not exceed 80%. The network is expected to handle momentary peaks above 100% capacity.

Layer 2 and Layer 3 trusted and untrusted ports

You can configure interface module ports as trusted or untrusted at both Layer 2 (802.1p) or Layer 3 (DSCP) for ingress packet classification.

The switch provides eight internal QoS levels. These eight levels, numbered zero to seven, map to the queues through

- the ingress 802.1p to (internal) QoS mapping table
- the ingress DSCP to (internal) QoS mapping table

To configure a port as trusted or untrusted, use the commands and the parameter values as shown in the following tables:

Layer 2 Trusted	Layer 2 Untrusted
802.1p-override	802.1p-override
disable	enable

Layer 3 Trusted		Layer 3 Untrusted	
enable-diffserv	access-diffserv *	enable-diffserv	access-diffserv *
enable	disable	disable	disable
		disable	enable
		enable	enable **

* Configure **access-diffserv** as either a core or access port. If enabled, this command specifies an access port and overrides incoming DSCP bits. If disabled, it specifies a core port that honors and services incoming DSCP bits.

** If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the packet is DSCP remarked at egress.

Layer 2 untrusted and Layer 3 untrusted

To configure a port as Layer 2 untrusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

For more information, see [Table 185](#) on page 2600.

Layer 2 untrusted and Layer 3 trusted

To configure a port as Layer 2 untrusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through the DSCP parameter for all IP packets, whether tagged or untagged. Use this configuration when another QoS or DiffServ enabled and configured switch marks the IP packets at the edge. These already-marked packets arrive Layer 3 trusted, and the switch continues with the trust (DiffServ core port operation). For tagged packets, the system does not examine the 802.1p bits. For non-IP packets, this configuration causes classification by port QoS settings.

Note

For IP switched and tagged packets, use the 802.1p bits to derive the internal QoS. For untagged or routed packets, use the DSCP to derive the internal QoS.

For more information, see [Table 185](#) on page 2600.

Layer 2 trusted and Layer 3 trusted

To configure a port as Layer 2 trusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through DSCP for all IP packets, and through 802.1p for all tagged non IP packets. If it is an IP packet, DSCP is used. If it is a tagged non IP packet, 802.1p bits are used. If it is an untagged non IP packet, the port QoS is used.

For more information, see [Table 185](#) on page 2600.

Layer 2 trusted and Layer 3 untrusted

To configure a port as Layer 2 trusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through 802.1p for all tagged packets, and port QoS levels for all untagged (IP or non-IP) packets. If the packet is an IP packet, the system does not modify or examine the DSCP parameter bits.

For more information, see [Table 185](#) on page 2600.

DiffServ disabled

If you disable the DiffServ parameter, the system ignores the Layer 3 DSCP parameter. For more information, see [Table 185](#) on page 2600.

Broadcast and multicast traffic bandwidth limiters per ingress port

Interface modules support bandwidth limiters for ingress broadcast and multicast traffic. The system drops traffic that violates the bandwidth limit. Enable this feature and configure the rate limit on an individual port basis.

QoS and VoIP

Table 194: QoS and VoIP product support

Feature	Product	Release introduced
Platform specific considerations for QoS behavior are documented in QoS Behavior Differences, which is in <i>VOSS User Guide</i> .		
Automatic QoS	5420 Series	Not Supported Use Auto-sense with IP Phone support instead
	5520 Series	Not Supported Use Auto-sense with IP Phone support instead
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
XA1400 Series	VOSS 8.0.50	

VoIP traffic requires low latency and jitter.

If you use edge routers, configure ingress ports as core ports to treat VoIP traffic appropriately. In this case, the system trusts QoS markings that apply to VoIP traffic, and the system does not re-mark QoS settings. However, if this configuration is not sufficient, you can also apply filters, route policies, or re-mark traffic.

Automatic QoS

Automatic QoS specifically supports converged voice deployments. Automatic QoS automatically recognizes the DSCP value voice applications can use, and associates these DSCP values with the proper queue.

When you use Automatic QoS, the system recognizes application traffic and prioritizes the traffic through the system. Automatic QoS offers a simplified and resource-efficient mechanism to prioritize application traffic within the network. Automatic QoS supersedes DiffServ mode configuration.

The following table shows the traffic types, the standard DSCP value, the specific Automatic QoS DSCP values, and the queue mappings for the Automatic QoS DSCP values.

Table 195: Automatic QoS DSCP values

Traffic type	Automatic QoS DSCP value	Queue
VoIP data (Premium)	0x2F (47)	6
VoIP signaling (Platinum)	0x29 (41)	5

Table 195: Automatic QoS DSCP values (continued)

Traffic type	Automatic QoS DSCP value	Queue
Video (Platinum)	0x23 (35)	5
Streaming (Gold)	0x1B (27)	4

The traffic that the system identifies, based on these DSCP values, receives preferential queuing treatment within the system and is re-marked for preferential downstream processing.

The system associates additional filtering (ACL filters) to ensure that Auto-QoS DSCP values are honored no matter what the QoS configuration of the ingress is.

These additional filtering components target ingress traffic with the designated private DSCP values. After a match occurs, the system re-marks the traffic based on the application mode. Ingress traffic that is not marked with a recognized private DSCP value receives the same treatment as it receives without the Automatic QoS feature.

The switch activates Automatic QoS automatically; you cannot deactivate this feature but you can remap these DSCP values to use a different queue. The system displays a warning that these values should not be modified.

```
Switch:1(config)#qos ingressmap ds 47 2
DSCP values should not be modified.
Do you want to continue ? (y/n) ? y
```

You do not need to configure individual QoS components across a variety of platforms. Automatic QoS applies end-to-end.

**Important**

For VSP 8600 Series switches, automatic QoS derives internal QoS based on DSCP and is honored for routed traffic *only*. For switched traffic, Automatic QoS does not work and falls back to deriving internal QoS based on VLAN .1p bits or uses the port's default QoS level.

QoS re-marking on a Transparent Port UNI

A Transparent Port UNI port is normally configured as a Layer 2 trusted port. The T-UNI port honors incoming customer 802.1p bits and derives an internal QoS level. The 802.1p bit marking of the Backbone VLAN (B-VLAN) is derived from the internal QoS level. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned. Customer packet headers are not modified.

The T-UNI port QoS configurations are:

- DiffServ = disable
- Layer3Trusted = access (for EDM configuration)
- access-diffserv enable (for CLI configuration)

QoS considerations when a port is associated with a T-UNI I-SID

- You cannot configure `access-diffserv` and `enable diffserv` on a T-UNI port.
- When a port is associated with a T-UNI I-SID, the T-UNI QoS configuration automatically takes effect.

- When the port is removed from the T-UNI I-SID, the default port QoS configuration takes effect.

QoS considerations when an MLT is associated with a T-UNI I-SID

- When an MLT, static or LACP, is added to a T-UNI I-SID, the T-UNI QoS configuration take effect on all the ports of the MLT.
- When an MLT, static or LACP, is removed from a T-UNI I-SID, the port default QoS configuration is configured on all the member ports of the MLT.
- If a port is added dynamically to a T-UNI MLT, static or LACP, the port inherits the QoS properties of the T-UNI MLT ports.
- If a port is dynamically removed from a T-UNI MLT, static or LACP, the port retains the QoS configuration inherited from the MLT.

QoS and channelization

Use channelization to configure a single port to operate as four subports. By default, the ports are not channelized.

You can enable or disable channelization on a channelization-capable port. Enabling or disabling channelization on a port resets the port QoS configuration to default values. For more information on channelization, see [Enable Channelization](#) on page 544.

QoS examples and Best Practices

The sections that follow present QoS network scenarios for bridged and routed traffic over the core network.

Bridged traffic

If you bridge traffic over the core network, you keep customer VLANs separate (similar to a Virtual Private Network). Normally, a service provider implements VLAN bridging (Layer 2) and no routing. In this case, the 802.1p-bit marking determines the QoS level assigned to each packet. If DiffServ is active on core ports, the level of service received is based on the highest of the DiffServ or 802.1p settings.

The following cases provide sample QoS design guidelines you can use to provide and maintain high service quality in a network.

If you configure a core port, you assume that, for all incoming traffic, the QoS value is properly marked. All core switch ports simply read and forward packets; they are not re-marked or reclassified. All initial QoS markings are performed at the customer device or on the edge devices.

The following figure illustrates the actions performed on three different bridged traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

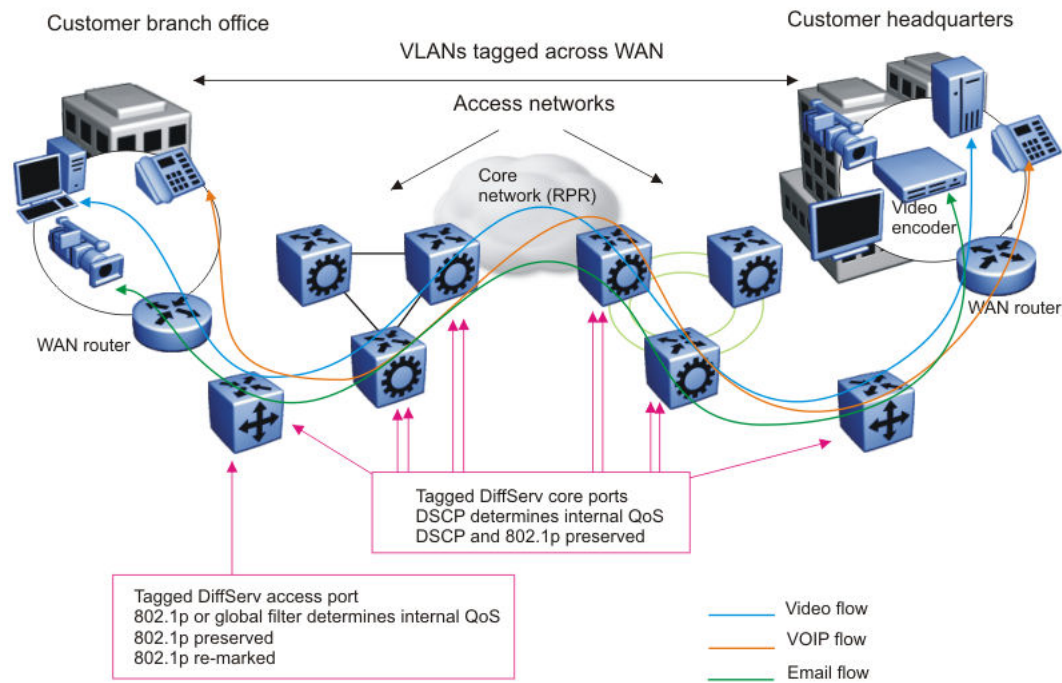

Figure 211: Trusted bridged traffic

For bridged, untrusted traffic, if you configure the port to access, mark and prioritize traffic on the access node using global filters. Reclassify the traffic to ensure it complies with the class of service specified in the SLA.

For Resilient Packet Ring (RPR) interworking, you can assume that, for all incoming traffic, the QoS configuration is properly marked by the access nodes. The core switch ports, configured as core or trunk ports, perform the RPR interworking. These ports preserve the DSCP marking and re-mark the 802.1p bit to match the 802.1p bit of the RPR. The following figure shows the actions performed on three different traffic flows (VoIP, video conference, and email) over an RPR core network.

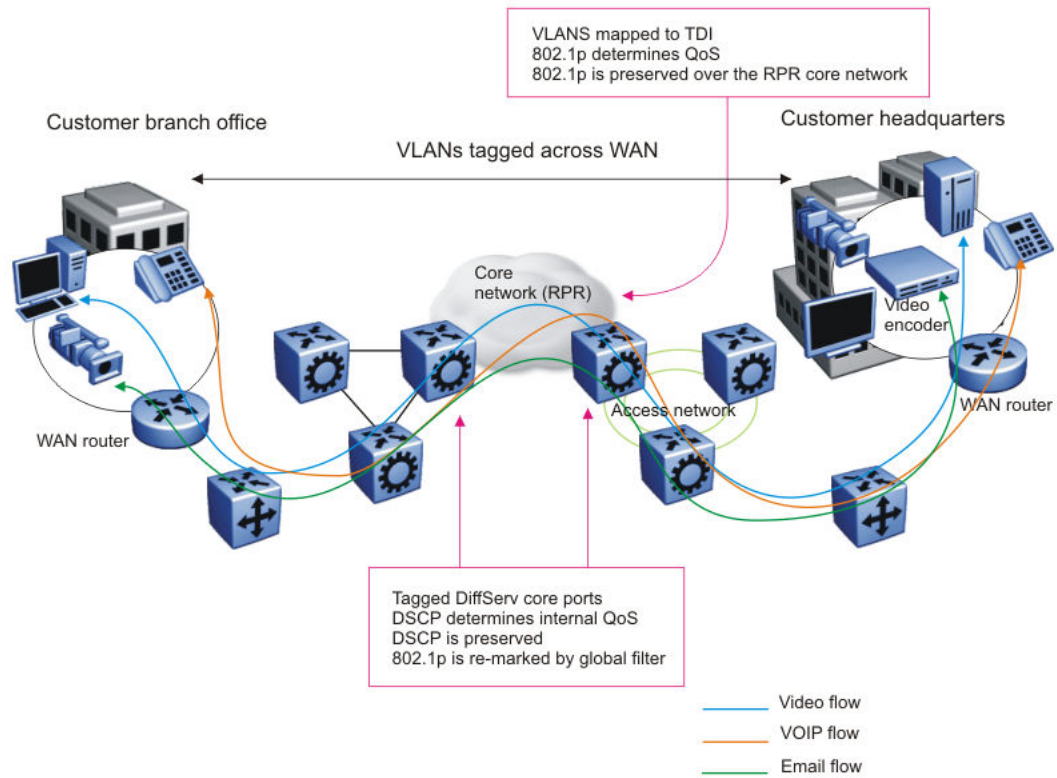

Figure 212: RPR QoS internetworking

Routed traffic

If you route traffic over the core network, VLANs are not kept separate.

If you configure the port to core, you assume that, for all incoming traffic, the QoS configuration is properly marked. All core switch ports simply read and forward packets. The switch does not re-mark or classify the packets. The customer device or the edge devices perform all initial QoS markings.

The following figure shows the actions performed on three different routed traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

Figure 213: Trusted routed traffic

For routed, untrusted traffic, in an access node, packets that enter through a tagged or untagged access port exit through a tagged or untagged core port.

QoS Behavior Differences

The implementation of QoS is similar in all VOSS switches but there are some differences as summarized in the following table.

QoS	VSP 4450 Series	VSP 4900 Series/VSP 7200 Series/VSP 8200 Series/VSP 8400 Series	5420 Series, 5520 Series/VSP 7400 Series	VSP 8600 Series	XA1400 Series
Ingress traffic	Policing	Port-rate limiting	Not available	Port-rate limiting	Not available
Egress traffic	Shaping	Shaping	Shaping	Shaping	Follows default queue profile weights
Egress queuing CoS 0-5	WDRR	WRR	WRR	WRR	Heirarchy Token Bucket (HTB)
Classification	Routed packet classification	No routed packet classification	No routed packet classification	No routed packet classification	No routed packet classification

QoS	VSP 4450 Series	VSP 4900 Series/VSP 7200 Series/VSP 8200 Series/VSP 8400 Series	5420 Series, 5520 Series/VSP 7400 Series	VSP 8600 Series	XA1400 Series
Internal QoS derivation for ingress Layer 3 trusted port	<ul style="list-style-type: none"> Routed IP packet-derived from DSCP Switched IP packet-derived from 802.1p 	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP
Automatic QoS	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP Not Supported on 5420 Series or 5520 Series	Derived from DSCP for routed traffic only. Automatic QoS is not available for switched traffic.	Always derived from DSCP

For QoS scaling and filter scaling information, see [VOSS Release Notes](#).

Egress Tunnel Shaping

Table 196: Egress Tunnel Shaping product support

Feature	Product	Release introduced
Egress Tunnel Shaping	5420 Series	Not Supported
	5520 Series	Not Supported
	VSP 4450 Series	Not Supported
	VSP 4900 Series	Not Supported
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	Not Supported
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.1

Egress Tunnel Shaping shapes traffic on a Fabric Extend (FE) tunnel. Egress Tunnel Shaping limits transmission rate by shaping the output load. Egress Tunnel Shaping differs from Port Egress Shaping. Port Egress Shaping limits transmission rate by port and by queue. Egress Tunnel Shaping operates on VXLAN virtual ports.

On XA1400 Series the default egress tunnel shaper is 1 Gbps on all FE tunnels and has only one QoS queue.

When you enable Egress Tunnel Shaping, it shapes unicast, multicast, and unknown unicast egress traffic according to the feature configuration. Shapers you configure shape all traffic on the tunnel. Shapers you configure can have between 1 Mbps and 1 Gbps of bandwidth allocated to them.

Eight traffic queues are created for the tunnel traffic when a new shaper is configured. Packets are mapped to any of these queues based on the internal Class of Service (CoS) of the packets. When multiple tunnels use the common shaper value, an internally unique shaper is associated for each tunnel. The following table shows the default minimum weight for each queue.

Queue	Default Minimum Weight
0	5
1	20
2	30
3	40
4	50
5	50
6	Rate limited to 50% of configured shaper rate
7	Rate limited to 5% of configured shaper rate

Queues 6 and 7 are rate limited and have a higher priority. The maximum traffic allowed out of queue 6 and queue 7 would be shape rate/2 (50% bandwidth) and shape rate/20 (5% bandwidth).

The XA1400 Series uses a Hierarchical Token Bucket (HTB) scheduling algorithm. HTB controls the use of the outbound bandwidth on a link, allowing the use of one physical link or virtual link to simulate several slower links and to send different kinds of traffic on different simulated links. HTB shapes traffic based on the Token Bucket Filter algorithm which does not depend on interface characteristics, or the underlying bandwidth of the outgoing interface.

The configured bandwidth sum of all shaped FE tunnels is higher than the total amount of available head-end bandwidth. Egress Tunnel Shaping is oversubscribed so that all the available and unused bandwidth is allotted to a branch node if other branch nodes are not using it.

Buffer allocation and burst rate are fixed and cannot be configured.

Note

Tunnel shaping granularity may not be accurate, and differ from the user configured values, when packets are fragmented if the packet size is greater than the FE tunnel MTU. This is because when packet fragmentation happens there is a higher packet header overhead.

Configuration of Egress Tunnel Shaping requires supporting SPBM and Fabric Extend configurations. For more information on these configurations, see the following sections:

- [Fabric Basics and Layer 2 Services](#) on page 893
- [Fabric Layer 3 Services](#) on page 1308

- [IP Multicast over Fabric Connect](#) on page 1622

Basic DiffServ configuration using CLI

Use Differentiated Services (DiffServ) to provide appropriate Quality of Service (QoS) to specific traffic types.

Enabling DiffServ on a port

Enable DiffServ so that the system provides DiffServ-based QoS on the port. By default, DiffServ is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DiffServ:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

3. Disable DiffServ:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

Variable definitions

Use the data in the following table to use the **enable-diffserv** command.

Variable	Value
<i>enable</i>	Enables DiffServ for the specified port. The default is enabled.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted (core) port honors incoming Differentiated Services Code Point (DSCP) markings. An untrusted (access) port overrides DSCP markings. The default configuration is trusted.

Before You Begin

Enable DiffServ.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as an access port, use one of the following options:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] [enable]
```

OR configure both parameters:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] [enable]
```

```
access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] [enable]
```

3. Configure the port as a core port:

```
no access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] [enable]
```

Variable definitions

Use the data in the following table to use the **access-diffserv** commands.

Variable	Value
<i>enable</i>	If enabled, specifies an access port and overrides incoming DSCP bits. If disabled, specifies a core port that honors and services incoming DSCP bits.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override disabled) honors incoming 802.1p bit markings. An untrusted port (override enabled) overrides 802.1p bit markings.

Before You Begin

Enable DiffServ.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as Layer 2 untrusted:

```
qos 802.1p-override [enable]
```

3. Configure the port as Layer 2 trusted:

```
no qos 802.1p-override [enable]
```

Variable Definitions

Use the data in the following table to use the `qos 802.1p-override` command.

Variable	Value
<code>enable</code>	If you use this variable, the port overrides incoming 802.1p bits; if you do not use this variable, the port honors and services incoming 802.1p bits. The default is disable (Layer 2 trusted).

Viewing the port 802.1p override status

Use this procedure to view the port 802.1p override status. The system displays the port and 801.1p override status.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. View the port 802.1p override status:

```
show qos 802.1p-override
```

Example

```
Switch:1# show qos 802.1p-override
```

```

=====
                        Port 802.1p-Override Status
=====
-----
PORT      802.1P OVERRIDE
-----
1/1       DISABLED
1/2       DISABLED
1/3       DISABLED
1/4       DISABLED
1/5       DISABLED
1/6       DISABLED
1/7       DISABLED
1/8       DISABLED
1/9       DISABLED
1/10      DISABLED
1/11      DISABLED
1/12      DISABLED
1/13      DISABLED
1/14      DISABLED
1/15      DISABLED
1/16      DISABLED

```

Configuring the port QoS level

Configure the port QoS level to assign a default QoS level for all traffic if the packet does not match an access control list (ACL) that re-marks the packet. If you configure port QoS levels, Layer 2 and Layer 3 traffic from the same port use the same QoS level. The default value is 1.

About This Task

For VoIP traffic, as a best practice, use QoS level 6.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port QoS level:

```
qos level [port {slot/port[sub-port]}] <0-6>
```

Variable definitions

Use the data in the following table to use the **qos level** command.

Variable	Value
<0-6>	Specifies the default QoS level for the port traffic. The system reserves QoS level 7 for network control traffic. The default is 1.
<i>port {slot/port[/sub-port]}</i>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Basic DiffServ configuration using EDM

Use DiffServ to implement classification and mapping functions at the network boundary or access points to regulate packet behavior. You can configure a port as a trusted (core) or an untrusted (access) port at both Layer 2 and Layer 3.

You can also perform many of the procedures in this section on the Interface tab for the selected port. The procedures in this section show only one configuration method.

Enabling DiffServ for a port

Enable DiffServ so that the switch provides DiffServ-based Quality of Service (QoS) on the port.

About This Task

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **Port QoS Config**.

3. In the row for the port, double-click the cell in the **DiffServ** column.
4. Select **true**.
5. Click **Apply**.

QoS Port Config field descriptions

Use the data in the following table to use the **Port QoS Config** tab.

Name	Description
Index	Specifies an index value that uniquely identifies a port.
DiffServ	Specifies whether DiffServ is enabled (true) or disabled (false) on the port. The default is true. This variable works in conjunction with Layer3Trust. The DiffServ variable is a global parameter that affects QoS DSCP operations. If the DiffServ parameter is false (DiffServ disabled), the system does not use the DSCP parameter for classification or modify it. If this variable is true, it activates the Layer3Trust parameter.
Layer3Trust	Configures the Layer 3 trusted port as an access or core port. The default is core. Core configures the port to a trusted state and access configures the port to an untrusted state. The DiffServ parameter determines the operation of this variable. If DiffServ is false, Layer3Trust has no effect; no modification of the DSCP or TOS bits occurs. If DiffServ is true, the core and access configuration take effect.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (true) or disabled (false) on the port. The default is false. This variable primarily affects tagged packet treatment. If Layer2Override8021p is false, the port trusts the 802.1p-bits portion of a Q-tagged packet. The port trusts the 802.1p-bits marking regardless of the port setting (tagged or untagged); however, if the discard tagged packets parameter (DiscardTaggedFrames) on an untagged port is true, the system discards the packet. If Layer2Override8021p is true, the port does not trust the 802.1p bit marking. In this case, the QoS operation depends on other parameters, such as the port QoS level.
QoSLevel	Specifies the QoS level to use when the system processes packets carried on this port. Values range from level 0–6 (the system reserves 7 for network control traffic). The default is 1.

Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted port honors incoming DSCP markings. An untrusted port overrides DSCP markings. The default is trusted.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer3Trust** column.
4. Select **core** (trusted) or **access** (untrusted) as the port setting.

5. Click **Apply**.

Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override false) honors incoming 802.1p bit markings. An untrusted port (override true) overrides 802.1p bit markings.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer2 Override 8021p** column.
4. To configure the port as a Layer 2 untrusted port, select **true**. To configure it as a Layer 2 trusted port, select **false**.
By default, all ports are Layer 2 trusted (Layer2 Override 8021p is false).
5. Click **Apply**.

Configuring the port QoS level

Use the default port QoS level to assign a default QoS level for all traffic, if the packet does not match an access control list (ACL) to remark the packet.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **QoSLevel** column.
4. Select the new level.
5. Click **Apply**.

QoS configuration using CLI

Use the procedures in this section to configure Quality of Service (QoS) on the switch.

Configuring broadcast and multicast bandwidth limiting

Configure broadcast and multicast bandwidth limiting to limit the amount of ingress broadcast and multicast traffic on a port. The switch drops traffic that violates the bandwidth limit.

You can configure broadcast and multicast bandwidth limiting through CLI only; you cannot use Enterprise Device Manager (EDM).

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure broadcast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
broadcast <1-65535>
```

3. Configure multicast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
multicast <1-65535>
```

Variable definitions

Use the data in the following table to use the **rate-limit** command.

Variable	Value
<1-65535>	Specifies the bandwidth limit for broadcast and multicast traffic from 1-65535 packets per second.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing the port-based shaper information

About This Task

Use this procedure to view the port-based shaper information. The system displays the port, egress rate limit in Kbps, and the rate limit status.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the ingress port-rate limit information:

```
show qos shaper interface gigabitEthernet [{slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]}
```

Example

```
Switch:1# show qos shaper interface gigabitEthernet 1/1
```

Port Egress Rate-Limiting (Shape)		
PORT	EGRESS RATE-LIMIT (kbps)	ENABLED/DISABLED
1/1	0	DISABLED

Configuring the port-based shaper

Use port-based shaping to rate-limit all outgoing traffic to a specific rate.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port-based shaping:

```
qos if-shaper [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] shape-rate <shape-rate>
```

Variable definitions

Use the data in the following table to use the **qos if-shaper** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the slot and port number to which to apply shaping. This variable is optional. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>shape-rate <shape-rate></code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: <code>Error: port slot/port, The QOS Egress shaper rate can not exceed the port capability.</code> The default is 0, which means shaping is disabled on the port.

Configuring a port-based policer

Use a port policer to bandwidth-limit incoming traffic. The port drops or re-marks violating traffic.

**Note**

This command does not apply on all hardware platforms.

About This Task

The interface policer has two configurable rates: peak rate (PIR) and service or committed rate (CIR). Traffic above PIR is marked as red. Traffic above CIR is qualified as yellow. Normally, CIR is lower than PIR. However, in CLI you can configure these rates to equal values. Each rate has a maximum burst size associated with it, peak burst size (PBS) and committed burst size (CBS) respectively. You cannot configure the burst sizes. These values ensure maximum traffic fairness between the ports; the CBS value is lower than the PBS value. Depending on the traffic pattern, this configuration can result in a small percentage of traffic qualified as yellow or above CIR, but not red or above PIR, even if the rates are equal.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the policing limit:

```
qos if-policer [port {slot/port[-slot/port] [,...]}] peak-rate
<64-100000000> svc-rate <64-100000000>
```

Example

Configure the policing limit to a peak-rate of 10000 and the service rate limit to 5000 for port 4/10:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 4/10
Switch:1(config-if)#qos if-policer port 4/10 peak-rate 10000 svc-rate 5000
```

Variable Definitions

Use the data in the following table to use the **qos if-policer** command.

Variable	Value
<code>peak-rate<64-100000000></code>	Specifies the peak rate limit in Kbps.
<code>port {slot/port[-slot/port] [,...]}</code>	Identifies the slot and the port.
<code>svc-rate<64-100000000></code>	Specifies the service rate limit in Kbps.

Viewing Ingress Policer Statistics

Use this procedure to view the ingress policer statistics. The system displays individual policer statistics for specific ports to manage network performance.

Note

This command is not available on all hardware platforms.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

- View the policer statistics:

```
show interfaces gigabitethernet statistics policer {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]
```

Example

```
Switch:1# show interfaces gigabitethernet statistics policer 1/3
```

```
=====
=====
                                     QoS Ingress Port Policer Stats
=====
=====
PORT      TOTAL          TOTAL          YELLOW          RED
NUM       PKTS          BYTES          BYTES          BYTES
-----
1/3       420           31628         0              0
```

Variable Definitions

Use the data in the following table to use the **show interfaces gigabitethernet statistics policer** command.

Variable	Value
<code>{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring the ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic.

Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the ingress port-rate limit:

```
qos if-rate-limiting [port {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] rate <1000-40000000>
```

3. Disable the ingress port-rate limit:

```
no qos if-rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Variable definitions

Use the data in the following table to use the **qos if-rate-limiting** command.

Variable	Value
<code>1000-40000000</code>	Specifies the ingress rate limit in Kbps. The range is 1000-40000000.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View the Ingress Port-Rate Limit Information

Use this procedure to view the ingress port-rate limit information. The system displays the port, rate limit in Kbps, and rate limit status.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the ingress port-rate limit information:

```
show qos rate-limiting interface gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1# show qos rate-limiting interface gigabitEthernet 1/1
```

```

=====
                        Port Ingress Rate-Limiting
=====
-----
PORT    RATE (kbps)    ENABLED/DISABLED
-----
1/1     0                DISABLED

```

Variable definitions

Use the data in the following table to use the **show qos rate-limiting interface gigabitEthernet** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing Ingress Port-rate Limit Statistics

Use this procedure to view the ingress port-rate limit statistics. The system displays the statistics of the dropped packets and bytes.

**Note**

This command is not available on all hardware platforms.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the ingress port-rate limit statistics:

```
show interfaces gigabitethernet statistics rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
```

Example

```
Switch:1# show interfaces gigabitethernet statistics rate-limiting 1/1
```

```

=====
                        QOS Interface Ingress Rate-Limiting Stats
=====
PORT      DROPPING      DROPPING      DROPPING      DROPPING
          PKTS RATE   BYTES RATE   PKTS          BYTES
-----
1/1       9224          1436481032   9260507
1430758

```

Variable Definitions

Use the data in the following table to use the **show interfaces gigabitethernet statistics rate-limiting** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring ingress mappings

You can modify the ingress mappings to change traffic priorities. However, as a best practice, use the default mappings.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure 802.1p bit to QoS ingress mappings:

```
qos ingressmap 1p <0-7> <0-6>
```
3. Configure DSCP to QoS ingress mappings:

```
qos ingressmap ds <0-63> <0-6>
```
4. Ensure the configuration is correct:

```
show qos ingressmap [1p <0-7>]

show qos ingressmap [ds <0-63>]
```

Variable Definitions

Use the data in the following table to use the **qos ingressmap** command.

Variable	Value
<code>1p <0-7> <0-6></code>	<p>Maps the IEEE 802.1p bit to QoS level. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> • level 0—1 • level 1—0 • level 2—2 • level 3—3 • level 4—4 • level 5—5 • level 6—6 <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos ingressmap 1p</code></p>
<code>ds <0-63> <0-6></code>	<p>Maps the DS byte to QoS level. The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos ingressmap ds</code></p>

Configuring egress mappings

You can modify the egress mappings to change traffic priorities. However, as a best practice, use the default mappings.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure QoS to 802.1p bit egress mappings:

```
qos egressmap 1p <0-6> <0-7>
```
3. Configure QoS to DSCP egress mappings:

```
qos egressmap ds <0-7> WORD<1-6>
```
4. Ensure the configuration is correct:

```
show qos egressmap [1p <0-7>]

show qos egressmap [ds <0-7>]
```

Variable Definitions

Use the data in the following table to use the **qos egressmap** command.

Variable	Value
<i>1p</i> <0-6> <0-7>	<p>Maps the QoS level to IEEE 802.1p bit. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> • level 0—1 • level 1—0 • level 2—2 • level 3—3 • level 4—4 • level 5—5 • level 6—6 <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos egressmap 1p</code></p>
<i>ds</i> <0-7> <i>WORD</i> <1-6>	<p>Maps the QoS level to DS byte. You can specify the DSCP in either hexadecimal, binary, or decimal format. To use the default configuration, use the default option in the command: <code>default qos egressmap ds</code></p>

View Port Egress CoS Queue Statistics

View the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

About This Task

Note

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

Procedure

1. Enter Privileged EXEC mode:
`enable`

- View the port egress CoS queue statistics:

```
show qos cosq-stats interface <PT_PORT>
```

Note

The show command output varies based on your hardware platform. On all VSP platforms except the VSP 8600 Series, the show command output displays Out Packets and Out Bytes per interface which shows the number of unicast packets sent out on each queue for an egress port. VSP 8600 Series uses VoQ queuing architecture which enables to read the Accepted Packets and Accepted Bytes on each queue. The Accepted Packets and Accepted Bytes show the number of packets and bytes that enter the VoQ for a particular queue on the egress port. The Drop Packets and Drop Bytes show the number of packets and bytes that are dropped when the VoQ is full.

Variable Definitions

Use the data in the following table to use the **show qos cosq-stats interface <PT_PORT>** command.

Variable	Value
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

Clearing port egress CoS queue statistics

Clear the port egress CoS queue statistics in the hardware.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Clear the port egress CoS queue statistics:

```
clear qos cosq-stats interface <PT_PORT>
```

Variable Definitions

Use the data in the following table to use the **clear qos cosq-stats interface <PT_PORT>** command.

Variable	Definition
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

View CPU Queue Statistics

View the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

Note

When a neighbor transitions to the STALE state, to initiate Neighbor Unreachability detection (NUD), a duplicate copy of the traffic destined to this neighbor is sent to the switch Control Processor (CP) on a low priority queue (queue 0). The original packet is forwarded to this neighbor. Once NUD is initiated, the hardware records are updated and the traffic is no longer sent to the CP. When a high rate of such traffic is sent to CP, the switch can drop some of these packets due to the in built CP rate limiting feature, which protects the CP from DOS attacks.

Use the command **show qos cosq-stats cpu-port** to view drop statistics on the CPU queue. This design does not result in loss of traffic.

Use the command **ipv6 nd reachable-time <0-3600000>** to increase the default value of 3000 milliseconds which in turn delays the scenario of data path sending STALE neighbor destined packets to the CP.

About This Task

Note

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View the CPU queue statistics:

```
show qos cosq-stats cpu-port
```

Note

Product Notice: The show command output varies based on your hardware platform. On all platforms except VSP 8600 Series, the show command output displays Out Packets and Out Bytes per interface which shows the number of unicast packets sent out on each queue for an egress port. VSP 8600 Series uses VoQ queuing architecture which supports an increased number of available queues, hence the output displays the number of packets accepted and dropped on each protocol type going to the CPU.

Clearing CPU queue statistics

Clear the CPU queue statistics.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Clear CPU queue statistics:

```
clear qos cosq-stats cpu-port
```

Display CPU COSQ Counters**Note**

This procedure only applies to XA1400 Series.

Use the following procedure to display the CPU COSQ statistics and counters.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display CPU COSQ counter statistics:

```
show io cpu-cosq-counters
```

Example

```
Switch:1# show io cpu-cosq-counters

===== PORT 1 COSQ STATS =====

bash-4.3# tc -s filter show dev veth101 ingress | grep 'match\|Sent'

Sent 0 bytes 0 pkts (dropped 0, overlimits 0)
```

Configure an Egress QoS Queue Profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports.

About This Task

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

Note

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the minimum weight for a specific queue:
`qos queue-profile queue <1-6> <0-7> min-weight <1-100>`
3. Enable rate limiting on a weighted queue:
`qos queue-profile queue <1-6> <0-7> rate-limit-enable`
4. Add a queue-profile port member:
`qos queue-profile <1-6> member add {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
5. Add a queue-profile name:
`qos queue-profile <1-6> name WORD<0-64>`
6. Apply the queue profile:
`qos queue-profile <1-6> apply`
7. Verify the egress queue configuration:
`show qos queue-profile [<1-6> queue <0-7>|all]`

8. (Optional) Configure the default settings for an egress queue:

- Configure the default minimum weight using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> min-weight
```

```
no qos queue-profile queue <1-6> <0-7> min-weight
```

- Configure the default rate limiting on a weighted queue using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> rate-limit-enable
```

```
no qos queue-profile queue <1-6> <0-7> rate-limit-enable
```

Examples

Configure the queue profile for queue 6 to use a weight of 20.

```
Switch:1(config)#qos queue-profile 6
Switch:1(config)#qos queue-profile queue 6 1 min-weight 20
Switch:1(config)#qos queue-profile 6 apply
```

View the queue profile configuration.

```
Switch:1#show qos queue-profile
```

```
=====
                        Qos Queue Profile
=====
```

Profile ID	Profile Name	Profile Port List
1	default	1/1-1/42,2/1-2/42
6	profile-6	

The value in the `Weight Applied` column is the maximum bandwidth for Strict Priority queues (Rate Limit Enabled) and the weight in the WRR scheduling algorithm applied per queue. Strict Priority queues are serviced first and limited to the configured percentage of bandwidth. WRR queues (no rate limit applied) have no upper boundary, other than the delta between the available bandwidth per port and the one consumed by Strict Priority queues. For WRR queues, there is no association with the bandwidth percentage servicing this queue; the bandwidth that can be served is relative to the available bandwidth at a certain moment and the load of other queues.

```
Switch:1(config)#show qos queue-profile 1 queue 1
```

```

Profile ID	Profile Name	Queue ID	Weight Applied	Weight Configured	Rate-limit Applied	Rate-limit Configured
1	default	0	10	10	DISABLE	DISABLE
1	default	1	20	20	DISABLE	DISABLE
1	default	2	30	30	DISABLE	DISABLE
1	default	3	40	40	DISABLE	DISABLE
1	default	4	50	50	DISABLE	DISABLE
1	default	5	50	50	DISABLE	DISABLE
1	default	6	50	50	DISABLE	ENABLE
1	default	7	5	5	ENABLE	ENABLE

Variable Definitions

The following table defines parameters for the `qos queue-profile queue` command.

Variable	Value
<1-6>	Specifies the queue profile ID. Note: The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue to configure.
<i>min-weight</i> <1-100>	Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this parameter configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue: <ul style="list-style-type: none"> • Queue 0 – 10 • Queue 1 – 20 • Queue 2 – 30 • Queue 3 – 40 • Queue 4 – 50 • Queue 5 – 50 • Queue 6 – Rate limited to 50% of configured shaper rate • Queue 7 – Rate limited to 5% of configured shaper rate
<i>member add</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies a port member of the queue-profile to add or remove.
<i>name</i> WORD<0-64>	Specifies a profile name.
<i>rate-limit-enable</i>	Enables rate limiting on the queue. By default, rate limiting is enabled for queues 6 and 7 only; it is disabled for queues 0 through 5.

The following table defines parameters for the **show qos queue-profile** command.

Variable	Value
<1-6>	Specifies the queue profile ID. If you do not include a queue profile ID, the command output displays all configured profiles. Note: The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue. Displays configuration settings of the specified egress queue.
<i>all</i>	The command output displays the configuration settings of all eight egress queues of the queue profile.

Configure Egress Tunnel Shaping

About This Task

Perform this procedure to configure Egress Tunnel Shaping on a logical interface.

Procedure

- To enter User EXEC mode, log on to the switch.
- Enter Global Configuration mode:
`enable`

`configure terminal`
- Enable SPBM globally:
`spbm`
- Enter IS-IS Router Configuration mode:
`router isis`
- Create a global SPBM instance:
`spbm <1-100>`
- Create a nickname for the global SPBM instance:
`spbm <1-100> nick-name x.xx.xx`
- Add the backbone VLANs to the SPBM instance and set the primary VLAN:
`spbm <1-100> b-vid {vlan-id[-vlan-id] [, ...]} primary <1-4059>`
- Exit IS-IS Router Configuration mode:
`exit`
- Enter IS-IS Router Configuration mode:
`router isis`
- Configure the system name:
`sys-name WORD<0-255>`
- Configure the global router type:
`is-type 11`

12. Configure the manual area:
`manual-area xx.xxx.xxx...xxxx`
13. Exit IS-IS Router Configuration mode:
`exit`
14. Create two SPBM Backbone VLANs that correspond to those configured in the previous step using the following command twice:
`vlan create <1-4059> type spbm-bvlan`
15. Enable IS-IS globally:
`router isis enable`
16. Remove the brouter port from all VLANs:
`vlan members remove <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {`
17. Enter Interface Configuration mode:
`interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`
18. Configure a brouter port:
`brouter port {slot/port[/sub-port]} vlan <1-4059> subnet {A.B.C.D/X}
mac-offset <MAC-offset>`
19. Exit Interface Configuration mode:
`exit`
20. Enter IS-IS Router Configuration mode:
`router isis`
21. Configure the IP tunnel source address:
`ip-tunnel-source-address {A.B.C.D}`
22. Exit IS-IS Router Configuration mode:
`exit`
23. Create a logical IS-IS interface and enter Logical Interface Configuration mode:
`logical-intf isis <1-255> dest-ip {A.B.C.D} name WORD <1-64> [mtu <750-9000>]`
24. Create an IS-IS circuit and interface:
`isis`
25. Enable the SPBM instance:
`isis spbm <1-100>`
26. Enable the IS-IS circuit and interface:
`isis enable`
27. Configure the Egress Tunnel Shaper:
`egress-shaping-rate <1-1000>`
28. Exit Logical Interface Configuration mode:
`exit`

Variable Definitions

Use the data in the following table to use the **vlan members** command.

Variable	Value
<code>remove <1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **spbm** command.

Variable	Value
<code><1-100></code>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.

Use the data in the following table to use the **spbm** command to create a system nickname for an SPBM instance.

Variable	Value
<code><1-100></code>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.
<code>nick-name x.xx.xx</code>	Specifies the system nickname (2.5 bytes in the format).

Use the data in the following table to use the **spbm** command to assign Backbone VLANs to the SPBM instance.

Variable	Value
<code><1-100></code>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.
<code>b-vid {vlan-id[-vlan-id] [,...]}</code>	Specifies the VLANs to add to the Shortest Path Bridging MAC (SPBM) instance as Backbone VLANs (B-VLANs). Sets the IS-IS SPBM instance data VLANs.
<code>primary <1-4059></code>	Specifies the primary B-VLAN by VLAN ID.

Use the data in the following table to use the **sys-name** command.

Variable	Value
<i>WORD<0-255></i>	Specifies the system name.

Use the data in the following table to use the **is-type** command.

Variable	Value
<i>11</i>	Configures the router type as Level 1 Intermediate-System-to-Intermediate-System (IS-IS).

Use the data in the following table to use the **manual-area** command.

Variable	Value
<i>xx.xxxx.xxxx...xxxx</i>	Configures the manual area in a size up to 13 octets. The current release supports one area. For Intermediate-System-toIntermediate-System (IS-IS) to operate, you must configure at least one area.

Use the data in the following table to use the **vlan create** command.

Variable	Value
<i><1-4059></i>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>type spbm-bvlan</i>	Specifies the VLAN type as the backbone VLAN (B-VLAN) for Shortest Path Bridging MAC (SPBM).

Use the data in the following table to use the **interface GigabitEthernet** command.

Variable	Value
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **router port** command.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>vlan <1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>subnet <A.B.C.D/X></code>	Assigns an IP address and mask for the management port.
<code>mac-offset <MAC-offset></code>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

Use the data in the following table to use the **ip-tunnel-source-address** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the IS-IS IPv4 tunnel source address.

Use the following table to use the **logical-intf** command.

Variable	Value
<code>isis <1-255></code>	Specifies the ISIS logical interface ID.
<code>dest-ip {A.B.C.D}</code>	Specifies the destination IP address for the logical interface.
<code>name WORD <1-64></code>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<code>mtu <750-9000></code>	Specifies the Maximum Transmission Unit (MTU) size for each packet. Default mtu value is 1950.
Note: Exception: only supported on XA1400 Series	

Use the data in the following table to use the **egress-shaping-rate** command.

Variable	Value
<1-1000>	Specifies the shaper bandwidth in Mbps.

Egress Tunnel Shaping Configuration Example

The following is an example of an Egress Tunnel Shaping configuration.

SPBM Configuration

```
Switch> enable
Switch# config terminal
Switch(config)# vlan members remove 1 1/8
Switch(config)# spbm
Switch(config-isis)# router isis
Switch(config-isis)# spbm 1
Switch(config-isis)# spbm 1 nick-name 1.11.40
Switch(config-isis)# spbm 1 b-vid 2,3 primary 2
Switch(config-isis)# exit
Switch(config)# router isis
Switch(config-isis)# sys-name XA1400
Switch(config-isis)# is-type ll
Switch(config-isis)# manual-area c0.2000.0000.00
Switch(config-isis)# exit
Switch(config)# vlan create 2 type spbm-bvlan
Switch(config)# vlan create 3 type spbm-bvlan
```

Fabric Extend Configuration

```
Switch(config)# router isis enable
Switch(config)# interface GigabitEthernet 1/8
Switch(config-if)# brouter port 1/8 vlan 2500 subnet 192.0.2.1/255.255.255.0 mac-offset 0
Switch(config-if)# exit
Switch(config)# router isis
Switch(config-isis)# ip-tunnel 192.0.2.1
Switch(config-isis)# exit
```

Egress Tunnel Shaping Configuration

```
Switch(config)# logical-intf isis 1 dest-ip 192.0.2.2 name "bang"
Switch(config-isis-1)# isis
Switch(config-isis-1)# isis spbm 1
Switch(config-isis-1)# isis enable
Switch(config-isis-1)# egress-shaping-rate 500
Switch(config-isis-1)# exit
```

Viewing Logical Interface CoS Queue Statistics

View the QoS CoS queue statistics for IS-IS logical interfaces. These statistics are useful for debugging purposes.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View the logical interface queue statistics:
`show qos cosq-stats logical-intf [isis <1-255>]`

Clearing Logical Interface CoS Queue Statistics

Clear the QoS CoS queue statistics for IS-IS logical interfaces.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Clear the logical interface queue statistics:
`clear qos cosq-stats logical-intf [isis <1-255>]`

QoS configuration using EDM

Configure Quality of Service (QoS) to allocate network resources where you need them most.

Configuring port-based shaping

Configure egress port-based shaping to bind the maximum rate at which traffic leaves the port.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **EgressRateLimitState**, select **enable**.
6. In the **EgressRateLimit** box, type an egress rate limit in kilobits per second (Kb/s).
7. Click **Apply**.

Configure Port-Based Policing

Use a port-based policer to bandwidth-limit ingress traffic. The system drops or re-marks violating traffic.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. From **IngressRatePeak**, type the value for the peak rate in Kbps.
The peak rate must be greater than or equal to the service rate.

6. From **IngressRateSvc**, type the value for the service rate in Kbps.
7. Select **Apply**.

Viewing Port Policer Statistics

View port policer statistics to manage network performance.

This tab does not appear for all hardware models.

Procedure

1. In the navigation pane, expand the **Configuration > Graph** folders.
2. Click **Port**.
3. Click the **Policer** tab.

Policer Field Descriptions

Use the data in the following table to use the **Policer** tab.

Name	Description
TotalPkts	Shows the total number of packets received on the port.
TotalBytes	Shows the total number of bytes received on the port.
YellowBytes	Shows the total number of bytes received on the port that were above the committed rate but below the peak rate.
RedBytes	Shows the total number of bytes received on the port that were above the peak rate.

Configuring ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The system drops or re-marks violating traffic.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **IngressRateLimit**, type the value in Kbps to set the traffic rate limit.
The ingress rate limit must be between 1000 and 40000000.
6. Click **Apply**.

Graphing Stat Rate Limit Statistics for a Port

View stat rate limit statistics to view the total dropped packets and bytes.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Stat Rate Limit** tab.
5. Select one or more values.
6. Click the type of graph to create.

Stat Rate Limit Field Descriptions

Use the data in the following table to use the **Stat Rate Limit** tab.

Name	Description
DropPktRate	Indicates the drop packet rate.
DropByteRate	Indicates the drop byte rate.
DropTotalBytes	Indicates the total bytes dropped.
DropTotalPkts	Indicates the total packets dropped.

Modifying ingress 802.1p to QoS mappings

Modify the ingress mappings to change traffic priorities. As a best practice, use the default mappings.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QoS**.
2. Click **Mapping Tables**.
3. Click the **Ingress 8021p to QoS** tab.
4. Double-click a QosLevel field to change the value.
5. Click **Apply**.

Ingress 8021p To QoS field descriptions

Use the data in the following table to use the **Ingress 8021p to QoS** tab.

Name	Description
InIeee8021P	Specifies the value of the IEEE 802.1p bit of the incoming packet.
QosLevel	Specifies the equivalent egress QoS level (0–7).

Modifying ingress DSCP to QoS mappings

Modify the ingress Differentiated Services Code Point (DSCP) to QoS mappings to change traffic priorities. As a best practice, use the default mappings. Changes to the mapping table take effect after you restart the system.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **Mapping Tables**.
3. Click the **Ingress Dscp To QoS** tab.
4. Double-click a QosLevel field to change the value.
5. Click **Apply**.

Ingress Dscp To QoS field descriptions

Use the data in the following table to use the **Ingress Dscp To QoS** tab.

Name	Description
InDscp	Specifies the value of the DiffServ codepoint (in decimal format) in the IP header of the incoming packet.
InDscpBinaryFormat	Specifies the value of the DiffServ codepoint (in binary format) in the IP header of the incoming packet.
QosLevel	Specifies the equivalent QoS level.

Modifying egress QoS to 802.1p mappings

Modify the egress mappings to change the mappings between the QoS levels and the IEEE 802.1p bits.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS to 8021p** tab.
4. Double-click the Outleee8021P field to change the value.
5. Click **Apply**.

Egress QoS to 8021p field descriptions

Use the data in the following table to use the **Egress QoS to 8021p** tab.

Name	Description
QoSLevel	Specifies the QoS level of the outgoing packet.
Outleee8021P	Specifies the equivalent value of the IEEE 802.1p bit.

Modifying egress QoS to DSCP mappings

Modify the egress QoS to DSCP mappings to change traffic priorities. As a best practice, use the default mappings.

About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS To Dscp** tab.
4. Double-click the OutDscp file to change the value.
5. Click **Apply**.

Egress QoS To Dscp field descriptions

Use the data in the following table to use the **Egress QoS To Dscp** tab.

Name	Description
QoSLevel	Specifies the QoS level of the outgoing packet.
OutDscp	Specifies the equivalent value of the DiffServ code point (in decimal format).
OutDscpBinaryFormat	Specifies the equivalent value of the DiffServ code point (in binary format).

Viewing port egress CoS queue statistics

Use the following procedure to retrieve the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **Interface** tab.

Interface Field Descriptions

The following table describes the fields from the CoS Queue Stats **Interface** tab.

Name	Description
Index	Indicates the loopback port number from 192(1/1) to 241(1/50).
ClearStat	Clears the port egress statistics.
Que<0-7>OutPackets	Indicates the out packets by CoS queue number 0-7.
Que<0-7>OutBytes	Indicates the out bytes by CoS queue number 0-7.
Que<0-7>DropPackets	Indicates the drop packets by CoS queue number 0-7.
Que<0-7>DropBytes	Indicates the drop bytes by CoS queue number 0-7.

Clearing CPU statistics for the chassis

Use the following procedure to clear the CPU statistics for the chassis.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Stats-Clear** tab.
4. Select the **CpuStatsClear** check box.
5. Click **Apply**.

Viewing CPU queue statistics

Use the following procedure to retrieve the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Port** tab.

CPU-Port Field Descriptions

Use the data in the following table to use the **CPU-Port** tab.

Name	Description
Index	Indicates the CoS queue number.
OutPackets	Indicates the out packets for the CPU port.

Name	Description
OutBytes	Indicates the out bytes for the CPU port.
DropPackets	Indicates the drop packets for the CPU port.
DropBytes	Indicates the drop bytes for the CPU port.

View Tunnel CoS Queue Statistics

Note

This procedure only applies to XA1400 Series.

Use the following procedure to retrieve the tunnel CoS queue statistics. The system opens the statistics of the forwarded packets and bytes and the dropped packets and bytes.

Procedure

1. In the navigation tree, expand: **Configuration** > **QOS**.
2. Select **CoS Queue Stats**.
3. Select the **Tunnel** tab.

Tunnel Field Descriptions

The following table describes the fields from the CoS Queue Stats **Tunnel** tab.

Name	Description
Index	Indicates the loopback port number from 192(1/1) to 241(1/50).
Que<0-7>OutPackets	Indicates the out packets by CoS queue number 0-7.
Que<0-7>OutBytes	Indicates the out bytes by CoS queue number 0-7.
Que<0-7>DropPackets	Indicates the drop packets by CoS queue number 0-7.
Que<0-7>DropBytes	Indicates the drop bytes by CoS queue number 0-7.

Configuring an egress QoS queue profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports. You must apply the profile before the changes take effect.

About This Task

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **QoS**.

2. Click **Queue Profile**.
3. Click the **Queue Profile** tab.
4. Click **Insert**.
5. In the **Id** field, type the queue profile value.
6. In the **Name** field, specify a name for the queue profile.
7. To add a port to this queue, click the **PortList** ellipsis (...), choose a port or ports, and then click **Ok**.
8. Select the **Apply** check box.
9. Click **Insert**.

Queue Profile field descriptions

Use the data in the following table to use the **Queue Profile** tab.

Field	Description
Id	Specifies the ID for the queue profile.
Name	Specifies the queue profile name.
Apply	Applies the queue profile.
PortList	Indicates the port members of the queue profile.

Editing queue profile information

About This Task

Use the following procedure to edit queues of a queue profile, to configure a queue weight or enable rate limiting on the queue.

Note

After you make the configuration changes, you must apply the queue profile before the changes take effect.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > QoS**.
2. Click **Queue Profile**.
3. Update a queue to configure queue weight or rate limiting.
 - a. Click the **Queue** tab.
 - b. Edit the **AdminWeight** and **AdminRateLimitStatus** fields by double-clicking on them, and then selecting or typing the new value.
 - c. Click **Apply**.
4. Apply the queue profile for the queue configuration to take effect.
 - a. Click the **Queue Profile** tab.
 - b. In the **Apply** field, double-click and select **true**.
 - c. Click **Apply**.
5. Click the **Queue** tab again, to verify updates to the **OperWeight** and the **OperRateLimitStatus** fields, for the respective queue.

Queue field descriptions

Use the data in the following table to use the **Queue** tab.

Field	Description
PId	Displays the queue profile ID.
Id	Displays the queue ID.
AdminWeight	<p>Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this field configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue:</p> <ul style="list-style-type: none"> • Queue 0 – 10 • Queue 1 – 20 • Queue 2 – 30 • Queue 3 – 40 • Queue 4 – 50 • Queue 5 – 50 • Queue 6 – Rate limited to 50% of configured shaper rate • Queue 7 – Rate limited to 5% of configured shaper rate
OperWeight	Displays the operational weight of the profile, described as a percentage.
AdminRateLimitStatus	Enables rate limiting on the queue. By default, rate limiting is enabled (true) for queues 6 and 7 only; it is disabled (false) for queues 0 through 5.
OperRateLimitStatus	Displays the operational status of the queue rate limit.

Configuring Rate Limits

About This Task

Configure the rate limit of broadcast or multicast packets to determine the total bandwidth limit on the port.

Procedure

1. On the Device Physical View, select a port or multiple ports.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Rate Limiting** tab.
5. Configure the parameters as required.

6. Click **Apply**.

Rate Limiting *Field Descriptions*

Use the data in the following table to use the **Rate Limiting** tab.

Name	Description
Index	The port number.
TrafficType	The type of traffic being rate limited, either broadcast or multicast traffic. The default is broadcast.
AllowedRatePps	This variable is the allowed traffic rate limit for the port in packets per second. 1 to 25 configures the limit in a percentage of the total bandwidth on the port from 1-25 percent. On gigabit ports and MDAs, there can be up to a 2 percent difference between the configured and actual rate limiting values. 1-65535 configures the limit in packets for each second.
Enable	Double-click in the field and select to enable (True) or disable (False) rate limiting. The default is false.

Configuring Rate Limits on an Extreme Integrated Application Hosting Port

About This Task

Perform this procedure to configure the rate limit of broadcast or multicast packets and determine the total bandwidth limit on the Extreme Integrated Application Hosting (IAH) port.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Rate Limiting** tab.
4. In the **AllowedRatePps** column, enter a time duration for the specific Extreme Integrated Application Hosting port.
5. In the **Enable** column, select **true** to enable rate limiting for the specific IAH port.
6. Select **Apply**.

Rate Limiting *Field Descriptions*

Name	Description
Index	Specifies the Extreme Integrated Application Hosting (IAH) port.
TrafficType	Shows the traffic type. The default is broadcast.
AllowedRatePps	Specifies the allowed traffic rate limit for the IAH port in packets per second (pps).
Enable	Enables or disables rate limiting for the specific IAH port. The default is false (disabled).

**Note**

DEMO FEATURE - Secure AAA server communication, which includes RADIUS secure communication using IPSec for IPv4 and IPv6, is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

RADIUS Fundamentals

Remote Access Dial-In User Services (RADIUS) is a distributed client/server system that assists in securing networks against unauthorized access, allowing a number of communication servers and clients to authenticate users identity through a central database. The database within the RADIUS server stores information about clients, users, passwords, and access privileges including the use of shared secret.

RADIUS is a fully open and standard protocol, defined by two Requests for Comments (RFC) (Authentication: RFC2865, Accounting: RFC2866). You use RADIUS authentication to get secure access to the system (console/Telnet/SSH/EDM), and RADIUS accounting to track the management sessions (CLI only).

RADIUS Server Support for IPv6

RADIUS supports both IPv4 and IPv6 with no differences in functionality or configuration in all but the following case. When you add or update a RADIUS server in Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

How RADIUS Works

A RADIUS application has two components:

<ul style="list-style-type: none"> • RADIUS server 	<p>A computer equipped with server software (for example, a UNIX workstation) that is located at a central office or campus. The server has authentication and access information in a form that is compatible with the client. Typically, the database in the RADIUS server stores client information, user information, password, and access privileges, including the use of a shared secret. A network can have one server for both authentication and accounting, or one server for each service.</p>
<ul style="list-style-type: none"> • RADIUS client 	<p>A device, router, or a remote access server, equipped with client software, that typically resides on the same local area network (LAN) segment as the server. The client is the network access point between the remote users and the server.</p>

The two RADIUS processes are

- RADIUS authentication—Identifies remote users before you give them access to a central network site.
- RADIUS accounting—Performs data collection on the server during a remote user's dial-in session with the client.

Configuration of the RADIUS Server and Client

For more information about how to configure a RADIUS server, see the documentation that came with the server software.

The switch software supports BaySecure Access Control (BSAC) and the Merit Network servers. To use these servers, you must first obtain the software for the server you will use. Also, you must make changes to one or more configuration files for these servers.

RADIUS Authentication

You can use RADIUS authentication to use a remote server to authenticate logons. The RADIUS server also provides access authority. RADIUS assists network security and authorization by managing a database of users. The device uses this database to verify user names and passwords as well as information about the type of access priority available to the user.

When the RADIUS client sends an authentication request requesting additional information such as a SecurID number, it sends it as a challenge-response. Along with the challenge-response, it sends a reply-message attribute. The reply-message is a text string, such as `PLEASE enter the next number on your SecurID card:`. The RFC defined maximum length of each reply-message attribute is 253 characters. If you have multiple instances of reply-message attributes that together form a large message that displays to the user, the maximum length is 2000 characters.

You can use additional user names to access the device, in addition to the six existing user names of ro, L1, L2, L3, rw, and rwa. The RADIUS server authenticates the user name and assigns one of the existing access priorities to that name. Unauthenticated user names are denied access to the device. You must

add user names ro, L1, L2, L3, rw, and rwa to the RADIUS server if you enable authentication. Users not added to the server are denied access.

The limitation on the number of characters in a username for users logging into CLI or EDM configured with RADIUS authentication is 64 characters.

Note

RADIUS server used-by snmp does not support authentication.

The following list shows the user configurable options of the RADIUS feature:

- Up to 10 RADIUS servers in each device for fault tolerance (each server is assigned a priority and is contacted in that order).
- A secret key for each server to authenticate the RADIUS client
- The server UDP port
- Maximum retries allowed
- Time-out period for each attempt

Note

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information on system access fundamentals and configuration, see [System Access](#) on page 3265.

Use of RADIUS to Modify User Access to CLI Commands

The switch provides CLI command access based on the configured access level of a user. However, you can use RADIUS to override CLI command access provided by the switch.

To override user access to CLI commands, you must configure the `command-access-attribute` on the switch and on the RADIUS server. (The switch uses decimal value 194 as the default for this parameter.) On the RADIUS server, you can then define the commands that the user can or cannot access.

Important

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPs, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch fall backs to the local authentication, so that you can access the switch using your local login credentials.

Regardless of the RADIUS server configuration, you must configure the user's access on the switch based on the six platform access levels.

RADIUS Accounting

RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Session-IDs for each RADIUS account generate as 12-character strings. The first four characters in the string form a random number in hexadecimal format. The last eight characters in the string indicate the number of user sessions started since the last restart, in hexadecimal format.

The Network Address Server (NAS) IP address for a session is the address of the device interface to which the remote session is connected over the network. For a console session, modem session, and sessions running on debug ports, this value is set to 0.0.0.0, as is the case with RADIUS authentication.

The following table summarizes the events and associated accounting information logged at the RADIUS accounting server.

Table 198: Accounting Events and Logged Information

Event	Accounting information logged at server
Accounting is turned on at router	<ul style="list-style-type: none"> Accounting on request: NAS IP address
Accounting is turned off at router	<ul style="list-style-type: none"> Accounting off request: NAS IP address
User logs on	<ul style="list-style-type: none"> Accounting start request: NAS IP address Session ID User name
More than 40 CLI commands are executed	<ul style="list-style-type: none"> Accounting interim request: NAS IP address Session ID CLI commands User name
User logs off	<ul style="list-style-type: none"> Accounting stop request: NAS IP address Session ID Session duration User name Number of input octets for session Number of octets output for session Number of packets input for session Number of packets output for session CLI commands

When the device communicates with the RADIUS accounting server, the following actions occur:

1. If the server sends an invalid response, the response is silently discarded and the server does not make an attempt to resend the request.

2. User-specified number of attempts are made if the server does not respond within the user-configured timeout interval. If a server does not respond to any of the retries, requests are sent to the next priority server (if configured). You can configure up to 10 RADIUS servers for redundancy.

**Note**

RADIUS server used-by endpoint-tracking does not support accounting.

RFC 4675 RADIUS Attributes: Egress VLAN

Egress VLAN controls egress traffic. Egress VLAN supports two standard RADIUS attributes as defined in RFC 4675:

- Egress-VLANID
- Egress-VLAN-Name

RADIUS attributes control the 802.1Q tagging for traffic egressing a port where RADIUS authentication is performed for a connected EAP or NEAP client.

Egress VLANs are standard attributes, therefore the RADIUS server supports the attributes by default and offer the ability to configure the attributes. Each attribute has two parts:

1. Indicates if the frames on the VLAN egress must be tagged or untagged
2. Specifies the VLAN name or VLAN ID

The switch applies the VLAN received in the Egress-VLAN attributes to the port where the client is authenticated through RADIUS and then sets the tagging rules (tagged or untagged) accordingly.

The switch processes the Egress-VLAN attributes when decoding the RADIUS packet, therefore the switch adds the port to the VLANs first and then sets the proper tagging for the VLANs. You must create VLANs in advance on the switch.

In the MultiVlan operation mode, the EAP applies ingress hardware rules to ensure untagged traffic from each authenticated client goes into its own VLAN. The unauthenticated clients send traffic to the Guest VLAN, which matches the default VLAN ID.

For more information, see [VLAN RADIUS Attributes](#) on page 2732.

RADIUS Server Reachability

Configure up to 10 EAP RADIUS servers on the switch to manage fault tolerance. Each server is assigned a priority and is contacted in the priority order. If the first server is unavailable, the switch tries the second server, and so on, until the switch establishes a successful connection. Higher priority means lower integer value.

RADIUS server reachability prevents clients from trying to establish a connection with non reachable servers. RADIUS server reachability runs a periodic check in the background to identify the available servers. The switch is aware of the first available EAP RADIUS server without going through each of the servers and wait for time-outs.

Use RADIUS server reachability to configure the switch to use RADIUS requests to determine the reachability of the RADIUS server. The switch regularly performs the reachability test to determine if the

switch should fail over to the secondary RADIUS server or activate the Fail Open VLAN, if configured on the switch.

Use one of the following modes to configure RADIUS reachability:

- **status-server mode:** Status-Server packets provide a standard-compliant alternative to configuring dummy RADIUS requests. You can configure the switch to send status-server packets when the keep-alive timer or the unreachable timer expires. In order to use status-server mode, the configured RADIUS servers must support RFC5997.
- **use-radius mode:** Configure user-radius mode if any of the RADIUS servers do not support RFC5997. In user-radius mode, the switch regularly generates a dummy RADIUS request with the username `reachme` and password `reachme`. The switch interprets either Request Accept or Request Reject responses as a confirmation for server reachability, therefore it is not necessary to add the credentials on the server to test server reachability. You can configure the username and password for the dummy account through CLI. Use-radius is the default mode for RADIUS reachability.

You can configure the RADIUS reachability mode in either CLI or EDM.

Note

RADIUS server reachability is enabled on the switch and is not a configurable option. The reachability process starts when at least one RADIUS server used by EAP is configured, and RADIUS is enabled globally.

Based on the number of EAP RADIUS servers configured, the switch performs the following:

- If the highest priority EAP RADIUS server is reachable, the server status is updated to reachable and further authentication will use this server. As long as the highest priority EAP RADIUS server is reachable, the rest of the EAP RADIUS servers are not tested for reachability.
- If the highest priority EAP RADIUS server is not reachable, then the switch tests the rest of the EAP RADIUS servers for reachability. The servers are checked one by one for reachability based on their priority from highest to lowest. The first server that is reachable is used for authentication and the rest of the lower priority EAP RADIUS servers if any, are skipped from the reachability test.
- If all the EAP RADIUS servers are unreachable, then no further authentication occurs until the next successful reachability check.

The intervals between two consecutive reachability checks can be configured. The default values are as follows:

- one minute, if the last check result was unreachable
- three minutes, if the last check result was reachable

A server is marked as unreachable after a number of retries and time-outs. The default number of retries is 1 and the default time-out value is 8 seconds, but you can also configure these values in CLI.

RFC 3580 RADIUS Attributes: IEEE 802.1X Remote Authentication Dial In User Service

RFC 3580 provides support for EAP and NEAP clients for the following RADIUS attributes:

- **Called-Station ID attribute:** For IEEE 802.1X authenticators, the Called-Station ID stores the bridge or access point MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.

In IEEE 802.11, where the SSID is known, the SSID must be appended to the access point MAC address and separated from the MAC address with a colon (:). For example: 00-10-A4-23-19-C0:AP1.

- Calling-Station ID: For IEEE 802.1X authenticators, the Calling-Station ID is used to store the supplicant MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.
- NAS-Port ID: The NAS-Port ID is used to identify the IEEE 802.1X Authenticator port which authenticates the Supplicant. The NAS-Port-Id differs from the NAS-Port in that it is a string of variable length whereas the NAS-Port is a 4 octet value.

RFC 5176 — Dynamic Session Change

RFC 5176 allows you to dynamically change the following user session characteristics:

- You can disconnect an authenticated user on a port and remove all associated session context.

If the RADIUS server issues a disconnect command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- Notify the user of the disconnect by sending an 802.1x disconnect message to the client.
 - Remove all session context from the port.
 - Remove the port from the RADIUS-assigned VLAN, if applicable.
 - Send the disconnect response Disconnect-ACK to the RADIUS server if the user session is disconnected and all steps successfully performed.
 - Send the Disconnect-NAK response to the RADIUS server if the user session is not found or if the Network Access Server (NAS) cannot disconnect the session and discard the session context.
- You can use the Change of Authorization command to dynamically change the VLAN used by the RADIUS server.

If the RADIUS server issues a Change of Authorization command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- If the Change of Authorization command specifies a valid VLAN ID for a port, the port is removed from the VLAN specified by RADIUS and added to the VLAN specified in the request.
 - A CoA-ACK response is sent to the RADIUS server.
 - If the user session is not found or an error is encountered in processing the Change of Authorization command, then a CoA-NAK response is sent to the RADIUS server.
 - If the Change of Authorization request specifies a VLAN that is not port-based, a CoA-NAK response is sent to the RADIUS server.
- You can dynamically initiate client re-authentication.

Re-authenticate requests can be made with Change of Authorization or Disconnect packet IDs, but they must have the Re-authentication Request Vendor-Specific Attributes (VSA) set to True.

Dynamic session changes are directed to specific user sessions, as identified by RADIUS attributes.

To enable dynamic session changes, configure the following:

- You must enable EAP or Endpoint Tracking globally and at the port level.
- You must enable RADIUS dynamic extensions commands at the port level.

You can use the **show radius dynamic-server statistics** command to view statistics about dynamic session changes.

```
Switch:1#enable
Switch:1#show radius dynamic-server statistics

=====
                        RADIUS Dynamic Authorization Global Statistics
=====
Disconnects From Invalid Client Addresses:      0
CoAs From Invalid Client Addresses:             0
=====
```

RADSec

Remote Access Dial-In User Services (RADIUS) Security (RADSec) provides secure communication between RADIUS peers using Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP), or Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP).

RADSec peers use certificates to establish trust relationships. Certificates are specified in the RADSec profile on the switch, which can be the default profile or a profile that you configure. You must configure the client and secure server with the same certificate authority (CA) certificate file, server certificate, certificate key file and password to establish a RADSec connection. The password is used for packet encryption and decryption.

You can configure the RADSec security mode to use TLS protocol or DTLS protocol. Both TLS and DTLS modes support IPv4 addresses, but IPv6 addresses are supported only by TLS mode.

RADSec uses radsecproxy to encrypt packets sent between RADIUS clients and a secure server. A radsecproxy process starts when radius and secure-mode are enabled both globally and for the current server. Radsecproxy uses multiple instances on the switch, one for each one for each security-configured RADIUS server. The maximum number of radsecproxy instances is 10, which is equivalent to the maximum number of radius servers you can configure on the switch.

Note

You must use radsecproxy version 1.8.1 or later. Using an earlier version of radsecproxy can result in authentication failures.

The following events cause all radsecproxy processes to restart:

- A Segmented Management Instance interface is deleted, enabled, or disabled.
- An IPv4 address or route is changed.
- An IPv6 address or route is changed.
- RADIUS global enable and secure-enable change.

The following changes only affect a radsecproxy instance and result only in the associated process restarting:

- Enabling or disabling the RADIUS server state or secure state.
- Modifying the RADIUS server secure mode, associated profile, or secure log level.

A RADSec profile configuration change causes all processes associated with the profile to restart.

A RADSec process automatically stops when the corresponding RADIUS server entry is deleted, or if RADIUS or secure mode is disabled for the server.

If one of the global radius flags (radius state, radius secure state) is disabled, all radsecproxy instances stop.

RADIUS configuration using CLI

You can configure Remote Access Dial-In User Services (RADIUS) to secure networks against unauthorized access, and allow communication servers and clients to authenticate users identity through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Configure RADIUS Attributes

Configure RADIUS to authenticate user identity through a central database.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure RADIUS access priority:
`radius access-priority-attribute <192-240>`
3. Configure RADIUS accounting:
`radius accounting {attribute-value <192-240>|enable|include-cli-commands}`
4. Configure the RADIUS authentication info attribute value:
`radius auth-info-attr-value <0-255>`
5. Clear RADIUS statistics:
`radius clear-stat`
6. Configure the value of the CLI commands:
`radius cli-commands-attribute <192-240>`

7. Configure the value of the command access attribute:
`radius command-access-attribute <192-240>`
8. Configure the maximum number of servers allowed:
`radius maxserver <1-10>`
9. Configure the multicast address attribute:
`radius mcast-addr-attr-value <0-255>`
10. Enable RADSec globally:
`radius secure-flag`

**Note**

RADSec is not supported on the VSP 8600 Series.

11. Configure the RADSec profile:
`radius secure-profile WORD<1-16> [ca-cert-file | cert-file | key-file
| key-pwd]`

**Note**

RADSec is not supported on the VSP 8600 Series.

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Configure RADIUS access priority:

```
Switch:1(config)#radius access-priority-attribute 192
```

Configure RADIUS accounting to include CLI commands:

```
Switch:1(config)#radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<code>access-priority-attribute <192-240></code>	Specifies the value of the access priority attribute in the range of 192 to 240. The default is 192.
<code>accounting {attribute-value <192-240> enable include-cli-commands}</code>	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false. Use the no option to disable the accounting attribute value: no radius accounting enable .
<code>auth-info-attr-value <0-255></code>	Specifies the value of the authentication information attribute in the range of 0 to 255. The default is 91.
<code>clear-stat</code>	Clears RADIUS statistics.

Variable	Value
<i>cli-cmd-count</i> <1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.
<i>cli-commands-attribute</i> <192-240>	Specifies the value of CLI commands attribute in the range of 192 to 240. The default is 195.
<i>cli-profile</i>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<i>command-access-attribute</i> <192-240>	Specifies the value of the command access attribute in the range of 192 to 240. The default is 194.
<i>enable</i>	Enable RADIUS authentication globally on the switch.
<i>maxserver</i> <1-10>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The range is between 1 and 10. The default is 10.
<i>mcast-addr-attr-value</i> <0-255>	Specifies the value of the multicast address attribute in the range of 0 to 255. The default is 90.
<i>secure-flag</i> Note: Exception: not supported on VSP 8600 Series.	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.
<i>secure-profile</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the RADSec profile name.

Variable	Value
<pre>server host WORD<0-46> key WORD<0-32> [used-by {cli snmp web} [acct-enable] [acct-port <1-65536>] [enable] [port <1-65536>] [priority <1-10>] [retry <0- 6>secure-enablesecure-log- level {critical debug error info warning}secure-mode{dtls tls}secure- profileWORD<1-16>] [source- ip WORD<0-46>] [timeout <1- 60>]</pre>	<ul style="list-style-type: none"> • <i>host WORD<0-46></i> Creates a host server. WORD<0-46> signifies an IP address. • <i>key WORD<0-32></i> Specifies a secret key in the range of 0-32 characters. • <i>used-by {cli eapol endpoint-tracking snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> ◦ cli authentication ◦ eapol authentication ◦ endpoint-tracking authentication ◦ snmp accounting ◦ web authentication • <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default. • <i>acct-port <1-65536></i> Specifies a UDP port of the RADIUS accounting server (1 to 65536). The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server. • <i>enable</i> Enables the server. The default is true. • <i>port <1-65536></i> Specifies a UDP port of the RADIUS server. The default value is 1812. • <i>priority <1-10></i> Specifies the priority value for this server. The default is 10. • <i>retry <0-6></i> Specifies the maximum number of authentication retries. The default is 3. • <i>secure-enable</i> Enable secure mode on the server. Note: Exception: not supported on VSP 8600 Series. • <i>secure-log-level {critical debug error info warning}</i> Specifies the RADIUS secure server log severity level.

Variable	Value
	<p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>secure-mode{dtls tls}</code> <p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>secure-profileWORD<1-16></code> <p>Specifies the secure profile name.</p> <p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>source-ip WORD<0-46></code> <p>Specifies a configured IP address as the source address when transmitting RADIUS packets. WORD<0-46> signifies an IP address.</p> <p>Note: Exception: Only supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>timeout <1-60></code> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>
<p><code>sourceip-flag</code></p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Enable the source IP so the switch uses a configured source IP address. If the outgoing interface on the switch fails, a different source IP address is used — requiring that you make configuration changes to define the new RADIUS client on the RADIUS server. To simplify RADIUS server configuration, you can configure the switch to use a Circuitless IP (CLIP) address as the source IP and NAS IP address when transmitting RADIUS packets. A CLIP is not associated with a physical interface and is always in an active and operational state. You can configure the switch with multiple CLIP interfaces.</p> <p>By default, the switch uses the IP address of the outgoing interface as the source IP, and the NAS Ip address for RADIUS packets that it transmits.</p>

Configuring RADIUS profile

Use RADIUS CLI profiling to grant or deny CLI command access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration file on the radius server, and you can specify the command-access mode for these commands. The default is false.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enable RADIUS CLI profiling:
radius cli-profile

Example

```
Switch:1> enable  
  
Switch:1# configure terminal  
  
Switch:1(config)# radius cli-profile
```

Enabling RADIUS authentication

About This Task

Enable or disable RADIUS authentication globally on the device to allow further configuration to take place. Use the no option to disable RADIUS authentication globally. The default is false or disabled.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enable RADIUS authentication globally on the switch:
radius enable

Enable the Source IP Flag for the RADIUS Server

**Note**

This procedure only applies to VSP 8600 Series.

Before You Begin

- To configure the CLIP as the source IP address, you must enable the global RADIUS sourceip-flag. You can then configure the source-ip address parameter while defining the RADIUS server on the switch. The source IP address must be a CLIP address, and that you can configure a different CLIP address for each RADIUS server.

**Important**

Use the source IP option only for the RADIUS servers connected to the in-band network.

About This Task

By default, the switch uses the IP address of the outgoing interface as the source IP, and the NAS IP address for RADIUS packets that it transmits. Enable the source IP so the switch uses a configured

source IP address instead. Therefore, if the outgoing interface on the switch fails, a different source IP address is used—requiring that you make configuration changes to define the new RADIUS Client on the RADIUS server.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration in CLI.

To simplify RADIUS Server configuration, you can configure the switch to use a Circuitless IP Address (CLIP) as the source IP and NAS IP address when transmitting RADIUS packets. A CLIP is not associated with a physical interface and is always in an active and operational state. You can configure the switch with multiple CLIP interfaces.

The default for **radius sourceip-flag** is false.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable the RADIUS packet source IP flag:
`radius sourceip-flag`

Enabling RADIUS accounting

Before You Begin

- You must configure a RADIUS server before you can enable RADIUS accounting.

About This Task

Enable Remote Access Dial-in User Services (RADIUS) accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable RADIUS accounting globally:
`radius accounting enable`
3. Include or exclude CLI commands in RADIUS accounting updates:
`radius accounting include-cli-commands`
4. Specify the integer value of the CLI commands attribute:
`radius accounting attribute-value <192-240>`

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# radius accounting enable

Switch:1(config)# radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius accounting** command.

Variable	Value
<i>enable</i>	Enable RADIUS globally.
<i>include-cli-commands</i>	Include CLI commands in RADIUS accounting updates.
<i>attribute-value</i> <192-240>	Specify the integer value of the CLI commands attribute.

Enabling RADIUS-SNMP accounting

Before You Begin

- You must configure a RADIUS server before you can enable RADIUS-SNMP accounting.

About This Task

Enable Remote Access Dial-in User Services (RADIUS) Simple Network Managing Protocol (SNMP) accounting globally. Use SNMP to remotely collect management data. An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Enable RADIUS Simple Network Management Protocol (SNMP) accounting globally:

```
radius-snmp acct-enable
```
- Set a timer to send a stop accounting message for RADIUS Simple Network Management Protocol (SNMP):

```
radius-snmp abort-session-timer <30-65535>
```
- Set the timer for re-authentication of the SNMP session:

```
radius-snmp re-auth-timer <30-65535>
```
- Specify the user name for SNMP access:

```
radius-snmp user WORD <0-20>
```

Example

```
Switch:1> enable

Switch:1# configure terminal
```

```
Switch:1 (config) # radius-snmp acct-enable

Switch:1 (config) # radius-snmp abort-session-timer 30
```

Variable Definitions

The following table defines parameters for the **radius-snmp** command.

Variable	Value
<i>acct-enable</i>	Enables RADIUS accounting globally. You cannot enable RADIUS accounting before you configure a valid server. The system disables RADIUS accounting by default. The default is false. Use the no option to disable RADIUS accounting globally: no radius-snmp acct-enable
<i>abort-session-timer</i> <30-65535>	Set the timer, in seconds, to send a stop accounting message. The default is 180.
<i>re-auth-timer</i> <30-65535>	Sets timer for re-authentication of the SNMP session. The timer value ranges from 30 to 65535 seconds. The default is 180.
<i>user</i> WORD <0-20>	Specifies the user name for SNMP access. WORD <0-20> specifies the user name in a range of 0 to 20 characters. The default is snmp_user.

Configuring RADIUS accounting interim request

About This Task

Configure RADIUS accounting interim requests to create a log whenever a user executes more than the number of CLI commands you specify.

If the packet size equals or exceeds 1.8 KB, an interim request packet is sent even if the configured limit is not reached. Therefore, the trigger to send out the interim request is either the configured value or a packet size greater than, or equal to 1.8 KB, whichever happens first.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Configure RADIUS accounting interim requests:
radius cli-cmd-count <1-40>
3. Include or exclude CLI commands in RADIUS accounting:
radius accounting include-cli-commands

Important

You must configure the **radius accounting include-cli-commands** command for accounting interim requests to function.

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal

Switch:1(config)# radius cli-cmd-count 30

Switch:1(config)# radius accounting include-cli-commands
```

Variable Definitions

The following table defines parameters for the **radius cli-cmd-count** command.

Variable	Value
<1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.

Configure RADIUS Authentication and RADIUS Accounting Attributes

About This Task

Configure RADIUS authentication and RADIUS accounting attributes to determine the size of the packets received.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the RADIUS authentication attribute value:

```
radius command-access-attribute <192-240>
```
3. Configure the RADIUS accounting attribute value:

```
radius accounting attribute-value <192-240>
```

Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#radius command-access-attribute 192

Switch:1(config)#radius accounting attribute-value 192
```

Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<i>access-priority-attribute</i> <192-240>	Specifies the value of the access priority attribute in the range of 192 to 240. The default is 192.
<i>accounting</i> { <i>attribute-value</i> <192-240> <i>enable</i> <i>include-cli-commands</i> }	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false. Use the no option to disable the accounting attribute value: no radius accounting enable .
<i>auth-info-attr-value</i> <0-255>	Specifies the value of the authentication information attribute in the range of 0 to 255. The default is 91.
<i>clear-stat</i>	Clears RADIUS statistics.
<i>cli-cmd-count</i> <1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.
<i>cli-commands-attribute</i> <192-240>	Specifies the value of CLI commands attribute in the range of 192 to 240. The default is 195.
<i>cli-profile</i>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<i>command-access-attribute</i> <192-240>	Specifies the value of the command access attribute in the range of 192 to 240. The default is 194.
<i>enable</i>	Enable RADIUS authentication globally on the switch.
<i>maxserver</i> <1-10>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The range is between 1 and 10. The default is 10.
<i>mcast-addr-attr-value</i> <0-255>	Specifies the value of the multicast address attribute in the range of 0 to 255. The default is 90.
<i>secure-flag</i> Note: Exception: not supported on VSP 8600 Series.	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.
<i>secure-profile</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the RADSec profile name.

Variable	Value
<pre>server host WORD<0-46> key WORD<0-32> [used-by {cli snmp web} [acct-enable] [acct-port <1-65536>] [enable] [port <1-65536>] [priority <1-10>] [retry <0- 6>secure-enablesecure-log- level {critical debug error info warning}secure-mode{dtls tls}secure- profileWORD<1-16>] [source- ip WORD<0-46>] [timeout <1- 60>]</pre>	<ul style="list-style-type: none"> • <i>host WORD<0-46></i> Creates a host server. WORD<0-46> signifies an IP address. • <i>key WORD<0-32></i> Specifies a secret key in the range of 0-32 characters. • <i>used-by {cli eapol endpoint-tracking snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> ◦ cli authentication ◦ eapol authentication ◦ endpoint-tracking authentication ◦ snmp accounting ◦ web authentication • <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default. • <i>acct-port <1-65536></i> Specifies a UDP port of the RADIUS accounting server (1 to 65536). The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server. • <i>enable</i> Enables the server. The default is true. • <i>port <1-65536></i> Specifies a UDP port of the RADIUS server. The default value is 1812. • <i>priority <1-10></i> Specifies the priority value for this server. The default is 10. • <i>retry <0-6></i> Specifies the maximum number of authentication retries. The default is 3. • <i>secure-enable</i> Enable secure mode on the server. <p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> • <i>secure-log-level {critical debug error info warning}</i> Specifies the RADIUS secure server log severity level.

Variable	Value
	<p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>secure-mode{dtls tls}</code> <p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>secure-profileWORD<1-16></code> <p>Specifies the secure profile name.</p> <p>Note: Exception: not supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>source-ip WORD<0-46></code> <p>Specifies a configured IP address as the source address when transmitting RADIUS packets. WORD<0-46> signifies an IP address.</p> <p>Note: Exception: Only supported on VSP 8600 Series.</p> <ul style="list-style-type: none"> <code>timeout <1-60></code> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>
<p><code>sourceip-flag</code></p> <p>Note: Exception: only supported on VSP 8600 Series.</p>	<p>Enable the source IP so the switch uses a configured source IP address. If the outgoing interface on the switch fails, a different source IP address is used — requiring that you make configuration changes to define the new RADIUS client on the RADIUS server. To simplify RADIUS server configuration, you can configure the switch to use a Circuitless IP (CLIP) address as the source IP and NAS IP address when transmitting RADIUS packets. A CLIP is not associated with a physical interface and is always in an active and operational state. You can configure the switch with multiple CLIP interfaces.</p> <p>By default, the switch uses the IP address of the outgoing interface as the source IP, and the NAS Ip address for RADIUS packets that it transmits.</p>

Add a RADIUS Server

About This Task

Add a RADIUS server to allow RADIUS service on the switch.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a RADIUS server:

```
radius server host WORD <0-46> key WORD<0-32> [used-by {cli|eapol|
endpoint-tracking|snmp|web}] [acct-enable][acct-port <1-65536>]
[enable] [port <1-65536>][priority <1-10>][retry <0-6>] [secure-
enable] [secure-log-level] [secure-mode] [secure-profile] [source-ip
WORD <0-46>] [timeout <1-60>]
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Add a RADIUS server:

```
Switch:1(config)#radius server host
4717:0000:0000:0000:0000:0000:7933:0001 key testkey1 used-by snmp port
12 retry 5 timeout 10 enable
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by {cli eapol endpoint-tracking snmp web}</i>	<p>Configures how the server functions:</p> <ul style="list-style-type: none"> • cli—configure the server for CLI authentication. • eapol—configure the server for EAPoL authentication. • endpoint-tracking—configure the server for Endpoint Tracking authentication. • snmp—configure the server for SNMP accounting. • web—configure the server for HTTP(s) authentication. <p>Use the no option to remove a host server: no radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}. The default is cli. The default command is: default radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}.</p>
<i>host WORD <0-46></i>	<p>Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.</p>

Variable	Value
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.
<i>acct-port</i> <1-65536>	Configures the UDP port of the RADIUS accounting server (1 to 65536). The default value is 1813. Important: The UDP port value set for the client must match the UDP value set for the RADIUS server.
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key</i> <i>WORD</i> <0-20>	Configures the secret key of the authentication client.
<i>port</i> <1-65536>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority</i> <1-10>	Configures the priority value for this server. The default is 10.
<i>retry</i> <0-6>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i> Note: Exception: not supported on VSP 8600 Series.	Enable RADIUS Security (RADSec).
<i>secure-log-level</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> • critical • debug • error • info • warning
<i>secure-mode</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i> Note: Exception: not supported on VSP 8600 Series.	Configures the secure profile for the server.
<i>source-ip</i> <i>WORD</i> <0-46> Note: Exception: only supported on VSP 8600 Series.	Configures an IP address as the source address when transmitting RADIUS packets. To use this option, you must have the global RADIUS sourceip-flag set to true. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>timeout</i> <1-180>	Configures the number of seconds before the authentication request times out. The default is 8.

Modify RADIUS Server Settings

About This Task

Change a specified RADIUS server value without having to delete the server and recreate it again.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Modify a RADIUS server:

```
radius server host WORD <0-46> {[used-by {cli|eapol|endpoint-tracking|  
snmp|web}}] [key WORD<0-20>]} [port 1-65536] [priority <1-10>] [retry  
<0-6>] [timeout <1-180>] [enable] [acct-port <1-65536>] [acct-enable]  
[source-ip WORD <0-46>]
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Modify a RADIUS server:

```
Switch:1(config)#radius server host  
4717:0000:0000:0000:0000:0000:7933:0001 used-by snmp port 12 retry 5  
timeout 10 enable
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by</i> {cli eapol endpoint-tracking snmp web}	<p>Configures how the server functions:</p> <ul style="list-style-type: none"> cli—configure the server for CLI authentication. eapol—configure the server for EAPoL authentication. endpoint-tracking—configure the server for Endpoint Tracking authentication. snmp—configure the server for SNMP accounting. web—configure the server for HTTP(s) authentication. <p>Use the no option to remove a host server: no radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}. The default is cli. The default command is: default radius server host WORD<0-46> used-by {cli eapol endpoint-tracking snmp web}.</p>
<i>host</i> WORD <0-46>	Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.
<i>acct-port</i> <1-65536>	<p>Configures the UDP port of the RADIUS accounting server (1 to 65536). The default value is 1813.</p> <p>Important: The UDP port value set for the client must match the UDP value set for the RADIUS server.</p>
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key</i> WORD <0-20>	Configures the secret key of the authentication client.
<i>port</i> <1-65536>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority</i> <1-10>	Configures the priority value for this server. The default is 10.
<i>retry</i> <0-6>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i>	Enable RADIUS Security (RADSec).
Note: Exception: not supported on VSP 8600 Series.	

Variable	Value
<i>secure-log-level</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> critical debug error info warning
<i>secure-mode</i> Note: Exception: not supported on VSP 8600 Series.	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i> Note: Exception: not supported on VSP 8600 Series.	Configures the secure profile for the server.
<i>source-ip WORD <0-46></i> Note: Exception: only supported on VSP 8600 Series.	Configures an IP address as the source address when transmitting RADIUS packets. To use this option, you must have the global RADIUS sourceip-flag set to true. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>timeout <1-180></i>	Configures the number of seconds before the authentication request times out. The default is 8.

View RADIUS Information

View the global status of RADIUS information to ensure you configured the RADIUS feature according to the needs of the network.

Procedure

- To enter User EXEC mode, log on to the switch.
- View the global status of RADIUS information:

```
show radius
```

Example

```
Switch:1>show radius
  acct-attribute-value : 193
    acct-enable       : false
  acct-include-cli-commands : false
  access-priority-attribute : 192
    auth-info-attr-value : 91
  command-access-attribute : 194
  cli-commands-attribute : 195
    cli-cmd-count      : 40
  cli-profile-enable : false
    enable             : false
  igap-passwd-attr : standard
```

```

igap-timeout-log-fsize : 512
      maxserver : 10
mcast-addr-attr-value : 90
      sourceip-flag : false
supported-vendor-ids : 1584, 562, 1916
      secure-flag : false

```

**Note**

The *sourceip-flag* only applies to VSP 8600 Series.

The *secure-flag* field does not apply to VSP 8600 Series.

The Extreme Networks vendor ID 1916 in the *supported-vendor-ids* field does not apply to VSP 4450 Series, VSP 8600 Series, and XA1400 Series.

View RADIUS Server Information

If your system is configured with a RADIUS server you can display the RADIUS server information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. To view the RADIUS server information enter the following command:

```
show radius-server
```

**Note**

If no RADIUS server is configured, the system displays the following message:
no RADIUS server configured

Example

```

=====
                        Radius Server Entries
=====

```

Showing RADIUS Server Statistics

About This Task

You cannot collect the following network statistics from a console port: the number of input and output packets, and the number of input and output bytes. All other statistics from console ports are available to assist with debugging.

Procedure

1. Enter Privileged EXEC mode:
enable

2. Display RADIUS server statistics:
`show radius-server statistics`
3. Clear server statistics:
`clear radius statistics`

Example

```
Switch:1#show radius-server statistics

Responses with invalid server address: 0

  Radius Server(UsedBy) : 192.0.2.58 (cli)
-----
    Access Requests : 52
    Access Accepts  : 0
    Access Rejects  : 0
    Bad Responses   : 52
    Client Retries  : 52
    Pending Requests : 0
    Acct On Requests : 1
    Acct Off Requests : 0
    Acct Start Requests : 47
    Acct Stop Requests : 46
    Acct Interim Requests : 0
    Acct Bad Responses : 94
    Acct Pending Requests : 0
    Acct Client Retries : 94
    Access Challenges : 0
    Round-trip Time :
    Nas Ip Address : 192.0.2.32

  Radius Server(UsedBy) : 192.0.2.58 (snmp)
-----
    Access Requests : 0
    Access Accepts  : 0
    Access Rejects  : 0
    Bad Responses   : 0
    Client Retries  : 0
    Pending Requests : 0
    Acct On Requests : 0
    Acct Off Requests : 0
    Acct Start Requests : 0
    Acct Stop Requests : 0
    Acct Interim Requests : 0
    Acct Bad Responses : 0
    Acct Pending Requests : 0
    Acct Client Retries : 0
    Access Challenges : 0
    Round-trip Time :
    Nas Ip Address : 192.0.2.32

```

Configuring RADIUS server reachability

About This Task

Use this procedure to configure the RADIUS server reachability settings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the RADIUS keep-alive timer:

```
radius reachability keep-alive-timer <30-600>
```
3. Configure the RADIUS reachability mode:

```
radius reachability mode <status-server | use-radius>
```
4. If you selected `use-radius` as the RADIUS reachability mode, configure the RADIUS request username and password:

```
radius reachability username WORD<1-16> password WORD<1-16>
```
5. Configure the RADIUS reachability unreachable timer:

```
radius reachability unreachable-timer <30-600>
```

Example

Configure values for RADIUS server reachability:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

Configure the RADIUS keep-alive timer:

```
Switch:1(config)#radius reachability keep-alive-timer 30
```

Configure the RADIUS reachability mode:

```
Switch:1(config)#radius reachability mode status-server
```

Configure the RADIUS reachability unreachable timer:

```
Switch:1(config)#radius reachability unreachable-timer 30
```

Variable Definitions

The following table defines parameters for the **radius reachability** command.

Variable	Value
keep-alive-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.
mode <status-server use-radius>	Specifies status-server mode or use-radius mode. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
password WORD<1-16>	Configures the RADIUS request password. The default is extremenetworks.

Variable	Value
unreachable-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
username <i>WORD</i> <1-16>	Configures the RADIUS request username. The default is extremenetworks.

Displaying RADIUS server reachability

About This Task

Use this procedure to display the RADIUS server reachability settings.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the RADIUS server reachability settings:

```
show radius reachability
```

Example

Display the RADIUS server reachability settings.

```
Switch:1#show radius reachability
EAP RADIUS reachability mode      : use-radius
EAP RADIUS reachability status    : RADIUS is disabled globally
EAP RADIUS reachable server      : none
Time until next check             : N/A
RADIUS username                   : reachme
RADIUS password                   : reachme
RADIUS keep-alive-timer           : 180
RADIUS unreachable-timer          : 60
```

Showing RADIUS SNMP configurations

Display current RADIUS SNMP configurations.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the current RADIUS server SNMP configurations:

```
show radius snmp
```

Example

```
Switch:1>show radius snmp
abort-session-timer : 180
acct-enable         : false
                    user : snmp_user
                    enable : false
re-auth-timer      : 180
```

Displaying RADIUS dynamic server information

About This Task

Use the following procedure to display information about the configuration of RADIUS dynamic session changes.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about dynamic change configuration:

```
show radius dynamic-server [client | statistics]
```

Example

```
Switch:1#show radius dynamic-server

=====
                        RADIUS Dynamic Authorization General Info
=====
CLIENT ADDRESS                UDP PORT      CLIENT ENABLED  SECRET KEY
-----
192.0.2.15                     1026        Disabled      *****
192.0.2.16                     1027        Disabled      *****
-----

All 2 out of 2 Total Num of RADIUS Dynamic Authorization clients displayed
```

Display dynamic server statistics:

```
Switch:1#show radius dynamic-server statistics

=====
                        RADIUS Dynamic Authorization Global Statistics
=====
Disconnects From Invalid Client Addresses:      0
CoAs From Invalid Client Addresses:             0
-----
```

Variable Definitions

The following table defines parameters for the **show radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Display RADIUS Dynamic Authorization configuration values for the specified client.
statistics	Display statistics for RADIUS Dynamic Authorization clients.

Configuring a RADIUS dynamic-server client

About This Task

Configure a client to allow processing of dynamic session changes.

Before You Begin

You must enable EAPOL globally and at the port level.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure values for client IP address, port, and secret key:

```
Switch:1(config)#radius dynamic-server client WORD<0-46> port
<1024-65535> secret WORD<0-32> enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius dynamic-server client 192.0.2.15 port 1025 secret 123 enable
```

Variable Definitions

The following table defines parameters for the **radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Specifies the client address.
enable	Enable processing of dynamic session changes.
port <1024-65535>	Specifies the port value.
secret WORD<0-32>	Specifies a value for secret key.

RADSec Configuration Using CLI

This section contains procedures for configuring RADSec using Command Line Interface (CLI).

Create and Configure a RADIUS Secure Profile

Note

This procedure does not apply to VSP 8600 Series.

You configure RADIUS secure profiles with certificate information, certificate key information, and password information, which enables RADSec peers to establish connections.

About This Task

Note

- All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.
- A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/radsec directory.
- Profile configuration file “profile_info.cfg” is available in /intflash/.radsec/profile directory.
- You can configure a maximum of 10 RADSec profiles.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a name for the RADIUS profile:

```
radius secure-profile WORD<1-16>
```

3. Configure the full file path of the certificate authority (CA) certificate for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> CA-cert-file WORD<0-128>
[WORD<1-128>]
```

4. Configure the full path of the server certificate for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> cert-file WORD<0-128> [WORD<1-128>]
```

5. Configure the full path of the private key file for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> key-file WORD<0-128> [WORD<1-128>]
```

6. Configure the private key password for the RADIUS secure profile:

```
radius secure-profile WORD<1-16> key-pwd WORD<0-255>
```

Variable Definitions

The following table defines parameters for the **radius secure-profile** command.

Variable	Value
WORD<1-16>	Specifies the RADIUS secure profile name.
CA-cert-file WORD<0-128>	Specifies the full file path of the certificate authority (CA) certificate.
cert-file WORD<0-128>	Specifies the full file path of the server certificate.
key-file WORD<0-128>	Specifies the full file path of the private key file.
WORD<1-128>	Specifies the file name.
key-pwd WORD<0-255>	Specifies the private key password.

Display RADIUS Secure Profile information

About This Task

Use the following procedure to display information about the configuration of RADIUS secure profiles.

Note

This procedure does not apply to VSP 8600 Series.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about RADIUS secure profile configuration:
show radius secure-profile

Example

```
Switch:1>enable
Switch:1#show radius secure-profile
```

```
=====
                        Secure RADIUS profile
=====
```

```
Profile default:
  Name : default
  RootCert : n/a
  Cert : n/a
  Key : n/a
  Password : *****
```

Associate a RADSec Profile with a RADIUS Server

Before You Begin

Add a RADIUS Server. For more information, see [Add a RADIUS Server](#) on page 2686.

About This Task

RADSec peers use certificates to establish trust relationships. You must associate a RADSec profile with a RADIUS server in order to use certificates.

Note

This procedure does not apply to VSP 8600 Series.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Associate a RADSec profile with a RADIUS server:
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-profile WORD<1-16>

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
WORD<0-46>	Specifies the IPv4 address or the IPv6 address of the RADIUS server.
used-by	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> cli authentication eapol authentication endpoint-tracking authentication snmp accounting web authentication
secure-enable	Enables RADSec on the RADIUS server.

Configure RADSec Secure Mode

About This Task

Configure the secure mode for RADSec as either Transport Layer Security (TLS) protocol or Datagram Transport Layer Security (DTLS) protocol.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the secure mode:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking  
| snmp | web} secure-mode {tls | dtls}
```

Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>WORD<0-46></i>	Specifies the IPv4 address or the IPv6 address.
<i>used-by</i>	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> cli authentication eapol authentication endpoint-tracking authentication snmp accounting web authentication
<i>secure-mode</i>	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) <p>The default is tls.</p>

Enable RADSec

About This Task

Note

This procedure does not apply to VSP 8600 Series.

You must enable RADSec globally and at the RADIUS server level in order for RADSec to be enabled for a RADIUS server.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable RADSec globally:

```
radius secure-flag
```

3. Enable RADSec on the RADIUS server:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking  
| snmp | web} secure-enable
```

Change the logging level for RADSec secure profile

About This Task

Note

This procedure does not apply to VSP 8600 Series.

Use the following procedure to change the logging level for a RADSec secure profile.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Change the logging level of the RADIUS secure profile:

```
radius server host WORD<0-46> used-by cli secure-log-level debug
```

Variable Definitions

The following table defines parameters for the **radius server host WORD<0-46> used-by cli secure-log-level debug** command.

Variable	Value
<i>WORD<0-46></i>	Specifies the IPv4 address or the IPv6 address.

Display Log Information for Secure RADIUS Instance

About This Task

Use the following procedure to display log information for secure instance of RADIUS.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display log information for a secure instance of RADIUS:

```
show radius secure-server log <0-9>.
```

Variable Definitions

The following table defines parameters for the **show radius secure-server** command.

Variable	Value
<i>log<0-9></i>	Specifies the log for a secure RADIUS instance.

RADIUS configuration using Enterprise Device Manager

You can configure Remote Access Dial-In User Services (RADIUS) to assist in securing networks against unauthorized access, and allow communication servers and clients to authenticate the identity of users through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Enable RADIUS Authentication

About This Task

Enable RADIUS authentication globally to allow all features and functions of RADIUS to operate with the RADIUS server.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. In the **RADIUS Global** tab, select the **Enable** check box.
4. In the **MaxNumberServer** field, type a value for the maximum number of servers.
5. In the **AccessPriorityAttrValue** field, type an access policy value (by default, this value is 192).
6. Configure the rest of the parameters in the RADIUS global tab.
7. Click **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.

Name	Description
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
SourceIpFlag Note: Exception: only supported on VSP 8600 Series.	Includes a configured IP address as the source address in RADIUS packets. The default is false. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Enable RADIUS Accounting

Before You Begin

- You must set up a RADIUS server and add it to the configuration file of the device before you can enable RADIUS accounting on the device. Otherwise, the system displays an error message.

About This Task

Enable RADIUS accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, select the **AcctEnable** check box.
- In the **AcctAttrValue** field, type an access policy value (by default, this value is 193).
- Click **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.

Name	Description
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
SourceIpFlag Note: Exception: only supported on VSP 8600 Series.	Includes a configured IP address as the source address in RADIUS packets. The default is false. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Disable RADIUS Accounting

Before You Begin

- You cannot globally disable RADIUS accounting unless a server entry exists.

About This Task

Disabling RADIUS accounting removes the accounting function from the RADIUS server.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, disable RADIUS accounting by clearing the **AcctEnable** check box.
- Click **Apply**.

Enable RADIUS Accounting Interim Request

About This Task

Enable the RADIUS accounting interim request feature to create a log whenever more than the specified number of CLI commands are executed.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. In the **RADIUS Global** tab, type the number of CLI commands in the **CliCmdCount** field.
4. Click **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttriValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.

Name	Description
SourceIpFlag Note: Exception: only supported on VSP 8600 Series.	Includes a configured IP address as the source address in RADIUS packets. The default is false. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Configure the Source IP Option for the RADIUS Server

Note

This procedure only applies to VSP 8600 Series.

Before You Begin

- To configure the CLIP as the source IP address, you must configure the global RADIUS **sourceip-flag** parameter as true. You can configure the **source-ip** address parameter while you define the RADIUS Server on the switch. The source IP address must be a CLIP address, and you can configure a different CLIP address for each RADIUS server. For more information about configuring the source IP address, see [Add a RADIUS Server](#) on page 2710.

Important

Use the source IP option only for the RADIUS servers connected to the in-band network.

About This Task

By default, the switch uses the IP address of the outgoing interface as the source IP and NAS IP address for RADIUS packets that it transmits. When you configure the RADIUS server, this IP address is used when defining the RADIUS Clients that communicate with it. Therefore, if the outgoing interface on the

switch fails, a different source IP address is used—requiring that you make configuration changes to define the new RADIUS client on the RADIUS server.

To simplify RADIUS Server configuration, you can configure the switch to use a Circuitless IP Address (CLIP) as the source IP and NAS IP address when transmitting RADIUS packets. A CLIP is not associated with a physical interface and is always in an active and operational state. You can configure the switch with multiple CLIP interfaces.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. In the **RADIUS Global** tab, select **SourceIpFlag**.
4. Select **Apply**.

RADIUS Global Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.

Name	Description
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
SourceIpFlag Note: Exception: only supported on VSP 8600 Series.	Includes a configured IP address as the source address in RADIUS packets. The default is false. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Add a RADIUS Server

About This Task

Add a RADIUS server to allow RADIUS service on the switch.

Remote Dial-In User Services (RADIUS) supports both IPv4 and IPv6 addresses, with no differences in functionality or configuration in all but the following case. When adding a RADIUS server or updating a RADIUS server in Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. Click **Insert**.
5. Configure the server as required.
6. Click **Insert**.

RADIUS Servers Field Descriptions

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
AddressType	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
Address	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.
UsedBy	Configures how the server functions: <ul style="list-style-type: none"> cli—configure the server for CLI authentication. eapol—configure the server for EAPoL authentication. endpointTracking—configure the server for Endpoint Tracking authentication. snmp—configure the server for SNMP accounting. web—configure the server for HTTP(s) authentication. The default is cli.
Priority	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
TimeOut	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
Enable	Enables or disables authentication on the server. The default is true.
MaxRetries	Specifies the maximum number of retransmissions allowed. The default is 1.
UdpPort	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.
SecretKey	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
AcctEnable	Enables or disable RADIUS accounting. The default is true.
AcctUdpPort	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
SecureEnable Note: Exception: not supported on VSP 8600 Series.	Enable RADIUS Security (RADSec).
SecureMode Note: Exception: not supported on VSP 8600 Series.	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) The default is tls.

Name	Description
SecureProfile Note: Exception: not supported on VSP 8600 Series.	Specifies the name of the secure profile.
SecureLogLevel Note: Exception: not supported on VSP 8600 Series.	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> • critical • error • warning • info • debug
SourceIpAddr	Specifies the IP address to use as the source address in RADIUS packets. To use this option, you must set the global RADIUS SourceIpFlag to true. RADIUS supports IPv4 and IPv6 addresses.

Showing RADIUS Server Statistics

About This Task

Use the server statistics feature to display the number of input and output packets and the number of input and output bytes. Statistics from console ports are available to assist with debugging.

Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **RADIUS**.
3. Click the **RADIUS Servers Stats** tab.

RADIUS Server Stats Field Descriptions

Use the data in the following table to use the **RADIUS Server Stats** tab.

Name	Description
AddressType	Specifies the type of IP address. RADIUS supports IPv4 addresses only.
Address	Shows the IP address of the RADIUS server.
Used by	Identifies the client.
AccessRequests	Shows the number of access-response packets sent to the server; does not include retransmissions.
AccessAccepts	Shows the number of access-accept packets, valid or invalid, received from the server.
AccessRejects	Shows the number of access-reject packets, valid or invalid, received from the server.
BadResponses	Shows the number of invalid access-response packets received from the server.

Name	Description
PendingRequests	Shows the access-request packets sent to the server that have not yet received a response or that have timed out.
ClientRetries	Shows the number of authentication retransmissions to the server.
AcctOnRequests	Shows the number of accounting on requests sent to the server.
AcctOffRequests	Shows the number of accounting off requests sent to the server.
AcctStartRequests	Shows the number of accounting start requests sent to the server.
AcctStopRequests	Shows the number of accounting stop requests sent to the server.
AcctInterimRequests	Number of Accounting Interim requests sent to the server. Important: The AcctInterimRequests counter increments only if you select AcctIncludeCli from the RADIUS Global tab.
AcctBadResponses	Shows the number of Invalid responses discarded from the server.
AcctPendingRequests	Shows the number of requests waiting to be sent to the server.
AcctClientRetries	Shows the number of retries made to this server.
RoundTripTime	Shows the time difference between the instance when a RADIUS request is sent and the corresponding response is received.
AccessChallenges	Shows the number of RADIUS access-challenges packets sent to this server. This does not include retransmission.
NasIpAddress	Shows the RADIUS client NAS Identifier for this server.

Reauthenticate the RADIUS SNMP Server Session

About This Task

Specify the number of challenges that you want the RADIUS SNMP server to send to authenticate a given session.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS SNMP** tab.
The system displays RADIUS SNMP tab.
4. Select the **Enable** check box.
5. In the **ReauthenticateTimer** field, enter a value to specify the interval between RADIUS SNMP server reauthentications.

The timer for reauthentication of the RADIUS SNMP server session is enabled.

Important

To end the RADIUS SNMP server session, enter a value for the AbortSessionTimer, and then select Enable.

6. Select the **AcctEnable** check box if desired.
7. Select **Apply**.

RADIUS SNMP field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
Enable	Enables or disables timer authentication on the server. The default is true.
AbortSessionTimer	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
ReAuthenticateTimer	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.
AcctEnable	Enables or disables the RADIUS SNMP session timer.
UserName	Specifies the user name for the RADIUS SNMP accounting.

Configure RADIUS SNMP

About This Task

Configure RADIUS SNMP parameters for authentication and session times.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Select the **RADIUS SNMP** tab.
4. Select the **Enable** check box to enable RADIUS SNMP.
5. In the **AbortSessionTimer** field, enter the period after which the session expires in seconds.
6. In the **ReAuthenticateTimer** field, enter the period of time the system waits before reauthenticating in seconds.
7. Select the **AcctEnable** check box to enable RADIUS accounting for SNMP.
8. In the **UserName** field, type the RADIUS SNMP user name.
9. Click **Apply**.

RADIUS SNMP field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
Enable	Enables or disables timer authentication on the server. The default is true.
AbortSessionTimer	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
ReAuthenticateTimer	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.

Name	Description
AcctEnable	Enables or disables the RADIUS SNMP session timer.
UserName	Specifies the user name for the RADIUS SNMP accounting.

Modify a RADIUS Configuration

About This Task

Use this procedure to modify an existing RADIUS configuration or single function such as retransmissions and RADIUS accounting.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all except the following case. When modifying a RADIUS configuration in Enterprise Device Manager (EDM), you must specify if the address type is an IPv4 or an IPv6 address.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. In the row and field to modify, type the information or use the lists to make a selection. Access the lists by double-clicking in a field.
5. When you are done with modifying the RADIUS configuration, click **Apply**.

RADIUS Servers Field Descriptions

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
AddressType	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
Address	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.
UsedBy	Configures how the server functions: <ul style="list-style-type: none"> • cli—configure the server for CLI authentication. • eapol—configure the server for EAPoL authentication. • endpointTracking—configure the server for Endpoint Tracking authentication. • snmp—configure the server for SNMP accounting. • web—configure the server for HTTP(s) authentication. The default is cli.
Priority	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
TimeOut	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
Enable	Enables or disables authentication on the server. The default is true.

Name	Description
MaxRetries	Specifies the maximum number of retransmissions allowed. The default is 1.
UdpPort	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.
SecretKey	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
AcctEnable	Enables or disable RADIUS accounting. The default is true.
AcctUdpPort	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
SecureEnable Note: Exception: not supported on VSP 8600 Series.	Enable RADIUS Security (RADSec).
SecureMode Note: Exception: not supported on VSP 8600 Series.	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> • tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP) • dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP) The default is tls.
SecureProfile Note: Exception: not supported on VSP 8600 Series.	Specifies the name of the secure profile.
SecureLogLevel Note: Exception: not supported on VSP 8600 Series.	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> • critical • error • warning • info • debug
SourcelpAddr	Specifies the IP address to use as the source address in RADIUS packets. To use this option, you must set the global RADIUS SourcelpFlag to true. RADIUS supports IPv4 and IPv6 addresses.

Delete a RADIUS Configuration

About This Task

Delete an existing RADIUS configuration.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. Identify the configuration to delete by clicking anywhere in the row.
5. Click **Delete**.

Configure RADIUS Server Reachability**About This Task**

Use this procedure to configure the RADIUS server reachability settings.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Global** tab.
4. In **RadiusReachability**, select either **useStatusServerPackets** or **useDummyRadiusRequests**.
5. In the **UserName** field, type the reachability user name.
6. In the **Password** field, type the reachability password.
7. In the **Confirm Password** field, retype the reachability password.
8. In the **Unreachable Timer** field, type the interval in seconds between checks when the RADIUS server is unreachable.
9. In the **KeepAlive Timer** field, type the interval in seconds between checks when the RADIUS server is reachable.
10. Click the **Apply**.

***RADIUS Global* Field Descriptions**

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
Enable	Enables the RADIUS authentication feature globally.
MaxNumberServer	Specifies the maximum number of servers to be used, between 1 and 10, inclusive.
AccessPriorityAttrValue	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The valid values are 192 through 240. The default is 192.
AcctEnable	Enables RADIUS accounting.
AcctAttrValue	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The valid values are 192 through 240. The default value is 193.

Name	Description
AcctIncludeCli	Specifies whether you want CLI commands included in RADIUS accounting requests.
ClearStat	Clears RADIUS statistics from the device.
McastAttributeValue	Specifies the value of the Mcast attribute. The valid values are 0 through 255. The default value is 90.
AuthInfoAttrValue	Specifies the value of the authentication information attribute. The valid values are 0 through 255. The default value is 91.
CommandAccessAttrValue	Specifies the value of the command access attribute. The valid values are 192 through 240. The default value is 194.
CliCommandAttrValue	Specifies the value of the CLI command attribute. The valid values are 192 through 240. The default value is 195.
AuthInvalidServerAddress	Displays the number of access responses from unknown or invalid RADIUS servers.
SourceIpFlag Note: Exception: only supported on VSP 8600 Series.	Includes a configured IP address as the source address in RADIUS packets. The default is false. RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration.
CliCmdCount	Gives the value for the CLI command count. Specify an integer from 1 to 40. The default is 40.
CliProfEnable	Enables RADIUS CLI profiling.
SupportedVendorIds	Shows the vendor IDs that the software supports for RADIUS.
RadiusReachability	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
SecureEnable	Enable RADIUS Security (RADSec).
UserName	Specifies the username for RADIUS server reachability. The default is extremenetworks.
Password	Specifies the password for RADIUS server reachability. The default is extremenetworks.
Confirm Password	Confirms the password for RADIUS server reachability.
Unreachable Timer	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
Keep Alive Timer	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

Configure a RADIUS Dynamic-server Client

About This Task

Use this procedure to configure a client to allow processing of dynamic session changes.

Before You Begin

You must enable EAPOL globally and at the port level.

You must enable RADIUS dynamic extensions commands processing at the port level.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click **Global**.
4. Click **Insert**.
5. In the **Address** field type a client address.
6. (Optional) In the **UdpPort** field, type a value for client port.
7. (Optional) In the **Secret** field, type a value for the secret key.
8. Select the **Enable** checkbox to enable dynamic session processing for the client.
9. Click **Insert**.

Global field descriptions

Use the data in the following table to use the **Global** tab.

Name	Description
AddressType	Specifies the type of address contained in the corresponding instance of a RADIUS Dynamic Authorization Client configured in this entry.
Address	Specifies the internet address of a RADIUS Dynamic Authorization Client configured in this entry.
UdpPort	Specifies the UDP port number the server/NAS listens on for requests from the RADIUS Dynamic Authorization Client configured in this entry.
Secret	Specifies the secret key shared between the RADIUS Dynamic Authorization Client and Server. Note that when this object is retrieved, it's value will always be a zero-length octet string.
Enable	Enable processing of dynamic session changes.

Displaying RADIUS CoA Disconnect Statistics

About This Task

Use this procedure to display RADIUS CoA Disconnect statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Disconnect Stats** tab.

Disconnect Stats Field Descriptions

Use the data in the following table to use the **Disconnect Stats** tab.

Name	Description
DisconRequests	Specifies the number of RADIUS disconnect requests received from this Dynamic Authorization Client. This also includes the RADIUS disconnect requests that have a Service-Type attribute with a value of Authorize Only.
DisconAuthOnlyRequests	Specifies the number of RADIUS disconnect requests that include a Service-Type attribute with a value of Authorize Only received from this Dynamic Authorization Client.
DupDisconRequests	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
DisconAcks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
DisconNaks	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-NAK packets sent with a Service-Type attribute with a value of Authorize Only and the RADIUS Disconnect-NAK packets sent because no session context was found.
DisconNakAuthOnlyRequests	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
DisconNakSessNoContext	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
DisconUserSessRemoved	Specifies the number of user sessions removed for the disconnect requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single disconnect request can remove multiple user sessions. In cases where this Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each such disconnect request counts as a single affected user session only.
MalformedDisconRequests	Specifies the number of malformed RADIUS Disconnect-Request packets received from this Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed disconnect requests
DisconBadAuthenticators	Specifies the number of RADIUS Disconnect-Request packets that contain an invalid Authenticator field received from this Dynamic Authorization Client.

Name	Description
DisconPacketsDropped	Specifies the number of incoming disconnect requests from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed packets, bad authenticators, or unknown types.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

Displaying RADIUS CoA Reauthenticate Statistics

About This Task

Use this procedure to display RADIUS CoA Reauthenticate statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Reauthenticate Stats** tab.

Reauthenticate Stats Field Descriptions

Use the data in the following table to use the **Reauthenticate Stats** tab.

Name	Description
Requests	Specifies the number of RADIUS Reauthentication-Requests received from this Dynamic Authorization Client. This also includes the Reauthentication requests that have a Service-Type attribute with a value of Authorize Only.
AuthOnlyRequests	Specifies the number of RADIUS Reauthentication-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.
DupRequests	Specifies the number of duplicate RADIUS Reauthentication-Request packets received from this Dynamic Authorization Client.
Acks	Specifies the number of incoming Reauthentication packets from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
Nacks	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Reauthentication-NAK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Reauthentication-NAK packets sent because no session context was found.

Name	Description
NacksAuthOnlyRequests	Specifies the number of RADIUS Reauthentication-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
NacksNoSess	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client because no session context was found.
SessReauthenticated	Specifies the number of user sessions reauthenticated for the Reauthentication-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Reauthentication-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each CoA-Request counts as a single affected user session.
Malformed	Specifies the number of malformed RADIUS Reauthentication-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Reauthentication-Requests.
Dropped	Specifies the number of incoming Reauthentication packets from the Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
BadAuths	Specifies the number of RADIUS Reauthentication-Request packets that contained an invalid Authenticator field received from the Dynamic Authorization Client.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

Displaying RADIUS CoA Statistics

About This Task

Use this procedure to display information about RADIUS CoA statistics.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **CoA Stats** tab.

CoA Stats Field Descriptions

Use the data in the following table to use the **CoA Stats** tab.

Name	Description
AddressType	Specifies the RADIUS Dynamic Authorization Client IP address type.
Address	Specifies the RADIUS Dynamic Authorization Client IP address.
DisconRequests	Specifies the number of RADIUS Disconnect-Requests received from this Dynamic Authorization Client. This also includes the Disconnect requests that have a Service-Type attribute with a value of Authorize Only.
DisconAuthOnlyRequests	Specifies the number of RADIUS Disconnect-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.
DupDisconRequests	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
DisconAcks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
DisconNaks	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-ACK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Disconnect-ACK packets sent because no session context was found.
DisconNakAuthOnlyRequests	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
DisconNakSessNoContext	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
DisconUserSessRemoved	Specifies the number of user sessions removed for the Disconnect-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Disconnect-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each Disconnect-Request counts as a single affected user session.

Name	Description
MalformedDisconRequests	Specifies the number of malformed RADIUS Disconnect-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Disconnect-Requests.
UnknownTypes	Specifies the number of incoming requests that have an invalid ID type.

RADSec Configuration Using EDM

This section contains procedures for configuring RADSec with Enterprise Device Manager (EDM).

Configure a RADIUS Secure Profile

Configure a RADIUS Security (RADSec) profile to specify certificate information used by RADSec to develop trust between peers. You can also specify a password used for RADSec encryption.

Note

Secure profile is not supported on VSP 8600 Series.

About This Task

Note

- All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.
- A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/radsec directory.
- Profile configuration file “profile_info.cfg” is available in /intflash/.radsec/profile directory.
- You can configure a maximum of 10 RADsec profiles.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **Secure Certificate Profile**
4. Select **Insert**.
5. For **Name**, enter the name for the profile.
6. For **RootCert**, enter the full path for the profile root certificate.
7. For **Cert**, enter the full path for the profile certificate.
8. For **Key**, enter the full path for the profile private key.
9. For **Password**, enter the full path to decrypt the profile private key.
10. For **RootCertDestFile**, enter the file name to use when installing the root certificate.
11. For **CertDestFile**, enter the file name to use when installing the certificate.
12. For **KeyDestFile**, enter the file name to use when installing the key.

13. Select **Insert**.

Secure Certificate Profile Field Descriptions

Use the data in the following table to use the **Secure Certificate Profile** tab.

Name	Description
Name	Specifies the profile name.
RootCert	Specifies the full path of the profile root certificate.
Cert	Specifies the full path of the profile certificate.
Key	Specifies the full path of the profile private key.
Password	Specifies the password used to decrypt the profile private key.
RootCertDestFile	Specifies the file name to use when installing the root certificate.
CertDestFile	Specifies the file name to use when installing the certificate.
KeyDestFile	Specifies the file name to use when installing the key.

RADIUS Attributes

[Vendor Specific Attributes on page 2726](#)

[IETF Attributes on page 2732](#)

The following topics list RADIUS attributes for EAP.

Vendor Specific Attributes

RADIUS Vendor Specific Frame Format

The following figure shows the frame format for RADIUS vendor specific attributes (VSA).

Figure 214: RADIUS vendor-specific frame format

FA-VLAN-ISID

On EAP-enabled Flex-UNI ports, the context for the authenticating MAC is the association using the FA-VLAN-ISID attribute. This attribute provides one VLAN:ISID binding.

- defined under vendor IDs 562 and 1584 and uses the value 171
- I-SID values are 0-15999999
- VLAN values are 0 - 4096 to create untagged S-UNIs in MHSA mode and MAC-BasedS-UNIs in MHMV mode
- RADIUS server provides up to 94 bindings
- for MHMV with multiple bindings, only the last binding is created

FA-Client-Type

This attribute is used in packets transmitted to the RADIUS server to inform that the current authenticated MAC is associated to a FA Client of type x. This attribute is defined under Nortel vendor id (562) and uses the value 182.

Only one FA Client per port is supported.

The following values are defined for FA Client type:

- 0: FA Element Not Found
- 1: FA Element Type Other
- 2: FA Server
- 3: FA Proxy
- 4: FA Server No Authentication
- 5: FA Proxy No Authentication
- 6: FA Client Wireless AP Type 1 [clients direct network attachment]
- 7: FA Client Wireless AP Type 2 [clients tunneled to controller]
- 8: FA Client Switch
- 9: FA Client Router
- 10: FA Client IP Phone
- 11: FA Client Camera
- 12: FA Client IP Video
- 13: FA Client Security Device
- 14: FA Client Virtual Switch
- 15: FA Client Server Endpoint
- 16: FA Client ONA SDN mode
- 17: FA Client ONA SPBOIP mode
- 63: FA Client Unknown

Any integer value provided by the FA is sent to the RADIUS server without any check from the EAP application.

Extreme-Dynamic-MHSA

On EAP-enabled Flex UNI ports, this attribute changes the current interface EAPoL operating mode from MHMV to MHSA.

- defined under Extreme Networks vendor ID 1916 and uses the value 250
- parsed only on ports with Flex-UNI enabled
- value contained in this attribute must be 1

Extreme-Dynamic-ACL

On EAP-enabled ports, this attribute assigns a dynamic ACL for an EAP-enabled port. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA).

- defined under Extreme Networks vendor ID 1916 and uses the value 251

For more information, see [RADIUS Dynamic User-Based Policies](#) on page 762.

Examples

The following examples provide the RADIUS configuration for the corresponding CLI filter configuration. This example is for MAC 0a:0a:0a:0a:0a:0a on port 1/1 and EAP is in MHMV mode.

```
filter acl 1 type inPort
filter acl port 1 1/1

filter acl ace 1 1 name RadiusGuest-Rule01
filter acl ace ethernet 1 1 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 1 ether-type eq 0x800
filter acl ace ip 1 1 ip-protocol-type eq 17
filter acl ace protocol 1 1 dst-port eq 53
filter acl ace 1 1 action permit
filter acl ace 1 1 enable

filter acl ace 1 2 name RadiusGuest-Rule02
filter acl ace ethernet 1 2 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 2 ether-type eq 0x800
filter acl ace ip 1 2 dst-ip mask 192.0.2.1 24
filter acl ace 1 2 action permit
filter acl ace 1 2 enable

filter acl ace 1 3 name RadiusGuest-Rule03
filter acl ace ethernet 1 3 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace 1 3 action deny
filter acl ace 1 3 enable
```

The RADIUS VSA does not specify the MAC or the port number because they are already known at the EAP level.

```
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec ethernet ether-type eq 0x800 & ip ip-protocol-type eq
17 & protocol dst-port eq 53 action permit",
Extreme-Dynamic-ACL += "ace 2 sec ethernet ether-type eq 0x800 & ip dst-ip mask 192.0.2.1
24 action permit",
Extreme-Dynamic-ACL += "ace 3 sec action deny"
```

Extreme-Dynamic-Config

This attribute configures port and VLAN based attributes.

- Name: Extreme-Dyn-Config
- Value: 252
- Type: String
- Vendor: Extreme
- Extreme Vendor ID is 1916

The following features can be configured using Extreme-Dynamic-Config RADIUS VSA.

DAI

This setting enables Dynamic ARP Inspection (DAI) on the VLAN received from the RADIUS server. For a Flex-UNI port, DAI enables on the platform VLAN associated with the I-SID received from the RADIUS server.

DAI also enables on the default VLAN of the port to prepare for IP Source Guard (IPSG), which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DAI enables on the default VLAN. For Flex-UNI ports, DAI enables on the platform VLAN associated with the untagged I-SID.

DHCPSNOOP

This setting enables DHCP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, DHCP Snooping enables on the platform VLAN associated with the I-SID received from the RADIUS server.

DHCP Snooping also enables on the default VLAN of that port to prepare for IP Source Guard (IPSG), which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DHCP Snooping enables on the default VLAN. For Flex-UNI ports, DHCP Snooping enables for the platform VLAN associated with the untagged I-SID.

IGMPSNOOP

This setting enables IGMP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, IGMP Snooping enables on the platform VLAN associated with the I-SID received from the RADIUS server.

IPSG

This setting enables IP Source Guard (IPSG) on the port where the client resides.

In order to apply IPSG, DHCP Snooping and DAI must be configured on the RADIUS server. DHCP Snooping and DAI must be enabled on all VLANs.

The following is an example of a log message that displays if a setting is not configured correctly:

```
GlobalRouter EAP WARNING Cannot apply Radius IP Source Guard attribute on port 3/15 without DHCP Snooping and DAI attributes.
```

WOL

This setting enables EAP traffic-control (Wake On LAN) on the port where the client resides.

SLPPGUARD

This setting enables Simple Loop Prevention Protocol (SLPP) Guard on the port where the client resides.

BPDU

This setting enables Bridge Protocol Data Unit (BPDU) Guard on the port where the client resides.

AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H

AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H settings configure Custom Auto-Negotiation Advertisements (CANA) speed and duplex to the following supported values:

- 10Half
- 100Full
- 100Half

- 100Full
- 1000Full

Examples

The following example enables DHCP Snooping and Dynamic ARP Inspection (DAI) on VLAN 100 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000001"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example enables DHCP Snooping and DAI on platform VLAN associated with I-SID 10000 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000002"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example enables IGMP Snooping on VLAN 100:

```
Auth-Type := Local
User-Password == "000000000003"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enables IGMP Snooping platform VLAN associated with I-SID 10000:

```
Auth-Type := Local
User-Password == "000000000004"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enable EAP traffic-control on authentication port:

```
Auth-Type := Local
User-Password == "000000000005"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "WOL"
```

The following example enable BPDU Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000006"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "BPDU"
```

The following example enable SLPP Guard on authentication port:

```
Auth-Type := Local
User-Password == "000000000007"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "SLPPGUARD"
```

The following example configure the Custom Auto-Negotiation Advertisements (CANA) to 100Half on authentication port:

```
Auth-Type := Local
User-Password == "000000000008"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "AN-ADVERTISEMENTS:100H"
```

EAP-Port-Priority

Important

Configure these attributes only if you require dynamic port priority.

Port priority (vendor-specific) attributes:

- Vendor ID: value 562 (Nortel)

Note

Vendor ID 1916 (Extreme) does not support port priority.

- Attribute Number: value 1, Port Priority
- Attribute Value: value 0 (zero) to 6 (this value indicates the port priority value assigned to the specified user)

The following list provides the switch Port Priority frame format:

- vendor specific type = 26
- length = 12
- vendor-id = 562
- string = vendor type = 1 + vendor length = 6 + attribute specific = priority

The following figure shows an example of the port priority frame format.

26	12	562	01	06	(0..6)
----	----	-----	----	----	--------

Figure 215: Port priority frame format

IETF Attributes

VLAN RADIUS Attributes

To control the tagging for traffic egressing a port, configure the preferred tagging option and one of the following attributes on the RADIUS server:

- EGRESS-VLAN-ID
- EGRESS-VLAN-NAME

VLAN attributes are defined by RFC 4675.

EGRESS-VLAN-ID

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- untagged EGRESS-VLAN-ID + VLAN:ISID -> VLAN from S-UNI becomes untagged
- untagged EGRESS-VLAN-ID + vid[NEW_RADIUS_VID] + autolsidOffset -> create S-UNI for I-SID (VLAN+autolsidOffset)

Examples

From the RADIUS attributes, for untagged VLAN 15. The VLAN from S-UNI becomes untagged:

```
Egress-VLANID = "838860815" (untagged vlan 15)
Fabric-Attach-ISID += "15:23513"
```

The following example results in the value 0:1015 for creating an untagged S-UNI.

From the RADIUS attributes, for untagged VLAN 15 and RADIUS-assigned VLAN. Creates S-UNI for I-SID (VLAN+autolsidOffset):

```
Egress-VLANID = "838860815"
Tunnel-Private-Group-Id = "15"
```

From the EAP configuration:

```
eapol auto-isid-offset 1000
eapol auto-isid-offset enable
```

Considerations

Consider the following when using this attribute:

- Any combinations with EGRESS-VLAN-ID for a tagged VLAN are ignored.
- When EGRESS-VLAN-ID and VLAN:ISID binding attributes are used, the VLAN must have the same value.
- The RADIUS server can provide more than one VLAN:ISID binding but one must match the VLAN used in EGRESS-VLAN-ID to create an untagged S-UNI.

- Only one EGRESS-VLAN-ID attribute is used. If more than one is found in the packet, only the first one is used.
- If the untagged S-UNI is derived from EGRESS-VLAN-ID + VLAN-ID + VLAN attribute + auto-isid-offset, the packet must not contain any S-UNI bindings.

EGRESS-VLAN-NAME

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- EGRESS-VLAN-ID + VLAN:I-SID
- EGRESS-VLAN-ID + VLAN + autolsidOffset

This attribute includes the following information:

- Egress-VLAN-Name = "1VLAN_NAME" for tagged VLAN
- Egress-VLAN-Name = "2VLAN_NAME" for untagged VLAN
- VLAN_NAME is the name of the VLAN on the switch

Example

The following example creates an untagged Switched UNI with I-SID 1000. VLAN 10 is named "Dummy_VLAN".

```
b0adaa41b830 Cleartext-Password := "b0adaa41b830"
                Service-Type = Framed-User,
                Framed-Protocol = PPP,
                Auth-Type := Accept,
                Fabric-Attach-ISID = "10:1000",
                Egress-VLAN-name = "2Dummy_VLAN"
```

RADIUS Tunnel Attributes

The switch uses the RADIUS tunnel attributes to place a port into a particular VLAN to support dynamic VLAN switching based on authentication. The server must send these attributes together in the same RADIUS packet. If one attribute is missing, the switch ignores the others.

The RADIUS server indicates the desired VLAN by including the tunnel attribute within the Access-Accept message. RADIUS uses the following tunnel attributes for VLAN membership:

- RAD_ATTR_TUNNEL_TYPE(64)
 - Tunnel-Type: value 13, Tunnel-Type-VLAN
- RAD_ATTR_TUNNEL_MEDIUM_TYPE(65)
 - Tunnel-Medium-Type: value 6, Tunnel-Medium-Type-802
- RAD_ATTR_TUNNEL_PRI_GROUP_ID
 - Tunnel-Private-Group-ID: ASCII value 1-4094 (this value identifies the specified VLAN)

Tunnel attributes are defined by RFC 2868.

Important

Configure these attributes only if you require Dynamic VLAN membership.

The VLAN ID is 12 bits, uses a value from <1–4094>, and is encoded as a string.

In addition, you can configure the RADIUS server to send a vendor-specific attribute (VSA) to configure port priority. You can assign the switch Supplicant port a QoS value from 0 to 6.

For more information, see [EAP-Port-Priority](#) on page 2731.

Representational State Transfer Configuration Protocol (RESTCONF)

[Representational State Transfer Configuration Protocol \(RESTCONF\) Fundamentals](#) on page 2735

[RESTCONF configuration using CLI](#) on page 2737

[RESTCONF Configuration using EDM](#) on page 2741

[Use Representational State Transfer Configuration Protocol \(RESTCONF\) to Configure a Switch](#) on page 2743

Table 199: Representational State Transfer Configuration Protocol (RESTCONF) product support

Feature	Product	Release introduced
Representational State Transfer Configuration Protocol (RESTCONF)	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 8.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 8.0
	VSP 8400 Series	VOSS 8.0
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

Note

Product Notice: Using RESTCONF on VSP4900-48P or VSP4900-24S reduces the number of supported port-based VLANs on those platforms. For known issues, see [VOSS Release Notes](#).

Representational State Transfer Configuration Protocol (RESTCONF) Fundamentals

Representational State Transfer Configuration Protocol (RESTCONF) is a next generation northbound interface that provides an additional way to configure and monitor the switch. RESTCONF is an HTTP-based protocol that provides a programmatic interface to access data defined in a YANG model using

the datastore concepts defined in NETCONF. RESTCONF uses a client-server model. The server acts as an entry point to a datastore, a conceptual place to store and access information. Clients use HTTP or HTTPS to interface with the server to configure and monitor devices.

RESTCONF Client and Server

A typical RESTCONF interaction consists of an HTTP/HTTPS request sent by a RESTCONF client and an HTTP/HTTPS response sent by the server. The HTTP/HTTPS request and response contain a required set of expected HTTP headers and may contain a request or response message body. The message body is encoded in JSON.

An HTTP request consists of the HTTP method (such as GET or POST) identifier, resource identifier, HTTP protocol version, HTTP headers, and HTTP body. The HTTP resource identifier is the string that identifies a service or resource that the server makes available to the client. The RESTCONF request contains the Universal Resource Identifier or URI which starts with `/rest/restconf/data/` or `/rest/restconf/operations/`.

YANG Model

YANG is the data modeling language used for modeling configuration and state data for manipulation by using remote procedure calls (RPCs). The RESTCONF interface is generated with YANG Data Model. The YANG model is based on Open config model, which is a non vendor specific model that captures the key components found in multiple vendor solutions. RESTCONF is described by the Internet Engineering Task Force (IETF) in RFC 8040.

RESTCONF Authentication

RESTCONF uses the CLI user account and supports both local and remote authentication. Local authentication uses the local CLI user account while remote authentication can use either a RADIUS or TACACS+ server.

You can only use a CLI account with the RWA access level.

With RADIUS or TACACS+ enabled, if the remote server is not available, authentication falls back to local authentication and uses the local CLI user on the switch.

When the RESTCONF client posts for authentication, the HTTP server validates the login username and password if you have not enabled CLI remote authentication. If the remote server is not reachable, the HTTP server uses the local user for login validation.

For HTTPs access to the RESTCONF server, you must enable TLS and install a certificate.

RESTCONF APIs

You can access the RESTCONF API documentation on your switch using the following URL:

```
http(s)://<IP>:<tcp-port>/apps/restconfdoc/
```

Replace `<IP>` with the management IP address of your switch and `<tcp-port>` with the TCP port configured for RESTCONF. For example, `http://192.0.2.16:8080/apps/restconfdoc/`.

The on-switch URL works only if the RESTCONF feature is enabled on the switch.

You can also access the RESTCONF API documentation online at www.extremenetworks.com/support/documentation-api/.

VOSS Support

VOSS RESTCONF server supports the following actions:

HTTP Action	VOSS Instrumentation
GET	Corresponds to SHOW
POST	Corresponds to SET for creation
PATCH	Corresponds to SET for modification
DELETE	Maps to SET for deletion

VOSS RESTCONF supports the following features:

- System (authorization, authentication, and accounting)
- Link Layer Discovery Protocol (LLDP)
- Interfaces (IPv4, Ethernet, and LAG)
- VLAN (under network instance)
- Virtual Service (Extreme YANG model)

The RESTCONF feature is disabled by default. The RESTCONF server uses the same management IP address as the other applications and TCP port. The default TCP port that RESTCONF server listens to is port 8080. The TCP port delivers the message to the HTTP server for RESTCONF.

RESTCONF configuration using CLI

Enable the RESTCONF Server

About This Task

Use the following procedure to enable the RESTCONF server.

Before You Begin

Run the **show application restconf conflict-ifname** command to see if any conflict in interface names exist. To enable RESTCONF, the interface names (VLAN name, MLT name, and Port interface name) must be unique.

Run the **show application restconf invalid-name mlt** and **show application restconf invalid-name vlan** commands to see if any MLT or VLAN names contain special characters. To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (_) and en dash (-).

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. Enable the RESTCONF server:

```
restconf enable
```

**Note**

If the interface names (VLAN, MLT, and Port) are not unique, or if VLAN or MLT names contain prohibited special characters, an error occurs indicating that you cannot enable RESTCONF. You must change the interface names before you enable RESTCONF.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#restconf enable
```

Configure HTTPS Access to the RESTCONF Server

About This Task

By default, the RESTCONF server uses HTTP. If you need to use HTTPS, generate a certificate file and transfer the certificate file to the `/intflash` directory on the switch.

For more information on generating certificate files, see [Manage an SSL Certificate](#) on page 2943.

Before You Begin

Ensure that you have the certificate file in the `/intflash` directory on the switch.

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. If RESTCONF is enabled, disable RESTCONF:

```
no restconf enable
```

3. Install the certificate file for the RESTCONF server:

```
restconf install-cert-file WORD<1-128>
```

4. Enable HTTPS:

```
restconf tls
```

5. Enable RESTCONF:

```
restconf enable
```

Example

```
Switch:1>enable
Switch:1# configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#no restconf enable
Switch:1(config-app)#restconf install-cert-file /intflash/.cert/restconf-cert.pem
Switch:1(config-app)#restconf tls
Switch:1(config-app)#restconf enable
```

Variable Definitions

The following table defines parameters for the **restconf** command.

Variable	Value
<i>enable</i>	Enables the RESTCONF Server.
<i>install-cert-file WORD<1-128></i>	Installs the certificate file for the RESTCONF server.
<i>tcp-port <1-49151></i>	Set RESTCONF Server TCP port number.
<i>tls</i>	Enables TLS for the RESTCONF server. The default is disabled.
<i>trap-notification</i>	Enables trap notification.

Modifying the RESTCONF Server Settings

About This Task

Use this procedure to modify the RESTCONF server settings.

Note

These steps are considered optional and RESTCONF can operate with the default configuration of these values.

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```
2. Disable trap notification when the RESTCONF server is not available:

```
no restconf trap-notification
```
3. Modify the TCP port number for the RESTCONF server:
 - a. Disable RESTCONF:

```
no restconf enable
```
 - b. Change the value of the TCP port:

```
restconf tcp-port <1-49151>
```

- c. Enable RESTCONF: `restconf enable`
- 4. Disable TLS for the RESTCONF server:
 - a. Disable RESTCONF: `no restconf enable`
 - b. Disable TLS: `no restconf tls`
 - c. Enable RESTCONF: `restconf enable`

Variable Definitions

Use the data in the following table to modify the RESTCONF server settings.

Variable	Value
<code>enable</code>	Enables or disables the RESTCONF server. The default is disabled.
<code>tcp-port <1-49151></code>	Specifies the TCP port to use for the RESTCONF server. The default is 8080.
<code>trap-notification</code>	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.

Showing the RESTCONF Configuration Information

About This Task

Use this procedure to show the RESTCONF configuration information and operation status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF configuration:

```
show application restconf
```

Example

```
Switch:1>show application restconf
=====
                        RESTCONF Info
=====
Admin State           : true
TCP Port              : 8080
Certificate File Status : install
TLS Enable            : false
Trap Notification     : true
Oper State            : up
Web Server Version    : 1.0.1.11
RESTCONF Server Version : 1.0.1.39
=====
```

Show Conflicting Interface Name Information

About This Task

To enable RESTCONF, the interface name (VLAN name, MLT name, and Port interface name) must be unique. Use this procedure to display conflicting interface name information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF conflicting interface name information:
`show application restconf conflict-ifname`

Example

```
Switch:1>show application restconf conflict-ifname
-----
Conflicting Interface IfName - Port, VLAN Name and MLT Name
-----
Mlt 1 name is same as Vlan 1001 name - "Interface-1"
Mlt 2 name is same as Vlan 1002 name - "VLAN-1002"
Vlan 1003 name is Mlt 1 Default Name - "MLT-1"
-----
Total Conflict Count: 3
```

What to Do Next

If a conflict exists, change the conflicting interface name to a unique name.

Show Special Characters in VLAN or MLT Names

About This Task

To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (_) and en dash (-). Use this procedure to display VLAN or MLT names that contain prohibited special characters.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF VLAN or MLT names that contain prohibited special characters:
`show application restconf invalid-name vlan`

`show application restconf invalid-name mlt`

Example

```
Switch:1>show application restconf invalid-name mlt
-----
Invalid MLT names - Only "-" and "_" special characters are allowed
-----
Mlt 3 name has special characters - "gigi#g"
Mlt 4 name has special characters - "my%mlt"
Mlt 5 name has special characters - "isa.text"
-----
Total Invalid Names Count: 3
```

What to Do Next

If any of the names contain prohibited special characters, change the names to remove the special characters.

RESTCONF Configuration using EDM

This section contains procedures for configuring RESTCONF with Enterprise Device Manager (EDM).

Configuring the RESTCONF Server

About This Task

To configure the server, you must enable RESTCONF. RESTCONF is disabled by default.

After RESTCONF is enabled, you must disable RESTCONF to modify some of the RESTCONF parameters.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Click **RESTCONF**.
3. Click the **RESTCONF** tab.
4. Select the **GlobalEnable** check box to enable the RESTCONF server.
5. Configure optional parameters as required.
6. Click **Apply**.

RESTCONF Field Descriptions

Use the data in the following table to use the RESTCONF tab.

Name	Description
GlobalEnable	Enables or disables the RESTCONF server. The default is disabled (cleared).
TcpPort	Specifies the TCP port to use for the RESTCONF server. The default is 8080. The RESTCONF status must be disabled before you can modify this field.
TlsEnable	Enables or disables TLS/SSL if you require HTTPS access to the RESTCONF server. The default is disabled. The RESTCONF status must be disabled before you can modify this field.
CertificateFilename	If HTTPS access is required, specifies the file name and path of the TLS/SSL certificate. The certificate file must be in the <code>/intflash</code> directory on the switch.
CertificateAction	Installs or uninstalls the TLS/SSL certificate file. It also shows the current status of the certificate installation.
NotificationEnable	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.
OperStatus	Shows the operational status of the RESTCONF server.
WebServerVersion	Shows the RESTCONF web server version that is running on the server.
RestConfServerVersion	Shows the RESTCONF server version that is running on the server.

Use Representational State Transfer Configuration Protocol (RESTCONF) to Configure a Switch

The documentation does not include information about how to use RESTCONF clients. This example documents some common tasks using Python.

For additional details, see [Extreme API with Python](#).

Before You Begin

Configure the RESTCONF server on the switch.

Procedure

1. Import classes, define variables, and prepare the session object:

```
#!/usr/bin/env python
import sys
import json
import requests
from requests import Request, Session
from requests.auth import HTTPBasicAuth
from requests.packages.urllib3.exceptions import InsecureRequestWarning
requests.packages.urllib3.disable_warnings(InsecureRequestWarning)
#####
Host      = '192.0.2.1'
TcpPort   = '8080'
UserName  = 'rwa'
Password  = 'rwa'
LoginUrl  = 'https://%s:%s/auth/token' % (Host, TcpPort)
QueryUrl  = 'https://%s:%s/rest/restconf/data/' % (Host, TcpPort)
vlan      = 123
#####
session   = Session()
session.verify = False
session.timeout = 5

session.headers.update({
    'Accept':          'application/json',
    'Accept-Encoding': 'gzip, deflate, br',
    'Connection':      'keep-alive',
    'Cache-Control':   'no-cache',
    'Pragma':          'no-cache', })
```

2. Learn the authentication token:

Note

The token expires after 24 hours.

```
body = '{"username": "%s", "password" : "%s" }' % (UserName, Password)

response = session.put( LoginUrl, body )

if response.status_code != 200:
    print "ERROR: Login failed"
    sys.exit(1)
else:
    session.headers.update({
        'X-Auth-Token': response.headers['X-Auth-Token']
    })
    print "INFO: login passed"
```

3. Query all VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan' )
if response.status_code != 200:
    print 'ERROR: can't fetch VLANs'
```

4. Query specific VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan=vlan=%s' % vlan )

if response.status_code != 200:
    print 'INFO: VLAN %s doesn't exist' % vlan
else:
    print 'INFO: VLAN %s exists' % vlan
```

5. Access data:

```
inbound_data = json.loads( response.text )

for vlan in inbound_data['openconfig-vlan:vlan']:
    print 'VLAN: %s [%s]' % ( vlan['state']['name'], vlan['vlan-id'] )
```

6. Present data:

```
inbound_data = json.loads( response.text )

for dataVlan in inbound_data[ dataObject ]['vlan']:
    print ''
    print 'VLAN: ' + dataVlan['state']['name'] + '[' + dataVlan['vlan-id'] + ']'
    interfaces = ''
    if 'members' in dataVlan :
        for interface in dataVlan['members']['member']:
            interfaces = interfaces + interface['interface-ref']['state']['interface']
    + ','

    print interfaces
```

7. Add a VLAN:

```
dataObject = 'openconfig-vlan:vlan'

data = { "openconfig-vlan:vlan": [
    { "config":
        { "name": "Test-VLAN",
          "extreme-mod-oc-vlan:stg-id": 1,
          "vlan-id": vlan
        }
    }
]

response = session.post( QueryUrl + dataObject, json=data )

if response.status_code != 201:
    print "ERROR: add VLAN %s failed" % vlan
else:
    print "INFO: VLAN %s added " % vlan
```

8. Update a VLAN:

```
dataObject = 'openconfig-vlan:vlan=vlan=%s/config' % vlan

data = { "openconfig-vlan:config":
    { "name": "New-VLAN-Name" }
}

response = session.patch( QueryUrl + dataObject )

if response.status_code != 204:
```

```
    print "ERROR: update VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s updated" % vlan
```

9. Delete a VLAN:

```
dataObject = 'openconfig-vlan:vlan=vlan=%s' % vlan
response = session.delete( QueryUrl + dataObject )

if response.status_code != 204:
    print "ERROR: delete VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s deleted" % vlan
```

RIP fundamentals

Use the information in these sections to help you understand the Routing Information Protocol (RIP). For more information about the Border Gateway Protocol (BGP), see [BGP](#) on page 377.

Routing Information Protocol

In routed environments, routers communicate with one another to track available routes. Routers can dynamically learn about available routes using the RIP. The switch software implements standard RIP to exchange IP route information with other routers.

RIP uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. Each router advertises routing information by sending a routing information update every 30 seconds (one interval). If RIP does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

RIP is a distance vector protocol. The vector is the network number and next hop, and the distance is the cost associated with the network number. RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost or hop count is the metric (see the following figure).

Figure 216: Hop count or metric in RIP

RIP version 1 (RIPv1) advertises default class addresses without subnet masking. RIP version 2 (RIPv2) advertises class addresses explicitly, based on the subnet mask.

The switch supports RIPv2, which supports variable length subnet masks (VLSM) and triggered router updates. RIPv2 sends mask information. If RIP does not receive information about a network for 90 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 180 seconds (six update intervals), it removes the network from the routing table. You can change the default timers by configuring the RIP interface timeout timer and the holddown timer.

A directly connected network has a metric of zero. An unreachable network has a metric of 16. Therefore, the highest metric between two networks can be 15 hops or 15 routers.

RIP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if RIP routes exist in a router and they must travel through a BGP network, configure redistribution of RIP routes through BGP. Redistribution sends RIP routes to a router that uses BGP.

You can redistribute routes

- on an interface basis
- on a global basis between protocols on a single VRF instance (intraVRF)
- between the same or different protocols on different VRF instances (interVRF)

To configure interface-based redistribution, configure a route policy, and then apply it to the interface. Configure the match parameter to the protocol from which to learn routes.

You can redistribute routes on a global basis, rather than for every interface. The switch adds support for global RIP redistribution. Use the **ip rip redistribute** command to accomplish the (intraVRF) redistribution of routes through RIP, so that RIP redistribution occurs globally on all RIP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to RIP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

RIPng fundamentals

Routing Information Protocol next generation (RIPng) allows routers to exchange information for computing routes through an IPv6-based network. You should implement RIPng only on routers. IPv6 provides neighbor router information required by RIPng protocol to function as intended. A RIPng router is assumed to have interfaces in several networks and the protocol relies primarily on the metric of each network to compute routes using the distance vector algorithm.

RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost, or hop count, is the metric.

RIPng-enabled routers use UDP port 521 (the RIPng port) to exchange routing information. RIPng responds to a request by sending a message to the port from which the request originates. Specific queries can be sent from ports other than the RIPng port, but they must be directed to the RIPng port on the target machine.

Each router advertises routing information by sending an update every 30 seconds (one interval). If RIPng does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

Note

These time interval values are default values which are configurable by the user.

Each router that implements RIPng contains a routing table. This table contains one entry for every destination that is reachable throughout the system operating RIPng. At a minimum, each routing table entry contains the following information:

- The IPv6 prefix of the destination.
- A metric that represents the total cost of getting a datagram from the router to that destination. The metric is the sum of the costs of traversing the networks to arrive at the destination.
- The IPv6 address of the next router in the path to the destination (the next hop). The next-hop IPv6 address is a linklocal address.
- The VLAN or brouter port on which the RIPng routes were learned.
- The age of the RIPng route.

RIPng protocol implementation is specified in IETF document RFC 2080.

RIPng messages and packet format

RIPng-enabled routers use UDP port 521 (the RIPng port) to send and receive datagrams.

The following figure shows the RIPng packet format:

Figure 217: RIPng packet format

A RIPng packet header consists of the following components:

- **command:** Specifies the purpose of the message.
- **version:** The version of RIPng.

Originate Default route

Generally you use a default route when it is not convenient to list every possible network in RIPng updates, and one or more routers in the system are able to handle traffic to networks that RIPng does not explicitly list.

RIPng is enabled with the default route only option. When you enable default route only on an interface, it suppresses all other routes in the update sent for the interface, and advertises only the default route.

Timers

RIPng states four different timer intervals for protocol operation:

- **Update timer:** The RIPng process sends a complete routing table to each neighboring router every 30 seconds. To prevent collisions on broadcast networks, the process adds an offset value to the timer.
- **Timeout time interval:** This is a 180 second time interval associated with every route. If the time interval expires, the metric for this route updates to the value of infinity (16) and the route is no longer valid. However, the routing table retains the value for another 120 seconds.
- **Garbage collection time interval:** After the timeout time interval expires and the route becomes invalid, it remains in the routing table until the garbage collection time interval expires. The garbage collection time interval is 120 seconds. Until the garbage collection time interval expires all updates sent by this router include the invalid route. When the garbage collection timer expires, the process removes the route from the routing table.
- **Triggered update time interval:** The triggered update time interval is set to a random value between 1 and 5 seconds after a triggered update is sent. A single update is sent even if multiple triggered updates occur before the timer expires.

Configuration of timers or time intervals is supported only at the CLI/SNMP/EDM level. Configuration of timers or time intervals is not supported at the interface/port level.

RIP configuration using CLI

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use the command line interface (CLI) to configure and manage RIP.

Configuring RIP globally

Configure RIP parameters on the switch so you can control RIP behavior on the system.

Before You Begin

- You configure RIP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip rip**. The VRF must have an RP Trigger of RIP. Not all parameters are configurable on non0 VRFs.

About This Task

All router interfaces that use RIP use the RIP global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

Procedure

1. Enter RIP Router Configuration mode:

```
enable

configure terminal

router rip
```

2. Define the default-import-metric for the switch:
`default-metric <0-15>`
3. (Optional) Configure one or more timer values:
`timers basic timeout <15-259200> [holddown <0-360>] [update <1-360>]`
4. Enable RIP on an IP network:
`network {A.B.C.D}`
5. Exit to Global Configuration mode:
`exit`
6. After the configuration is complete, enable RIP globally:
`router rip enable`
- 7.
8. Check that your configuration is correct:
`show ip rip [vrf WORD<1-16>] [vrfids WORD<0-512>]`

Example

Define the default-import-metric as 1, the timeout interval as 180, the holddown time as 120, and the update time as 30. Enable RIP on an IP network, and ensure your configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#router rip
Switch:1(config-rip)#default-metric 1
Switch:1(config-rip)#timers basic timeout 180 holddown 120 update 30
Switch:1(config-rip)#network 192.0.2.11
Switch:1(config-rip)#exit
Switch:1(config)#router rip enable
Switch:1(config)#show ip rip
=====
                        RIP Global - GlobalRouter
=====
Default Import Metric : 1
      HoldDown Time   : 120
          Queries    : 0
              Rip     : Enabled
      Route Changes   : 0
      Timeout Interval : 180
          Update Time  : 30
```

Variable definitions

The following table defines parameters for the RIP commands.

Variable	Value
<code>default-metric <0-15></code>	Configures the value of default import metric to import a route into a RIP domain. To announce OSPF internal routes into RIP domain, if the policy does not specify a metric value, the default is used. For OSPF external routes, the external cost is used. The default is 8.
<code>domain <0-39321></code>	Specifies the RIP domain from 0-39321. The default is 0.

Variable	Value
<code>holddown <0-360></code>	Configures the RIP hold-down timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<code>network {A.B.C.D}</code>	Enables RIP on an IP network.
<code>timeout <15-259200></code>	Configures the RIP timeout interval. The default is 180.
<code>update <1-360></code>	Configures the RIP update timer. The update time is the time interval, in seconds, between RIP updates. The default is 30.

The following table defines parameters for the **show ip rip** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF by name.
<code>vrfids WORD<0-512></code>	Specifies a range of VRF IDs.

Configuring RIP on an interface

Configure RIP on Ethernet ports and VLANs so that they can participate in RIP routing.

Before You Begin

- Assign an IP address to the port or VLAN.
- Configure RIP and enable it globally.
- Configure in and out policies.

About This Task

RIP does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

To configure RIP on a VRF instance for a port or VLAN, you configure RIP on the port or VLAN, and then associate the port or VLAN with the VRF.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Define the cost:

```
ip rip cost <1-15>
```

3. Specify an in policy for filtering inbound RIP packets:
`ip rip in-policy WORD<0-64>`
4. Specify an out policy for filtering outbound RIP packets:
`ip rip out-policy WORD<0-64>`
5. Enable RIP:
`ip rip enable`
6. Specify the send mode:
`ip rip send version <notsend|rip1|rip1comp|rip2>`
7. Specify the receive mode:
`ip rip receive version <rip1|rip2|rip1orrip2>`
8. Change other RIP parameters from their default values as required.

Example

The following configuration example shows how to configure the switch (labeled R1) to operate only in RIP version 2 mode.

Figure 218: Configuration example-RIPv2 only

Enable RIPv2 send mode on VLAN 2:

```
Switch:1(config-if)# ip rip send version rip2
```

Enable RIPv2 receive mode on VLAN 2:

```
Switch:1(config-if)# ip rip receive version rip2
```

Repeat these commands on VLAN 3 and the port interfaces.

Variable definitions

The following table defines parameters for the **ip rip** command.

Variable	Value
<i>advertise-when-down enable</i>	Enables or disables AdvertiseWhenDown. If enabled, RIP advertises the network on this interface as up, even if the port is down. The default is disabled. If you configure a port with no link and enable advertise-when-down, it does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link status, you must disable this parameter.
<i>auto-aggregation enable</i>	Enables or disables automatic route aggregation on the port. If enabled, the switch automatically aggregates routes to their natural mask when an interface in a different class network advertises them. The default is disable.
<i>cost <1-15></i>	Configures the RIP cost for this port (link).
<i>default-listen enable</i>	Enables DefaultListen. The switch accepts the default route learned through RIP on this interface. The default is disabled.
<i>default-supply enable</i>	Enables DefaultSupply. If enabled, this interface must advertise a default route. The default is false. RIP advertises the default route only if it exists in the routing table.
<i>enable</i>	Enables RIP routing on the port.
<i>holddown <0-360></i>	Configures the RIP holddown timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<i>in-policy WORD<0-64></i>	Configures the policy name for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when RIP adds it to the routing table.
<i>listen enable</i>	Specifies that the routing switch learns RIP routes through this interface. If enabled, the switch listens for a default route without listening for all routes. The default is enable.
<i>out-policy WORD<0-64></i>	Configures the policy name for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface. This policy also specifies the parameters of the advertisement. <i>WORD<0-64></i> is a string of length 0-64 characters.
<i>poison enable</i>	Enables Poison Reverse. If you disable Poison Reverse (<i>no poison enable</i>), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>receive version <rip1 rip2 rip1orrip2></code>	Indicates which RIP update version to accept on this interface. The default is rip1orrip2.
<code>send version <notsend rip1 rip1comp rip2></code>	Indicates which RIP update version the router sends from this interface. ripVersion1 implies sending RIP updates that comply with RFC1058. rip1comp implies broadcasting RIP2 updates using RFC1058 route subassumption rules. The default is rip1Compatible.
<code>supply enable</code>	Specifies that the switch advertises RIP routes through the port. The default is enable.
<code>timeout <15-259200></code>	Configures the RIP timeout interval in seconds. The default is 180.
<code>triggered enable</code>	Enables automatic triggered updates for RIP.

Configuring route redistribution to RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, Open Shortest Path First (OSPF), IS-IS, or Border Gateway Protocol (BGP). Optionally, use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.

Procedure

1. Enter RIP Router Configuration mode:

```
enable

configure terminal
```

```
router rip
```

2. Create the redistribution instance:

```
redistribute <bgp|direct|isis|ospf|rip|static> [vrf-src WORD<1-16>]
```

3. Apply a route policy, if required:

```
redistribute <bgp|direct|isis|ospf|rip|static> route-map WORD<0-64>
[vrf-src WORD<1-16>]
```

4. Configure other parameters.

5. Enable the redistribution:

```
redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#redistribute rip
Switch:1(config-rip)#redistribute rip route-map test1
Switch:1(config-rip)#redistribute rip enable
Switch:1(config-rip)#exit
Switch:1(config)#ip rip apply redistribute rip
```

Variable definitions

The following table defines parameters for the **redistribute** command.

Variable	Value
<i>metric</i> <0-65535>	Configures the metric to apply to redistributed routes.
<i>route-map</i> WORD<0-64>	Configures the route policy to apply to redistributed routes.
[<i>vrf-src</i> WORD<1-16>]	Specifies the optional source VRF instance. You can use this variable with the other command variables.
WORD<0-32>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrfids</i> WORD<1-512>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrf-src</i> WORD<1-16>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
< <i>bgp direct isis ospf rip static</i> >	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

Configuring interVRF route redistribution for RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, OSPF, IS-IS, or BGP. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Configure the VRFs.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static>
```

3. Apply a route policy, if required:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> route-map  
WORD<0-64> [vrf-src WORD<1-16>]
```

4. Configure other parameters.

5. Enable the redistribution:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src  
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<1-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf  
WORD<1-16>] [vrf-src WORD<1-16>]
```

Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1#router vrf red  
Switch:1(router-vrf)#ip rip redistribute ospf  
Switch:1(router-vrf)#ip rip redistribute ospf route-map test1  
Switch:1(router-vrf)#ip rip redistribute ospf enable  
Switch:1(router-vrf)#exit  
Switch:1(config)#ip rip apply redistribute ospf
```

Variable definitions

The following table defines parameters for the **ip rip redistribute** `<bgp|isis|ospf|static|direct|rip>` command.

Variable	Value
<code><bgp direct isis ospf rip static></code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code>metric <0-65535></code>	Configures the metric to apply to redistributed routes.
<code>route-map WORD<0-64></code>	Configures the route policy to apply to redistributed routes.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrfids WORD<1-512></code>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code><bgp direct isis ospf rip static></code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

Forcing a RIP Update for a Port or VLAN

Force RIP to update the routing table so that the port or VLAN uses the latest routing information.

About This Task

If you perform this procedure, you also update the tables for all VRFs associated with the port or VLAN.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the triggered-update flag:

```
ip rip triggered enable
```

**Note**

You can enable this flag in either the GigabitEthernet or VLAN Interface Configuration mode. However, you can update the RIP routes in the GigabitEthernet Interface Configuration mode only.

3. Update the routing table:

```
action triggerRipUpdate
```

Example

Update the routing table:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#ip rip triggered enable
```

Viewing the RIP redistribution configuration information

Displays the RIP redistribution configuration information.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the RIP redistribution configuration information:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

View the RIP redistribution configuration information:

```
Switch(config-ospf)#show ip rip redistribute
```

```
=====
RIP Redistribute List - GlobalRouter
=====
```

```

SRC-VRF          SRC  MET  ENABLE  RPOLICY
-----
GlobalRouter    ISIS  0    FALSE

```

Variable definitions

The following table defines parameters for the **show ip rip redistribute** command or the **show ipv6 rip redistribute** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies a VRF by name.
<code>vrfids WORD<0-512></code>	Specifies a range of VRF IDs.

RIPng Configuration using CLI

Use the procedures in this section to configure RIPng using CLI.

Configuring RIPng globally

Configure RIPng parameters on the router so you can control RIPng behavior on the system.

Before You Begin

You can configure RIPng only on a global router. You cannot configure RIPng on a VRF instance.

Procedure

1. Enter Global Configuration mode:

```
enable
configure terminal
```
2. Enable RIPng globally:

```
router rip ipv6-enable
```

Configuring RIPng on an interface

Configure RIPng on Ethernet ports and VLANs so that they can participate in RIPng routing.

About This Task

RIPng does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

Before You Begin

- Assign an IP address to the port or VLAN.
- Configure RIPng and enable it globally.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a RIPng interface:

```
ipv6 rip
```

3. Enable the RIPng interface:

```
ipv6 rip enable
```

4. Verify the operational status of the RIPng interface:

```
show ipv6 rip interface
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 22
Switch:1(config-if)#ipv6 rip
Switch:1(config-if)#ipv6 rip enable
Switch:1(config-if)#show ipv6 rip interface
```

```
Total RIPng interfaces: 2
```

```

Variable Definitions

The following table defines parameters for the **ipv6 rip** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring RIPng custom values

Configure custom values for RIPng parameters to replace default values.

Before You Begin

- Configure RIPng and enable it globally.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RIPng poison:

```
ipv6 rip poison enable
```

3. Specify the RIPng cost:

```
ipv6 rip cost <1-15 Cost>
```

4. Access router RIPng configuration mode:

```
router rip
```

5. Specify the RIPng holddown timer value:

```
ipv6 timers basic holddown <0-360>
```

6. Specify the RIPng timeout timer value:
`ipv6 timers basic timeout <15-259200>`
7. Specify the RIPng update timer value:
`ipv6 timers basic update <1-360>`
8. Specify the default route metric value:
`ipv6 default-information metric <1-15>`
9. Enable default information globally:
`ipv6 default-information enable`
10. Ensure the configuration is correct:
`show ipv6 rip`

Example

Configure custom values for RIPng.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 default-information metric 1
Switch:1(config-rip)#ipv6 default-information enable
Switch:1(config-rip)#ipv6 timers basic update 30
Switch:1(config-rip)#ipv6 timers basic timeout 180
Switch:1(config-rip)#ipv6 timers basic holddown 120
Switch:1(config-rip)#router rip ipv6-enable
Switch:1(config)#show ipv6 rip
```

```
=====
                        RIPng Global - GlobalRouter
=====

                Rip : Enabled
                HoldDown Time : 120
                Timeout Interval : 180
                Update Time : 30
                Default Info Metric : 1
                Default Info State : Enabled
                Default Import Metric : 1
```

Variable definitions

Use the data in the following table to use the **ipv6 rip poison**, **ipv6 default-information** and **ipv6 timers basic** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
poison enable	Enables Poison Reverse. If you disable Poison Reverse (no poison enable), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.
<1-15 Cost>	Configures the RIPng cost for this port (link).
holddown <0-360>	Configures the RIPng holddown timer value, the length of time (in seconds) that RIPng continues to advertise a network after it determines that the network is unreachable. The default is 120.
timeout <15-259200>	Configures the RIPng timeout interval. The default is 180.
update <1-360>	Configure the RIPng update timer. The update time is the time interval between RIPng updates.
default-information <1-15>	Configure the default route metric value.

Configuring RIPng route distribution

Configure a redistribute entry to announce certain routes into the RIPng domain, including static routes, direct routes, Open Shortest Path First (OSPFv3), IS-IS, or Border Gateway Protocol (BGP+).

Before You Begin

- Enable RIPng globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Access router RIP configuration mode:

```
router rip
```
3. Enable the redistribution:

```
ipv6 redistribute {direct|isis|static|ospf|bgp} enable
```
4. Ensure the configuration is correct:

```
show ipv6 rip redistribute
```

Example

Enable the redistribution instance.

```
Switch:1#enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 redistribute bgp enable
Switch:1(config-rip)#ipv6 redistribute direct enable
Switch:1(config-rip)#ipv6 redistribute isis enable
Switch:1(config-rip)#ipv6 redistribute ospf enable
Switch:1(config-rip)#ipv6 redistribute static enable
Switch:1(config-rip)#show ipv6 rip redistribute
```

RIPng Redistribute List

```
=====
direct          : enabled
static          : enabled
ospf            : enabled
bgp             : enabled
isis            : enabled
=====
```

Variable definitions

Use the data in the following table to use the **ipv6 redistribute** command.

Variable	Value
<bgp direct isis ospf static>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, ospf, or static.

RIP configuration using EDM

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use Enterprise Device Manager (EDM) to configure and manage RIP.

Configuring RIP globally

Configure RIP global parameters on the switch so you can control RIP behavior on the system.

Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

All router interfaces that use RIP use the RIP global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIP parameters as required.
6. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Operation	Enables or disables RIP on all interfaces. The default is disabled.
UpdateTime	Specifies the time interval between RIP updates for all interfaces. The default is 30 seconds, and the range is 0–360.
RouteChanges	Specifies the number of route changes RIP made to the IP route database. RouteChanges does not include the refresh of a route age.
Queries	Specifies the number of responses sent to RIP queries received from other systems.
HoldDownTime	Configures the length of time that RIP continues to advertise a network after the network is unreachable. The range is 0–360 seconds. The default is 120 seconds.
TimeOutInterval	Configures the RIP timeout interval. The range is 15–259200 seconds. The default is 180 seconds.
DefImportMetric	Configures the default import metric used to import a route into a RIP domain. To announce OSPF internal routes into a RIP domain, if the policy does not specify a metric, you must use the default import metric. OSPF external routes use the external cost. The range is 0–15 and the default is 8.

Viewing RIP status

View RIP status.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Status** tab.

Status field description

Use the following table to use the RIP Status tab.

Name	Description
Address	Specifies the IP address of the router interface.
RcvBadPackets	Specifies the number of RIP response packets received by the RIP process which were subsequently discarded; for example, version 0 packet, or an unknown command type.
RcvBadRoutes	Specifies the number of routes, in valid RIP packets, that are ignored; for example, unknown address family, or invalid metric.
SentUpdates	Specifies the number of triggered RIP updates sent on this interface, that do not include full updates sent containing new information.

Configuring RIP interface compatibility

Configure RIP parameters on an interface so you can control RIP behavior on the interface. You can specify the RIP version to use on interfaces that you configure to send (supply) or receive (listen to) RIP updates.

Before You Begin

- Configure a routing interface (either a router port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIP globally.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

Although visible, the switch does not support the AuthType and AuthKey parameters.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Interface** tab.
4. Double-click the **Send** value to edit it, and then select the RIP version datagrams the router sends.
5. Double-click the **Receive** value to edit it, and then select the RIP version datagrams for which the router listens.
6. Click **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Address	Specifies the IP address of the router interface.
Domain	Specifies the value inserted into the routing domain parameter of all RIP packets sent on this interface.
AuthType	Specifies the type of authentication to use on this interface.
AuthKey	Specifies the authentication key whenever AuthType is not noAuthentication.
Send	Specifies the update version the router sends on this interface: <ul style="list-style-type: none"> • DoNotSend—no RIP updates sent on this interface • ripVersion1—RIP updates compliant with RFC1058 • rip1Compatible—broadcast RIPv2 updates using RFC1058 route subassumption rules • ripVersion2—multicast RIPv2 updates The default is rip1compatible.
Receive	Indicates which versions of RIP updates to accept: <ul style="list-style-type: none"> • rip1 • rip2 • rip1OrRip2 The default is rip1OrRip2. Rip2 and rip1OrRip2 imply receipt of multicast packets.

Job Aid

Choose one of three options for receiving RIP updates:

- rip1OrRip2—accepts RIPv1 or RIPv2 updates
- rip1—accepts RIPv1 updates only
- rip2—accepts RIPv2 updates only

The following table describes the four RIP send modes that the switch supports. You can configure RIP send modes on all router interfaces.

Table 202: RIP send modes

Send mode	Description	Result
rip1Compatible	Broadcasts RIPv2 updates using RFC1058 route consumption rules. This is the default mode.	<ul style="list-style-type: none"> Destination MAC is a broadcast, ff-ff-ff-ff-ff Destination IP is a broadcast for the network (for example, 192.0.2.255) RIP update is formed as a RIP-2 update, including network mask RIP version = 2
ripVersion1	Broadcasts RIP updates that are compliant with RFC1058	<ul style="list-style-type: none"> Destination MAC is a broadcast, ff-ff-ff-ff-ff Destination IP is a broadcast for the network (for example, 198.0.2.255) RIP update is formed as a RIP-1 update, no network mask included RIP version = 1
ripVersion2	Broadcasts multicast RIPv2 updates	<ul style="list-style-type: none"> Destination MAC is a multicast, 01-00-5e-00-00-09 Destination IP is the RIP-2 multicast address, 224.0.0.9 RIP update is formed as a RIP-2 update including network mask RIP version = 2
doNotSend	Does not send RIP updates on the interface	None

Configuring RIP on an interface

Configure RIP parameters to control and optimize RIP routing for the interface.

Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

Procedure

- In the navigation pane, expand **Configuration > IP**.
- Click **RIP**.
- Click the **Interface Advance** tab.
- Double-click a RIP parameter to edit it, as required.
- Click **Apply**.

Interface Advance field descriptions

Use the data in the following table to use the RIP **Interface Advance** tab.

Name	Description
Address	Shows the address of the entry in the IP RIP interface table.
Interface	Indicates the index of the RIP interface.
Enable	Shows if the RIP interface is enabled or disabled.
Supply	Enables (true) or disables (false) the ability to send RIP updates on this interface.
Listen	Configures whether the switch learns routes on this interface.
Poison	Configures whether to advertise RIP routes learned from a neighbor back to the neighbor. If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, RIP poisons the RIP updates, sent to the neighbor from which a route is learned, with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network.
DefaultSupply	Enables (true) or disables (false) an advertisement of a default route on this interface. This command takes effect only if a default route exists in the routing table.
DefaultListen	Enables (true) or disables (false) the switch to accept the default route learned through RIP on this interface. The default is disabled. Enable DefaultListen to add a default route to the route table if another route advertises it.
TriggeredUpdate	Enables (true) or disables (false) the switch to send RIP updates from this interface.
AutoAggregate	Enables (true) or disables (false) automatic route aggregation on this interface. If enabled, the switch automatically aggregates routes to their natural mask when an interface advertises them. The default is disabled.
InPolicy	Determines if RIP can learn routes on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if RIP advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The range is 1-15. The default is 1.

Job aid

The following table indicates the relationship between switch action and the RIP supply and listen settings.

Table 203: RIP supply and listen settings and switch action

RIP supply settings		RIP listen settings		Switch action
Supply	Default supply	Listen	Default listen	
Disabled (false)	Disabled (false)			Sends no RIP updates.
Enabled (true)	Disabled (false)			Sends RIP updates except the default.
Disabled (false)	Disabled (false)			Sends only the default (default route must exist in routing table).
Enabled (true)	Enabled (true)			Sends RIP updates including the default route (if it exists).
		Disabled (false)	Disabled (false)	Does not listen to RIP updates.
		Enabled (true)	Disabled (false)	Listens to all RIP updates except the default.
		Disabled (false)	Enabled (true)	Listens only to the default.
		Enabled (true)	Enabled (true)	Listens to RIP updates including the default route (if it exists).

Configuring RIP on a port

Configure RIP on a port so that the port can participate in RIP routing.

Before You Begin

- Assign an IP address to the port.
- Configure RIP and enable it globally.

Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

- Enable RIP on the interface.

About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **RIP** tab.

5. Configure the RIP parameters as required.
6. Click **Apply**.

RIP field descriptions

Use the data in the following table to use the **RIP** tab.

Name	Description
Enable	Enables or disables RIP on the port.
Supply	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
Listen	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
Poison	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.
DefaultSupply	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
DefaultListen	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
TriggeredUpdateEnable	Enables or disables triggered RIP updates. The default is false (disabled).
AutoAggregateEnable	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
AdvertiseWhenDown	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the port is down. The default is false. If you configure a port with no link and enable AdvertiseWhenDown, the port does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
InPolicy	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if this interface advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.

Name	Description
HolddownTime	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
TimeOutInterval	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

Configuring RIP on a VLAN

Configure RIP on a VLAN so that the VLAN acts as a routed VLAN (a virtual router).

Before You Begin

- Configure the VLAN.
- Assign an IP address to the VLAN.
- Enable RIP globally.
- Enable RIP on the interface.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RIP** tab.
7. Configure the VLAN RIP parameters as required.
8. Click **Apply**.

RIP field descriptions

Use the data in the following table to use the **RIP** tab.

Name	Description
Enable	Enables or disables RIP on the VLAN.
Supply	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
Listen	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
Poison	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.

Name	Description
DefaultSupply	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
DefaultListen	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
TriggeredUpdateEnable	Enables or disables triggered RIP updates. The default is false (disabled).
AutoAggregateEnable	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
AdvertiseWhenDown	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the interface is down. The default is false. If you configure a VLAN with no link and enable AdvertiseWhenDown, the VLAN does not advertise the route until the VLAN is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
InPolicy	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
OutPolicy	Determines if this interface advertises a route from the routing table. This policy also specifies the parameters of the advertisement.
Cost	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.
HolddownTime	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
TimeOutInterval	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

Configuring route redistribution to RIP

Configure a redistribute entry to announce routes of a certain source protocol type into the RIP domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

About This Task

Important

Changing the RIP redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. As a best practice, change default preferences for a RIP redistribute context, you must do so before you enable the protocols.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source of the routes to redistribute.
6. Select **enable**.
7. Select the route policy to apply to redistributed routes.
8. Configure a metric value.
9. Click **Insert**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination VRF instance. You cannot configure this variable.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.
SrcVrfId	Specifies the source VRF instance. You cannot configure this variable.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) a RIP redistribute entry for a specified source type.
RoutePolicy	Configures the route policy (by name) that redistributes external routes from a specified source into an RIP domain. Click the ellipsis (...) button and choose from the list in the Route Policy dialog box.
Metric	Configures the RIP route redistribution metric for basic redistribution. The value can be in the range 0–65535. A value of 0 indicates to use the original cost of the route.

RIPng Configuration using EDM

Use the procedures in this section to configure RIPng using EDM.

Configuring RIPng globally

Configure RIPng global parameters on the switch so you can control RIPng behavior on the system.

About This Task

All router interfaces that use RIPng use the RIPng global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIPng global parameters.

You can configure RIPng on interfaces while RIPng is globally disabled. This way, you can configure all interfaces before you enable RIPng for the switch

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIPng parameters as required.
6. Click **Apply**.

Globals field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
AdminState	Enables or disables RIPng globally. The default is disabled.
UpdateTime	Specifies the time interval between RIPng updates for all interfaces. The default is 30 seconds, and the range is 1-360.
GlobalHoldDownTime	Configures the length of time that RIPng continues to advertise a network after the network is unreachable. The range is 0-360 seconds. The default is 120 seconds.
GlobalTimeOutInterval	Configures the RIPng timeout interval. The range is 15-259200 seconds. The default is 180 seconds.
DefaultInfoMetric	RIPng default-information metric.
DefaultInfoState	Default-information enable or disable at the global level
DefaultImportMetric	Specifies the RIPng default import metric.

Configuring an IPv6 RIPng interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View** , selecting a port, and following the **Edit > Port > IPv6** navigation path. You can configure an IPv6 RIPng interface for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 RIPng navigation path where you can create both types of interfaces.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Interfaces** tab.
4. Click **Insert**.
5. In the **IfIndex** box, type a value to identify the IPv6 interface.
6. In the **RipAdminStatus** option box, select **enable**.
7. Configure other parameters as required.
8. Click **Insert**.

Interfaces field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	RIPng interface index.
RipAdminStatus	Enable or disable RIPng on an interface.
DefaultInfoState	Enable or disable default information at the interface level.
Cost	Specifies the RIPng metric cost.
Poison	Enable or disable poison reverse on an RIPng interface.
RipOperStatus	Enable or disable the RIPng operational state on an interface.

Configuring an IPv6 RIPng VLAN interface

Configure RIPng parameters on a VLAN interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View**, selecting a port, and following the **Edit > Port > IPv6** navigation path.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a row, and click **IPv6**.
5. Click **Insert**.
6. Configure other parameters, as required.
7. Click **Insert**.
8. Click **Apply**.

IPv6 Interfaces VLAN Field Descriptions

Use the data in the following table to use the **IPv6 Interfaces** tab.

Name	Description
Interface	Specifies the port or VLAN.
Identifier	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.
IdentifierLength	Shows the length of the identifier, in bits.
Descr	Specifies a description of the interface. The network management system also configures this string.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
Type	Shows the interface type.
ReasmMaxSize(MTU)	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.
PhysAddress	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
AdminStatus	Specifies if IPv6 is active on this interface. The default is false (disabled).
OperStatus	Specifies the current operational status of the interface.
ReachableTime	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.
RetransmitTimer	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
MulticastAdminStatus	The option to select MulticastAdminStatus is disabled. You cannot configure the administrative status for multicast in this context.

Name	Description
MacOffset	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
ForwardingEnabled	Indicates whether IPv6 forwarding is enabled. The default is enabled.
RSMLTEnable	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).

Configuring an IPv6 RIPng brouter port interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration >EditPort** folders.
3. Click **IPv6**.
4. Click the **RIPng** tab.
5. In the **RipAdminStatus** option box, select **enable**.
6. Configure other parameters as required.
7. Click **Apply**.

RIPng Field Descriptions

Use the data in the following table to use the **RIPng** tab.

Name	Description
RipAdminStatus	Enable or disable RIPng on an interface.
DefaultInfoState	Enable or disable default information at the interface level. The default is disable.
Cost	Specifies the RIPng metric cost. The default is 1.
Poison	Enable or disable poison reverse on an RIPng interface. The default is disable.
RipOperStatus	Shows the RIPng operational state on an interface.

Graphing IPv6 RIPng statistics

Use the following procedure to graph RIPng statistics for monitoring RIPng behavior on the interface.

About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

Procedure

1. In the navigation pane, expand the **Configuration > Ipv6** folders.
2. Click the **IPv6 RIPng**.
3. Click the **Stats** tab.
4. Select an interface row.
5. Click **Graph**.
6. Click **Apply**.

Configuring route redistribution to RIPng

Configure a redistribute entry to announce routes of a certain source protocol type into the RIPng domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

Before You Begin

- Enable RIP globally.
- Configure a route policy.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Redistribute** tab.
4. Double-click the value in the **Enable** column that corresponds with the source protocol type you want to enable or disable.
5. Select **enable** or **disable** from the list.
6. Click **Apply**.

Redistribute field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
DstVrfiled	Specifies the destination VRF ID used in the redistribution.
Protocol	Specifies the dynamic routing protocol that receives the external routing information.

Name	Description
SrcVrfId	Specifies the source VRF ID used in the redistribution.
RouteSource	Specifies the route source protocol for the redistribution entry.
Enable	Enables (or disables) a RIPng redistribute entry for a specified source type.

Viewing stats for RIPng interfaces

View statistics for RIPng interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Stats** tab.

Stats field descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
IfIndex	Shows the unique value to identify an IPv6 interface.
RcvBadPackets	The number of RIPng response packets received by the RIP process that were subsequently discarded for any reason (examples: a version 0 packet or an unknown command type).
RcvBadRoutes	The number of routes, in valid RIPng packets, that were ignored for any reason (examples: unknown address family or invalid metric).
SentUpdates	The number of triggered RIPng updates actually sent on this interface.
RcvUpdates	The number of triggered RIPng updates actually received on this interface. This explicitly does not include full updates received containing new information.

	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.2
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.2

Remote Monitoring

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). Use CLI, or EDM, to globally enable RMON on the system. After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

You can use RMON1 to:

- Configure alarms for user-defined events.
- Collect Ethernet statistics.
- Log events.
- Send traps for events.

Within EDM, you can configure RMON1 alarms that relate to specific events or variables. You can also specify events associated with alarms to trap or log-and-trap. In turn, the system traps or logs tripped alarms.

You can view all RMON1 information using CLI or EDM. Alternatively, you can use any management application that supports SNMP traps to view RMON1 trap information.

This section describes RMON1 alarms, RMON1 history, RMON1 events, and RMON1 statistics.

RMON1 alarms

You can configure alarms to alert you if the value of a variable goes out of range. You can define RMON1 alarms on any MIB variable that resolves to an integer value. You cannot use string variables (such as system description) as alarm variables.

You can use RMON1 alarm to monitor anything that has a MIB OID associated with it and a valid instance.

All alarms share the following characteristics:

- A defined upper and lower threshold value.
- A corresponding rising and falling event.
- An alarm interval or polling period.

After you activate alarms, you can:

- View the activity in a log and/or a trap.
- Create a script directing the system to sound an audible alert at a console.
- Create a script directing the system to send an e-mail.
- Create a script directing the system to call a pager.

The system polls the alarm variable and the system compares the result against upper and lower limit values you select when you create the alarm. If the system reaches or crosses the alarm variable during the polling period, the alarm fires and generates an event that you can view in the event log or the trap

log. You can configure the alarm to either create a log, or have the alarm send a Simple Network Management Protocol (SNMP) trap to a Network Management System (NMS). You can view the activity in a log or a trap log, or you can create a script to cause a console to beep, send an e-mail, or call a pager.

The upper limit of the alarm is the rising value, and the lower limit is the falling value. RMON1 periodically samples data based upon the alarm interval. During the first interval that the data passes above the rising value, the alarm fires as a rising event. During the first interval that the data drops below the falling value, the alarm fires as a falling event.

The following figure shows how alarms fire:

Figure 219: How alarms fire

The alarm fires during the first interval that the sample goes out of range. No additional events generate for that threshold until the system crosses the opposite threshold. Therefore, you must carefully define the rising and falling threshold values for alarms. Incorrect thresholds cause an alarm to fire at every alarm interval, or never at all.

You can define one threshold value to an expected, baseline value, and then define the opposite threshold as the out-of-bounds limit. Because of sample averaging, the value is equal to ± 1 baseline unit. For example, assume you define an alarm with octets leaving a port as the variable. The intent of the alarm is to notify you if excessive traffic occurs on that port. You enable spanning tree, and then 52 octets transmit from the port every 2 seconds, which is equivalent to baseline traffic of 260 octets every 10 seconds. This alarm notifies you if you define the lower limit of exiting octets at 260 and you define the upper limit at 320 (or at any value greater than $260 + 52 = 312$).

The rising alarm fires the first time outbound traffic, other than spanning tree Bridge Protocol Data Units (BPDUs), occurs. The falling alarm fires after outbound traffic, other than spanning tree, ceases. This process provides the time intervals of any nonbaseline outbound traffic.

If you define the alarm with a falling threshold of less than 260 and the alarm polling interval is at 10 seconds, for example, 250, then the rising alarm can fire only once, as shown in the following example. The falling alarm (the opposite threshold) must fire for the rising alarm to fire a second time. The falling alarm cannot fire unless the port becomes inactive or you disable spanning tree, which causes the value for outbound octets to drop to zero, because the baseline traffic is always greater than the value of the falling threshold. By definition, the failure of the falling alarm to fire prevents the rising alarm from firing a second time.

The following figure shows an example of the alarm threshold:

Figure 220: Alarm example, threshold less than 260

When you create an alarm, you select a variable from the variable list and a port, or another system component to which it connects. Some variables require port IDs, card IDs, or other indexes, for example, spanning tree group IDs. You then select a rising and a falling threshold value. The rising and falling values compare to the actual value of the variable that you choose. If the variable falls outside of the rising or falling value range, an alarm triggers, and the system logs an event or trap.

When you create an alarm, you also select a sample type, which can be either absolute or delta. Define absolute alarms for alarms based on the cumulative value of the alarm variable. An example of an absolute alarm value is card operating status. Because this value is not cumulative, but instead represents states, such as card up (value 1) and card down (value 2), you configure the value as the absolute value. Therefore, you can create an alarm with a rising value of 2 and a falling value of 1 to alert you whether the card is up or down.

Configure most alarm variables related to Ethernet traffic as a delta value. Define delta alarms for alarms based on the difference in the value of the alarm variable between the start of the polling period and the end of the polling period.

Note

If you create an alarm that monitors a variable that does not exist, you will receive an error message and the creation will fail. Also, if the variable you are monitoring is no longer valid at the time of sampling, the switch removes the alarm automatically. For example, if you create an alarm that monitors some information about a VLAN, and that VLAN is later removed, then the switch silently removes the associated alarm at the next sampling interval.

RMON1 history

The RMON1 history group records periodic statistical samples from a network. A sample is a history and the system gathers the sample in time intervals referred to as buckets.

You can use RMON1 history for the MAC layer in the network. You cannot use RMON1 history for application and network layer protocols.

You enable and create histories to establish a time-dependent method to gather RMON1 statistics on a port. The following are the default values for history:

- Buckets are gathered at 30-minute intervals.
- The number of buckets gathered is 50.

You can configure both the time interval and the number of buckets. However, after the system reaches the last bucket, the system dumps bucket 1 and recycles the bucket to hold a new bucket of statistics. Then the system dumps bucket 2, and so forth.

RMON1 events

RMON1 events and alarms work together to notify you when values in your network go out of a specified range. After a value passes the specified range, the alarm fires. The event specifies how the system records the activity.

You can use RMON1 events to monitor anything that has a MIB OID associated with it and a valid instance.

An event specifies whether a trap, a log, or both a trap and a log generates to view alarm activity.

You must create an event before associating it with an alarm, otherwise an error occurs. Also, you cannot delete an event as long as there are alarms associated with it. If you try to do so, an error message displays.

RMON1 statistics

You can use EDM to gather and graph statistics in a variety of formats, or you can save the statistics to a file and export the statistics to a third-party presentation or graphing application.

RMON1 scaling limits

The following tables shows the scaling limits for RMON1 elements.

Note

When the log table reaches the maximum 500 log limit, the oldest third of the logs per event is removed to make room for new events. For all other elements, a message displays when you reach the maximum limit and no other element can be added.

Alarms	100
Events	100
History (entries in the history control table with 2000 buckets shared between them)	20
Logs	500
Statistics (entries in stats table)	100

RMON 2

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP).

Use CLI or EDM to globally enable RMON on the system.

After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

RMON2 monitors and counts network layer and application layer protocol packets on configured network hosts, either VLAN or port interfaces, that you enable for monitoring. RMON2 monitors Segmented Management Instances at the mgmt configuration level for out-of-band (OOB), circuitless IP (CLIP), and VLAN interfaces.

Note

RMON2 monitoring of Segmented Management Instances at the mgmt configuration level is not supported on VSP 8600 Series.

Note

RMON2 counters on Segmented Management Instance interfaces are cleared only when a Segmented Management Instance interface is newly enabled, or when RMON2 is newly enabled on a previously enabled Segmented Management Instance interface.

The following figure shows which form of RMON monitors which layers in the OSI model:

Figure 221: OSI model and RMON

The RMON2 feature is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). The switch supports a partial implementation of RMON2. The RMON2 feature adds the following MIBS: protocol directory, protocol distribution, address map, network-layer host and application layer host for the traffic passing through the (Control Processor) CP for these MIB tables.

The system only collects statistics for IP packets that pass through the CP. RMON2 does not monitor packets on other interfaces processed on the switch that do not pass through the CP. However, RMON2 monitors packets for applications listed in the RMON2 MIB, whether or not the application is enabled or supported on the switch.

After you globally enable RMON2, enable monitoring for individual devices. Identify the network hosts for the system to monitor with a manual configuration on the interfaces you want to monitor.

The RMON2 feature monitors a list of predefined protocols. The system begins to collect protocol statistics immediately after you enable RMON.

The RMON2 feature collects statistics on:

- Protocols predefined by the system.
- Address mapping between physical and network address on particular network hosts that you configure for monitoring.
- Network host statistics for particular hosts on a network layer protocol (IP) that you configure for monitoring.
- Application host statistics for a particular host on an application layer protocol that you configure for monitoring.

RMON2 MIBs

This section describes the following MIBs, on which RMON2 can collect statistics: protocol directory, protocol distribution, address map, network-layer host, and application layer host.

Protocol Directory MIB

The protocol directory is a master directory that lists all of the protocols RMON2 can monitor. The protocols include network layer, transport layer, and application layer protocols, under the OSI model. The system only monitors statistics for the predefined protocols. You cannot delete or add additional protocols to this table. The protocol directory MIB is enabled by default for the predefined protocols.

The predefined protocols include:

- Internet Protocol (IP)
- Secure Shell version 2 (SSHv2)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)
- File Transfer Protocol (FTP)
- Hypertext Transfer Protocol (HTTP)
- Telnet
- Remote login (rlogin)

Note

Rlogin application is only supported on VSP 8600 Series.

- Trivial File Transfer Protocol (TFTP)
- Simple Network Management Protocol (SNMP)

Protocol distribution MIB

The protocol distribution MIB collects traffic statistics that each protocol generates by local area network (LAN) segment. The switch acts as the probe and the system collects protocol statistics for the entire switch as part of the group for all of the protocols predefined in the protocol directory table. The protocol distribution control table is part of this group. The protocol distribution control table is predefined with an entry for the management IP for the switch to represent the network segment where the system collects the statistics.

No CLI or EDM support exists to add or delete entries in this table.

Address map MIB

The address map MIB maps the network layer IP to the MAC layer address.

The system populates the address map control table MIB with an entry for each host interface that you enable for monitoring on the switch.

Network layer host MIB

The network layer host MIB monitors the Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address. The network layer host controls the network and application layer host tables.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

Application layer host MIB

The application layer host MIB monitors traffic statistics by application protocol for each host.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

RMON2 Considerations

The following considerations apply to RMON2:

- You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.
- You must configure an IPv4 address for the Segmented Management Instance management interface before you enable RMON2 monitoring.
- You can enable RMON on a maximum of 30 IP interfaces on a host.

- You cannot directly configure RMON for a VOSS VLAN that is an underlying management VLAN. In this case, RMON must be configured at the mgmt vlan configuration level.
- RMON2 is not available if DHCP Client is configured on a Management Instance. DHCP Client is not available if RMON2 is configured on a Management Instance.
- You cannot delete the IPv4 manual address from a Segmented Management Instance management interface that is RMON enabled. If the only IPv4 address is deleted outside of the normal configuration process, RMON is administratively disabled on the Segmented Management Instance management interface.

RMON Configuration Using CLI

This section contains procedures to configure RMON using Command Line Interface (CLI).

For information about RMON statistics, see the following sections:

- [Displaying RMON Statistics for Specific Ports](#) on page 2800
- [View RMON Statistics](#) on page 2800

Configuring RMON

Enable RMON1 and RMON2 globally, and configure RMON1 alarms, events, history, statistics, and whether port utilization is calculated in half or full duplex. By default, RMON1 and RMON2 are disabled globally.

For RMON1, you enable RMON globally, and then you can use RMON1 alarm, history, events, and statistics for the MAC layer in the network. You cannot use RMON1 history or statistics for application and network layer protocols.

For RMON2, you enable RMON globally, and then you enable RMON on the host interfaces you want to monitor.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RMON1 and RMON2 globally:

```
rmon
```
3. Configure an RMON1 alarm:

```
rmon alarm <1-65535> WORD <1-1536> <1-3600> {absolute|delta} [falling-  
threshold <-2147483647-2147483647> event <1-65535>] [owner WORD<1-  
127>] [rising-threshold <-2147483647-2147483647> event <1-65535>]
```
4. Configure an RMON1 event:

```
rmon event <1-65535> [community WORD<1-127>] [description WORD<0-127>]  
[log] [owner WORD<1-127>] [trap] [trap_dest [{A.B.C.D}]] [trap_src  
{A.B.C.D}]
```
5. Configure RMON1 history:

```
rmon history <1-65535> {slot/port [/sub-port] [-slot/port [/sub-port]  
[,...]} [buckets <1-65535>] [interval <1-3600>] [owner WORD<1-127>]
```

6. Configure RMON1 statistics:

```
rmon stats <1-65535> {slot/port [/sub-port] [-slot/port[/sub-port]
[,...]} [owner <1-127>]
```

7. Configure whether the system calculates port utilization in half or full duplex:

```
rmon util-method [half|full]
```

Example

Configure RMON globally, an RMON1 alarm, and RMON1 event:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#rmon
Switch:1(config)#rmon event 60534 community public description "Rising Event" log trap
Switch:1(config)#rmon alarm 4 rcCliNumAccessViolations.0 10 absolute rising-threshold 2
event 60000
```

Variable Definitions

Use the data in this table to use the **rmon** command.

Variable	Value
<pre>alarm <1-65535> WORD <1-1536> <1-3600> {absolute delta} [falling-threshold <-2147483647-2147483647> event <1-65535>] [owner WORD<1-127>] [rising- threshold <- 2147483647-2147483647> event <1-65535>]</pre>	<p>Creates an alarm interface.</p> <ul style="list-style-type: none"> • <i><1-65535></i>— Specifies the interface index number from 1 to 65535. Each entry defines a diagnostics sample at a particular interval for an object on the device. The default is 1. • <i>WORD <1-1536></i>— Specifies the variable name or OID. The entry is case sensitive and can have a string length of 1 to 1536. • <i>{absolute delta}</i> — Specifies the sample type. • <i>rising-threshold <-2147483648-2147483647> [<i><event:1-65535></i>]</i> — Specifies the rising threshold from -2147483648 to 2147483647, which is a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is greater than or equal to the rising alarm, or the rising or falling alarm. After the system generates a rising event, the system does not generate another such event until the sampled value falls below this threshold and reaches the alarm falling threshold. You cannot modify this object if the associated alarm status is equal to valid. <p><i><1-65535></i>— Specifies the rising event index, which the system uses after the system crosses a rising threshold. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry exists in the event table, no association exists. In particular, if this value is zero, the system does not generate an associated event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid.</p> <ul style="list-style-type: none"> • <i>falling-threshold <-2147483648-2147483647> [<i><event:1-65535></i>]</i> — Specifies the falling threshold from -2147483648 to 2147483647, which specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is less than or equal to this threshold and the associated alarm startup alarm is equal to falling alarm or rising or falling alarm. After the system generates a falling event, the system does not generate another such event until the sampled value rises above this threshold, and reaches the alarm rising threshold. You cannot modify this object if the associated alarm status is equal to valid.

Variable	Value
	<p><1-65535> - Specifies the index of the event entry that the system uses after a falling threshold is crossed. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry in the event table exists, no association exists. In particular, if this value is zero, the system does not generate an event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid. The default is 60535.</p> <ul style="list-style-type: none"> • <i>owner WORD<1-127></i> - Specifies the name of the owner, with a string length 1 to 127. <p>Use the default operator to reset the RMON alarms to their default configuration: <code>default rmon alarm <65535></code></p> <p>Note: When configuring from CLI, the default owner is cli; when configuring with SNMP, the default owner is snmp. The default command only sets the owner to default. No other parameters can be changed after you create the alarm.</p> <p>Use the no operator to disable RMON alarms: <code>no rmon alarm [<1-65535>]</code></p>
<p><code>event <1-65535> [community WORD<1-127>] [description WORD<0-127>] [log] [owner WORD<1-127>] [trap]</code></p>	<p>Create an event.</p> <ul style="list-style-type: none"> • <1-65535> - Specifies the event index number. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1. • <i>log</i> - Specifies if this event stores a log when the event is triggered by the alarm. • <i>trap</i> - Specifies if this event sends a trap when the event is triggered by the alarm. The trap will be sent to all the snmp-server hosts configured in the snmp table. • <i>description WORD<0-127></i> - Specifies the event description, with a string length of 0 to 127. • <i>owner WORD<1-127></i> - Specifies the name of the owner, with a string length of 1 to 127. • <i>community WORD<1-127></i> - Specifies the SNMP community where you can send SNMP traps, with a string length 1 to 127. <p>You can set the community, but the trap is not filtered out. The trap is sent to all configured snmp-server hosts, regardless of the value of this field.</p> <p>Use the no operator to delete a RMON event: <code>no rmon event [<1-65535>] [log]</code></p>

Variable	Value
<pre>history <1-65535> {slot/port [/sub-port] [-slot/port[/ sub-port] [, ...]} [buckets <1- 65535>] [interval <1-3600>] [owner WORD<1-127>]</pre>	<p>Configures RMON history.</p> <ul style="list-style-type: none"> • <i><1-65535></i> – Specifies the history index number that uniquely identifies an entry in the history control table. Each entry defines a set of samples at a particular interval for an interface on the default. The default value is 1. • <i>{slot/port [/sub-port] [-slot/port[/sub-port] [, ...]}</i> – Specifies the single port interface. Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this history control entry. The source is an interface on this device. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface. • <i>buckets <1-65535></i>– Specifies the requested number of discrete time intervals where the system saves data in the part of the media-specific table associated with this history control entry. The default value is 50. • <i>interval <1-3600></i>– Specifies the time interval in seconds over which the system samples the data for each bucket in the part of the media-specific table associated with this history control entry. Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the history control interval to a value less than this interval, which is typically most important for the octets counter in a media-specific table. The default value is 1800. • <i>owner WORD<1-127></i>– Specifies the name of the owner.

Variable	Value
<code>stats <1-65535> {slot/port [/sub-port] [-slot/port [/sub-port] [, ...]} owner WORD<1-127></code>	<p>Configures RMON statistics.</p> <ul style="list-style-type: none"> <code><1-65535></code>— Specifies the control Ether statistics entry index number. <code>{slot/port [/sub-port] [-slot/port [/sub-port] [, ...]}</code>— Specifies the single port interface. <code>owner WORD<1-127></code>— Specifies the name of the owner. <p>Use the no operator to delete a RMON Ether stats control interface: <code>no rmon stats [<1-65535>]</code></p>
<code>util-method [half full]</code>	<p>Configures whether port utilization is calculated in half or full duplex to calculate port usage.</p> <ul style="list-style-type: none"> <code>half</code>—Configures the string to half duplex. <code>full</code>—Configures the string to full duplex. <p>After you select <code>half</code> for half duplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC 1271 convention). After you select <code>full</code> for full duplex, RMON uses InOctets and OutOctets, and 2X the speed of the port to calculate port usage. If you select <code>full</code>, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is <code>half</code>.</p>

Enable Remote Monitoring on an Interface

Use the following procedure to enable Remote Monitoring (RMON) on an interface.

Before You Begin

- Enable RMON globally.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable RMON on a particular VLAN:

```
vlan rmon <1-4059>
```

3. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port [/sub-port] [-slot/port [/sub-port]] [, ...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

4. Enable RMON on a particular port:

```
rmon
```

Examples

Enable RMON on VLAN 2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan rmon 2
```

Enable RMON on port 3/8:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/8
Switch:1(config-if)#rmon
```

Variable Definitions

Use the data in this table to use the **vlan rmon** command.

Variable	Value
<1-4059>	Specifies the VLAN ID on which to configure RMON.

Enable RMON2 on a Segmented Management Instance Interface

Before You Begin

Note

This procedure does not apply to VSP 8600 Series.

You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the configuration mode for the Management Instance:

```
mgmt <clip | oob | vlan>
```
3. Enable RMON2 on the Segmented Management Interface:

```
(mgmt:oob) rmon
```

View RMON Information

View RMON1 and RMON2 information on the switch. You can view information about RMON1 alarms, events, history, logs, and statistics. You can also view RMON2 information about application host statistics, control tables, network host statistics, and protocol distribution statistics.

Procedure

- View RMON1 information:

```
show rmon {alarm|event|history|log|stats}
```
- View RMON2 information:

```
show rmon {address-map|application-host-stats WORD<1-64>|application
protocols|ctl-table|protocol-dist-stats|network-host-stats}
```

Example

View RMON event, log, and statistics information:

```
Switch:1(config)#show rmon event

=====
                                Rmon Event
=====

INDEX DESCRIPTION          TYPE          COMMUNITY OWNER          LAST_TIME_SENT
-----

```

Variable Definitions

The following table defines parameters for the **show rmon** command.

Variable	Value
<i>address-map</i>	Displays the RMON2 address map. This RMON2 parameter expands RMON capacity to display information on network, transport, and application layers.
<i>alarm</i>	Displays the RMON1 alarm table.

Variable	Value
<i>application-host-stats WORD<1-64></i> Note: Exception: rlogin application is only supported on VSP 8600 Series. However, RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.	Displays RMON2 application host statistics from one of the following protocols: TCP, UDP, FTP, Telnet HTTP, rlogin, SSHv2, TFTP, SNMP, HTTPS. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>ctl-table</i>	Displays the RMON2 control tables. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>event</i>	Displays the RMON1 event table.
<i>history</i>	Displays the RMON1 history table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.
<i>log</i>	Displays the RMON1 log table.
<i>network-host-stats</i>	Displays RMON2 network-host statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>protocol-dist-stats</i>	Displays RMON2 protocol distribution statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>stats</i>	Displays the RMON1 statistics table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.

Displaying RMON Address Maps

View the maps of network layer address to physical address to interface.

The probe adds entries based on the source MAC and network addresses in packets without MAC-level errors.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON address maps:

```
show rmon address-map
```

Example

```
Switch:1# show rmon address-map
```

```
=====
                        Rmon Address Map Table
=====
PROTOIDX  HOSTADDR      SOURCE  PHYADDR      LASTCHANGE
-----

=====
```

View RMON Statistics

About This Task

View RMON statistics to manage network performance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON statistics:

```
show rmon stats
```

Example

```
Switch:1#show rmon stats
=====
                                Rmon Ether Stats
=====
INDEX  PORT    OWNER
-----
1      1/10    monitor
```

Displaying RMON Statistics for Specific Ports

Display individual RMON statistics for specific ports to manage network performance.

Note

Slot and port information can differ depending on hardware platform.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. View statistics for specific ports:

```
show interfaces GigabitEthernet statistics rmon {slot/port[/sub-port]
[-slot/port[/sub-port]][,...]}
```

Example

View RMON statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitEthernet statistics rmon 1/13
=====
                                Port Stats Rmon
=====
PORT  OCTETS   PKTS   MULTI  BROAD  CRC    UNDER  OVER  FRAG  COLLI
NUM   NUM      NUM    CAST   CAST   ALIGN  SIZE   SIZE  MENT  SION
-----
1/13  1943     21     8       13     0       0       0     0     0
```

Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics rmon** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View RMON Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON application host statistics:

```
show rmon application-host-stats WORD<1-64>
```

Example

```
Switch:1# show rmon application-host-stats ?
WORD<1-64> Select one of these application protocols
            {TCP|UDP|FTP|TELNET|HTTP|RLOGIN|SSH|TFTP|SNMP|HTTPS}
Switch:1# show rmon application-host-stats FTP
```

```
=====
                        Rmon Application Host Stats
=====
HOSTADDR      INPKT      OUTPKT      INOCT      OUTOCT      CREATETIME
-----
192.0.2.10    0           0           0           0           10/09/15 17:29:54
```

Note

Protocol support can vary across platforms.

Variable Definitions

The following table defines parameters for the **show rmon application-host-stats** command.

Variable	Value
WORD<1-64> Note: Exception: the rlogin application is only supported on VSP 8600 Series. However, RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.	Specifies one of the following application protocols: TCP, UDP, FTP, TELNET, HTTP, rlogin, SSH, TFTP, SNMP, HTTPS.

View RMON Control Tables

View RMON control tables to see the data source for both network layer and application layer host statistics.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON control tables:

```
show rmon ctl-table
```

Example

```
Switch:1# show rmon ctl-table

=====
                        Rmon Control Table

-----
```

**Note**

Protocol support can vary across platforms.

Displaying RMON Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON network host statistics:

```
show rmon network-host-stats
```

View RMON Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON protocol distribution statistics:

```
show rmon protocol-dist-stats
```

Example

```
Switch:1# show rmon protocol-dist-stats
```

```
=====
                          Rmon Protocol Dist Stats
=====
```

```
-----
PROTOCOL  PKTS      OCTETS
-----
IP        0         0
TCP       0         0
UDP       0         0
FTP       0         0
SSH       0         0
-----
```

TELNET	0	0
HTTP	0	0
RLOGIN	0	0
TFTP	0	0
SNMP	0	0
HTTPS	0	0

Note
Protocol support can vary across platforms.

Displaying RMON Status

View the current RMON status on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON status:
`show rmon`

Example

```
Switch:1# show rmon

RMON Info :
Status      : enable
```

View the RMON2 Configuration State of Management Interfaces

About This Task

Note
This procedure does not apply to VSP 8600 Series.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View information about the RMON2 configuration state:
`show mgmt rmon`

Example

```
Switch:1>show mgmt rmon

=====
Mgmt Rmon Information
=====

-----
1 Mgmt-oob1  disable  disable  0.0.0.0
3 Mgmt-clip  enable   enable   192.0.2.72
4 Mgmt-vlan  enable   enable   198.51.100.72
```

RMON Configuration Using EDM

This section contains procedures to configure RMON using Enterprise Device Manager (EDM).

For information about RMON statistics, see the following sections:

- [Enabling RMON Statistics](#) on page 2816
- [Viewing RMON Statistics](#) on page 2816

Enabling RMON Globally

About This Task

You must globally enable RMON before you can use RMON2 functions. If you attempt to enable an RMON2 function before the global flag is disabled, EDM informs you that the flag is disabled and prompts you to enable the flag. You can configure RMON1 while RMON is globally disabled.

If you want to use nondefault RMON parameter values, you can configure them before you enable RMON, or as you configure the RMON functions.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Options**.
3. Click the **Options** tab.
4. Select the **Enable** check box.
5. In the **UtilizationMethod** option, select a utilization method.
6. Click **Apply**.

Options Field Descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
Enable	Enables RMON. If you select the Enable check box, the RMON agent starts immediately. To disable RMON, clear the Enable check box and click Apply to save the new setting to NVRAM, and then restart the device. The default is disabled.
UtilizationMethod	Controls whether RMON uses a half-duplex or full-duplex formula to calculate port usage. After you select halfDuplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC1271 convention). After you select fullDuplex, RMON uses InOctets and OutOctets and 2X the speed of the port to calculate port usage. If you select fullDuplex, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is halfDuplex.

Enabling RMON on a Port or VLAN

Use the following procedure to enable RMON on an interface.

Before You Begin

- Enable RMON globally.

Procedure

1. Enable RMON on a VLAN:
 - a. In the navigation pane, expand the **Configuration > VLAN** folders.
 - b. Click **VLANs**.
 - c. Click the **Advanced** tab.
 - d. In the row for the VLAN, double-click the **RmonEnable** field, and then select **enable**.
 - e. Click **Apply**.
2. Enable RMON on a port:
 - a. In the Device Physical View, select a port.
 - b. In the navigation pane, expand the **Configuration > Edit > Port** folders.
 - c. Click **General**.
 - d. Click the **Interface** tab.
 - e. For the **RmonEnable** field, select **enable**.
 - f. Click **Apply**.

Enabling RMON1 History

About This Task

Use RMON1 to establish a history for a port and configure the bucket interval. For example, to gather RMON statistics over the weekend, you must have enough buckets to cover two days. Configure the history to gather one bucket every hour, and cover a 48-hour period. After you configure the history characteristics, you cannot modify them; you must delete the history and create another one.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, click **Insert**.
4. In the **Port** box, click the ellipsis (...) button.
5. Select a port.
6. Click **OK**.
7. In the **Buckets Requested** box, type the number of discrete time intervals to save data.
8. In the **Interval** box, type the interval in seconds.
9. In the **Owner** box, type the owner information.
10. Click **Insert**.

History Field Descriptions

Use the data in the following table to use the **History** tab.

Name	Description
Index	Specifies an index that uniquely identifies an entry in the historyControl table. Each entry defines a set of samples at a particular interval for an interface on the device. Index value ranges from 1-65535. The default value is 1.
Port	Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this historyControlEntry. The source is an interface on this device. To identify a particular interface, the object identifies the instance of the ifIndex object, defined in (4,6), for the desired interface. For example, if an entry receives data from interface 1, the object is ifIndex 1. The statistics in this group reflect all packets on the local network segment attached to the identified interface. You cannot modify this object if the associated historyControlStatus object is equal to valid(1).
BucketsRequested	Specifies the requested number of discrete time intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After this object is created or modified, the probe configures historyControlBucketsGranted as closely to this object as possible for the particular probe implementation and available resources. Values range from 1-65535. The default value is 50.
BucketsGranted	Specifies the number of discrete sampling intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After the associated BucketsRequested object is created or modified, the probe sets this object as closely to the requested value as possible for the particular probe implementation and available resources. The probe must not lower this value except as a result of a modification to the associated BucketsRequested object. Occasionally, the actual number of buckets associated with this entry is less than the value of this object. In this case, at the end of each sampling interval, the system adds a new bucket to the media-specific table. After the number of buckets reaches the value of this object and the system is going to add a new bucket to the media-specific table, the agent deletes the oldest bucket associated with this entry so the system can add the new bucket. After the value of this object changes to a value less than the current value, entries are deleted from the media-specific table associated with this entry. The agent deletes the oldest of these entries so that their number remains less than or equal to the new value of this object. After the value of this object changes to a value greater than the current value, the system allows the number of associated media-specific entries to grow.

Name	Description
Interval	Specifies the interval in seconds over which the system samples data for each bucket in the part of the media-specific table associated with this historyControlEntry. You can set this interval between 1–3600 seconds (1 hour). Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all of the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the historyControlInterval object to a value less than this interval, which is typically most important for the octets counter in a media-specific table. For example, on an Ethernet network, the etherHistoryOctets counter can overflow in approximately 1 hour at the maximum utilization. You cannot modify this object if the associated historyControlStatus object is equal to valid. The default value is 1800.
Owner	Specifies the entity that configured this entry and uses the assigned resources.

Disabling RMON1 History

About This Task

Disable RMON1 history on a port if you do not want to record a statistical sample from that port.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, select the row that contains the port ID to delete.
4. Click **Delete**.

Viewing RMON1 History Statistics

View RMON1 history statistics when you want to see a statistical sample from the switch. You can create a graph of the statistics in a bar, pie, chart, or line format.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **RMON History** tab.
5. Select the statistics you want to graph.
6. Click the button for the type of graph you require (bar, pie, chart, or line).

RMON History *Field Descriptions*

Use the data in the following table to use the **RMON History** tab.

Parameter	Description
SampleIndex	Identifies the particular sample this entry represents among all samples associated with the same history control entry. This index starts at one and increases by one as each new sample is taken.
Utilization	Specifies the best estimate of the mean physical layer network utilization on this interface during the sampling interval, in hundredths of a percent.
Octets	Specifies the total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets)
Pkts	Specifies the number of packets (including bad packets) received during this sampling interval.
BroadcastPkts	Specifies the number of good packets received during this sampling interval that were directed to the broadcast address.
MulticastPkts	Specifies the number of good packets received during this sampling interval that the system directs to a multicast address. This number does not include packets addressed to the broadcast address.
DropEvents	Specifies the total number of events in which the probe dropped packets due to lack of resources during this sampling interval. This number is not necessarily the number of packets dropped; it is only the number of times the system detects this condition.
CRCAAlignErrors	The number of packets the system receives during this sampling interval that had a length (excluding framing bits but including FCS octets) from 64–1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
UndersizePkts	Specifies the number of packets the system receives during this sampling interval that were less than 64 octets (excluding framing bits but including FCS octets), and were otherwise well formed.
OversizePkts	Specifies the number of packets the system receives during this sampling interval that were longer than 1518 octets (excluding framing bits but including FCS octets), but were otherwise well formed.

Parameter	Description
Fragments	Specifies the total number of packets received during this sampling interval that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for Fragments to increment because it counts both runts (which are normal occurrences due to collisions) and noise hits.
Collisions	Specifies the best estimate of the total number of collisions on this Ethernet segment during this sampling interval. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations transmit simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a small role when 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can detect only collisions when it transmits. Thus, probes placed on a station and a repeater can report the same number of collisions. An RMON probe inside a repeater can ideally report collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.

Creating an RMON1 Alarm

After you enable RMON1 globally, you also create a default rising and falling event. The default for the events is log-and-trap, which means that you receive notification through a trap as well as through a log entry.

Before You Begin

- You must globally enable RMON.

Procedure

- In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
- Click **Alarms**.
- Click the **Alarms** tab.
- Click **Insert**.
- In the **Variable** option, select a variable for the alarm.
If you select some variables, the system will prompt you for a port (or other object) on which you want to set an alarm.
- In the **SampleType** option, select a sample type.
- In the **Interval** box, type a sample interval in seconds.
- In the **Index** box, type an index number.
- In the **RisingThreshold** box, type a rising threshold value.

10. In the **RisingEventIndex** box, type a rising threshold event index.
11. In the **FallingThreshold** box, type a falling threshold value.
12. In the **FallingEventIndex** box, type a falling threshold event index.
13. In the **Owner** box, type the owner of the alarm.
14. Click **Insert**.

Alarms Field Descriptions

Use the data in the following table to use the **Alarms** tab.

Name	Description
Index	Uniquely identifies an entry in the alarm table. Each entry defines a diagnostic sample at a particular interval for an object on the device. The default is 1.
Interval	Specifies the interval, in seconds, over which the data is sampled and compared with the rising and falling thresholds. deltaValue sampling—Configures the interval short enough that the sampled variable is unlikely to increase or decrease by more than $2^{31}-1$ during a single sampling interval.
Variable	<p>Specifies the object identifier of the particular variable to be sampled. Only variables that resolve to an ASN.1 primitive type of INTEGER (INTEGER, Counter, Gauge, or TimeTicks) can be sampled.</p> <p>Alarm variables exist in three formats, depending on the type:</p> <ul style="list-style-type: none"> • A chassis, power supply, or fan-related alarm ends in x where the x index is hard-coded. No further information is required. • A card, spanning tree group (STG), or EtherStat alarm ends with a dot (.). You must enter a card number, STG ID, IP address, or EtherStat information. • A port alarm ends with no dot or index and requires that you use the port shortcut menu. An example of a port alarm is ifInOctets (interface incoming octet count). <p>Because the system articulates SNMP access control entirely in terms of the contents of MIB views, no access control mechanism exists to restrict the value of this object to identify only those objects that exist in a particular MIB view. Because no acceptable means of restricting the read access that is obtained through the alarm mechanism exists, the probe must grant only write access to this object in those views that have read access to all objects on the probe.</p> <p>After you configure a variable, if the supplied variable name is not available in the selected MIB view, the system returns a badValue error. After the variable name of an established alarmEntry is no longer available in the selected MIB view, the probe changes the status of this alarmEntry to invalid. You cannot modify this object if the associated alarmStatus object is equal to valid.</p>
SampleType	Specifies the method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is absoluteValue, the value of the system compares the selected variable directly with the thresholds at the end of the sampling interval. If the value of this object is deltaValue, the system subtracts the value of the selected variable at the last sample from the current value, and the system compares the difference with the thresholds. You cannot modify this object if the associated alarmStatus object is equal to valid. The default is deltaValue.

Name	Description
Value	Specifies the value of the statistic during the last sampling period. For example, if the sample type is <code>deltaValue</code> , this value is the difference between the samples at the beginning and end of the period. If the sample type is <code>absoluteValue</code> , this value is the sampled value at the end of the period. This system compares the value with the rising and falling thresholds. The value during the current sampling period is not made available until the period is completed and remains available until the next period is complete.
StartupAlarm	Specifies the alarm that is sent after this entry is first set to valid. If the first sample after this entry becomes valid is greater than or equal to the <code>risingThreshold</code> and <code>alarmStartupAlarm</code> is equal to the <code>risingAlarm</code> or the <code>risingOrFallingAlarm</code> , then the system generates a single rising alarm. If the first sample after this entry becomes valid is less than or equal to the <code>fallingThreshold</code> and <code>alarmStartupAlarm</code> is equal to the <code>fallingAlarm</code> or the <code>risingOrFallingAlarm</code> , then the system generates a single falling alarm. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .
RisingThreshold	Specifies a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes valid is greater than or equal to this threshold and the associated <code>alarmStartupAlarm</code> is equal to <code>risingAlarm</code> or <code>risingOrFallingAlarm</code> . After a rising event is generated, another such event is not generated until the sampled value falls below this threshold and reaches the <code>alarmFallingThreshold</code> . You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .
RisingEventIndex	Specifies the index of the <code>eventEntry</code> that is used after a rising threshold is crossed. The <code>eventEntry</code> identified by a particular value of this index is the same as identified by the same value of the <code>eventIndex</code> object. If no corresponding entry exists in the <code>eventTable</code> , no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> . Note: You must create the event prior to associating it to an alarm.
FallingThreshold	Specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes valid is less than or equal to this threshold and the associated <code>alarmStartupAlarm</code> is equal to <code>fallingAlarm</code> or <code>risingOrFallingAlarm</code> . After the system generates a falling event, the system does not generate another similar event until the sampled value rises above this threshold and reaches the <code>alarmRisingThreshold</code> . You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .

Name	Description
FallingEventIndex	Specifies the index of the eventEntry that the system uses after a falling threshold is crossed. The eventEntry identified by a particular value of this index is the same as identified by the same value of the eventIndex object. If there is no corresponding entry in the eventTable, no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated alarmStatus object is equal to valid. Note: You must create the event prior to associating it to an alarm.
Owner	Specifies the entity that configured this entry and is therefore using the resources assigned to it.
Status	Specifies the status of this alarm entry.

Viewing RMON1 Alarms

View the RMON1 alarm information to see alarm activity.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Alarm** tab.

Deleting an RMON1 Alarm

Delete an RMON1 alarm if you no longer display it in the log.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Select the alarm you must delete.
4. Click **Delete**.

Creating an RMON1 Event

Create a custom rising and falling RMON1 event to specify if alarm information is sent to a trap, a log, or both.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Click **Insert**.
5. In the **Description** box, type an event name.

6. In the **Type** option, select an event type.
The default configuration is log-and-trap. To save memory, configure the event type to log. To reduce traffic from the system, configure the event type to snmp-log.

If you select snmp-trap or log, you must configure trap receivers.
7. In the **Community** box, type an SNMP community.
8. In the **Owner** box, type the owner of this event.
9. Click **Insert**.

Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
Index	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
Description	Specifies a comment that describes this event entry.
Type	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
Community	Specifies the SNMP community where you can send SNMP traps.
LastTimeSent	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
Owner	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

Viewing RMON1 Events

View RMON1 events to see how many events occurred.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.

Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
Index	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
Description	Specifies a comment that describes this event entry.
Type	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
Community	Specifies the SNMP community where you can send SNMP traps.
LastTimeSent	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
Owner	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

Deleting an Event

Delete an event after you no longer require the alarm information.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Select the event you must delete.
5. Click **Delete**.

Viewing the RMON Log

About This Task

View the trap log to see which activity occurred.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Log** tab.

Log Field Descriptions

Use the data in the following table to use the **Log** tab.

Name	Description
EventIndex	Specifies an index that uniquely identifies an entry in the event table. Each entry defines one event that is generated under appropriate conditions.
Index	Specifies an index that uniquely identifies an entry in the log table generated by the same event entries.
Time	Specifies the creation time for this log entry.
Description	Specifies an implementation dependent description of the event that activated this log entry.

Enabling RMON Statistics

About This Task

Enable Ethernet statistics collection for RMON.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. Click the **Ethernet Statistics** tab.
4. Click **Insert**.
5. Next to the **Port** box, click the ellipsis (...) button.
6. Select a port.
7. Click **OK**.
8. In the **Owner** box, type the name of the owner entity.
9. Click **OK**.
10. Click **Insert**.

Ethernet Statistics Field Descriptions

Use the data in the following table to use the **Ethernet Statistics** tab.

Name	Description
Index	Uniquely identifies an entry in the Ethernet Statistics table. The default is 1.
Port	Identifies the source of the data that this etherStats entry is configured to analyze.
Owner	Specifies the entity that configured this entry and therefore uses the assigned resources.

Viewing RMON Statistics

Before You Begin

- You must enable RMON statistics collection.

About This Task

Use the following procedure to view RMON statistics for each port.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **RMON** tab.
5. Select the statistics you want to graph.
6. Select a graph type:
 - bar
 - pie
 - chart
 - line

RMON Field Descriptions

The following table describes fields on the **RMON** tab.

Name	Description
Octets	<p>Specifies the number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets).</p> <p>You can use this object as a reasonable estimate of Ethernet utilization. If additional precision is desired, sample the Pkts and Octets objects before and after a common interval. The differences in the sampled values are Pkts and Octets, and the number of seconds in the interval is Interval. These values are used to calculate the Utilization as follows:</p> $\text{Pkts} * (9.6+6.4) + (\text{Octets} * .8)$ <p>Utilization = Interval * 10,000</p> <p>The result of this equation is the value Utilization, which is the percent utilization of the Ethernet segment on a scale of 0 to 100 percent.</p>
Pkts	Specifies the number of packets (including bad packets, broadcast packets, and multicast packets) received.
BroadcastPkts	Specifies the number of good packets received that were directed to the broadcast address. This number does not include multicast packets.
MulticastPkts	Specifies the number of good packets received that were directed to a multicast address. This number does not include packets directed to the broadcast address.
CRCAAlignErrors	Specifies the number of packets received that had a length (excluding framing bits, but including FCS octets) between 64 and 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
UndersizePkts	Specifies the number of packets received that were less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.

Name	Description
OverSizePkts	Specifies the number of packets received that were longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.
Fragments	Specifies the number of packets received that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for Fragments to increment because it counts both runs (which are normal occurrences due to collisions) and noise hits.
Collisions	Specifies the best estimate of the number of collisions on this Ethernet segment. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations are transmitting simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a much smaller role when considering 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can only detect collisions when it is transmitting. Thus, probes placed on a station and a repeater reports the same number of collisions. An RMON probe inside a repeater reports collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.

View the Protocol Directory

View the protocol directory to see the list of protocols that RMON2 can monitor. You cannot change the list of protocols.

About This Task

The protocol directory MIB is enabled by default for the predefined protocols.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Directory**.
3. Click the **Protocol Directories** tab.

Protocol Directories Field Descriptions

The following table defines parameters for the **Protocol Directories** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
<p>Protocol</p> <p>Note: Exception: rlogin application is only supported on VSP 8600 Series. However, RMON2 counts application packets received on any platform on which the application is not enabled or supported, before dropping them.</p>	<p>Shows the protocols RMON2 can monitor:</p> <ul style="list-style-type: none"> • Internet Protocol (IP) • Secure Shell version 2 (SSHv2) • Transmission Control Protocol (TCP) • User Datagram Protocol (UDP) • File Transfer Protocol (FTP) • Hypertext Transfer Protocol (HTTP) • Telnet • Remote login (rlogin) • Trivial File Transfer Protocol (TFTP) • Simple Networking Management Protocol (SNMP)
AddressMapConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn <p>If the value is supportedOn, the probe adds entries to the Address Map tab that maps the network layer address to the MAC layer address.</p>
HostConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn <p>If the value is supportedOn, the probe adds entries to the Host Control tab to collect statistics for network layer and application layer hosts.</p>
MatrixConfig	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> • notSupported • supportedOff • supportedOn
Owner	Shows the entity that configured this entry.

Viewing the Data Source for Protocol Distribution Statistics

View the Distribution Control tab to see the network segment data source on which the protocol distribution statistics are measured. The management IP mentioned as a data source represents the IP that the SNMP agent uses to access the switch.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Control** tab.

Distribution Control Field Descriptions

Use the data in the following table to use the **Distribution Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Specifies the source of data for this protocol distribution.
DroppedFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.
Owner	Shows the entity that configured this entry.

Viewing Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Stats** tab.

Distribution Stats Field Descriptions

Use the data in the following table to use the **Distribution Stats** tab.

Name	Description
LocalIndex	Identifies the protocol distribution an entry is part of, as well as the particular protocol that it represents.
Pkts	Shows the number of packets without errors received for this protocol type. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
Octets	Shows the number of octets in packets received for this protocol type since it was added to the table. This value does not include octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.

Viewing the Host Interfaces Enabled for Monitoring

View the entries in the address map control tab to see which host interfaces are enabled for monitoring on the switch. Each entry in this table enables the discovery of addresses on a new interface.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map Control** tab.

Address Map Control Field Descriptions

Use the data in the following table to use the **Address Map Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Shows the source of data for the entry.
DroppedFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
Owner	Shows the entity that configured this entry.

Viewing Address Mappings

View the mappings of network layer address to physical address to interface.

About This Task

The probe adds entries on this tab based on the source MAC and network addresses in packets without MAC-level errors.

The probe populates this table for all protocols on the **Protocol Directories** tab with a value of **AddressMapConfig** equal to **supportedOn**.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map** tab.

Address Map Field Descriptions

Use the data in the following table to use the **Address Map** tab.

Name	Description
LocalIndex	Shows a unique identifier for the entry in the table.
HostAddress	Shows the network address for this entry. The format of the value depends on the protocol portion of the local index.
Source	Shows the interface or port on which the network address was most recently seen.
PhysicalAddress	Shows the physical address on which the network address was most recently seen.
LastChange	Shows the value of the sysUpTime when the entry was created or last changed. If this value changes frequently, it can indicate duplicate address problems.

Viewing the Data Source for Host Statistics

View the Host Control tab to see the data source for both network layer and application layer host statistics.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Host Control** tab.

Host Control Field Descriptions

Use the data in the following table to use the **Host Control** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
DataSource	Shows the source of data for the associated host table. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface.
NHDropFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
AHDropFrames	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
Owner	Shows the entity that configured this entry.

Viewing Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Network Host Stats** tab.

Network Host Stats Field Descriptions

Use the data in the following table to use the **Network Host Stats** tab.

Name	Description
LocalIndex	Shows a unique identifier for the entry in the table.
HostAddress	Shows the host address for this entry.
InPkts	Shows the number of packets without errors transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.

Name	Description
OutPkts	Shows the number of packets without errors transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
InOctets	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
OutOctets	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.

Viewing Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Application Layer Host**.
3. Click the **Application Host Stats** tab.

Application Host Stats Field Descriptions

Use the data in the following table to use the **Application Host Stats** tab.

Name	Description
Index	Shows a unique identifier for the entry in the table.
HostAddress	Identifies the network layer address of this entry.
LocalIndex	Identifies the network layer protocol of the address.
InPkts	Shows the number of packets for this protocol type, without errors, transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
OutPkts	Shows the number of packets for this protocol type, without errors, transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.

Name	Description
InOctets	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
OutOctets	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
CreateTime	Shows the value of the sysUpTime when the entry was last activated.

RMON Alarm Variables

RMON alarm variables are divided into three categories. Each category has subcategories.

The following table lists the alarm variable categories and provides a brief variable description.

Table 205: RMON alarm variables

Category	Subcategory	Variable	Definition
Security		rcCliNumAccessViolations.0	The number of CLI access violations detected by the system.
		rcWebNumAccessBlocks.0	The number of accesses the web server blocked.
		snmpInBadCommunityNames.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
Errors	Interface	ifInDiscards	The number of inbound packets discarded even though no errors were detected to prevent the packets being deliverable to a higher-layer protocol. One possible reason for discarding a packet is to free buffer space.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ifInErrors	For packet-oriented interfaces, the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors, preventing them from being deliverable to a higher-layer protocol.
		ifOutDiscards	The number of outbound packets discarded even though no errors were detected to prevent the packets being transmitted. One possible reason for discarding such a packet is to free buffer space.
		ifOutErrors	For packet-oriented interfaces, the number of outbound packets that were not transmitted because of errors. For character-oriented or fixed-length interfaces, the number of outbound transmission units that were not transmitted because of errors.
	Ethernet	dot3StatsAlignmentErrors	A count of frames received on a particular interface that are not an integral number of octets in length and do not pass the Frame Check Sequence (FCS) check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions exist are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsFCSErrors	A count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
		dot3StatsSingleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts object, the ifOutMulticastPkts object, or the ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsMultipleCollisionFrames object.
		dot3StatsMultipleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts, ifOutMulticastPkts, or ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsSingleCollisionFrames object.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsSQETestErrors	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation is described in section 7.2.4.6 of the same document.
		dot3StatsDeferredTransmissions	A count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.
		dot3StatsLateCollisions	The number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.
		dot3StatsExcessiveCollisions	A count of frames where the transmission on a particular interface fails due to excessive collisions.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsInternalMacTransmitErrors	<p>A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object.</p> <p>The precise meaning of the count represented by an instance of this object is implementation specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.</p>
		dot3StatsCarrierSenseErrors	<p>The number of times the carrier sense condition was lost or never asserted when the switch attempted to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.</p>
		dot3StatsFrameTooLongs	<p>A count of frames received on a particular interface that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.</p>

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot3StatsInternalMacReceiveErrors	<p>A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is counted by an instance of this object only if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object.</p> <p>The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.</p>
	IP	ipInHdrErrors.0	<p>The number of input datagrams discarded due to errors in the datagram IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, and errors discovered in processing IP options.</p>
		ipInDiscards.0	<p>The number of discarded input IP datagrams where no problems were encountered to prevent continued processing. An example of why they were discarded can be lack of buffer space. This counter does not include any datagrams discarded while awaiting reassembly.</p>
		ipOutDiscards.0	<p>The number of output IP datagrams where no problems were encountered to prevent transmission to the destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if packets meet this (discretionary) discard criterion.</p>

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ipFragFails.0	The number of IP datagrams discarded because they needed to be fragmented at this entity but were not, for example, because the Don't Fragment flag was set.
		ipReasmFails.0	The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so forth). This is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.
		icmpInParmProbs.0	The number of ICMP In parameter problem messages received.
		icmpOutParmProbs.0	The number of ICMP Out parameter problem messages received.
	MLT	rcStatMltEtherAlignmentErrors	The number of frames received on an MLT that are not an integral number of octets in length, but do not pass the FCS check.
		rcStatMltEtherFCSErrors	The number of frames received on an MLT that are an integral number of octets in length, but do not pass the FCS check.
		rcStatMltEtherSingleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by exactly one collision.
		rcStatMltEtherMultipleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by more than one collision.
		rcStatMltEtherSQETestError	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular MLT.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltEtherDeferredTransmiss	A count of frames where the first transmission attempt on a particular MLT is delayed because the medium is busy. The count represented by an instance of this object.
		rcStatMltEtherLateCollisions	The number of times that a late collision is detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512-bit-times corresponds to 51.2-microseconds on a 10 Mb/s system.
		rcStatMltEtherExcessiveCollis	The number of times that excessive collisions are detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10-Mb/s system.
		rcStatMltEtherMacTransmitError	A count of frames where the transmission on a particular MLT fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object.
		rcStatMltEtherCarrierSenseError	The number of times the carrier sense condition was lost or never asserted when attempting to transmit a frame on a particular MLT. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltEtherFrameTooLong	A count of frames received on a particular MLT that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user).
		rcStatMltEtherMacReceiveError	A count of frames for which reception on a particular MLT fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object.
	Other	rcTblArNoSpace	The number of entries not added to the address translation table due to lack of space.
		snmplnAsnParseErrs.0	The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when it decodes received SNMP messages.
		rcStgPortInBadBpdus	The number of bad BPDUs received by this port.
		dot1dTpPortInDiscards	Count of valid frames received that were discarded (that is, filtered) by the forwarding process.
Traffic	Interface	ifInOctets	The total number of octets received on the interface, including framing characters.
		ifInMulticastPkts	The number of packets, delivered by this sublayer to a higher sublayer, that are addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both Group and Functional addresses.
		ifInBroadcastPkts	The number of packets, delivered by this sublayer to a higher (sub) layer, that are addressed to a broadcast address at this sublayer.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		ifInUnkownProtos	For packet-oriented interfaces, the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that are discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0.
		ifOutOctets	The total number of octets transmitted from the interface, including framing characters.
		ifOutMulticastPkts	The total number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that are discarded or not sent. For a MAC layer protocol, this includes both Group and Functional addresses.
		ifoutBroadcastPkts	The total number of packets that higher level protocols requested transmitted, and that were addressed to a broadcast address at this sublayer, including those discarded or not sent.
		ifLastChange	The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, this object contains a value of zero.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
	RmonEther Stats	etherStatsOctets	The total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets). Use this object as a reasonable estimate of Ethernet utilization. For greater precision, sample the etherStatsPkts and etherStatsOctets objects before and after a common interval.
		etherStatsPkts	The total number of packets (including bad packets, broadcast packets, and multicast packets) received.
		etherStatsBroadcastPkts	The total number of good packets received that are directed to the broadcast address. This number does not include multicast packets.
		etherStatsMulticastPkts	The total number of good packets received that are directed to a multicast address. This number does not include packets directed to the broadcast address.
		etherStatsCRCAAlignErrors	The total number of packets received that had a length (excluding framing bits, but including FCS octets) of 64 to 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
		etherStatsUndersizePkts	The total number of packets received that are less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.
		etherStatsOversizePkts	The total number of packets received that are longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		etherStatsFragments	The total number of packets received that are less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for etherStatsFragments to increment because it counts both runts (which are normal occurrences due to collisions) and noise hits.
		etherStatsCollisions	The best estimate of the total number of collisions on this Ethernet segment.
	IP	ipInReceives.0	All incoming IP packets.
		ipInAddrErrors.0	The number of bad IP destination addresses.
		ipForwDatagrams.0	IP packets forwarded.
		ipInUnknownProtos.0	Number of unsupported IP protocols.
		ipInDelivers.0	The number of IP In packets delivered.
		ipOutRequests.0	The total number of IP datagrams that local IP user protocols supplied to IP in request for transmission.
		ipOutNoRoutes.0	The number of IP datagrams discarded because no route was found to transmit to the destination.
		ipFragOKs.0	The number of IP datagrams successfully fragmented.
		ipFragCreates.0	The number of IP datagram fragments generated as a result of fragmentation.
		ipReasmReqds.0	The number of requests to reassemble fragments.
		ipReasmOKs.0	The number of fragments reassembled successfully.
	ICMP	icmpInSrcQuenchs.0	The number of ICMP Source Quench messages received.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		icmpInRedirects.0	The number of ICMP redirect messages.
		icmpInEchos.0	The number of ICMP Echo requests messages received.
		icmpInEchosReps.0	The number of ICMP Echo reply messages received.
		icmpInTimeStamps.0	The number of ICMP timestamp request messages received.
		icmpInTimeStampsReps.0	The number of ICMP timestamp reply messages received.
		icmpInAddrMasks.0	The number of ICMP mask request messages reviewed.
		icmpInAddrMasksReps.0	The number of ICMP mask reply messages reviewed.
		icmpInDestUnreachs.0	The number of ICMP destinations unreachable messages received.
		icmpInTimeExcds.0	The number of ICMP Time Exceeded messages received.
		icmpOutSrcQuenchs.0	The number of ICMP Source Quench messages sent.
		icmpOutRedirects.0	The number of ICMP redirect messages sent.
		icmpOutEchos.0	The number of ICMP Echo request messages sent.
		icmpOutEchosReps.0	The number of ICMP Echo reply messages sent.
		icmpOutTimeStamps.0	The number of ICMP Timestamp request messages sent.
		icmpOutTimeStampsReps.0	The number of ICMP Timestamp reply messages sent.
		icmpOutAddrMasks.0	The number of ICMP Address mask messages sent.
		icmpOutAddrMasksReps.0	The number of ICMP Address mask reply messages sent.
		icmpOutDestUnreachs.0	The number of ICMP destination unreachable messages sent.
		icmpOutTimeExcds.0	The number of ICMP time exceeded messages sent.
	Snmp	snmpInPkts.0	The total number of messages delivered to the SNMP entity from the transport service.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpOutPkts.0	The total number of SNMP messages passed from the SNMP protocol entity to the transport service.
		snmpInBadVersions.0	The total number of SNMP messages delivered to the SNMP protocol entity that were intended for an unsupported SNMP version.
		snmpInBadCommunityUses.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation that was not allowed by the SNMP community named in the message.
		snmpInTooBigs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmpInNoSuchNames.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
		snmpInBadValues. 0	The total number of SNMP PDUs received that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmpInReadOnlys.0	The total number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU that contains the value readOnly in the error-status field; as such, this object is provided as a means of detecting incorrect implementations of the SNMP.
		snmpInGenErrs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is genErr.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpInTotalReqVars.0	The total number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs.
		snmpInTotalSetVars.0	The total number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.
		snmpInGetRequests.0	The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetNexts.0	The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity.
		snmpInSetRequests.0	The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetResponses.0	The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity.
		snmpInTraps.0	The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity.
		snmpOutTooBigs.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmpOutNoSuchNames.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is noSuchName.
		snmpOutBadValues.0	The total number of SNMP PDUs sent that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmpOutGenErrs.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is genErr.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		snmpOutGetRequests.0	The total number of SNMP Get-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetNexts.0	The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity.
		snmpOutSetRequests.0	The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetResponses.0	The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity.
		snmpOutTraps.0	The total number of SNMP Trap PDUs generated by the SNMP protocol entity.
	Bridge	rcStgTimeSinceTopologyChange	The time (in hundredths of a second) since the last topology change was detected by the bridge entity.
		rcStgTopChanges	The total number of topology changes detected by this bridge since the management entity was last reset or initialized.
		rcStgMaxAge	The maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded, in hundredths of a second. This is the actual value that this bridge is currently using.
		rcStgPortForwardTransitions	The number of times this port transitioned from the Learning state to the Forwarding state.
		rcStgPortInConfigBpdus	The number of Config BPDUs received by this port.
		rcStgPortInTcnBpdus	The number of Topology Change Notification BPDUs received by this port.
		rcStgPortOutConfigBpdus	The number of Config BPDUs transmitted by this port.
		rcStgPortOutTcnBpdus	The number of Topology Change Notification BPDUs transmitted by this port.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		dot1dTpPortInFrames	The number of frames received by this port from its segment. A frame received on the interface corresponding to this port is counted by this object only if it is for a protocol being processed by the local bridging function, including bridge management frames.
		dot1dTpPortOutFrames	The number of frames transmitted by this port to its segment. A frame transmitted on the interface corresponding to this port is counted by this object if and only if it is for a protocol processed by the local bridging function, including bridge management frames.
		dot1dTpLearnedEntryDiscards.0	The total number of Forwarding Database entries learned but discarded due to a lack of space to store them in the Forwarding Database. If this counter increases, it indicates that the forwarding database is regularly becoming full (a condition that has negative performance effects on the subnetwork). If this counter has a significant value but does not increase, it indicates that the problem occurred but is not persistent.
	Utilization	rcSysBufferUtil.0	Buffer utilization as a percentage of the total amount of buffer space in the system. A high value indicates congestion.
		rcSysNVRamUsed.0	Nonvolatile RAM (NVRAM) in use in kilobytes.
		rcSysLastChange.0	Last management-initiated configuration change since sysUpTime.
		rcSysLastVlanChange.0	Last management-initiated VLAN configuration change since sysUpTime.
	MLT	rcStatMltIfExtnIfInMulticastPkts	The total number of multicast packets delivered to this MLT interface.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfInBroadcastPkts	The total number of broadcast packets delivered to this MLT Interface.
		rcStatMltIfExtnIfOutMulticastPkts	The total number of MLT interface multicast packets delivered to this MLT interface.
		rcStatMltIfExtnIfOutBroadcastPkts	The total number of MLT interface broadcast packets delivered to this MLT interface.
		rcStatMltIfExtnIfHCInOctets	The total number of octets received on this MLT interface including framing characters detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInUcastPkts	The number of packets delivered by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInMulticastPkt	The total number of multicast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInBroadcastPkt	The total number of broadcast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOctets	The total number of octets transmitted from the MLT interface, including framing characters.
		rcStatMltIfExtnIfHCOutUcastPkts	The number of packets transmitted by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.

Table 205: RMON alarm variables (continued)

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfHCOutMulticast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a multicast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOutBroadcast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.

**Note**

In addition to these elements that are offered in a graphical way by EDM, you can manually set any valid OID in the variable field to be monitored by an alarm. For these cases, the name of the variable cannot be translated automatically in OID, the exact OID must be set as a sequence of numbers.

Route Filtering and IP Policies

When the switch routes IP traffic, you can apply a number of filters to manage, accept, redistribute, and announce policies for unicast routing table information. Filters apply differently to different unicast routing protocols.

Note

IPv6 ingress QoS ACL/Filters and IPv6 Egress Security and QoS ACL/Filters are not supported. For information on the maximum number of IPv6 ingress port/vlan security ACL/filters supported on the switch, see [VOSS Release Notes](#).

The following figure shows how filters apply to BGP, RIP, and OSPF protocols.

Figure 222: Route filtering for BGP, RIP, and OSPF routing protocols

The following figure shows how filters apply to the IS-IS protocol for Fabric Connect Layer 3 VSNs or IP Shortcuts.

Figure 223: Route filtering for the IS-IS routing protocol

Accept Policies

Accept policies are applied to incoming traffic to determine whether to add the route to the routing table. Accept policies are applied differently to protocols, as follows:

- RIP and BGP—filters apply to all incoming route information.

- OSPF—filters apply only to external route information. Internal routing information is not filtered because otherwise, other routers in the OSPF domain can have inconsistent databases that can affect the router view of the network topology.
- IS-IS —filters apply to all incoming route information.

In a network with multiple routing protocols, you can prefer specific routes from RIP instead of from OSPF. The network prefix is a commonly used match criterion for accept policies.

Redistribution Filters

Redistribution filters notify changes in the route table to the routing protocol (within the device). With redistribution filters, providing you do not breach the protocol rules, you can choose not to advertise everything that is in the protocol database, or you can summarize or suppress route information. By default, no external routes are leaked to protocols that are not configured.

Announce Policies

Announce policies are applied to outgoing advertisements to neighbors or peers in the protocol domain to determine whether to announce specific route information. Out filtering applies to RIP updates and BGP NLRI updates.

In contrast, announce policies are not applied to IS-IS or OSPF information because routing information must always be consistent across the domain. To restrict the flow of external route information in the IS-IS or OSPF protocol database, apply redistribution filters instead of announce policies.

Route Filtering Stages

The following figure shows the three distinct filter stages that are applied to IP traffic.

These stages are:

- Filter stage 1 is the accept policy or in filter that applies to incoming traffic to detect changes in the dynamic (protocol-learned) routing information, which are then submitted to the routing table.
- Filter stage 2 is the redistribution filter that applies to the entries in the routing table to the protocol during the leaking process.
- Filter stage 3 is the announce policy or out filter that applies to outgoing traffic within a protocol domain.

Figure 224: Route filtering stages

The following figure shows the logical process for route filtering on the switch.

Figure 225: Route filtering logic

Prefix list

In the switch software, you can create one or more IP prefix lists and apply these lists to IP route policy.

Route Policy Definition

You can define an IP route policy and its attributes globally, and then apply them individually to interfaces and protocols. You can also form a unified database of route policies that the RIP or OSPF protocol can use for type of filtering purpose. A name or ID identifies a policy.

Under a policy you can have several sequence numbers. If you do not configure a field in a policy, the system displays the field as 0 in CLI show command output. This value indicates that the device ignores the field in the match criteria. Use the clear option to remove existing configurations for the field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce or redistribute purposes.

You can only apply one policy for each purpose (RIP Announce, for example) on a given RIP interface. In this case, all sequence numbers under the policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

The following tables display the accept, announce, and redistribute policies for RIP, OSPF, IS-IS and BGP. The tables also display which matching criteria apply for a certain routing policy. In these tables, 1 denotes advertise router, 2 denotes RIP gateway, and 3 denotes that external type 1 and external type 2 are the only options.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Note

IPv4 and IPv6 route-maps cannot be configured on the same match statement.

IP policy configuration using the CLI

Configure IP policies to form a unified database of route policies that Routing Information Protocol (RIP) or Open Shortest Path First (OSPF) can use for filtering tasks.

A policy is identified by a name or an ID. Under a given policy you can have several sequence numbers, each of which is equal to one policy in the old convention. Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, use only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply one policy for one purpose, for example, RIP announce on a RIP interface. All sequence numbers under the given policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

About This Task

Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a prefix list:

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [id <1-2147483647>]
[le <0-32>]
```

3. (Optional) Rename an existing prefix list:

```
ip prefix-list WORD<1-64> name WORD<1-64>
```

4. Display the prefix list:

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [WORD <1-64>]
```

Example

Configure a prefix-list. Display the prefix list.

```
Switch> enable
Switch# configure terminal
Switch(config)# ip prefix-list LIST1 192.0.2.1/255.255.255.0
Switch(config)# show ip prefix-list LIST1
```

```
=====
Prefix List - GlobalRouter
```

```

=====
                PREFIX                MASKLEN FROM TO
-----
List 1      LIST1:
           192.0.1.2.1      24      24      24
1 Total Prefix List entries configured
-----
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range

```

Variable definitions

Use the data in the following table to use the **ip prefix-list** command.

Variable	Value
{A.B.C.D/X}	Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> a.b.c.d/x a.b.c.d/x.x.x.x default
ge <0-32>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
id <1-2147483647>	Specifies the Prefix list ID.
le <0-32>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
name WORD<1-64>	Renames the specified prefix list. The name length is 1-64 characters.
WORD<1-64>	Specifies the name for a new prefix list.

Use the data in the following table to use the **show ip prefix-list** command.

Variable	Value
{A.B.C.D}	Specifies the prefix to include in the command output.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0-512.
WORD<1-64>	Specifies a prefix list, by name, to use for the command output.

Use the following table to use the **show ip prefix-list** command output.

Variable	Value
PREFIX	Indicates the member of a specific prefix list.
MASKLEN	Indicates the prefix mask length in bits.
FROM	Indicates the prefix mask starting point in bits.
TO	Indicates the prefix mask endpoint in bits.

Configure IP Route Policies

Configure a route policy so that the device can control routes that certain packets can take. For example, you can use a route policy to deny certain Border Gateway Protocol (BGP) routes.

The route policy defines the matching criteria and the actions taken if the policy matches.

About This Task

After you create and enable the policy, you can apply it to an interface. You can apply one policy for one purpose, for example, RIP Announce, on a given RIP interface. In this case, all sequence numbers under the given policy apply to that filter.

Create and enable the policy for IS-IS accept policies for Fabric Connect for Layer 3 Virtual Services Networks (VSNs) and IP Shortcuts, then apply the IS-IS accept policy filters.

Note

After you configure route-map in Global Configuration mode or VRF Router Configuration mode, the device enters Route-Map Configuration mode, where you configure the action the policy takes, and define other fields the policy enforces.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Note

You cannot configure IPv4 and IPv6 route-maps on the same match statement.

Procedure

1. Enter Route-Map Configuration mode:

```
enable
```

```
configure terminal
```

```
route-map WORD<1-64> <1-65535>
```

2. At the route-map prompt, define the match criteria for the policy:

```
match {as-path WORD<0-256> | community WORD<0-256> | community-exact
enable | extcommunity WORD<0-1027> | interface WORD<0-259> | local-
preference <0-2147483647> | metric <0-65535> | metric-type-isis <any|
internal|external> | network WORD<0-259> | next-hop WORD<0-259> |
protocol WORD<0-60> | route-source WORD<0-259> | route-type <any|
local|internal|external|external-1|external-2> | tag WORD<0-256> | vrf
WORD<1-16> | vrfids WORD<0-512> }
```

3. Define the action the policy takes:

- a. Allow the route:

```
permit
```

OR

- b. Ignore the route:

```
no permit
```

4. Define the set criteria for the policy:

```
set {as-path WORD<0-256> | as-path-mode <tag|prepend> | automatic-tag
enable | community WORD<0-256> | community-mode <additive|none|
unchanged> | injectlist WORD<0-1027> | ip-preference <0-255> | local-
preference <0-2147483647> | mask <A.B.C.D> | metric <0-65535> |
metric-type <type1|type2> | metric-type-internal <0-1> | metric-type-
isis <none|internal|external> | metric-type-live-metric | next-hop
WORD<0-256> | nssa-pbit enable | origin <igp|egp|incomplete> | origin-
egp-as <0-65535> | tag WORD<0-256> | weight <0-65535> }
```

5. Display current information about the IP route policy:

```
show route-map [WORD<1-64>] [<1-65535>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

Example

Enter Route-Map Configuration mode. At the route-map prompt, define the fields the policy enforces. Define the action the policy takes. Display current information about the IP route policy.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#route-map RedisStatic 1
Switch:1(route-map)# match metric 0
Switch:1(route-map)# permit
Switch:1(route-map)# show route-map RedisStatic
=====

PRMT DIS

Variable Definitions

Use the data in the following table to use the **match** command.

Variable	Value
<i>as-path</i> WORD<0-256>	Configures the device to match the as-path attribute of the Border Gateway Protocol (BGP) routes against the contents of the specified AS-lists. This field is used only for BGP routes and ignored for all other route types. WORD <0-256> specifies the list IDs of up to four AS-lists, separated by a comma. Use the no operator to disable match as-path: no match as-path WORD<0-256>
<i>community</i> WORD<0-256>	Configures the device to match the community attribute of the BGP routes against the contents of the specified community lists. This field is used only for BGP routes and ignored for all other route types. WORD <0-256> specifies the list IDs of up to four defined community lists, separated by a comma. Use the no operator to disable match community: no match community WORD<0-256>
<i>community-exact</i> enable	When disabled, configures the device so match community-exact results in a match when the community attribute of the BGP routes match an entry of a community-list specified in match-community. When enabled, configures the device so match-community-exact results in a match when the community attribute of the BGP routes matches all of the entries of all the community lists specified in match-community. enable enables match community-exact. Use the no operator to disable match community-exact: no match community-exact enable
<i>extcommunity</i> WORD <0-1027>	Configures the device to match the extended community. WORD<0-1027> specifies an integer value from 1-1027 that represents the community list ID you want to create or modify.
<i>interface</i> WORD <0-259>	If configured, configures the device to match the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other route types. WORD <0-259> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match-interface: no match interface WORD <0-259>
<i>local-preference</i> <0-2147483647>	Configures the device to match the local preference, applicable to all protocols. <0-2147483647> specifies the preference value.

Variable	Value
<code>metric <0-65535></code>	Configures the device to match the metric of the incoming advertisement or existing route against the specified value. If 0, this field is ignored. <code><0-65535></code> specifies the metric value. The default is 0.
<code>network WORD <0-259></code>	Configures the device to match the destination network against the contents of the specified prefix lists. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match network: <code>no match network WORD <0-259></code>
<code>next-hop WORD<0-259></code>	Configures the device to match the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match next hop: <code>no match next-hop WORD<0-259></code>
<code>protocol WORD<0-60></code>	Configures the device to match the protocol through which the route is learned. <code>WORD <0-60></code> is xxx, where xxx is local, ospf, ebgp, ibgp,isis, rip, static, or a combination separated by . Use the no operator to disable match protocol: <code>no match protocol WORD<0-60></code>
<code>route-source WORD<0-259></code>	Configures the system to match the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. <code>WORD <0-259></code> specifies the name of up to four defined prefix lists, separated by a comma. Use the no operator to disable match route source: <code>no match route-source WORD<0-259></code>
<code>route-type {any local internal external external-1 external-2}</code>	Configures a specific route type to match (applies only to OSPF routes). <code>any local internal external external-1 external-2</code> specifies OSPF routes of the specified type only (External-1 or External-2). Another value is ignored.
<code>tag WORD<0-256></code>	Specifies a list of tags used during the match criteria process. Contains one or more tag values. <code>WORD<0-256></code> is a value from 0-256.
<code>[vrf WORD<1-16>] [vrfs WORD<0-512>]</code>	Configures a specific VRF to match (applies only to RIP routes).

Use the data in the following table to use the **set** command.

Variable	Value
<code>as-path WORD<0-256></code>	Configures the device to add the AS number of the AS-list to the BGP routes that match this policy. <code>WORD<0-256></code> specifies the list ID of up to four defined AS-lists separated by a comma. Use the no operator to delete the AS number: <code>no set as-path WORD<0-256></code>
<code>as-path-mode <tag prepend></code>	Configures the AS path mode. Prepend is the default configuration. The device prepends the AS number of the AS-list specified in <code>set-as-path</code> to the old <code>as-path</code> attribute of the BGP routes that match this policy. Note: Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy. For more information about iBGP, see BGP on page 377.
<code>automatic-tag enable</code>	Configures the tag automatically. Used for BGP routes only. Use the no operator to disable the tag: <code>no set automatic-tag enable</code>
<code>community WORD<0-256></code>	Configures the device to add the community number of the community list to the BGP routes that match this policy. <code>WORD <0-256></code> specifies the list ID of up to four defined community lists separated by a comma. Use the no operator to delete the community number: <code>no set community WORD<0-256></code>
<code>community-mode <additive none unchanged></code>	Configures the community mode. <code>additive</code> —the device prepends the community number of the community list specified in <code>set-community</code> to the old community path attribute of the BGP routes that match this policy. <code>none</code> —the device removes the community path attribute of the BGP routes that match this policy to the specified value.
<code>injectlist WORD<0-1027></code>	Configures the device to replace the destination network of the route that matches this policy with the contents of the specified prefix list. <code>WORD<0-1027></code> specifies one prefix list by name. Use the no operator to disable <code>set injectlist</code> : <code>no set injectlist</code>
<code>ip-preference <0-255></code>	Configures the preference. This applies to accept policies only. <code><0-255></code> is the range you can assign to the routes.
<code>local-preference <0-65535></code>	Configures the device to match the local preference, applicable to all protocols. <code><0-65535></code> specifies the preference value.

Variable	Value
<i>mask</i> <A.B.C.D>	Configures the mask of the route that matches this policy. This applies only to RIP accept policies. A.B.C.D is a valid contiguous IP mask. Use the no operator to disable set mask: <code>no set mask</code>
<i>metric</i> <0-65535>	Configures the metric value for the route while announcing a redistribution. The default is 0. If the default is configured, the original cost of the route is advertised into OSPF for RIP, the original cost of the route or default-import-metric is used (applies to IS-IS routes also).
<i>metric-type</i> {type1 type2}	Configures the metric type for the routes to announce into the OSPF domain that matches this policy. The default is type 2. This field is applicable only for OSPF announce policies.
<i>metric-type-internal</i> <0-1>	Configures the MED value for routes advertised to ebgp nbrs to the IGP metric value. <0-1> specifies the metric type internal.
<i>metric-type-isis</i> <none internal external>	Configures the metric type for IS-IS routes. The default is none. This field is applicable only for IS_IS policies.
<i>metric-type-live-metric</i>	Configures the metric type for BGP routes. The default is disabled. This field is applicable only for BGP policies.
<i>next-hop</i> WORD <1-256>	Specifies the IP address of the next-hop router. Both IPv4 and IPv6 addresses are supported. Use the no operator to disable set next-hop: <code>no set next-hop</code>
<i>nssa-pbit</i> enable	Configures the not so stubby area (NSSA) translation P bit. Applicable to OSPF announce policies only. Use the no operator to disable set nssa-pbit: <code>no set nssa-pbit enable</code>
<i>origin</i> {igp egp incomplete}	Configures the device to change the origin path attribute of the BGP routes that match this policy to the specified value.
<i>origin-egp-as</i> <0-65535>	Indicates the remote autonomous system number. Applicable to BGP only.
<i>tag</i> <0-65535>	Configures the tag of the destination routing protocol. If not specified, the device forwards the tag value in the source routing protocol. A value of 0 indicates that this parameter is not configured. Note: This parameter is not supported on all hardware platforms.
<i>weight</i> <0-65535>	Configures the weight value for the routing table. For BGP, this value overrides the weight configured through NetworkTableEntry, FilterListWeight, or NeighborWeight. Used for BGP only. A value of 0 indicates that this parameter is not configured.

Use the data in the following table to use the **name** command.

Variable	Value
<code>WORD<1-64></code>	Renames a policy and changes the name field for all sequence numbers under the given policy.

Configure a Policy to Accept External Routes from a Router

Perform this procedure to configure a policy to accept external routes from a specified advertising router.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter OSPF Router Configuration mode:

```
enable

configure terminal

router ospf
```
2. Create a policy to accept external routes from a specified advertising route:

```
accept adv-rtr <A.B.C.D>
```
3. Exit to the Privileged EXEC mode.

```
exit
```
4. Apply the OSPF accept policy change:

```
ip ospf apply accept adv-rtr <A.B.C.D>
```
5. Confirm your configuration:

```
show ip ospf accept
```

Example

Log on to the OSPF Router Configuration mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router ospf
```

Create a policy to accept external routes from a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122
```

Enable an OSPF accept entry for a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122 enable
```

Exit to the Privileged EXEC mode:

```
Switch:1(config-ospf)#exit
Switch:1(config)#exit
```

Apply the OSPF accept policy change and confirm your configuration:

```
Switch:1#ip ospf apply accept adv-rtr 192.0.2.122
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR          MET_TYPE  ENABLE  POLICY
-----
192.0.2.122     -             FALSE
```

Variable definitions

Use the data in the following table to use the **accept adv-rtr** command.

Variable	Value
<A.B.C.D>	Specifies the IP address.
<i>enable</i>	Enables an OSPF accept entry for a specified advertising router. Use the no operator to disable an OSPF accept entry: <code>no accept adv-rtr <A.B.C.D> enable</code>
<i>metric-type {type1 type2 }</i>	Indicates the OSPF external type. This parameter describes which types of OSPF external routes match this entry. <i>type1</i> means match all external routes. <i>type1</i> means match external type 1 only. <i>type2</i> means match external type 2 only. Use the no operator to disable metric-type: <code>no ip ospf accept adv-rtr <A.B.C.D> metric-type</code>
<i>route-map WORD<0-64></i>	Specifies the name of the route policy to use for filtering external routes advertised by the specified advertising router before accepting into the routing table.

Apply OSPF Accept Policy Changes

Apply OSPF accept policy changes to enable the configuration changes in the policy to take effect in an OSPF Accept context (and to prevent the device from attempting to apply the changes one by one after each configuration change).

About This Task

Important

Changing OSPF Accept contexts is a process-oriented operation that can affect system performance and network accessibility while you perform the procedures. If you want to change the default preferences for an OSPF Accept or a prefix-list configuration (as opposed to the default preference), do so before enabling the protocols.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Apply an OSPF accept policy change:
ip ospf apply accept [vrf WORD<1-16>]
3. Display information about the configured OSPF entries:
show ip ospf accept [vrf WORD<1-16>] [vrfs WORD<0-512>]

Example

Apply the OSPF accept policy and confirm the configuration:

```
Switch:1>enable
Switch:1#ip ospf apply accept
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR      MET_TYPE ENABLE POLICY
-----
192.0.2.11   type1    true  test1
```

Variable Definitions

Use the data in the following table to use the `ip ospf apply accept adv-rtr` command.

Variable	Value
<code>adv-rtr</code>	Commits entered changes. Issue this command after you modify a policy configuration that affects an OSPF accept policy.
<code>vrf WORD<1-16></code>	Specifies the name of the VRF.

Configure Inter-VRF Redistribution Policies

Configure redistribution entries to allow a protocol to announce routes of a certain source type, for example, static, RIP, or direct.

Before You Begin

- Ensure the routing protocols are globally enabled.
- You must configure the route policy, if required.
- Ensure the VRFs exist.
- You must create the route policy and prefix list under the source VRF context.

Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr>
```

3. Apply a route policy if required:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr> route-map <WORD 0-64> [vrf-src <WORD 1-16>]
```

4. Use the following variable definitions table to configure other parameters as required.

5. Enable the redistribution:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-
static|isis|ospf|ospfv3|rip|static|dvr> enable [vrf-src <WORD 1-16>]
```

6. Ensure that the configuration is correct:

```
show ip <bgp|ospf|rip> redistribute [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

For RIPv6, use `show ipv6 rip redistribute`.

7. Apply the redistribution:

```
ip <bgp|ospf|rip> apply redistribute <bgp|direct|ipv6-direct|ipv6-
isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr> [vrf WORD<1-16>]
[vrf-src WORD<1-16>]
```

Example

```
Switch:1>enable
Switch:1#config terminal
```

Log on to the VRF Router Configuration mode:

```
Switch:1(config)#router vrf test
```

Create the redistribution instance:

```
Switch:1(router-vrf)#ip rip redistribute ospf
```

Enable the redistribution

```
Switch:1(router-vrf)#ip rip redistribute ospf enable
```

Ensure that the configuration is correct:

```
Switch:1(router-vrf)#show ip rip redistribute
```

Exit to Global Configuration mode:

```
Switch:1(router-vrf)#exit
```

Apply the redistribution:

```
Switch:1(config)#ip rip apply redistribute ospf
```

Variable definitions

Use the data in the following table to use the redistribution commands.

Variable	Value
<code><bgp direct isis ospf rip static dvr></code>	Specifies the type of routes to redistribute—the protocol source.
<code>vrf WORD<1-16></code>	Specifies the VRF instance.
<code>vrfids WORD<0-512></code>	Specifies a list of VRF IDs.
<code>vrf-src WORD<1-16></code>	Specifies the source VRF instance. This parameter is not required for redistribution within the same VRF.

Use the data in the following table to use the `ip <bgp|ospf|rip> redistribute <bgp|direct|isis|ospf|rip|static|dvr>` command.

Variable	Value
<code>apply [vrf-src WORD<1-16>]</code>	Applies the redistribution configuration.
<code>enable [vrf-src WORD<1-16>]</code>	Enables the OSPF route redistribution instance.
<code>metric <metric-value> [vrf-src WORD<1-16>]</code>	Configures the metric to apply to redistributed routes.
<code>metric-type <type1 type2> [vrf-src WORD<1-16>]</code>	Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone.
<code>route-map <WORD 0-64> [vrf-src WORD<1-16>]</code>	Configures the route policy to apply to redistributed routes.
<code>subnets <allow suppress> [vrf-src WORD<1-16>]</code>	Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.

IP Policy Configuration using Enterprise Device Manager

You can form a unified database of route policies that the protocols (RIP, OSPF or Border Gateway Protocol [BGP]) can use for any type of filtering task.

For information about configuring a prefix list, see [Configuring a prefix list](#) on page 2866. For more information about community list, see [Configure a Community Access List](#) on page 481. For more information about AS path list, see [Configure an AS Path List](#) on page 481.

A name or an ID identifies a policy. Under a policy you can have several sequence numbers, each of which is equal to one policy in the old convention. If a field in a policy is not configured, the system displays it as 0 or any when the system displays it in Enterprise Device Manager (EDM). This means that the field is ignored in the match criteria. You can use the clear option to remove existing configurations for any field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a set-preference field set, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply only one policy for one purpose (for example, RIP Announce on a given RIP interface). In that example, all sequence numbers under the given policy are applicable for that filter. A sequence number also acts as an implicit preference: a lower sequence number is preferred.

Configuring a prefix list

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or non-contiguous routes. Reference prefix lists by name from within a routing policy.

Before You Begin

- Change the VRF instance as required to configure a prefix list on a specific VRF instance.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **Prefix List** tab.
4. Click **Insert**.
5. In the **Id** box, type an ID for the prefix list.
6. In the **Prefix** box, type an IP address for the route.
7. In the **PrefixMaskLength** box, type the length of the prefix mask.
8. Configure the remaining parameters as required.
9. Click **Insert**.

Prefix List field descriptions

Use the data in the following table to use the **Prefix List** tab.

Name	Description
Id	Configures the list identifier.
Prefix	Configures the IP address of the route.
PrefixMaskLen	Configures the specified length of the prefix mask. You must enter the full 32-bit mask to exact a full match of a specific IP address, for example, if you create a policy to match on the next hop.
Name	Names a specified prefix list during the creation process or renames the specified prefix list. The name length can use from 1 to 64 characters.
MaskLenFrom	Configures the lower bound of the mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.
MaskLenUpto	Configures the higher bound mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.

Configure a Route Policy

Configure a route policy so that all protocols use them for In, Out, and Redistribute purposes.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Policy** tab.
4. Select **Insert**.

5. Enter the appropriate information for your configuration in the Insert Route Policy dialog box.
6. Select **Insert**.

Route Policy Field Descriptions

Use the data in the following table to use the **Route Policy** tab.

Name	Description
Id	Specifies the ID of an entry in the Prefix list table.
SequenceNumber	Specifies a policy within a route policy group.
Name	Specifies the name of the policy. This command changes the name field for all sequence numbers under the given policy.
Enable	Indicates whether this policy sequence number is enabled or disabled. If disabled, the policy sequence number is ignored. The default is disabled.
Mode	Specifies the action to take when a policy is selected for a specific route. Select permit (allow the route) or deny (ignore the route). The default is permit.
MatchProtocol	Selects the appropriate protocol. If configured, matches the protocol through which the route is learned. This field is used only for RIP Announce purposes. The default is to enable all match protocols.
MatchNetwork	Specifies if the system matches the destination network against the contents of the specified prefix list.
MatchIpRouteSource	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. Select the ellipsis and choose from the list in the Match Route Source dialog box. You can select up to four entries. To clear an entry, use the ALT key. You can also change this field in the Route Policy tab of the Policy dialog box.
MatchIpRouteDest	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.
MatchNextHop	Specifies if the system matches the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. Select the ellipsis and choose from the list in the Match Next Hop dialog box. You can select up to four entries. To clear an entry, use the ALT key.
MatchInterface	Specifies if the system matches the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other type of route. Select the ellipsis and choose from the list in the Match Interface dialog box. You can select up to four entries. To clear an entry, use the ALT key.

Name	Description
MatchRouteType	Configures a specific route type to match (applies only to OSPF routes). Externaltypel and Externaltypel2 specify the OSPF routes of the specified type only. OSPF internal refers to intra- and inter-area routes. The default is any.
MatchMetric	Specifies if the system matches the metric of the incoming advertisement or existing route against the specified value (1 to 65535). If 0, this field is ignored. The default is 0.
MatchMetricTypelisis	Specifies the match metric type field in the incoming ISIS routes in accept policy.
MatchAsPath	Configures if the system matches the BGP autonomus system path. Applicable to BGP only. This overrides the BGP neighbor filter list information.
MatchCommunity	Filters incoming and outgoing updates based on a Community List. Applicable to BGP only. The default is disable.
MatchCommunityExact	Indicates if the match must be exact (that is, all of the communities specified in the path must match). Applicable to BGP only. The default is disabled.
MatchTag	Specifies a list of tags used during the match criteria process. Applicable to BGP only. It contains one or more tag values.
MatchVrf	Identifies the source VRFs that leaks routes to the local VRF (applies only to RIP routes).
MatchLocalPref	Specifies the local preference value to be matched.
NssaPbit	Configures or resets the P bit in specified type 7 link state advertisements (LSA). By default, the Pbit is always configured in case the user configures the Pbit to a disable state for a particular route policy other than all type 7. LSAs associated with that route policy have the Pbit cleared. With this intact, not so stubby area (NSSA) area border router (ABR) does not perform translation of these LSAs to type 5. The default is enable.
SetRoutePreference	Configures a value from 0 to 255. The default value is 0. If the default is configured, the global preference value is used. When configured to a value greater than zero, specifies the route preference value assigned to the routes that matches the policy. This feature applies to accept policies only.
SetMetricTypeInternal	Identifies the MED value for routes advertised to BGP numbers to the Interior Gateway Protocol (IGP) metric value. The value must be 0 or 1. The default is 0.
SetMetricTypelisis	Sets the metric type IS-IS.
SetMetric	Configures the system to use the metric value for the route while announcing or redistributing. The default-import-metric is 0. If the default is configured, the original cost of the route is advertised into OSPF; for RIP, the original cost of the route or the default value is used (applies to IS-IS routes also). The default is 0.

Name	Description
SetMetricType	Configures the metric type for the routes to announce into the OSPF routing protocol that matches this policy. Applicable to OSPF protocol only. The default is type 2. This field is applicable only for OSPF announce policies. The default is type2.
SetNextHop	Configures the IP address of the next-hop router. Applicable to BGP only. The default is 0.0.0.0.
SetInjectNetList	Configures the destination network of the route that matches this policy with the contents of the specified prefix list. Select the ellipsis and choose from the list in the Set Inject NetList dialog box.
SetMask	Configures the mask of the route that matches this policy. This applies only to RIP accept policies.
SetAsPath	Indicates the AS path value to use whether the SetAsPathMode field is Tag or Prepend. Applicable to BGP only. Note: Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy.
SetAsPathMode	Configures if the system converts the tag of a route into an AS path. Applicable to BGP protocol only. The mode is either Tag or Prepend tag. The value is applicable only while redistributing routes to BGP. The default is prepend. Note: Prepend is not applicable to an iBGP peer with outbound route policy.
SetAutomaticTag	Enables the automatic tag feature. Applicable to BGP protocol only. The default is disable.
SetCommunityNumber	Configures the community number for BGP advertisements. This value can be a number (1 to 42949672000) or no-export or no-advertise.
SetCommunityMode	Configures the community mode for the BGP protocol. This value can be either append, none, or unchanged. The default is unchanged. <ul style="list-style-type: none"> • Unchanged—keeps the community attribute in the route path as it is. • None—removes the community in the route path additive. • Append—adds the community number specified in SetCommunityNumber to the community list attribute.
SetExtCommunity	Configures a BGP community. The values are 0 to 256.

Name	Description
SetExtCommunityMode	Configures the extended-community mode. The value can be append, unchanged, or overwrite. The default value is unchanged. <ul style="list-style-type: none"> append — creates another community string. unchanged — keeps the community attribute as it is. overwrite — changes the current value.
SetOrigin	Configures the origin for the BGP protocol to IGP, EGP, incomplete, or unchanged. If not configured, the system uses the route origin from the IP routing table (protocol). The default is unchanged.
SetLocalPref	Configures the local preference for the BGP protocol only. The system uses this value during the route decision process for the BGP protocol. The default is 0.
SetOriginEgpAs	Indicates the remote autonomous system number for the BGP protocol. The default is 0.
SetWeight	Configures the weight value for the routing table for the BGP protocol. This field must be used with the match as-path condition. For BGP, this value overrides the weight configured through the NetworkTableEntry, FilterListWeight, or NeighborWeight. The default is 0.
SetTag	Configures the list of tags used during the match criteria process for the BGP protocol. The default is 0.
Ipv6SetNextHop	Specifies the address of the IPv6 next hop router.

Apply a Route Policy

Apply route policies to define route behavior.

About This Task

Important

Changing route policies or prefix lists that affect OSPF accept or redistribute is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. Therefore, if you want to change a prefix list or a routing protocol, you configure all route policies and prefix lists before enabling the protocols.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**
3. Select the **Applying Policy** tab.
4. Select the type of policy to apply.
5. Select **Apply**.

Applying Policy Field Descriptions

Use the data in the following table to use the **Applying Policy** tab.

Name	Description
RoutePolicyApply	Specifies that configuration changes in the policy take effect in an OSPF route policy context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled.
RedistributeApply	Specifies that configuration changes in the policy take effect for an OSPF Redistribute context. This prevents the system from attempting to apply the changes one-by-one after each configuration change. The default is enabled.
OspfInFilterApply	Specifies that configuration changes in a route policy or a prefix list take effect in an OSPF Accept context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled. Note: This field does not apply on all hardware platforms. If you do not see this command in EDM, the feature is not supported on your hardware.

Configure an OSPF Accept Policy

Perform the following procedure to create or configure an OSPF accept policy.

Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **OSPF Accept** tab.
4. Select **Insert**.
5. Configure the parameters as required.
6. Select **Insert**.

OSPF Accept field descriptions

Use the data in the following table to use the **OSPF Accept** tab.

Name	Description
AdvertisingRtr	Specifies the routing ID of the advertising router.
Enable	Enables or disables the advertising router. You can also enable or disable advertising in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting enable or disable from the menu. The default is disable.

Name	Description
MetricType	<p>Specifies the OSPF external type. This parameter describes which types of OSPF ASE routes match this entry.</p> <ul style="list-style-type: none"> Any means match either ASE type 1 or 2 Type1 means match any external type 1 Type2 means match any external type 2 <p>You can also select your entry in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting any, type1, or type2 from the menu. The default is any.</p>
PolicyName	<p>Specifies the name of the OSPF in filter policy. Click the ellipsis button and choose from the list in the Policy Name dialog box. To clear an entry, use the ALT key.</p>

Configuring inbound/outbound filtering policies on a RIP interface

About This Task

Configure inbound filtering on a RIP interface to determine whether to learn a route on a specified interface and to specify the parameters of the route when it is added to the routing table. Configure outbound filtering on a RIP interface to determine whether to advertise a route from the routing table on a specified interface and to specify the parameters of the advertisement.

The port on which the multimedia filter is enabled becomes a DIFFSERV access port.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column.
5. Select a preconfigured In/Out policy and click **OK**.

RIP In/Out Policy field descriptions

Use the data in the following table to use the **RIP In/Out Policy** tab.

Name	Description
Address	Specifies the IP address of the RIP interface.
Interface	Specifies the internal index of the RIP interface.
InPolicy	Specifies the policy name used for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when it is added to the routing table.
OutPolicy	Specifies the policy name used for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface and specifies the parameters of the advertisement.

Deleting inbound/outbound filtering policies on a RIP interface

About This Task

Delete a RIP In/Out policy when you no longer want to learn a route on a specified interface or advertise a route from the routing table on a specified interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Policy**.
3. Click the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column for the policy you want to delete.
5. In the **InPolicy** or **OutPolicy** dialog box, press **CTRL** and then, click the policy you want to delete.
6. Click **OK**.
The policy is deleted and you are returned to the RIP In/Out Policy tab.
7. Click **Apply**.

RSMLT

In many cases, core network convergence time depends on the length of time a routing protocol requires to successfully converge. Depending on the specific routing protocol, this convergence time can cause network interruptions that range from seconds to minutes.

Routed Split MultiLink Trunking (RSMLT) permits rapid failover for core topologies by providing an active-active router concept to core SMLT networks.

RSMLT scenarios include SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Routing protocols include the following:

- IP Unicast Static Routes
- RIP1
- RIP2
- OSPF
- BGP

In the event of core router failures, RSMLT manages packet forwarding, thus eliminating dropped packets during the routing protocol convergence.

IPv6 RSMLT

Routed Split Multi-Link Trunking (RSMLT) is an enhancement to SMLT that enables the exchange of Layer 3 information between peer nodes in a switch cluster. RSMLT provides two main advantages over SMLT:

- provides backup for the peer after the peer goes down
- routes traffic on behalf of the peer to prevent Virtual Inter-Switch Trunk (vIST) overload

IPv6 RSMLT enables the subsecond failover for IPv6 forwarding.

The overall model for IPv6 RSMLT is essentially identical to that of IPv4 RSMLT. In short, RSMLT peers exchange their IPv6 configuration and track their states by using vIST messages. An RSMLT node always performs IPv6 forwarding on the IPv6 packets destined to the MAC addresses of the peer. If an RSMLT node detects that the RSMLT peer is down, the node forwards IPv6 traffic destined to the IPv6 addresses of the peer.

With RSMLT enabled, an SMLT switch performs IP forwarding on behalf of the SMLT peer, which prevents IP traffic from being sent over the vIST.

IPv6 RSMLT supports the full set of topologies and features supported by IPv4 RSMLT, including SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Because you configure RSMLT on a VLAN, not at the IP layer, the configuration applies to both IPv4 and IPv6. You cannot enable or disable RSMLT on a VLAN for IPv6 but not IPv4; or for IPv4 but not IPv6.

With IPv6, you must configure the RSMLT peers to use the same set of IPv6 prefixes.

Supported routing protocols include the following:

- IPv6 static routes

- OSPFv3

**Note**

IPv6 RSMLT is not virtualized, therefore it is not possible to enable IPv6 and RSMLT together on a VLAN which is associated with a VRF.

The system will display the configuration errors if you attempt to perform the following:

- Create an IPv6 interface on a VLAN which is associated with a VRF and RSMLT is enabled on the VLAN.
- Enable RSMLT on an IPv6 enabled VLAN which is associated with a VRF.

IPv6 differences

The following list identifies ways in which the IPv6 implementation of RSMLT differs from the IPv4 implementation of RSMLT.

- After the switch begins to forward traffic on behalf of the peer, duplicate address detection (DAD) is not executed for the IPv6 address of the peer. The implementation assumes that the peer IPv6 address is already known to be unique.
- An RSMLT switch installs a neighbor entry for the peer IPv6 address immediately after the peer disappearance is detected, possibly while a route for the peer still exists. This action can result in packets destined to the peer IPv6 address being delivered to the CP for a short period of time.
- You cannot configure a vIST with IPv6 peer address
- In a dual-stack VLAN, adding or deleting IPv4 or IPv6 does not affect the RSMLT functionality of one another. If you add IPv4 or IPv6 to an existing IPv6 or IPv4 RSMLT VLAN, the RSMLT state for the protocol you add second will be the same as the previous RSMLT state.

SMLT and RSMLT Operation in Layer 3 Environments

Figure 226 on page 2880 shows a typical redundant network example with user aggregation, core, and server access layers. To minimize the creation of many IP subnets, one VLAN (VLAN 1, IP subnet A) spans all wiring closets.

SMLT provides the loop-free topology and forwards all links for VLAN 1, IP subnet A.

The aggregation layer switches are configured with routing enabled and provide active-active default gateway functionality through RSMLT.

After you enable RSMLT on a VLAN (on both aggregation devices), the cluster devices simply inform each other (over vIST messaging) of their physical IP and MAC on that VLAN. Thereafter, the two cluster devices take mutual ownership of their IP addresses on that VLAN. This action means each cluster device routes IP traffic that is directed to the physical MAC of the IP or the physical MAC of the peer IP on that VLAN, and when one of them is down the other cluster device:

- Replies to ARP requests for both the IP and the peer IP on that VLAN
- Replies to pings to the IP and the peer IP on that VLAN

In this case, routers R1 and R2 forward traffic for IP subnet A. RSMLT provides both router failover and link failover. For example, if the Split MultiLink Trunk link between R2 and R4 is broken, the traffic fails over to R1 as well.

For IP subnet A, VRRP with a backup master can provide the same functionality as RSMLT, as long as no additional router is connected to IP subnet A.

RSMLT provides superior router redundancy in core networks (IP subnet B), where OSPF is used for the routing protocol. Routers R1 and R2 provide router backup for each other, not only for the edge IP subnet A, but also for the core IP subnet B. Similarly routers R3 and R4 provide router redundancy for IP subnet C and also for core IP subnet B.

Router R1 Failure

The following figure shows SMLT and RSMLT in Layer 3 environments.

Figure 226: SMLT and RSMLT in Layer 3 environments

R3 and R4 both use R1 as their next hop to reach IP subnet A. Even though R4 sends the packets to R2, they are routed directly at R2 into subnet A. R3 sends its packets to R1 and they are also sent directly into subnet A. After R1 fails, all packets are directed to R2, with SMLT. R2 still routes for R2 and R1. After OSPF convergence, the routing tables in R3 and R4 change their next hop to R2 to reach IP subnet A. You can configure the hold-up timer (that is, for the amount of time R2 routes for R1 in a failure) for a time period greater than the routing protocol convergence, you can configure it as indefinite (that is, the members of the pair always route for each other).

Use an indefinite hold-up timer value for applications that use RSMLT at the edge instead of VRRP.

Router R1 Recovery

When R1 restarts after a failure, it does not route traffic for R2, nor does it provide backup for R2, until the hold-down timer expires. Similar to VRRP, the hold-down timer value must be greater than the time the routing protocol requires to converge its tables.

During the hold-down interval, R1 routes traffic if the destination MAC of the packet is its own routable VLAN MAC. R1 bridges incoming traffic to R2 if the destination MAC of the packet is the routable VLAN MAC of R2. A temporary default route (one having a route preference equal to 4) that points to R2 is installed on R1. R1 uses this temporary route to forward traffic to R2 that it cannot route itself because of the incomplete routing table; the default route is not saved in the configuration file.

After the hold-down timer expires, the temporary default route that points to R2 is deleted; from this moment on, in addition to routing packets destined to itself, R1 starts routing packets for R2, as well.

RSMLT Network Design and Configuration

Because RSMLT is based on SMLT, all SMLT configuration rules apply. In addition, RSMLT is enabled on the SMLT aggregation switches for each VLAN. The VLAN must be a member of SMLT links and vIST's L2VSN. For more information about how to configure SMLT in a Layer 2 environment, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2300.

The VLAN also must be routable (IP address configured) and you must configure an Interior Gateway Protocol (IGP) such as OSPF on all four routers, although it is independent of RSMLT. All routing protocols, even static routes, work with RSMLT.

The RSMLT pair switches provide backup for each other. As long as one of the two routers of an vIST pair is active, traffic forwarding is available for both next hops R1/R2 and R3/R4.

RSMLT Edge Support

The switch stores the peer MAC and IP address pair in its local configuration file and restores the configuration if the peer does not restore after a simultaneous restart of both RSMLT-peer switches.

The RSMLT edge support feature adds an enhancement whereby the peer MAC (for the IP on the VLAN) is committed to the config.cfg file after you use the **save config** command. If you power off both devices, and then power up only one of them, that single device can still take ownership of its peer IP on that VLAN even if it has not seen that peer switch since it started. This enhancement is necessary if you configure the peer (the device which is still down) IP as the default gateway in end stations.

If you enable RSMLT edge support, you must also ensure that the hold-up timer for RSMLT on those edge VLANs equals infinity (9999). This timer value ensures that if one cluster device fails, the remaining cluster device maintains ownership of the failed peer IP indefinitely.

The edge VLAN can be tagged over SMLT links, single attached links, or more SMLT links.

Important

If you clear the peer information the device can stop forwarding for the peer.

RSMLT implementation does not use a virtual IP address but instead uses physical IP addresses for redundancy. At the same time, you can deploy RSMLT in either routed configurations, or edge

configurations, where you previously used VRRP (and back-up master). Previously, if a power outage occurred or a shutdown of both switches within a dual core vIST pair, only one device came back up. Clients using the powered-off device IP/MAC as the default gateway lost connectivity to the network. In such a scenario, even with RSMLT enabled on the device, it cannot act as a backup for the peer as it was unaware of the peer IP or MAC address.

After both the dual core vIST switches come back, the vIST is operational. If an RSMLT peer-enabled message is received from the peer, normal RSMLT operation occurs.

If the peer has either an IP or MAC change, you must save the configuration for the RSMLT edge support to operate correctly. However, if the vIST peer up message is not received (for example, if you do not enable RSMLT properly), and you enable the RSMLT edge support flag, the RSMLT hold-down timer starts and permits routing protocols to converge; during this time user operation can be affected. After the hold-down timer expires, saved peer information is picked up and the device starts to act as backup for the peer by adding the previously saved MAC and ARP records.

The hold-up timer starts and after this timer expires the previously added MAC and ARP records are deleted and the device stops acting as backup for the peer, as the peer is not running proper RSMLT for the VLAN. The RSMLT is a parameter for each VLAN, and therefore all affects are on an individual VLAN basis, not necessarily a global device. Edge support mode uses the local values of the hold-down timer (default value of 60 seconds) and hold-up timer (default value of 180 seconds).

RSMLT Configuration using CLI

Use the procedures in this section to configure RSMLT using CLI.

Configure RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

Before You Begin

- An IP routing protocol is enabled on VLAN Layer 3 interfaces.
- VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6. By default, RSMLT is disabled on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable  
  
configure terminal  
  
interface vlan <1-4059>
```
2. Configure the holddown timer:

```
ip rsmlt holddown-timer <0-3600>
```

3. Configure the holdup timer:

```
ip rsmlt holdup-timer <0-9999>
```
4. Enable RSMLT on the VLAN:

```
ip rsmlt
```

Example

Configure and enable RSMLT on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ip rsmlt holddown-timer 100
Switch:1(config-if)#ip rsmlt holdup-timer 200
Switch:1(config-if)#ip rsmlt
```

Variable Definitions

The following table defines parameters for the **ip rsmlt** command.

Variable	Value
<i>holddown-timer</i> <0-3600>	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60. Configure this value to be longer than the anticipated routing protocol convergence. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.
<i>holdup-timer</i> <0-3600 9999>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.

The following table defines parameters for the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Enable RSMLT Edge Support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

If enabled, peer MAC and IP information for all RSMLT-enabled VLANs is saved after you next use the **save config** command.

About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6. You do not configure IPv4 and IPv6 separately.

The RSMLT Edge support default is disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable RSMLT Edge support:

```
ip rsmlt edge-support
```

Example

If you have enabled RSMLT Edge Support, disable the feature as follows:

```
Switch:1(config)#no ip rsmlt edge-support
```

View RSMLT Information

Show RSMLT information to view data about all RSMLT interfaces. The output of the command includes IPv6 information for the local and peer nodes.

About This Task

If you use the **show ip rsmlt** command after you delete an RSMLT, the RSMLT still shows in the command output until you restart the switch.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Show RSMLT information about the interface:

```
show ip rsmlt [local|peer] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
3. View the status of the switch to act as a peer forwarder:

```
show ip rsmlt edge-support
```

Examples

```
Switch:1>show ip rsmlt
```

```
=====
```

```
                          Ip Rsmlt Local Info - GlobalRouter
```

RSMILT Peer Info:
    rsmilt-peer-forwarding : disable

```

Variable definitions

Use the data in the following table to use the **show ip rsmlt** command.

Variable	Value
<i>local</i>	Shows local RSMLT information.
<i>peer</i>	Shows RSMLT information for the peer.
<i>vrf WORD<1-16></i>	Shows information for a specific VRF name.
<i>vrfids WORD<0-512></i>	Shows information for a specific VRF ID.

RSMLT Configuration using EDM

Use the procedures in this section to configure RSMLT using EDM.

Configuring RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

Before You Begin

- Enable an IP routing protocol on VLAN Layer 3 interfaces.
- Ensure VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6.

Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RSMLT** tab.
7. Select **Enable**.
8. In the **HoldDownTimer** field, type a hold-down timer value.
9. In the **HoldUpTimer** field, type a holdup timer value.
10. Click **Apply**.

RSMLT Field Descriptions

Use the data in the following table to use the **RSMLT** tab.

Name	Description
Enable	Enables RSMLT. The default is disabled.
HoldDownTimer	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.

Enabling RSMLT Edge support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

The default is disabled.

About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6.

Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **RSMLT**.
3. Click the **Globals** tab.
4. Select **EdgeSupportEnable**.
5. Click **Apply**.

View and Edit IPv4 RSMLT Local Information

About This Task

Perform the following procedure to view and edit RSMLT local VLAN information.

Procedure

1. In the navigation pane, expand **ConfigurationIP**.
2. Select **RSMLT**.
3. Select the **Local** tab.
4. Configure the parameters as required.

5. Select **Apply**.

Local field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
IfIndex	IP interface identification.
VlanId	Specifies the VLAN ID of the chosen VLAN.
IpAddr	Specifies the IP address on the RSMLT VLAN.
MacAddr	Specifies the MAC address of the selected VLAN.
Enable	Displays the RSMLT operating status as enabled or disabled.
OperStatus	Displays the RSMLT operating status as either up or down. The default is down.
HoldDownTimer	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
SmltId	Specifies the ID range for the SMLT. A valid range is 1 to 512.
VrfId	Identifies the VRF.
VrfName	Indicates the VRF name.

Modify the IPv6 RSMLT Local Information

Edit the existing RSMLT configuration for the local node in the cluster.

Procedure

1. In the navigation pane, expand **ConfigurationIPv6**.
2. Select **RSMLT**.
3. Select the **Local** tab.
4. Select a cell to change the value.
5. Select **Apply**.

Local field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
IfIndex	Shows the route SMLT operation index.
Ipv6Addr	Configures the IPv6 address of the RSMLT interface.
Ipv6PrefixLength	Configures the IPv6 prefix length.

Name	Description
Enable	Enables or disables RSMLT. The default is disabled.
HoldDownTimer	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60.
HoldUpTimer	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
OperStatus	Displays the RSMLT operating status as either up or down.
SmltId	Specifies the ID range for the SMLT.
VlanId	Configures the VLAN ID.
MacAddr	Configures the MAC address of the VLAN.
VrfId	Indicates the virtual router ID to which the local RSMLT instance belongs.
VrfName	Indicates the virtual router name to which the local RSMLT instance belongs.

Modify IPv6 RSMLT Peer Information

Edit the existing configuration for the RSMLT peer node in the cluster.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Peer** tab.
4. Select a cell to change the value.
5. Select **Apply**.

Peer Field Descriptions

Use the data in the following table to use the **Peer** tab.

Name	Description
IfIndex	Shows the route SMLT operation index.
Ipv6Addr	Configures the IPv6 address of the RSMLT interface.
Ipv6PrefixLength	Configures the IPv6 prefix length.
AdminStatus	Shows the administrative status of RSMLT on the peer.

Name	Description
HoldDownTimer	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 0.
HoldDownTimeRemaining	Indicates the time remaining in the HoldDownTimer.
HoldUpTimer	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
HoldUpTimeRemaining	Indicates the time remaining in the HoldUpTimer.
OperStatus	Displays the RSMLT operating status as either up or down.
SmltId	Specifies the ID range for the SMLT.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
MacAddr	Configures the MAC address of the VLAN.
VrfId	Indicates the virtual router ID to which the peer belongs.
VrfName	Indicates the virtual router name to which the peer belongs.

View IPv4 RSMLT Peer Information

About This Task

Perform this procedure to view and edit RSMLT peer information.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Peer** tab.

Peer field descriptions

Use the following table to use the **Peer** tab.

Name	Description
IfIndex	IP interface identification.
VlanId	Specifies the VLAN ID of the chosen VLAN.
IpAddr	Specifies the IP address on the RSMLT VLAN.
MacAddr	Specifies the MAC address of the selected VLAN.
Enable	Displays the RSMLT operating status as enabled or disabled.
OperStatus	Displays the RSMLT operating status as either up or down. The default is down.
HoldDownTimer	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 0.
HoldUpTimer	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
HoldDownTimeRemaining	Displays the time remaining of the HoldDownTimer. The default is 0.
HoldUpTimeRemaining	Displays the time remaining of the HoldUpTimer. The default is 0.
SmtId	Specifies the ID range for the Split MultiLink Trunk. A valid range is 1 to 32.
VrfId	Identifies the VRF.
VrfName	Indicates the VRF name.

View IPv6 RSMLT Edge Peers

View the RSMLT peers for which the switch acts as a peer forwarder.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

Edge Peers field descriptions

Use the data in the following table to use the **Edge Peers** tab.

Name	Description
PeerVlanId	Specifies the ID of the VLAN associated with this entry.
PeerIpv6Address	Specifies the IPv6 address of the peer RSMLT interface.
PeerIpv6PrefixLength	Specifies the peer IPv6 address prefix.
PeerMacAddress	Specifies the peer MAC address.

View IPv4 RSMLT Edge Support Information

About This Task

View RSMLT edge support information to verify the RSMLT peer MAC/IP address-pair in its local configuration file and restore the configuration if the peer does not restore it after a simultaneous restart of both RSMLT-peer systems.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

Edge Peers field descriptions

Use the data in the following table to use the **Edge Peers** tab fields.

Name	Description
VlanId	Specifies the VLAN ID of the chosen VLAN.
PeerIpAddress	Specifies the peer IP address.
PeerMacAddress	Specifies the peer MAC address.
PeerVrfId	Identifies the Peer VRF.
PeerVrfName	Specifies the Peer VRF name.

	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	VSP 8600 8.0 demonstration feature
	XA1400 Series	VOSS 8.0.50

Note

DEMO FEATURE - Secure AAA server communication is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Note

Secure AAA server communication is only supported on VSP 8600 Series. You can use RADsec for RADIUS security on VOSS devices running Release 8.2 or later.

The VSP 8600 Series supports IP Security (IPsec) for the AAA server communication. IPsec provides the ability to secure RADIUS and TACACS+ servers against unwanted traffic by filtering on specific network adapters, by allowing or blocking specific protocols and enabling the server to selectively allow traffic from specific source IP addresses.

An AAA server program deals with requests for access to computer resources and provides authentication, authorization, and accounting (AAA) services. The switch communicates with AAA servers using Remote Authorization Dial-in User Service (RADIUS) and Terminal Access Controller Access Control System Plus (TACACS+). It is not sufficient to protect authentication information with only RADIUS or TACACS+.

The following diagram shows the communication between AAA client and AAA server. The IPsec module on the client encrypts the packets to the AAA server and decrypts the packets from the AAA server. Similarly, the IPsec module on the server encrypts or decrypts the packets to or from the client.

To implement secure AAA server communication, the VSP 8600 Series software supports the following:

- IPsec with Internet Key Exchange (IKE) protocol for both IPv4 and IPv6.
- IPv4 implementation of IPsec, is mainly for protocols involved in communication with AAA servers, that is, RADIUS and TACACS+. However, it supports all UDP and TCP protocols.
- Digital signature as authentication method for IKE, in addition to the pre-shared key authentication method.
- Automatic and manual keying for session establishment. IKE is the default automated key management protocol for IPsec.
- IKEv1 and IKEv2 protocol.

Internet Key Exchange (IKE) protocol

Internet Key Exchange (IKE) protocol sets up a Security Association (SA) in IPsec. SA is the relationship between two network devices that define attributes such as authentication mechanism, encryption and hash algorithms, exchange mode, and key length for secured communications. SA should be agreed to by both the devices.

The IKE protocol is based on Internet Security Association and Key Management Protocol (ISAKMP) which helps in building a secured connection between two or more hosts using the following concepts:

- authentication
- encryption
- key management
- security association (SA)
- policy

IKE uses a key exchange mechanism based on the Diffie-Hellman encryption key exchange protocol. IKE provides periodic automatic key renegotiation, pre-shared and public key infrastructures, and anti-replay defence. It is layered on top of the UDP protocol and uses UDP port 500 to exchange information between peers.

IKE phases

A switch negotiates with a peer using IKE in two phases.

- In phase 1, the switch negotiates the IKE SA to protect the negotiations that take place in phase 2. The SAs negotiated in phase 1 are bi-directional, and are applicable to traffic originating in both directions.
- In phase 2, the peers negotiate and establish the SAs for IPsec and session keys through quick mode. A Diffie-Hellman key exchange is done to achieve perfect forward secrecy, which ensures that the compromise of a single key does not permit access to data other than that protected by that compromised key. The SAs in phase 2 are uni-directional. They are used according to the direction of the traffic. The quick mode is initiated by either of the peer endpoints irrespective of who initiated phase 1.

IKE modes

There are two modes of exchanging messages in Phase 1:

- Main mode

This is a secure mode of exchanging messages. It allows protection of the confidentiality of the peers during negotiation. This mode provides more flexibility in proposals compared to aggressive mode. As the main mode requires a total of 6 messages to be exchanged between peers, it is more time consuming.

- Aggressive mode

This mode is less secure than the main mode. It does not protect the confidentiality of the peers. However, it requires only a total of 3 messages to be exchanged for phase 1, which makes this mode faster than the main mode. The number of total message exchange is reduced in this mode because some messages are embedded in other messages.

The mode of message exchange in phase 2 is called quick mode. In this mode a total of 3 messages are exchanged between the peers. This mode is used to establish IPsec SA. The negotiations in the quick mode are protected during the phase 1 negotiations in main mode.

IKE policies

A combination of security parameters used during the IKE SA negotiation is called a policy. The policies must be configured on both the peers and at least one of the policies should match on both ends to have a successful negotiation for. If a policy is not configured on both peers or if a policy does not match on both ends, an SA cannot be setup and data cannot be exchanged.

The following are the attributes of an IKE policy:

- Encryption — This is the cryptographic algorithm that is sent in the proposal by the initiator or responder during the phase 1 negotiation. This cryptographic algorithm is used to encrypt phase 2 negotiation messages. The supported encryption algorithms are:
 - DES
 - 3DES
 - AES
- Hash function — This function is used as part of the authentication mechanism during the authentication of peers in phase 1. It is always used with the authentication algorithm. The supported values are:
 - MD5
 - SHA1
 - SHA256
- Authentication — This process authenticates the peers. Following are the supported authentication modes:
 - Digital Signatures — The digital signatures use digital certificate which is signed by the certificate authority (CA) for authentication.
 - Pre-shared keys (PSK) — The PSKs are shared out-of-band between the peers before hand. Using PSK in main mode exchange limits identifying the peer to an IP address (and not host name).
- Diffie-Hellman (DH) Group — This is an algorithm used by two peers that are unknown to each other to establish a shared secret key. This key that is decided during phase 1 is used to encrypt subsequent message exchanges during phase 2 to establish security associations (SA) and security policies (SP) for IPsec sessions. The supported DH Groups are as follows:
 - Group 1 (MODP768)
 - Group 2 (MODP1024)
 - Group 14 (MODP2048)
- Lifetime — This is a time and data limit agreed by peers to protect an SA from getting compromised. It ensures that the peers renegotiate the SAs just before the lifetime value expires, that is, when the time limit is reached.
- Dead-peer detection — This is a process in which the switch waits for a response from peer for a limited number of seconds before declaring the peer as dead. It is a keep-alive mechanism required to perform IKE peer fail-over and to reclaim lost resources by freeing up SAs that are no longer in use.

IKE authentication

The security gateway of a peer must authenticate the security gateway of the peer it intends to communicate with. This ensures that IKE SAs are established between the peers. The switch supports the following two authentication methods:

- Digital certificates (using RSA algorithms)

For digital certificate authentication, the initiator signs the message interchange data using the private key. The responder uses the public key of the initiator to verify the signature. The public key is exchanged by messages containing an X.509v3 certificate. This certificate provides an assurance that the identity of a peer, as represented in the certificate, is associated with a particular public key.

- Pre-shared keys

Pre-shared key authentication, the same secret must be configured on both security gateways before the gateways can authenticate each other.

Signature authentication

The switch receives the digital signature of its peer in a message exchange. The switch verifies the digital signature by using the public key of the peer. The certificate of the peer, received during the IKE negotiation, contains the public key. To ensure that the peer certificate is valid, the switch verifies its digital signature by using the certificate authority (CA) public key contained in the root CA certificate. The switch and its IKE peer require at least one common trusted root CA for authentication to work.

When IKE is configured to use digital certificates for authentication, the certificates are retrieved from the trusted certificate store in the switch, based on the provided distinguished name. The certificates received from the peer are verified with the public key.

IKEv2

The software supports IKEv2, which is an enhancement of the IKEv1 protocol. All IKEv2 communications consist of pairs of messages: a request and a response. The IKEv2 protocol uses a non-reliable transport protocol (UDP using ports 500). The pairs of exchanges allows ensuring of reliability to the IKEv2 protocol, as there is an expected response for each request.

IKEv2 provides a number of improvements over IKEv1, including the following:

- A simplified initial exchange of messages that reduces latency and increases connection establishment speed.
 - IKEv2 makes use of a single four-message exchange instead of the eight different initial exchanges of IKEv1.
 - It improves upon IKEv1's latency by making the initial exchange to be of two round trips of four messages, and allows the ability to add setup of a child SA on that exchange.
- Improved reliability through the use of sequence numbers, and acknowledgments.
 - IKEv2 reduces the number of possible error states by making the protocol reliable as all messages are acknowledged and sequenced.
- IKE SA integrity algorithms are supported only in IKEv2.
- Traffic Selectors are specified in IKEv2 by their own payloads type and not by overloading ID payloads. This makes the Traffic Selectors more flexible.
- No lifetime negotiations for IKEv2, but in IKEv1 SA lifetimes are negotiated.

IKEv2 OCSP validation

Confirmation of certificate reliability is essential to achieve the security assurances public key cryptography provides. One fundamental element of such confirmation is reference to certificate revocation status. IKEv2 enables the use of Online Certificate Status Protocol (OCSP) for in-band signaling of certificate revocation status. The IKEv2 supports the authentication methods as pre shared key and digital certificate. It allows the verification of the digital certificate sent by the peer whether it is revoked or not. This is done through a method by sending the digital certificate to the OCSP server. The

OCSP server in turn verifies the certificate status and sends the response back. Based on the response from OCSP server, the device validates the certificate.

Secure AAA server communication and IKE limitations

This section describes the limitations associated with secure AAA server communication feature.

- AAA server protection is provided only for SSH/CLI/web/Telnet/Console Access Protection.
- FQDN (Fully Qualified Domain Names) is not supported to identify endpoints. This is because, the user configures the IP address for the AAA servers in the switch.
- XAUTH (2-factor authentication) is not supported.
- Domain of Interpretation is not supported other than for IPsec.
- NAT Traversal is not supported.
- Custom IKE messages and vendor ID for the messages are not supported.
- IKE fragmentation is not supported.
- IKE and IPsec is not supported on the Segmented Management Instance interfaces, or with management applications such as RADIUS and TACACS+. You can configure RADIUS security with RADsec on supported devices.

Note

Exception: VSP 8600 Series supports IKE on Segmented Management Instance and RADIUS with IPsec as a DEMO FEATURE.

IKE Configuration for Secure AAA Server using CLI

This section describes procedures of IKE configuration for secure AAA server using CLI.

Configure an IKE Phase 1 Profile

About This Task

Use the following procedure to configure an IKE Phase 1 profile.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Create an IKE phase 1 profile:
`ike profile WORD<1-32>`
3. Configure the IKE phase 1 profile hash algorithm:
`ike profile WORD<1-32> hash-algo <md5|sha|sha256|any>`
4. Configure the IKE phase 1 profile encryption algorithm:
`ike profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>`
5. Configure the IKE phase 1 profile Diffie-Hellman group:
`ike profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any>`

- Configure the IKE phase 1 encryption key length:

```
ike profile WORD<1-32> encrypt-key-len <128|192|256>
```

- Configure the IKE phase 1 lifetime, in seconds:

```
ike profile WORD<1-32> lifetime-sec <0-4294967295>
```

- (Optional) Delete the IKE Phase 1 profile:

```
no ike profile WORD<1-32>
```

Variable Definition

The following table defines parameters for the **ike profile** commands.

Variable	Value
<code>profile WORD<1-32></code>	Specifies the IKE profile name.
<code>hash-algo <md5 sha sha256 any></code>	Specifies the type of hash algorithm. The default value is sha256. To set this option to the default value, use the default operator with the command: default ike profile WORD<1-32> hash-algo
<code>encrypt-algo <desCbc 3DesCbc aesCbc any></code>	Specifies the type of encryption algorithm. The default value is aesCbc. To set this option to the default value, use the default operator with the command: default ike profile WORD<1-32> encrypt-algo
<code>dh-group <modp768 modp1024 modp2048 any></code>	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048. To set this option to the default value, use the default operator with the command: default ike profile WORD<1-32> dh-group
<code>encrypt-key-len <128 192 256></code>	Specifies the length of the encryption key. The default is 256. To set this option to the default value, use the default operator with the command: default ike profile WORD<1-32> encrypt-key-len
<code>lifetime-sec <0-4294967295></code>	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. To set this option to the default value, use the default operator with the command: default ike profile WORD<1-32> lifetime-sec

Create an IKE Phase 1 Policy

IKE policy establishes Security Associations (SA) and message exchanges with IKE peers to successfully set up secured channels.

About This Task

Use the following procedure to create the IKE Phase 1 policy.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IKE Phase 1 profile:

```
ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
```

3. (Optional) Delete the IKE Phase 1 profile:

```
no ike policy WORD<1-32>
```

Variable Definition

The following table defines parameters for the **ike policy <1-320> laddr** command.

Variable	Value
<i>policy</i> WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
<i>laddr</i> WORD<1-256>	Specifies the local IPv4 or IPv6 address.
<i>raddr</i> WORD<1-256>	Specifies the remote IPv4 or IPv6 address.

Configuring profile to be used for IKE Phase 1 policy

Use the following procedure to configure the IKE Phase1 profile to be used for the IKE Phase 1 policy.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the profile name to be used for IKE Phase 1 policy:

```
ike policy WORD<1-32> profile WORD<1-32>
```

Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> profile WORD<1-32>** command.

Variable	Value
<i>policy</i> WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
<i>profile</i> WORD<1-32>	Specifies the name of the IKE Phase 1 profile to be used for the policy. To set this option to the default value, use the default operator with the command: default ike policy WORD<1-32> profile

Configure IKE Phase 2 Perfect Forward Secrecy

Use the following procedure to configure IKE Phase 2 perfect forward secrecy (PFS).

About This Task

A Diffie-Hellman key exchange is done to achieve perfect forward secrecy. This ensures that the compromise of even a single key does not permit access to data other than that protected by that key.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the IKE Phase 2 perfect forward secrecy:

```
ike policy WORD<1-32> p2-pfs <enable|disable> [use-ike-group <enable|
disable>] [dh-group <modp768|modp1024|modp2048|any]
```

3. (Optional) Disable Phase 2 perfect forward secrecy:

```
no ike policy <1-32> p2-pfs
```

Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> p2-pfs** command.

Variable	Value
<i>policy</i> WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
<i>p2-pfs</i>	Enables the Phase 2 perfect forward secrecy.
<i>dh-group</i> <modp768 modp1024 modp2048 any>	Configures the Diffie-Hellman (DH) group to be used for Phase 2 perfect forward secrecy (PFS). The default value is modp2048. To set this option to the default value, use the default operator with the command: default ike policy WORD<1-32> p2-pfs dh-group
<i>use-ike-group</i> <enable disable>	Specifies whether to use the IKE Phase 1 DH group for Phase 2 PFS or not to use it. The default is enable. To set this option to the default value, use the default operator with the command: default ike policy WORD<1-32> p2-pfs use-ike-group

Configure the IKE Authentication Method

Use the following procedure to configure the IKE authentication method. The default is pre-shared key.

About This Task

As part of the IKE protocol, one security gateway must authenticate another security gateway to make sure that IKE SAs are established with the intended party. The switch supports two authentication methods:

- Digital certificates

Configure peer identity name for IKE phase 1 and revocation check method.

- Pre-shared keys

Configure the same secret on both security gateways before the gateways can authenticate each other.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the IKE authentication method using one of the following:

- To use a digital certificate:

```
ike policy WORD<1-32> auth-method digital-certificate [peer-name  
WORD <1-64> | revocation-check-method <crl|none|ocsp>]
```

- To use a pre-shared key:

```
ike policy WORD<1-32> auth-method pre-shared-key
```

```
ike policy WORD<1-32> pre-shared-key WORD<0-32>
```

Variable Definitions

The following table defines parameters for the **ike policy WORD<1-32> auth-method** command.

Variable	Value
<i>pre-shared-key</i>	Specifies the authentication method as pre-shared key.
<i>digital-certificate peer-name WORD <1-64></i>	Specifies peer identity name for IKE phase 1.
<i>digital-certificate revocation-check-method<crl none ocsp></i>	Specifies the revocation check method. To set this option to the default value, use the default operator with the command: default ike policy WORD<1-32> revocation-check-method

The following table defines parameters for the **ike policy WORD<1-32> pre-shared-key** command.

Variable	Value
<i>pre-shared-key WORD<0-32></i>	Specifies the pre-shared key. For Federal Information Processing Standards (FIPS) compliance, the minimum length is 14 characters.

Configure Dead-Peer Detection Timeout

Use the following procedure to configure the dead-peer detection (DPD) timeout for the IKE Phase 1 policy.

About This Task

Dead Peer Detection (DPD) timeout is the interval for which the system sends messages to a peer to confirm its availability.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the DPD timeout:

```
ike policy WORD<1-32> dpd-timeout <1-4294967295>
```

Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> dpd-timeout** command.

Variable	Value
<i>policy</i> WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
<i>dpd-timeout</i> <1-4294967295>	Specifies the dead peer detection timeout in seconds for the IKE Phase 1 policy. The default is 300 seconds. To set this option to the default value, use the default operator with the command: default ike policy WORD<1-32> dpd-timeout

Enable the Admin State of IKE Phase 1 Policy

Use the following procedure to enable admin state of IKE Phase 1 policy.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable admin state of IKE Phase 1 policy:

```
ike policy WORD<1-32> enable
```
3. (Optional) Disable IKE Phase 1 policy:

```
no ike policy WORD<1-32> enable
```

Display IKE Profiles

Use the following procedure to display the configured IKE profiles:

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display all IKE profiles:

```
show ike profile
```
3. Display a specific ike profile:

```
show ike profile WORD<1-32>
```

Example

```
Switch:1#show ike profile
=====
                        IKE Profile
=====
Name                    Hash      Encrypt  Encrypt  DH      Exchange  Lifetime
                        Algo      Algo     Key Len  Group   Mode       seconds
-----
DFLT_IKE_PROFILE       sha256  aesCbc   256      modp2048 main       86400
ikePRO                  sha256  aesCbc   256      modp2048 main       180
test                    sha256  aesCbc   256      modp2048 main       86400
```

Variable Definition

The following table defines parameters for the **show ike profile** command.

Variable	Value
<i>profile</i> WORD<1-32>	Specifies the name of the profile to be displayed.

Display IKE Policies

Use the following procedure to display the configured IKE policies.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all IKE policies:
show ike policy
3. Display a specific IKE policy:
show ike policy WORD<1-32>
4. Display a specific IKE policy at local address.
show ike policy WORD<1-32> laddr WORD<1-256>
5. Display a specific IKE policy at remote address.
show ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>

Example

```
Switch:1#show ike policy
=====
                        IKE Policy

```

Variable Definition

The following table defines parameters for the **show ike policy** command.

Variable	Value
<i>policy</i> WORD<1-32>	Specifies the name of the policy to be displayed.
<i>laddr</i> WORD<1-256>	Specifies the local IPv4 or IPv6 address.
<i>raddr</i> WORD<1-256>	Specifies the remote IPv4 or IPv6 address.

Display IKE Security Association

Use the following procedure to display the configured IKE Phase 1 for version 1 and 2 security associations (SA).

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all the security associations:
show ike sa
3. Display security associations for IKE Phase 1 for version 1:
show ike sa version v1 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>

4. Display security associations for IKE Phase 1 for version 2:

```
show ike sa version v2 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
```

Example

```
Switch:1(config)#show ike sa version v1
```

```
=====

v2policy	300	sha256	aesCbc		modp2048	86400	active

Variable Definition

The following table defines parameters for the **show ike sa** command.

Variable	Value
<code>sa</code>	Specifies the IKE security association identifier.
<code>version v1</code> <code>WORD<1-32> laddr</code> <code>WORD<1-256> raddr</code> <code>WORD<1-256></code>	Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 1 SA.
<code>version v2</code> <code>WORD<1-32> laddr</code> <code>WORD<1-256> raddr</code> <code>WORD<1-256></code>	Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 2 SA.

Configure an IKEv2 Profile

About This Task

Use the following procedure to configure an IKEv2 profile.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Create an IKEv2-profile:
`ike v2-profile WORD<1-32>`
3. Configure the IKEv2 profile hash algorithm:
`ike v2-profile WORD<1-32> hash-algo <md5|sha|sha256|any>`
4. Configure the IKEv2 profile encryption algorithm:
`ike v2-profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>`
5. Configure the IKEv2 profile integrity algorithm
`ike v2-profile WORD<1-32> integrity-algo <hmac-md5|hmac-sha|hmac-sha256|aes-xcbc|any>`
6. Configure the IKEv2 profile dh group
`ike v2-profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any`
7. Configure the IKEv2 profile encryption key length:
`ike v2-profile WORD<1-32> encrypt-key-len <128|192|256>`
8. Configure the IKEv2 profile lifetime, in seconds:
`ike v2-profile WORD<1-32> lifetime-sec <0-4294967295>`
9. (Optional) Delete the IKEv2 profile:
`no ike v2-profile WORD<1-32>`

Variable Definition

The following table defines parameters for the **ike v2-profile** commands.

Variable	Value
<i>profile</i> WORD<1-32>	Specifies the IKE v2-profile name.
<i>hash-algo</i> <md5 sha sha256 any>	Specifies the type of hash algorithm. The default value is sha256. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> hash-algo
<i>encrypt-algo</i> <desCbc 3DesCbc aesCbc any>	Specifies the type of encryption algorithm. The default value is aesCbc. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> encrypt-algo
<i>integrity-algo</i> md5 sha-1 sha-256 aes-xcbc	Specifies the type of integrity algorithm. The default is sha256. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> integrity-algo
<i>dh-group</i> <modp768 modp1024 modp2048 any>	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> dh-group
<i>encrypt-key-len</i> <128 192 256>	Specifies the length of the encryption key. The default is 256. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> encrypt-key-len
<i>lifetime-sec</i> <0-4294967295>	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. To set this option to the default value, use the default operator with the command: default ike v2-profile WORD<1-32> lifetime-sec

Display IKEv2 Profiles

Use the following procedure to display the configured IKEv2 profiles.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all IKEv2 profiles:
show ike v2-profile
3. Display a specific IKEv2 profile:
show ike v2-profile WORD<1-32>

Example

```
Switch:1#show ike v2-profile test
```

```
=====

Variable Definitions

The following table defines parameters for the **show ike v-2profile** command.

Variable	Value
<i>WORD</i> <1-32>	Specifies the name of the policy.

IKE Configuration for Secure AAA Server using EDM

This section describes the procedures of IKE configuration for secure AAA server using EDM.

Configure IKE Phase 1 Profile

Use the following procedure to create and configure an IKE Phase 1 profile.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

IKE profile field descriptions

Use the data in the following table to use the **IKE > Profile** tab.

Name	Description
Name	Description
Name	Specifies the name of the profile.
HashAlgorithm	Specifies the hash algorithms that can be used during IKE Phase 1 SA negotiation. The default value is sha256.

Name	Description
EncryptionAlgorithm	Specifies the encryption algorithms that can be used during IKE Phase 1 SA negotiation. The default value is aesCbc.
EncryptKeyLen	Specifies the key length that should be used during IKE Phase 1 SA negotiation. The default value is 128.
DHGroup	Specifies the Diffie-Hellman groups that can be used during IKE Phase 1 SA negotiation. The default value is mod1024.
ExchangeMode	Specifies the IKE Phase 1 negotiation mode. The default value is main.
LifetimeSeconds	Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid. The default value is 86400 seconds.

Configure IKEv2 Profile

Use the following procedure to create and configure an IKEv2 profile.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **V2 Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

V2 Profile field descriptions

Use the data in the following table to use the **IKE > V2 Profile** tab.

Name	Description
Name	Specifies the IKE v2 profile name.
HashAlgorithm	Specifies the type of hash algorithm that can be used during IKE version 2 SA version 2 negotiation. The default value is sha256.
EncryptionAlgorithm	Specifies the encryption algorithms that can be used during IKE version 2 SA version 2 negotiation. The default value is aesCbc.
EncryptKeyLen	Specifies the type of encryption algorithm. The default value is keylen-256.

Name	Description
DHGroup	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048.
ExchangeMode	Specifies the IKE v2 profile negotiation mode. The default value is main.
LifetimeSeconds	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds.
IntegrityAlgorithm	Specifies the type of integrity algorithm.

Configure IKE Phase 1 Policy

Use the following procedure to create and configure an IKE Phase 1 policy.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **Policy** tab.
4. Click **Insert**.
5. In the **LocalIndex** field, click either **Port** or **Vlan**, and then select an interface.
6. In the **LocalAddrType** field, select the type of the local address.
7. In the **LocalAddr** field, type the address of the local peer.
8. In the **RemoteAddrType** field, select the type of the remote address.
9. In the **RemoteAddr** field, type the address of the remote peer.
10. In the **Name** field, type the name for the policy.

Name must be assigned when creating the policy. Once the policy is created, the name cannot be changed.

11. Complete the remaining optional configuration to customize the policy.
12. Click **Insert**.

Policy field descriptions

Use the data in the following table to use the **Policy** tab.

Name	Description
LocalIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.

Name	Description
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.
Name	Specifies the name given to the policy. The name should be assigned while creating the policy. You cannot change the name after the policy is created.
ProfileName	Specifies the name of the profile that should be used for this policy.
ProfileVersion	Specifies the profile version used for the policy.
PeerName	Specifies the peer name.
AuthenticationMethod	Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key.
PSKValue	Specifies the value of the Pre-Shared Key if the authentication method is set to PSK.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds. Default value is 300 seconds.
P2PFS	Specifies whether or not the perfect forward secrecy (PFS) is used when refreshing keys. To use PFS, select enable. The default value is disable.
P2PfsUseIkeGroup	Specifies whether or not to use the same GroupId (Diffie-Hellman Group) for phase 2 as was used in phase 1. Ignore this entry if P2PFS is disabled. The default value is enable.
P2PfsDHGroup	Specifies the Diffie-Hellman group to use for phase 2 when P2PFS is enabled and P2PfsUseIkeGroup is disabled. The default value is mod1024.
AdminState	Specifies whether the policy is administratively enabled or disabled. The default value is disable.
OperStatus	Shows is the policy is operationally up or down.
RevocationCheckMethod	Specifies the revocation check method as OCSP, CRL or none.

Display IKE Phase 1 Security Association

Use the following procedure to view the IKE Phase 1 security association.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **IKE**.
3. Click the **SA** tab.

IKE SA field descriptions

Use the data in the following table to use the **IKE > SA** tab.

Name	Description
Id	Specifies the profile ID.
LocalIfIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.
Name	Specifies the name given to the SA.
AuthenticationMethod	Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds.
HashAlgorithm	Specifies the hash algorithm negotiated for this IKE Phase 1 SA.
EncryptionAlgorithm	Specifies the encryption algorithm negotiated for this IKE Phase 1 SA.
EncryptKeyLen	Specifies the encryption key length negotiated for this IKE Phase 1 SA.
DHGroup	Specifies the Diffie-Hellman group negotiated for this IKE Phase 1 SA.
ExchangeMode	Specifies the IKE Phase 1 SA mode.
LifetimeSeconds	Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid.
Status	Specifies whether the SA is active or inactive.
Initiator	Specifies whether specifies the whether the SA is created by an initiator or a responder.

Display IKE V2 Security Association

Use the following procedure to view the IKE version 2 security association.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IKE**.
3. Click the **V2 SA** tab.

V2 SA field descriptions

Use the data in the following table to use the **IKE > V2 SA** tab.

Name	Description
Id	Specifies the profile ID.
LocalIfIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.
Name	Specifies the name given to the SA.
AuthenticationMethod	Specifies the proposed authentication method for the Version 2 security association. The default authentication method is pre-shared key.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds.
HashAlgorithm	Specifies the hash algorithm negotiated for this IKE Version 2 SA.
EncryptionAlgorithm	Specifies the encryption algorithm negotiated for this IKE Version 2 SA.
EncryptKeyLen	Specifies the encryption key length negotiated for this IKE Version 2 SA.
DHGroup	Specifies the Diffie-Hellman group negotiated for this IKE Version 2 SA.
ExchangeMode	Specifies the IKE Version 2 SA mode.
LifetimeSeconds	Specifies the amount of time for which an IKE Version 2 SA can remain valid during IKE Version 2 negotiation. A value of 0 means the SA always remains valid.
Status	Specifies whether the SA is active or inactive.
Initiator	Specifies whether specifies the whether the SA is created by an initiator or a responder.
IntegrityAlgorithm	Specifies the type of integrity algorithm.

Secure Shell Fundamentals

Methods of remote access such as Telnet or FTP generate unencrypted traffic. Anyone that can see the network traffic can see all data, including passwords and user names. Secure Shell (SSH) is a client and server protocol that specifies the way to conduct secure communications over a network. Secure Shell

can replace Telnet and other remote login utilities. Secure File Transfer Protocol (SFTP) can replace FTP with an encrypted alternative.

Note

If both SSH and SFTP are concurrently active, you have the ability to disable SFTP while allowing SSH to remain active. For more information, see [Disabling SFTP without disabling SSH](#) on page 2944.

The switch software supports Secure CoPy protocol (SCP), which is a secure file transfer protocol. Use SCP to securely transfer files between a local host and a remote host. SCP is in off state by default, but you can turn it on when you enable SSH using the **boot config flags** command in the global config mode. The switch supports SCP only as an SCP server, which means that clients can send files to the switch or can request files from the switch. Secure CoPy (SCP) can replace FTP with an encrypted alternative.

Secure Shell supports a variety of the different public and private key encryption schemes available. Using the public key of the host server, the client and server negotiate to generate a session key known only to the client and the server. This one-time key encrypts all traffic between the client and the server. The switch supports Secure Shell version 2 (SSHv2).

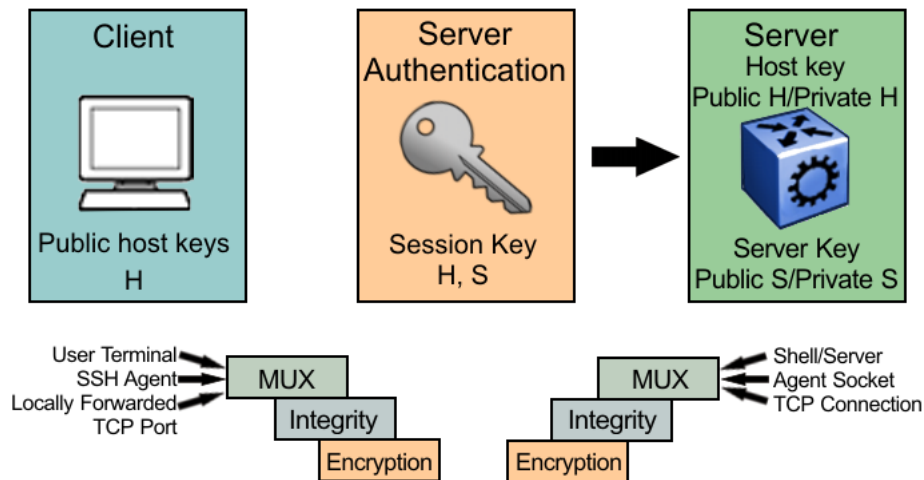

Figure 227: Overview of the SSHv2 protocol

By using a combination of host, server, and session keys, the SSHv2 protocol can provide strong authentication and secure communication over an insecure network, offering protection from the following security risks:

- IP spoofing
- IP source routing
- Domain name server (DNS) spoofing
- Man-in-the-middle/TCP hijacking attacks
- Eavesdropping and password sniffing

Even if network security is compromised, traffic cannot be played back or decrypted, and the connection cannot be hijacked.

The SSH secure channel of communication does not provide protection against break-in attempts or denial-of-service (DoS) attacks.

With the SSHv2 server in the switch, you can use an SSHv2 client to make a secure connection to the switch and work with commercially available SSHv2 clients. For more information about supported clients, see [Third-party SSH and SCP client software](#) on page 2926. The switch also supports outbound connections to remote SSHv2 servers to provide complete inbound and outbound secure access.

Outbound connections

The SSHv2 client supports SSHv2 DSA public key authentication and password authentication.

Note

You must enable SSH globally before you can generate SSH DSA user keys.

The SSHv2 client is a secure replacement for outbound Telnet. Password authentication is the easiest way to use the SSHv2 client feature.

Instead of password authentication, you can use DSA public key authentication between the SSHv2 client and an SSHv2 server. Before you can perform a public key authentication, you must generate the key pair files and distribute the key files to all the SSHv2 server systems. Because passphrase encrypts and further protects the key files, you must provide a passphrase to decrypt the key files as part of the DSA authentication.

To attempt public key authentication, the SSHv2 client looks for the associated DSA key pair files in the `/intflash/.ssh` directory. If no DSA key pair files are found, the SSHv2 client automatically prompts you for password authentication. If the SSHv2 client succeeds with the authentication, then a new secured SSHv2 session is established to the remote SSHv2 server. For more information, see [.DSA authentication access level and file name](#) on page 2928.

Important

If you configure the DSA user key with a passphrase but you do not supply the correct passphrase when you try to make the SSHv2 connection, then the system defaults back to the password authentication. If the SSHv2 client succeeds with the authentication, then a new secured SSHv2 session is established to the remote SSHv2 server.

SSH version 2

SSH version 2 (SSHv2) protocol is a complete rewrite of the SSHv1 protocol. In SSHv2 the functions are divided among three layers:

- SSH Transport Layer (SSH-TRANS)

The SSH Transport Layer manages the server authentication and provides the initial connection between the client and the server. After the connection is established, the Transport Layer provides a secure, full-duplex connection between the client and server.

- SSH Authentication Protocol (SSH-AUTH)

The SSH Authentication Protocol runs on top of the SSH Transport Layer and authenticates the client-side user to the server. SSH-AUTH defines three authentication methods: public key, host-based, and password. SSH-AUTH provides a single authenticated tunnel for the SSH connection protocol.

- SSH Connection Protocol (SSH-CONN)

The SSH Connection Protocol runs on top of the SSH Transport Layer and user authentication protocols. SSH-CONN provides interactive logon sessions, remote execution of commands, forwarded TCP/IP connections, and forwarded X11 connections. These services are multiplexed into the single encrypted tunnel provided by the SSH transport layer.

The following figure shows the three layers of the SSHv2 protocol.

Figure 228: Separate SSH version 2 protocols

The modular approach of SSHv2 improves on the security, performance, and portability of the SSHv1 protocol.

Important

The SSHv1 and SSHv2 protocols are not compatible. The switch does not support SSHv1.

Security features

The SSHv2 protocol supports the following security features:

- Authentication. This feature determines, in a reliable way, the SSHv2 client. During the log on process, the SSHv2 client is queried for a digital proof of identity.

Supported authentications with the switch as a server for SSHv2, are: RSA, DSA, and passwords. Supported authentications with the switch as a client for SSHv2, are: DSA and passwords. The switch does not support RSA when the switch acts as a client.

When the switch acts as an SSH server, by default the switch allows a maximum of only four sessions, although it can accommodate up to eight sessions at a time. However, only one SSH public key encryption per access level is allowed at a time. For instance, if multiple SSH public key encryption clients need to connect to the server with the same access level, such as rwa, then the clients must connect to the server one-by-one as the switch only supports one public key per access level.

- Encryption. The SSHv2 server uses encryption algorithms to scramble data and render it unintelligible except to the receiver.

Supported encryption and ciphers are: 3DES, AES128-cbc, AES192-cbc, AES256-cbc, AES128-ctr, AES192-ctr, AES256-ctr, MD5, secure hash algorithm 1 (SHA-1) and SHA-2.

- Integrity. This feature guarantees that the data transmits from the sender to the receiver without alterations. If a third party captures and modifies the traffic, the SSHv2 server detects this alteration.

Note

SCP is supported for RWA users only. RW or R level will not work and the switch logs a message on the device.

SSHv2 considerations using EDM

You must use CLI to initially configure SSHv2. You can use Enterprise Device Manager (EDM) to change the SSHv2 configuration parameters. CLI is the user interface for SSHv2 configuration and use the console port to configure the SSHv2 parameters. Depending on the hardware platform, the console port displays as console or 10101.

Important

Do not enable SSHv2 secure mode using Configuration and Orchestration Manager (COM). If you enable SSHv2 secure mode, then the system disables Simple Network Management Protocol (SNMP). This locks you out of a COM session. Enable SSH secure mode using CLI or EDM.

SSHv2 secure mode is different from enhanced secure mode and hsecure. SSHv2 secure mode disables unsecure management protocols on the device such as FTP, rlogin, SNMP, Telnet, and TFTP. SSHv2 secure mode is enabled through the **ssh secure** command.

When you enable SSHv2 secure mode, the system disables FTP, remote login (rlogin), SNMPv1, SNMPv2, SNMPv3, Telnet and TFTP. After SSHv2 secure mode is enabled, you can choose to enable individual non-secure protocols. However, after you save the configuration and restart the system, the non-secure protocol is again disabled, even though it is shown as enabled in the configuration file. After you enable SSHv2 secure mode, you cannot enable non-secure protocols by disabling SSHv2 secure mode.

Note

rlogin is supported only on the VSP 8600 Series.

You can disable block-snmp after you enable SSHv2 secure mode, and you can connect again using COM.

User ID Logs

User ID log of an SSH session established by SCP client

The switch logs the user ID of an SSH session initiated by the SCP client. If an SCP client establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:43:42.230:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:42.232:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SCP session
start by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.020:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SCP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.021:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

User ID log of an SSH session established by SFTP

The switch logs the user ID of an SSH session initiated by SFTP. If SFTP establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:45:32.903:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:32.905:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
start: user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.775:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SFTP
session end: user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by server for user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

User Key Files

Generating keys requires that you have free space on the flash. A typical configuration requires less than 2 kbyte of free space. Before you generate a key, verify that you have sufficient space on the flash, using the **dir** command. If the flash is full when you attempt to generate a key, the system displays an error message and the key is not generated. You must delete some unused files and regenerate the key.

If you remove only the public keys, enabling the SSH does not create new public keys.

SSHv2 password authentication uses the same login and password authentication mechanism as Telnet. The SSHv2 client also supports DSA public key authentication compatible with the switch SSHv2 server and Linux SSHv2 server for SSHv2.

If the switch is the client, use the following table to locate the DSA user key files for DSA authentication for user access level `rwa`.

Table 215: DSA user key files

SSH server	SSH client side	SSH server side
switch with enhanced secure mode disabled	Private and public keys by access level: <ul style="list-style-type: none"> • <code>rwa—/intflash/.ssh/id_dsa_rwa</code> (private key), <code>/intflash/.ssh/id_dsa_rwa.pub</code> (public key) • <code>rw—/intflash/.ssh/id_dsa_rw</code> (private key), <code>/intflash/.ssh/id_dsa_rw.pub</code> (public key) • <code>ro—/intflash/.ssh/id_dsa_ro</code> (private key), <code>/intflash/.ssh/id_dsa_ro.pub</code> (public key) • <code>rwl1—/intflash/.ssh/id_dsa_rwl1</code> (private key), <code>/intflash/.ssh/id_dsa_rwl1.pub</code> (public key) • <code>rwl2—/intflash/.ssh/id_dsa_rwl2</code> (private key), <code>/intflash/.ssh/id_dsa_rwl2.pub</code> (public key) • <code>rwl3—/intflash/.ssh/id_dsa_rwl3</code> (private key), <code>/intflash/.ssh/id_dsa_rwl3.pub</code> (public key) 	Public keys on the server side based on access level: <ul style="list-style-type: none"> • <code>rwa—/intflash/.ssh/dsa_key_rwa</code> (public key) • <code>rw—/intflash/.ssh/dsa_key_rw</code> (public key) • <code>ro—/intflash/.ssh/dsa_key_ro</code> (public key) • <code>rwl1—/intflash/.ssh/dsa_key_rwl1</code> (public key) • <code>rwl2—/intflash/.ssh/dsa_key_rwl2</code> (public key) • <code>rwl3—/intflash/.ssh/dsa_key_rwl3</code> (public key)
switch with enhanced secure mode enabled	Private and public keys by access role level: <ul style="list-style-type: none"> • <code>administrator—/intflash/.ssh/id_dsa_admin</code> (private key), <code>/intflash/.ssh/id_dsa_admin.pub</code> (public key) • <code>operator —/intflash/.ssh/id_dsa_operator</code> (private key), <code>/intflash/.ssh/id_dsa_operator.pub</code> (public key) • <code>security —/intflash/.ssh/id_dsa_security</code> (private key), <code>/intflash/.ssh/id_dsa_security.pub</code> (public key) • <code>auditor —/intflash/.ssh/id_dsa_auditor</code> (private key), <code>/intflash/.ssh/id_dsa_auditor.pub</code> (public key) • <code>privilege —/intflash/.ssh/id_dsa_priv</code> (private key), <code>/intflash/.ssh/id_dsa_priv.pub</code> (public key) 	Public keys on the server side based on access level: <ul style="list-style-type: none"> • <code>administrator—/intflash/.ssh/dsa_key_admin</code> (public key) • <code>operator—/intflash/.ssh/dsa_key_operator</code> (public key) • <code>security—/intflash/.ssh/dsa_key_security</code> (public key) • <code>privilege—/intflash/.ssh/dsa_key_priv</code> (public key) • <code>auditor—/intflash/.ssh/dsa_key_auditor</code> (public key)

Table 215: DSA user key files (continued)

SSH server	SSH client side	SSH server side
Linux with Open SSH	~/.ssh/id_dsa (private key) file permission 400 ~/.ssh/id_dsa.pub (public key) file permission 644	~/.ssh/authorized_keys (public key) file
ERS 8600/8800		/flash/.ssh/dsa_key_rwa (public key)

When you attempt to make an SSH connection from the switch, the SSHv2 client looks in its own internal flash for the public key pair files. If the key files exist, the SSHv2 client prompts you for the passphrase to decrypt the key files. If the passphrase is correct, the SSHv2 client initiates the DSA key authentication to the remote SSHv2 server. The SSHv2 client looks for the login user access level public key file on the SSHv2 server to process and validate the public key authentication. If the DSA authentication is successful, then the SSHv2 session is established.

If no matching user key pair files exist on the client side when initiating the SSHv2 session, or if the DSA authentication fails, you are automatically prompted for a password to attempt password authentication.

If the remote SSHv2 server is a Linux system, the server looks for the login user public key file `~/.ssh/authorized_keys` by default for DSA authentication. For a Linux SSHv2 client, the user DSA key pair files are located in the user home directory as `~/.ssh/id_dsa` and `~/.ssh/id_dsa.pub`.

Block SNMP

The boot flag setting for block-snmpp (**boot config flags block-snmpp**) and the runtime configuration of SSH secure (**ssh secure**) each modify the block-snmpp boot flag. If you enable SSH secure mode, the system automatically sets the block-snmpp boot flag to true; the change takes effect immediately. After enabling SSH in secure mode, you can manually change the block-snmpp flag to false to allow both SSH and SNMP access.

Important

The block flag setting for block-snmpp blocks Simple Network Management Protocol (SNMP)v1, SNMPv2, and SNMPv3.

SCP command

Use short file names with the Secure CoPy (SCP) command. The entire SCP command, including all options, user names, and file names must not exceed 80 characters. The switch supports incoming SCP connections but does not support outgoing connections using an SCP client.

Third-party SSH and SCP client software

Tested software

The following table describes the third-party SSH and SCP client software that has been tested but is not included with the switch software.

Table 216: Tested software

SSH Client	Secure Shell (SSH)	Secure Copy (SCP)
Tera Term Pro with TTSSH extension MS Windows	<ul style="list-style-type: none"> • Supports SSHv2. • Authentication: <ul style="list-style-type: none"> - RSA is supported when the switch acts as a server. The switch does not support RSA as a client. - DSA - Password • Provides a keygen tool. • It creates both RSA and DSA keys. 	<ul style="list-style-type: none"> • Client distribution does not include SCP client.
Secure Shell Client Windows 2000	<ul style="list-style-type: none"> • Supports SSHv2 client. • Authentication <ul style="list-style-type: none"> ◦ DSA ◦ Password • Provides a keygen tool. • It creates a DSA key in SSHv2 format. • The switch generates a log message stating that a DSA key has been generated. 	<ul style="list-style-type: none"> • Client distribution includes an SCP client that is not compatible with switch.
OpenSSH Unix Solaris 2.5 / 2.6	<ul style="list-style-type: none"> • Supports SSHv2 clients. • Authentication: <ul style="list-style-type: none"> - RSA is supported when the switch acts as a server. The switch does not support RSA as a client. - DSA - Password • Provides a keygen tool. • It creates both RSA and DSA keys. 	<ul style="list-style-type: none"> • Client distribution includes an SCP client that is supported on switch.
WinSCP	N/A	This SCP client is unsupported on the switch.

Switch as client

The switch acting as the SSHv2 client generates a DSA public and private server key pair. The public part of the key for DSA is stored in the following location:

```
/intflash/.ssh/dsa_key_rwa
```

The public part of the key must be copied to the SSH server and be named according to the naming requirement of the server.

Consult [DSA authentication access level and file name](#) on page 2928 for proper naming convention.

If a DSA key pair does not exist, you can generate the DSA key pair using the **ssh dsa-user-key [WORD<1-15>] [size <1024-1024>]** command.

You need to copy the DSA public key to the SSHv2 server that you connect to using the switch as a client. RSA is not supported when using the switch as a client, but you can use RSA when the switch is acting as the server.

Switch as server

After you install one of the SSHv2 clients you must generate a client and server key using the RSA or DSA algorithms.

To authenticate an SSHv2 client using DSA, the administrator must copy the public part of the client DSA key to /intflash/.ssh directory on the switch that acts as the SSHv2 server. The file that is copied over to the SSHv2 server must be named according to [DSA authentication access level and file name](#) on page 2928.

DSA authentication access level and file name

The following table lists the access levels and file names that you must use to store the SSHv2 client authentication information using DSA onto the switch that acts as the SSHv2 server.

Table 217: DSA authentication access levels and file names

Client key format or WSM	Access level	File name
Client key in non IETF and IETF format with enhanced secure mode disabled Note: The switch supports IETF and non-IETF for DSA.	RWA	/intflash/.ssh/dsa_key_rwa
	RW	/intflash/.ssh/dsa_key_rw
	RO	/intflash/.ssh/dsa_key_ro
	L3	/intflash/.ssh/dsa_key_rwl3
	L2	/intflash/.ssh/dsa_key_rwl2
	L1	/intflash/.ssh/dsa_key_rwl1

Table 217: DSA authentication access levels and file names (continued)

Client key format or WSM	Access level	File name
Client key in enhanced secure mode	administrator	/intflash/.ssh/dsa_key_admin
	operator	/intflash/.ssh/dsa_key_operator
	security	/intflash/.ssh/dsa_key_security
	privilege	/intflash/.ssh/dsa_key_priv
	auditor	/intflash/.ssh/dsa_key_auditor

The switch generates an RSA public and private server key pair. The public part of the key for RSA is stored in /intflash/.ssh/ssh_key_rsa_pub.key. If an RSA key pair does not exist, then the switch automatically generates one when you enable the SSH server. To authenticate a client using RSA, the administrator must copy the public part of the client RSA key to the switch.

RSA authentication access level and file name

The following table lists the access levels and file names you can use for storing the SSH client authentication information using RSA.

Table 218: RSA authentication access levels and file names

Client key format or WSM	Access level	File name
Client key in IETF format with enhanced secure mode disabled.	RWA	/flash/.ssh/rsa_key_rwa
	RW	/flash/.ssh/rsa_key_rw
	RO	/flash/.ssh/rsa_key_ro
	L3	/flash/.ssh/rsa_key_rwl3
	L2	/flash/.ssh/rsa_key_rwl2
	L1	/flash/.ssh/rsa_key_rwl1
Client key with enhanced secure mode enabled	administrator	/intflash/.ssh/rsa_key_admin
	operator	/intflash/.ssh/rsa_key_operator
	security	/intflash/.ssh/rsa_key_security
	privilege	/intflash/.ssh/rsa_key_priv
	auditor	/intflash/.ssh/rsa_key_auditor

SSH rekeying

SSH rekeying is an SSHv2 feature that allows the SSH server or client to force a key exchange between server and client, while changing the encryption and integrity keys. After you enable SSH rekeying, key exchanges occur after a pre-determined time interval or after the data transmitted in the session reaches the data-limit threshold. The default time-interval is 1 hour and the default data-limit is 1 GB. You can configure these values using the **ssh rekey** command.

SSH rekey is optional. You can enable SSH rekey only when SSH is enabled globally. Most SSH clients and servers do not provide a rekey mechanism, do not enable SSH rekey in such cases. Active sessions shut down if the rekey fails.

**Note**

You cannot enable SSH rekey selectively for either SSH client or server, it is enabled both on the SSH client and server together.

Configure Secure Shell using CLI

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network integrity.

Before You Begin

- Disable the sshd daemon. All SSHv2 commands, except enable, require that you disable the sshd daemon.
- Set the user access level to read/write/all community strings.
- Disable all nonsecure access services. As a best practice, disable the following services: Trivial File Transfer Protocol (TFTP), File Transfer Protocol (FTP), Telnet, and Remote login (rlogin). For more information about disabling access services, see [Enable Remote Access Services](#) on page 149.

**Note**

Rlogin is only supported on VSP 8600 Series.

- Use the console port to configure the SSHv2 parameters. Depending on your hardware platform, the console port displays as console or 10101.

Enabling the SSHv2 server

Enable the SSHv2 server to provide secure communications for accessing the switch. The switch does not support SSHv1.

Before You Begin

To enable SSH, ensure to enable RSA or DSA authentication, or both using command **ssh rsa-auth** or **ssh dsa-auth**.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the SSH server:

```
boot config flags sshd
```
3. Save the configuration file:

```
save config
```

Example

Enable the SSHv2 server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags sshd
Switch:1(config)#save config
```

Changing the SSH server authentication mode

Use this procedure to change the SSH server authentication mode from the default of password-authentication to keyboard-interactive.

About This Task

If you enable keyboard-interactive authentication mode, the server uses that mode over other authentication methods, except for public-key authentication, if the SSH client supports it.

If you enable keyboard-interactive authentication mode, the server generates the password prompts to display to the client rather than the client generating the prompts automatically like with password-authentication.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable keyboard-interactive authentication:
`ssh keyboard-interactive-auth`

Configure SSH Authentication Type

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the authentication type to use:
`ssh authentication-type {[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh]
[hmac-sha1] [hmac-sha2-256]}`

Variable Definitions

The following table defines parameters for the **ssh authentication-type** command.

Variable	Value
<code>[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh] [hmac-sha1] [hmac-sha2-256]</code>	Specifies the authentication type. Select from one of the following: <ul style="list-style-type: none"> • aead-aes-128-gcm-ssh • aead-aes-256-gcm-ssh • hmac-sha1 • hmac-sha2-256

Enable DSA Authentication

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable DSA authentication:

```
ssh dsa-auth
```

Generate the DSA Host Key

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Generate a new DSA host key:

```
ssh dsa-host-key [<1024-1024>]
```

Variable Definitions

The following table defines parameters for the **ssh dsa-host-key** command.

Variable	Value
<code><1024-1024></code>	The DSA host key size is 1024.

Generate a DSA User Key

Before You Begin

You must enable SSH globally before you can generate DSA user keys.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Generate a new DSA user key:

```
ssh dsa-user-key WORD<1-15>
```

Variable Definitions

The following table defines parameters for the **ssh dsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level. You must enable SSH globally before you can generate SSH DSA user keys.</p> <p>If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • rwa — Specifies read-write-all. • rw — Specifies read-write. • ro — Specifies read-only. • rw1 — Specifies read-write for Layer 1. • rw2 — Specifies read-write for Layer 2. • rw3 — Specifies read-write for Layer 3. <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • auditor—Specifies a user role that can view log files and view all configurations, except password configuration. • security—Specifies a user role with access only to security settings and the ability to view the configurations. • priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.

Configure Encryption Type

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the type of encryption to use:

```
ssh encryption-type {[3des-cbc] [aead-aes-128-gcm-ssh ] [aead-aes-256-
gcm-ssh] [aes128-cbc] [aes128-ctr] [aes192-cbc] [aes192-ctr] [aes256-cbc]
[aes256-ctr] [blowfish-cbc] [rijndael128-cbc] [rijndael192-cbc]}
```

Variable Definitions

The following table defines parameters for the **ssh encryption-type** command.

Variable	Value
<i>[3des-cbc] [aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh] [aes128-cbc] [aes128-ctr] [aes192-cbc] [aes192-ctr] [aes256-cbc] [aes256-ctr] [blowfish-cbc] [rijndael128-cbc] [rijndael192-cbc]</i>	Configures the encryption-type. Select an encryption-type from one of the following: <ul style="list-style-type: none"> • 3des-cbc • aead-aes-128-gcm-ssh • aead-aes-256-gcm-ssh • aes128-cbc • aes128-ctr • aes192-cbc • aes192-ctr • aes256-cbc • aes256-ctr • blowfish-cbc • rijndael128-cbc • rijndael192-cbc

Configure the Key-Exchange Method

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the key-exchange to use:

```
ssh key-exchange-method {[diffie-hellman-group1-sha1] [diffie-hellman-
group14-sha1]}
```

Variable Definitions

The following table defines parameters for the **ssh key-exchange-method** command.

Variable	Value
<code>[diffie-hellman-group1-sha1][diffie-hellman-group14-sha1]</code>	Configures the key-exchange method. Select a key-exchange method from one of the following: <ul style="list-style-type: none"> diffie-hellman-group1-sha1 diffie-hellman-group14-sha1

Configure the Maximum Number of SSH Sessions

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure the maximum number of SSH sessions:

```
ssh max-sessions <0-8>
```

Variable Definitions

The following table defines parameters for the **ssh max-sessions** command.

Variable	Value
<code><0-8></code>	Specifies the maximum number of SSH sessions allowed. A value from 0 to 8. Default is 4.

Enable SSH Password Authentication

Enable password authentication. The default is enabled.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable password authentication:

```
ssh pass-auth
```

Configure the SSH Connection Port

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Configure the SSH connection port:

```
ssh port <22,1024..49151>
```

Variable Definitions

The following table defines parameters for the **ssh port** command.

Variable	Value
<22,1024-49151>	Specifies the TCP port number. The default is 22. Important: You cannot configure TCP port 6000 as the SSH connection port.

Enable RSA Authentication

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the RSA authentication:

```
ssh rsa-auth
```

Generate an RSA Host Key

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Generate a new RSA host key:

```
ssh rsa-host-key [<1024-2048>]
```

Variable Definitions

The following table defines parameters for the **ssh rsa-host-key** command.

Variable	Value
<1024-2048>	Specify an optional key size from 1024 to 2048. The default is 2048.

Generate an RSA User Key

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Generate a new RSA user key.

```
ssh rsa-user-key WORD<1-15>
```

Variable Definitions

The following table defines parameters for the **ssh rsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • rwa — Specifies read-write-all • rw — Specifies read-write • ro — Specifies read-only • rwl1 — Specifies read-write for Layer 1 • rwl2 — Specifies read-write for Layer 2 • rwl3 — Specifies read-write for Layer 3 <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the value user access levels for the switch are:</p> <ul style="list-style-type: none"> • admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • auditor—Specifies a user role that can view log files and view all configurations, except password configuration. • security—Specifies a user role with access only to security settings and the ability to view the configurations • priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.

Enable SSH Secure Mode

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable SSH secure mode:
`ssh secure`

Configure the SSH version

Configure Secure Shell version 2 (SSHv2). The switch does not support SSHv1.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the SSH version:
`ssh version <v2only>`

Configure the SSH Authentication Timeout

Configure the timeout for SSH connection authentication.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the authentication timeout:
`ssh timeout <1-120>`

Variable Definitions

The following table defines parameters for the **ssh timeout** command.

Variable	Value
<1-120>	Specifies the SSH connection authentication timeout in seconds. Default is 60 seconds.

Configure X.509 V3 Authentication

Note

DEMO FEATURE - Two-Factor Authentication-X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable X.509 V3 authentication:
`ssh x509v3-auth enable`
3. Configure X.509 V3 revocation:
`ssh x509v3-auth revocation-check-method {none | ocsp}`
4. Configure X.509 V3 username:
`ssh x509v3-auth username {overwrite | strip-domain | use-domain WORD<1-254>}`

Variable Definitions

The following table defines parameters for the **ssh x509v3-auth** command.

Variable	Value
<code><none ocsp></code>	<p>Specifies the X.509 V3 authentication revocation check method. The default is OCSP.</p> <ul style="list-style-type: none"> none - Specifies no revocation check method. ocsp - Specifies Online Certificate Status Protocol (OCSP) as revocation check method. <p>x509v3-auth is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix.</p>
<code>overwrite strip-domain use-domain WORD<1-254></code>	<p>Specifies the X.509 V3 username configuration. The default is disabled.</p> <ul style="list-style-type: none"> overwrite - Specifies the switch to send the principal name and domain name from the certificate to the RADIUS server for authorization. strip-domain - Specifies the switch to send the principal name from the certificate without the domain name to the RADIUS server for authorization. use-domain WORD<1-254> - Specifies the switch to send the principal name from the certificate, with the domain name you entered to the RADIUS server for authorization. <p>x509v3-auth is available for demonstration purposes on some products. For more information, see VOSS Feature Support Matrix.</p>

Verifying and displaying SSH configuration information

Verify that SSH services are enabled on the switch and display SSH configuration information to ensure that the SSH parameters are properly configured.

Procedure

- To enter User EXEC mode, log on to the switch.
- Verify that SSH services are enabled and view the SSH configuration:

```
show ssh <global|session>
```

Example

Display global system SSH information:

```
Switch:1>show ssh global

Total Active Sessions      : 0
      version                : v2only
```

```

port : 22
max-sessions : 4
timeout : 60
action rsa-host key : rsa-hostkeysize 2048
action dsa-host key : dsa-hostkeysize 1024
rsa-auth : false
dsa-auth : true
pass-auth : true
keyboard-interactive-auth : false
sftp enable : true
enable : true
authentication-type : aead-aes-128-gcm-ssh aead-aes-256-gcm-ssh hmac-sha1
hmac-sha2-256
encryption-type : 3des-cbc aead-aes-128-gcm-ssh aead-aes-256-gcm-ssh
aes128-cbc aes128-ctr aes192-cbc aes192-ctr aes256-cbc aes256-ctr blowfish-
cbc rijndael128-cbc rijndael192-cbc
key-exchange-method : diffie-hellman-group1-sha1 diffie-hellman-group14-sha1

```

Variable Definitions

The following table defines parameters for the **show ssh** command.

Variable	Value
<i>global</i>	Display global system SSH information.
<i>session</i>	Display the current session SSH information.

Connect to a Remote Host using the SSH Client

Make an SSH connection to a remote host.

Before You Begin

Enable the SSH server on the remote host.

About This Task

The command format, for the CLI SSH client command, is similar to Telnet with two additional parameters: *-l login* and an optional *-p port* parameter.

On IPv6 networks, the switch supports SSH server only. The switch does not support outbound SSH client over IPv6. On IPv4 networks, the switch supports both SSH server and SSH client.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Connect to a remote host:

```
ssh WORD<1-256> -l WORD<1-32> [-p <1-32768>]
```

Example

Connect to the remote host:

```
Switch:1>enable
Switch:1#ssh 192.0.2.1 -l rwa
```

Variable Definitions

The following table defines parameters for the **ssh** command.

Variable	Value
<i>WORD</i> <1-32>	Specifies the user login name of the remote SSH server.
<i>-p</i> <1-32768>	Specifies the port number to connect to the remote SSH server. The default is 22.

Generating user key files

Configure the SSH parameters to generate DSA user key files.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable SSH server.
3. Create the DSA user key file:

```
ssh dsa-user-key [WORD<1-15>][size <1024-1024>]
```
4. Enter the encryption password to protect the key file.
5. Copy the user public key file to the remote SSH servers.
6. If you are generating the compatible keys on a Linux system, use the following steps:
 - a. Create the DSA user key file:

```
ssh-keygen -t dsa
```
 - b. Copy the user public key to the remote SSH servers.

Note

The DSA pair key files can be generated on the Linux system and used by the SSH client on the switch.

Example

Create the DSA user key file with the user access level set to read-write-all and size of the DSA user key set to 1024 bits:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ssh dsa-user-key rwa size 1024
```

Variable Definitions

The following table defines parameters for the **ssh dsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15 >	<p>Specifies the user access level. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • <i>rwa</i>—Specifies read-write-all. • <i>rw</i>—Specifies read-write. • <i>ro</i>—Specifies read-only • <i>rw13</i>—Specifies read-write for Layer 3. • <i>rw12</i>—Specifies read-write for Layer 2. • <i>rw11</i>—Specifies read-write for Layer 1. <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> • <i>admin</i>—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles. • <i>operator</i>—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands. • <i>auditor</i>—Specifies a user role that can view log files and view all configurations, except password configuration. • <i>security</i>—Specifies a user role with access only to security settings and the ability to view the configurations. • <i>priv</i>—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.
<i>size</i> <1024- 1024>	Specifies the size of the DSA user key. The default is 1024 bits.

Manage an SSL Certificate

The TLS server selects the server certificate in the following order:

1. A certificate authority (CA)-signed certificate if the certificate is already present in the `/intflash/.cert/` folder on the switch.
2. A self-signed certificate if the certificate is already present in the `/intflash/.cert/` folder on the switch.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. The self-signed certificate is available in `/intflash/.cert/.ssl`. You can choose to use an online or offline CA-signed certificate, which will take precedence over the self-signed certificate.

For more information about SSL certificate manipulation, see [Certificate Order Priority](#) on page 2968.

About This Task

If a certificate is already present, you must confirm that it can be deleted before a new one is created.

After you create a certificate, the system logs one of the following INFO alarms:

- New default Server Certificate and Key are generated and installed
- Current Server Certificate and Key are installed

The default certificate key length for a certificate generated on the switch is 2,048 bits.

Note

The **ssl certificate [validity-period-in-days <30-3650>]** command in this procedure does not require a system reboot.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create and install a new self-signed certificate:

```
ssl certificate [validity-period-in-days <30-3650>]
```

3. Delete a certificate:

```
no ssl certificate
```

Note

The certificate loaded in memory remains valid until you use the **ssl reset** command or reboot the system.

Variable Definitions

The following table defines parameters for the **ssl certificate** command.

Variable	Value
<i>validity-period-in-days</i> <30-3650>	Specifies an expiration time for the certificate. The default is 365 days.

Disabling SFTP without disabling SSH

Disable SFTP while allowing SSH to remain active.

Before You Begin

Enhanced secure mode must be enabled. For information about enabling enhanced secure mode, see [Enabling enhanced secure mode](#) on page 3288.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable the SSHv2 server:

```
no ssh sftp enable
```
3. Save the configuration file:

```
save config
```

Enabling SSH rekey

Before You Begin

Enable SSH globally.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the following command:

```
ssh rekey enable
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable SSH rekeying globally:

```
Switch:1(config)#ssh rekey enable
```

Variable Definitions

The following table defines parameters for the **ssh rekey** command.

Variable	Value
<i>enable</i>	Enables SSH rekey globally.

Configuring SSH rekey data-limit

Use the following procedure to configure the limit for data transmission during the session.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Enter the following command:

```
ssh rekey data-limit <1-6>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Configure the SSH rekey data-limit to 2 GB:

```
Switch:1(config)#ssh rekey data-limit 2
```

Variable Definitions

The following table defines parameters for the **ssh rekey data-limit** command.

Variable	Value
<1-6>	Sets the SSH rekey data limit in GB, range is 1-6.

Configuring SSH rekey time-interval

Use the following procedure to configure a time interval, after which the key exchange takes place.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command:

```
ssh rekey time-interval <1-6>
```

Example

```
Switch:1> enable
Switch:1# configure terminal
```

Configure the SSH rekey time-interval to 3 hours:

```
Switch:1(config)# ssh rekey time-interval 3
```

Variable Definitions

The following table defines parameters for the **ssh rekey time-interval** command.

Variable	Value
<1-6>	Sets the time-interval for SSH rekeying in hours, the range is 1 to 6.

Display SSH Rekey Information

Use the following procedure to display the SSH rekey information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Enter the following command:
show ssh rekey

Example

```
Switch:1> enable
Switch:1#show ssh rekey
    Rekey Status      : TRUE
    Rekey data limit  : 1 GB
    Rekey time interval : 1 hours
```

Enabling or Disabling the SSH Client

About This Task

You can disable the SSH client functionality on the switch. By default, the SSH client functionality is enabled.

Note

In order to enable the SSH client functionality, SSH must be enabled globally.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Disable the SSH client functionality:
no ssh client <enable>
3. Use one of the following commands to enable the SSH client functionality:
 - ssh client <enable>
 - default ssh client <enable>

Note

You must enable SSH globally before the SSH client functionality can be re-enabled.

Example

Display the general SSH settings::

```
Switch:1(config)# show ssh global
Total Active Sessions : 0
    version            : v2only
    port               : 22
    max-sessions       : 4
    timeout            : 60
    action rsa-host key : rsa-hostkeysize 2048
    action dsa-host key : dsa-hostkeysize 1024
```

```
rsa-auth          : true
dsa-auth          : true
pass-auth        : true
keyboard-interactive-auth : false
sftp enable      : true
enable           : true
client enable    : true
```

Disable SSH client functionality:

```
Switch:1(config)# no ssh client
```

```
Switch:1(config)# show ssh global
```

```
Total Active Sessions : 0
  version              : v2only

```

Downgrading or Upgrading from Releases that Support Different Key Sizes

Use this procedure if you need to downgrade or upgrade from a release that supports different key sizes.

Different releases can support different DSA host key, RSA host key, and DSA user key sizes. If you need to upgrade or downgrade to an earlier release that does not support the same key size, you must delete all of the keys from the .ssh directory and generate new keys for SSH. If you do not do this, key sizes that are no longer supported will no longer function.

You only need to perform this procedure if you have previously generated DSA host, RSA host, or DSA user keys with a release that supports different key sizes.

Procedure

1. Use the following command to disable SSH:

```
no ssh
```
2. From the config terminal go to the .ssh directory using the command:

```
cd /intflash/.ssh
```
3. After you upgrade or downgrade, delete the following keys from the .ssh directory.

```
ssh_dss.key
ssh_rsa.key
moc_sshc_dsa_file
moc_sshc_rsa_file
id_dsa_rwa
id_dsa_rwa.pub
id_rsa_rwa
id_rsa_rwa.pub
```

```
noc_sshc_dsa_file_fed
noc_sshc_rsa_file_fed
known_hosts
ssh_ecdsa.key
dsa_key <access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: dsa_key_rwa
rsa_key <access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: rsa_key_rwa
```

4. Generate a new DSA host key:

```
ssh dsa-host-key [<1024-1024>]
```

5. Generate a new SSH DSA user key:

```
ssh dsa-user-key WORD<1-15> [size <1024-1024>]
```

6. Generate a new RSA host key:

```
ssh rsa-host-key [<1024-2048>]
```

Secure Shell configuration using Enterprise Device Manager

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network Integrity.

On IPv6 networks, the switch supports SSHv2 server only. The switch does not support outbound SSHv2 client over IPv6. On IPv4, the switch supports both SSHv2 server and SSHv2 client.

For more information, see [Change Secure Shell Parameters](#) on page 2949.

Change Secure Shell Parameters

You can use Enterprise Device Manager to change the SSHv2 configuration parameters. However, as a best practice, use the CLI to perform the initial configuration of SSHv2. The switch does not support SSHv1.

Before You Begin

- The user access level is read/write/all community strings.
- You must disable the SSH service before you configure the SSH service parameters. If the SSHv2 service is enabled, the system displays all fields dimmed until the SSH service is disabled.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **SSH**.
3. Click the **SSH** tab.
4. In the **Enable** field, select the type of SSH service you want to enable.
5. In the **Version** field, select a version.
6. In the **Port** field, type a port.
7. In the **MaxSession** field, type the maximum number of sessions allowed.
8. In the **Timeout** field, type the timeout.
9. From the **KeyAction** field, choose a key action.
10. In the **RsaKeySize** field, type the RSA key size.
11. In the **DSAKeySize** field, type the DSA key size.

12. Select the **RsaAuth** check box for RSA authentication.
13. Select the **DsaAuth** check box for DSA authentication.
14. Select the **PassAuth** check box for password authentication.
15. In the **AuthType** section, select the authentication types you want.
16. In the **Encryption Type** section, select the authentication types you want.
17. In the **KeyExchangeMethod** section, select the authentication types you want.
18. Click **Apply**.

SSH Field Descriptions

Use the data in the following table to use the **SSH** tab.

Name	Description
Enable Note: Exception: rlogin is only supported on VSP 8600 Series.	Enables, disables, or securely enables SSHv2. The options are: <ul style="list-style-type: none"> • false • true • secure Select false to disable SSHv2 services. Select true to enable SSHv2 services. Select secure to enable SSH and disable access services (SNMP, FTP, TFTP, rlogin, and Telnet). The default is false. Important: Do not enable SSHv2 secure mode using Enterprise Device Manager. Enabling secure mode disables SNMP. This locks you out of the Enterprise Device Manager session. Enable SSHv2 secure mode using CLI.
Version	Configures the SSH version. The options are: <ul style="list-style-type: none"> • v2only The default is v2only.
Port	Configures the SSHv2 connection port number. <22 or 1024-49151> is the port range of SSHv2. Important: You cannot configure the TCP port 6000 as SSHv2 connection port.
MaxSession	Configures the maximum number of SSHv2 sessions allowed. The value can be from 0 to 8. The default is 4.
Timeout	Configures the SSHv2 authentication connection timeout in seconds. The default is 60 seconds.
KeyAction	Configures the SSHv2 key action. The options are: <ul style="list-style-type: none"> • none • generateDsa • generateRsa • deleteDsa • deleteRsa
RsaKeySize	Configures SSHv2 RSA key size. The value can be from 1024 to 2048. The default is 2048.

Name	Description
DsaKeySize	Configures the SSHv2 DSA key size. The value can be from 512 to 1024. The default is 1024.
RsaAuth	Enables or disables SSHv2 RSA authentication. The default is enabled.
DsaAuth	Enables or disables SSHv2 DSA authentication. The default is enabled.
PassAuth	Enables or disables SSHv2 RSA password authentication. The default is enabled.
RekeyEnable Note: Exception: Not supported on XA1400 Series or VSP 8600 Series	Enables SSH rekey globally. The default is disabled.
RekeyTimeInterval Note: Exception: Not supported on XA1400 Series or VSP 8600 Series	Configures a time interval, after which the key exchange takes place. The default is 1 hour.
RekeyDataLimit Note: Exception: Not supported on XA1400 Series or VSP 8600 Series	Configures the limit for data transmission during the session. The default is 1 GB.
SftpEnable	Enables or disables SFTP. You can use this check box to disable SFTP without affecting the SSH status. The default is enabled.
KeyboardInteractiveAuth	Changes the SSH server authentication mode from the default of password authentication to keyboard interactive.
ClientEnable	Enables SSH client functionality on the switch. By default, the SSH client functionality is enabled. To enable the SSH client functionality, SSH must be enabled globally.
AuthType	Specifies the authentication type. Select from one of the following: <ul style="list-style-type: none"> • hmacSha1 • hmacSha2256 • aeadAes128GcmSsh • aeadAes256GcmSsh By default, all authentication types are selected.

Name	Description
EncryptionType	Configures the encryption-type. Select an encryption-type from one of the following: <ul style="list-style-type: none">• aes128Cbc• aes256Cbc• threeDesCbc• aeadAes128GcmSsh• aeadAes256GcmSsh• aes128Ctr• rijndael128Cbc• aes256Ctr• aes192Ctr• aes192Cbc• rijndael192Cbc• blowfishCbc
KeyExchangeMethod	Configures the key-exchange type. Select from one of the following: <ul style="list-style-type: none">• diffieHellmanGroup14Sha1• diffieHellmanGroup1Sha1

Security

[Security Fundamentals](#) on page 2953

[Security Configuration using CLI](#) on page 2970

[Security Configuration using EDM](#) on page 3013

Security Fundamentals

This section provides conceptual content to help you configure and customize the security services on the switch.

Security overview

Security is a critical attribute of networking devices. Security features are split into two main areas:

- Control path—protects the access to the device from a management perspective.
- Data path—protects the network from malicious users by controlling access authorization to the network resources (such as servers and stations). This protection is primarily accomplished by using filters or access lists.

You can protect the control path using the following mechanism:

- logon and passwords
- access policies to specify the network and address that can use a service or daemon
- secure protocols, such as Secure Shell (SSH), Secure Copy (SCP), and the Simple Network Management Protocol version 3 (SNMPv3)
- the Message Digest 5 Algorithm (MD5) to protect routing updates, Open Shortest Path First (OSPF), and Border Gateway Protocol (BGP)

You can protect the data path using the following mechanism

- Media Access Control (MAC) address filtering
- Layer 3 filtering, such as Internet Protocol (IP) and User Datagram Protocol (UDP)/Transmission Control Protocol (TCP) filtering
- routing policies to prevent users from accessing restricted areas of the network
- mechanisms to prevent denial-of-service (DOS) attacks

Security Modes

The switch support three security modes:

- Enhanced secure
- Hsecure
- SSH secure

Enable SSH secure mode to allow only SSH to be used and disable all other protocols which include Telnet, rlogin, FTP, SNMP, TFTP, HTTP, and HTTPS. Enabling this mode disables Telnet, rlogin, FTP, SNMP, TFTP, HTTP, and HTTPS by setting the boot flags for these protocols to off. You can over-ride the configuration and enable required protocols individually for run-time use. The administrator must enable required protocols individually for run-time use again following a reboot even if you save the configuration. This is because the SSH secure mode enable takes precedence at the time of reboot and the other protocols will be disabled even though the configuration file has them set to enabled.

Note

Rlogin is only supported on VSP 8600 Series.

Note

Disabling SSH secure mode will not automatically enable the OA&M protocols that were disabled. The boot flags for the required protocols will have to be individually set to enabled.

The following table lists the differences between enhanced secure mode and hsecure mode.

Table 219: Enhanced secure mode versus hsecure mode

Feature	Enhanced secure	Hsecure
Authentication	Role-based: <ul style="list-style-type: none"> • admin • privilege • operator • security • auditor 	Access-level based: <ul style="list-style-type: none"> • rwa • rw • ro • l3 • l2 • l1
Password length	Minimum of 8 characters with the exception of the Admin, which requires a minimum of 15 characters	10 characters, minimum
Password rules	1 or 2 upper case, lower case, numeric and special characters	Minimum of 2 upper case, 2 lower case, 2 numeric and 2 special characters
Password expiration	Per-user minimum change interval is enforced, which is programmed by the Administrator	Global expiration, configured by the Admin
Password-unique	Previous passwords and common passwords between users are prevented	The same
Password renewal	Automatic password renewal is enforced	The same
Audit logs	Audit logs are encrypted, and authorized users are able to view, modify, and delete.	Standard operation

Table 219: Enhanced secure mode versus hsecure mode (continued)

Feature	Enhanced secure	Hsecure
SNMPv3	Password rules apply to SNMPv3 Auth&Priv. SNMPv3 is required (V1/V2 disabled)	SNMPv1 and SNMPv2 can be enabled.
EDM	Site Admin to enable or disable	Disabled
Telnet and FTP	Site Admin to enable or disable	The same
DOS attack Prevention	Not available	Prevents DOS attacks by filtering IP addresses and IP address ranges.

For information on Enhanced secure mode and SSH, see [Enhanced secure mode authentication access levels](#) on page 3272.

hsecure Mode

The switch supports a flag called high secure (hsecure). hsecure introduces the following behaviors for passwords:

- 10-character enforcement
- aging time
- limitation of failed logon attempts
- protection mechanism to filter certain IP addresses

After you enable the hsecure flag, the software enforces the 10-character rule for all passwords. This password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

After you enable hsecure, the system requires you to save the configuration file and reboot the system for hsecure to take effect. If the existing password does not meet the minimum requirements for hsecure, the system prompts you to change the password during the first login.

The default username is rwa and the default password is rwa. In hsecure, the system prompts you to change these during first login because they do not meet the minimum requirements for hsecure.

When you enable hsecure, the system disables Simple Network Management Protocol (SNMP) v1, SNMPv2 and SNMPv3. If you want to use SNMP, you must re-enable SNMP, using the command **no boot config flag block-snmp**.

Aging Enforcement

After you enable the hsecure flag, you can configure a duration after which you must change your password. You configure the duration by using the aging parameter.

For SNMP and File Transfer Protocol (FTP), after a password expires, access is denied. Before you access the system, you must change a community string to a new string consisting of more than eight characters.

Important

Consider the following after you enable the hsecure flag:

- You cannot enable the web server for Enterprise Device Manager (EDM) access.
- You cannot enable the Secure Shell (SSH) password authentication.

Filtering Mechanism

Incorrect IP source addresses as network or broadcast addresses are filtered at the virtual router interface. Source addresses 192.168.168.0 and 192.168.168.255 are discarded.

This change is valid for all IP subnets, not only for /24.

You can filter addresses only if you enable the hsecure mode.

CLI Passwords

The switch ships with default passwords assigned for access to Command Line Interface (CLI) through a console or management session. If you have read/write/all access authority, and you are using SNMPv3, you can change passwords that are in an encrypted format. If you are using Enterprise Device Manager (EDM), you can also specify the number of available Telnet sessions and rlogin sessions.

Note

Rlogin is only supported on VSP 8600 Series.

Important

The default passwords are documented and well known. Change the default passwords and community strings immediately after you first log on.

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System Access](#) on page 3265.

Port Lock feature

You can use the Port Lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until the ports are first unlocked.

Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the device through various services, such as Telnet, SNMP, Trivial File Transfer

Protocol (TFTP), File Transfer Protocol (FTP), Hypertext Transfer Protocol (HTTP), remote shell (rsh), and remote login (rlogin). You can enable or disable access services by setting flags from CLI.

**Note**

rlogin and rsh are only supported on VSP 8600 Series.

You can define network stations that can explicitly access the switch or stations that cannot access it. For each service you can also specify the level of access, such as read-only or read-write-all.

**Important**

A third-party security scan shows the switch service ports open and in the listen state. No connections are accepted on these ports unless you enable the particular daemon. The switch does not dynamically start and stop the daemons at runtime and needs to keep them running from system startup.

For more information about configuring access policies, see [Access Policies for Services](#) on page 3269.

User-based policy support

You can set up a user-based policy (UBP) system by using Enterprise Policy Manager (EPM), a RADIUS server.

EPM is an application designed to manage the traffic prioritization and network access security for business applications. It provides centralized control of advanced packet classification and the ability to priority mark, police, meter, or block traffic.

EPM 5.0 supports UBPs, which allow security administrators to establish and enforce roles and conditions for each user for all access ports in the network. The UBP feature in EPM works in conjunction with Extensible Access Protocol (EAP) technology to enhance the security of the network. Users log on to the networks and are authenticated as the network connection is established.

The UBP feature works as an extension to the Roles feature in EPM. In a UBP environment, role objects are linked directly to specific users (as RADIUS attributes), as opposed to being linked simply to device interfaces. The role object then links the users to specific policies that control the user's access to the network.

When the RADIUS server successfully authenticates a user, the device sends an EAP session start event to the EPM policy server. The policy server then sends user-based policy configuration information for the new user roles to the interface, based on the role attribute that was assigned to that user on the RADIUS server.

Denial-of-Service Attack Prevention

Table 220: Denial-of-service attack prevention product support

Feature	Product	Release introduced
Directed Broadcast	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.1.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.1
	VSP 8400 Series	VOSS 5.1.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported
High Secure mode (hsecure boot configuration flag)	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VSP 4450 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

Hsecure

The switch supports a configurable flag, called high secure (hsecure). High secure mode introduces a protection mechanism to filter certain IP addresses, and two restrictions on passwords: 10-character enforcement and aging time.

If the device starts in hsecure mode with default factory settings, and no previously configured password, the system will prompt you to change the password. The new password must follow the rules mandated by high secure mode. After you enable hsecure and restart the system, if you have an invalid-length password you must change the password.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

The following information describes hsecure mode operations:

- When you enable the hsecure flag, after a certain duration you are asked to change your password. If not configured, the aging parameter defaults to 90 days.
- For SNMP and FTP, access is denied when a password expires. You must change the community strings to a new string made up of more than eight characters before accessing the system.
- You cannot enable the web server at any time.
- You cannot enable the SSH password-authentication feature at any time.

Hsecure is disabled by default. When you enable hsecure, the desired behavior applies to all ports.

For more information, see [Preventing certain types of DOS attacks](#) on page 2976.

Prioritization of Control Traffic

The switch uses a sophisticated prioritization scheme to schedule control packets on physical ports. This scheme involves two levels with both hardware and software queues to guarantee proper handling of control packets regardless of the switch load. In turn, this scheme guarantees the stability of the network. Prioritization also guarantees that applications that use many broadcasts are handled with lower priority.

You cannot view, configure, or modify control-traffic queues.

Directed Broadcast Suppression

You can enable or disable forwarding for directed broadcast traffic on an IP-interface basis. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcasts on an interface, you cause all frames sent to the subnet broadcast address for a local router interface to be dropped. Directed broadcast suppression protects hosts from possible DoS attacks.

To prevent the flooding of other networks with DoS attacks, such as the Smurf attack, the switch is protected by directed broadcast suppression. This feature is enabled by default. As a best practice, do not disable it.

For more information, see [Configuring directed broadcast](#) on page 2975.

ARP Request Threshold

The Address Resolution Protocol (ARP) request threshold defines the maximum number of outstanding unresolved ARP requests. The default value for this function is 500 ARP requests. To avoid excessive amounts of subnet scanning that a virus can cause, as a best practice, change the ARP request threshold to a value between 100 and 50. This configuration protects the CPU from causing excessive ARP requests, protects the network, and lessens the spread of the virus to other PCs. The following list provides further ARP threshold values:

- Default: 500
- Severe conditions: 50
- Continuous scanning conditions: 100
- Moderate: 200
- Relaxed: 500

For more information about how to configure the ARP threshold, see [Address Resolution Protocol](#) on page 282.

Multicast Learning Limitation

The Multicast Learning Limitation feature protects the CPU from multicast data packet bursts generated by malicious applications. If more than a certain number of multicast streams enter the CPU through a port during a sampling interval, the port is shut down until the user or administrator takes the appropriate action.

For more information, see [IP Multicast](#) on page 1401.

Authentication for Privileged EXEC Command Mode

Table 221: Authentication for Privileged EXEC Mode product support

Feature	Product	Release introduced
Authentication for Privileged EXEC CLI Command Mode	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.2
	VSP 4900 Series	VOSS 8.2
	VSP 7200 Series	VOSS 8.2
	VSP 7400 Series	VOSS 8.2
	VSP 8200 Series	VOSS 8.2
	VSP 8400 Series	VOSS 8.2
	VSP 8600 Series	VSP 8600 8.0
	XA1400 Series	VOSS 8.2

For enhanced security, you can enable user authentication to enter Privileged EXEC command mode. Use the **sys priv-exec-password** command to enable password authentication.

After you enable password authentication for Privileged EXEC command mode, the system prompts you to enter a password to access Privileged EXEC command mode from User EXEC command mode. You must enter the same password that you used to log on to the switch.

Considerations

- The same username and password used to Telnet or SSH to the switch is used to access Privileged EXEC command mode when authentication is enabled.
- RADIUS and TACACS+ protocols are supported. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch.
- No timeout exists for the password used to log on to the Privileged EXEC command mode.
- No limit to the number of retries if you enter an incorrect password.
- VSP 8600 Series authentication for Privileged EXEC command mode only allows HA support in hot-standby mode.

Configuration Considerations

Use the information in this section to understand the limitations of some security functions, such as BSAC RADIUS servers and Layer 2 protocols before you attempt to configure security.

Attribute Format for a Third-party RADIUS Server

If you use a third-party RADIUS server and need to modify the dictionary files, you must add a vendor-specific attribute (attribute #26) and use 1584 as vendor code for all the devices and then send back access-priority vendor-assigned attribute number 192 with a decimal value of 1 to 6, depending upon whether you want read only to read-write-all.

Authentication for Privileged EXEC Command Mode

Authentication for Privileged EXEC command mode supports RADIUS and TACACS+ protocols. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch

RADIUS on Management Ports

The management port supports the RADIUS protocol. When RADIUS packets are sent out of the management port, the SRC-IP address is properly entered in the RADIUS header.

For more information about the supported RADIUS servers, see the documentation of the RADIUS server.

RADIUS Server SNMP Accounting

An SNMP query sent by an unreachable RADIUS server configured as used-by snmp and with accounting enabled, can cause a timeout. A timeout can occur if the device that receives the SNMP query attempts to send accounting packets to the unreachable server. You can mitigate the timeout issue by configuring lower retry and timeout values on the RADIUS server. Alternatively, you can configure a higher timeout value for SNMP.

Single Profile Enhancement for BSAC RADIUS Servers

Before enabling Remote Access Dial-In User Services (RADIUS) accounting on the device, you must configure at least one RADIUS server.

The switch software supports Microsoft Radius Servers (NPS Windows 2008, Windows 2003 IAS Server), BaySecure Access Control (BSAC), Merit Network servers and Linux based servers. To use these servers, you must first obtain the software for the server. You must also make changes to one or more configuration files for these servers.

Single Profile is a feature that is specific to BSAC RADIUS servers. In a BSAC RADIUS server, when you create a client profile, you can specify all the returnable attributes. When you use the same profile for different products, you specify all the returnable attributes in the single profile.

SNMP Cloned User Considerations

If the user from which you are cloning has authentication, you can choose for the new user to either have the same authentication protocol as the user from which it was cloned, or no authentication. If you choose authentication for the new user, you must provide a password for that user. If you want a new

user to have authentication, you must indicate that at the time you create the new user. You can assign a privacy protocol only to a user that has authentication.

If the user from which you are cloning has no authentication, then the new user has no authentication.

Source IP Configuration

Note

The following Source IP configuration considerations are only applicable on hardware platforms running VOSS Release 8.2 and later.

The Source IP is the Internet Protocol address of the device sending the IP data packet. For devices running VOSS Release 8.2 and later, the system limits the Source IP to a maximum of three interfaces; the management Out-of-Band (OOB) management interface, the VLAN management interface, or the Circuitless IP (CLIP) management interface. The system uses separate routing tables for each Segmented Management Instance interface, plus a default main table. Since multiple routing tables are in use, each management interface can have overlapping or identical static routes without interfering with each other. The main table has a super-set of all routes where the weight of the static route can tie-break routes to the same destination going through different segmented management interfaces. By default, the following weights are used and the default route priority is management CLIP, then management VLAN, then management OOB:

- mgmt CLIP - 100
- mgmt VLAN - 200
- mgmt OOB - 300

You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

For example, if the default route uses mgmt CLIP and you want to use the mgmt OOB interface as the source IP to reach a RADIUS server, you must perform one of the following options:

- Configure a specific source IP static route for the mgmt OOB interface:

```
mgmt oob
ip route 192.0.2.0/24 next-hop 198.51.100.1
```

OR

- Configure the default mgmt OOB route weight lower than the default mgmt CLIP route weight:

```
mgmt oob
no ip route 0.0.0.0/24 next-hop 198.51.100.1
ip route 0.0.0.0/24 next-hop 198.51.100.1 weight 50
```

Note

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

For VOSS Release 8.1.5 and earlier, there was a potential for thousands of different Source IP management interfaces for applications initiating an outbound connection without a Source IP specified. To avoid Source IP fluctuations for many management interfaces with frequent route updates,

you could specify the Source IP for applications where the source IP identifies the client. Configuring a Source IP for specific management applications is deprecated in VOSS Release 8.2 and later.

Note

This applies only to client mgmt applications initiating an outgoing connection, where the source IP address is not specified. If an application is running in server mode, the source IP address of the reply packet is configured to the destination IP address of the original request for TCP connections.

Interoperability configuration

The switch is compatible with RADIUS servers.

Unicast Reverse Path Forwarding (uRPF)

Table 222: Unicast Reverse Path Forwarding product support

Feature	Product	Release introduced
Unicast Reverse Path Forwarding (URPF) checking (IPv4)	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.0

	XA1400 Series	Not Supported

The Unicast Reverse Path Forwarding (uRPF) feature prevents packet forwarding for incoming unicast IP packets that have incorrect or forged (spoofed) IP addresses. The uRPF feature checks that the traffic

received on an interface comes from a valid IP address, thereby preventing address spoofing. On a reverse path check, if the source IP address of the received packet at the interface is not reachable using the FIB, the system drops the packet as the packet may have originated from a misconfigured or a malicious source.

You can configure uRPF for each IP interface or VLAN. When uRPF is enabled on an interface, the switch checks all routing packets that come through that interface. It ensures that the system displays the source address and source interface in the routing table, and that it matches the interface, on which the packet was received.

You can use one of two modes for uRPF:

- **Strict mode:** In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. If the routing engine finds the source IP entry, uRPF further checks if the source IP interface matches the incoming interface of the packet. If they match, the system forwards the packet as usual, otherwise, the system discards the packet.

**Note**

The number of packets dropped due to uRPF check on the ingress interface gets incremented along with other general dropped statistics under the `IN-DISCARD` column in the output of the command `show interfaces gigabitEthernet error <collision|verbose> {slot/port[-slot/port] [,...]}`.

- **Loose mode:** In loose mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

uRPF can be enabled independently for IPv4 and IPv6. However, on a given interface, if uRPF is enabled for both IPv4 and IPv6, the `urpf-mode` can be either `strict-mode` or `loose-mode` for both IPv4 and IPv6. That means we cannot have IPv4 `urpf-mode` configured differently than that of IPv6.

**Note**

When you enable uRPF mode the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

**Note**

uRPF check cannot detect spoofed source IP address if the source IP address belongs to a known subnet.

Digital Certificate/PKI

Table 223: Digital Certificate/PKI product support

This section provides information on the digital certificate framework and offline certificate management.

A digital certificate is an electronic document that identifies the subject, proves the ownership of a public key, and is digitally signed by a certificate authority (CA) that certifies the validity of the information in the certificate. A digital certificate is valid for a specific time period.

The switch uses Public Key Infrastructure (PKI) support to obtain and use digital certificates for secure communication in the network.

To be certified, a switch performs the following tasks:

- Generate a certificate signing request.
- Verify that a present certificate has not been revoked.
- Validate the certificate.
- Renew the certificate before it expires.
- Remove the certificate, if required.

Subject

An administrator configures the subject parameters such as common name, organization name, organization unit, locality, state, and country for requesting the identity certificate.

Subject Alternative Name

A subject alternative name associates host name values such as an email address, an IP address, or a Fully qualified domain name (FQDN) with a security certificate. You can protect these additional host names with a single certificate.

Challenge Password

A password is required for Simple Certificate Enrollment Protocol (SCEP) operations such as the enrollment and renewal of identity certificates. This password is given offline by the CA during end entity registration. The administrator provides this password during enroll and renew operations.

UsePost

There are different types of CAs such as EJBCA, Win2012, and others. The `usePost` parameter enables you to choose the style of HTTP request. The value for the `usePost` parameter can be **True** or **False**.

For example, if Win2012 SCEP does not support the POST mode of HTTP request, configure the `usePost` as `False` for Win2012 and configure `usePost` as `True` for EJBCA.

Root CA Certificate

The Root CA certificate obtained offline from a CA must be installed for SCEP operations. This Root CA certificate is transferred to the device during the certificate installation. The system does not allow any SCEP operations if the offline Root CA certificate is not installed and if error messages are logged.

Key Generation

The supported key type is RSA with RSA key of size 2048. There can be only one active key-pair associated with the trustpoint CA and digital certificate. The system does not allow generating a new key-pair if there is a key-pair already associated with the active digital certificate. The system logs the error message if such new key generation is attempted. In such a case, the certificate must be revoked before a new key-pair is generated.

Trustpoint CA

Use trustpoints to manage and track CAs and certificates. A trustpoint is a representation of a CA or of an identity pair. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one generated key. The switch can enroll with a trustpoint to obtain an identity certificate. Trustpoint is configured after the RSA key pair is generated and the CA identity and other configuration parameters are available. The CA name to configure a trustpoint should be unique.

You can configure a SHA-256 fingerprint to authenticate a received CA certificate that matches the configured common name. The switch first checks for an installed, offline root certificate and validates against it. If no root certificate is present, the switch checks the SHA-256 fingerprint in the received CA certificate. The SHA-256 fingerprint does not authenticate the root certificate.

Certificate Enrollment

Certificate enrollment involves generating a certificate signing request (CSR). Before certificate enrollment, the trustpoint CA must be configured and the user configuration parameters should be available. The key usage extension parameter is required as an input; it indicates the purpose of the key contained in the certificate, that the key can be used for encipherment, digital signature, certificate signing and so on.

The certificate enrollment is not allowed if there is an active certificate already available. If new certificate enrollment is required, the existing active certificate must be revoked first. The system logs the enrollment success or failure responses.

Certificate Renewal

The administrator must renew the certificate before it expires. A trap is configured for a pre-defined period before the expiry date of the certificate, and the system logs the certificate renewal due warning message. The system does not allow a certificate renewal request if an active certificate is not available. The system replaces the existing certificate with the newly obtained certificate on successful renewal. The system logs the renewal success or failure responses.

Certificate Revocation or Removal

The certificate can be revoked or withdrawn from the specific device for a specific reason at any time. The system does not allow a certificate revocation request if an active certificate is not available. The system releases the existing certificate on successful revocation. The system logs the revocation success or failure responses.

During boot up, the system checks whether an active installed certificate is available. If a valid certificate is not available, the system logs the warning message.

Offline Certificate Management

Offline certificate management supports switches that cannot communicate with the Certificate Authority to obtain the identity certificate online by certificate enrollment operation.

Configure the subject and RSA key-pair to obtain the offline identity certificate. The configured subject parameters and RSA key are used to generate the CSR. This CSR is used to obtain the offline identity certificate.

You must install the Root CA certificate and all the intermediate CA certificates of the certificate chain in the device before installing the offline identity or device certificate. All the intermediate and Root CA

certificates are stored in the certificate store and are used for CA certificate chain validation. The CA certificate chain validation is performed starting from the issuing CA certificate to the Root CA certificate during the installation of offline identity certificate. The offline identity certificate is installed only if the CA certificate chain validation, subject, and key match.

Storage

No digital certificate configuration is visible if you use the **show running-config** command. Instead, use the commands appropriate for displaying digital certificate information. For more information, see [View the Certificate Details](#) on page 2994.

Certificate Order Priority

Table 224: Certificate order priority product support

Feature	Product	Release introduced
Note: VOSS Releases 6.0 and 6.0.1 do not support this feature.	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 5.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.0.50

Use the following information to understand the certificate order priority when the Transport Layer Security (TLS) server and switch connect.

The TLS server selects the server certificate in the following order:

1. A certificate authority (CA)-signed certificate if the certificate is already present in the `/intflash/.cert/` folder on the switch.
2. A self-signed certificate if the certificate is already present in the `/intflash/.cert/` folder on the switch.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. The self-signed certificate is available in `./intflash/.cert/.ssl`. You can choose to use an online or offline CA-signed certificate, which will take precedence over the self-signed certificate.

SSL-Based Self-Signed Certificate

Some earlier releases use the default certificate available in the `/intflash/.ssh` folder, which is the open SSL-based self-signed certificate that is named `host.cert`.

To use the Mocana stack-based self-signed certificate, delete the open SSL self-signed certificate prior to upgrading your software release. The Mocana certificate offers better and stronger encryption than open SSL-based certificates.

If you do not delete the `host.cert` file in the `/intflash/.ssh` folder used in earlier releases, you must generate a self-signed certificate automatically during upgrade or post upgrade using the command **`config ssl certificate`**.

If you have a subscribed CA-signed certificate renamed as `host.cert` in folder `/intflash/.ssh` in a previous release, it cannot be reused.

To use your subscribed CA-signed certificate, upgrade with the Mocana-based self-signed certificate, and then use the digital certificates feature to install a CA-signed certificate through the online or offline method.

You cannot obtain a CA-signed certificate and rename the certificate as `host.cert`. You must use the online or offline method to obtain a certificate.

Two-Factor Authentication for SSH

Table 225: Two-Factor Authentication for SSH product support

Feature	Product	Release introduced
Two-Factor Authentication for SSH	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 8.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 8.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 8.0
	VSP 8400 Series	VOSS 8.0
	VSP 8600 Series	VSP 8600 8.0 demo feature
	XA1400 Series	VOSS 8.0.50

Note

DEMO FEATURE - Two-Factor Authentication-X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use the following information to understand the Two-Factor Authentication feature.

Two-Factor Authentication uses smart card technology for remote device management. Two-Factor Authentication requires enhanced secure mode with Secure Shell (SSH) and X.509 V3 authorization

enabled on the switch. You must provide the digital certificates to enable the identity management for the SSH client and SSH server. Two-Factor Authentication requires the following items:

- a VSP Operating System Software (VOSS) switch
- a computer with Secure CRT 8.3.2 or 8.3.3 as the SSH client
- a smart card reader
- a Common Access Card (CAC) or Personal Identity Verification (PIV) card for each configured user

You can also use a Windows Server 2008, or newer, configured with a Remote Access Dial-In User Services (RADIUS) server and Active Directory.

Digital certificates in the X.509 V3 format provide identity management. A chain of signatures by a trusted certificate authority (CA) and its intermediate certificate CAs binds a given public signing key to a given digital identity. For user authentication, the SSH client sends the user certificate stored on the CAC or PIV card to the SSH server for verification. The SSH server validates the incoming user certificate using Public Key Infrastructure (PKI) trust-store.

After the switch validates the SSH certificate, the system parses for a username to forward to the RADIUS server for authorization. The switch prompts you to enter a password for the username. If the RADIUS server is unreachable or not configured, the authorization occurs locally on the switch for the username and password.

Two-Factor Authentication on the switch uses SSH and the X.509 V3 certificates stored on the smart card. X.509 V3 digital certificates are documented in RFC5280.

Smart Card Authentication Process

The process for PIV or CAC card authentication is as follows:

1. The PIV Authentication or the Card Authentication certificate is read from the PIV Card Application.
2. The relying system validates the PIV Authentication certificate from the PIV Card Application using standards-compliant PKI path validation to ensure that the certificate is valid and from a trusted source.
3. The cardholder is prompted to submit a PIN to activate the card.
4. The relying system issues a challenge string to the card and requests an asymmetric operation in response.
5. The card responds to the previously issued challenge by signing using the PIV Authentication private key.
6. The relying system verifies that the response from the card is expected for the issued challenge.
7. A unique identifier from the PIV Authentication certificate is extracted and passed as input to the access control decision.

Security Configuration using CLI

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using CLI](#) on page 3276.

Enable hsecure

The hsecure flag is disabled by default. When you enable it, the software enforces the 10 character rule for all passwords.

About This Task

When you upgrade from a previous release, if the password does not have at least 10 characters, you receive a prompt to change your password to the mandatory 10-character length.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable or disable hsecure mode:
`boot config flags hsecure`

The system displays the following warning messages:

```
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet,
SNMP are disabled. Individually enable the required services.
Warning: Please save boot configuration and reboot the switch for this to take effect.
```

Note

Warning message text can vary across hardware models.

3. Save the configuration and restart the device for the change to take effect.

Example

Enable hsecure mode. Save the configuration. Restart the switch.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet, SNMP
are disabled. Individually enable the required services. Warning: Please save boot
configuration and reboot the switch for this to take effect.
Switch:1(config)#save config
Switch:1(config)#reset
Are you sure you want to reset the switch (y/n)?y
```

Changing an invalid-length password

Before You Begin

Important

When you enable **hsecure**, passwords must contain a minimum of 10 characters or numbers with a maximum of 20. The password must contain a minimum of: two uppercase characters, two lowercase characters, two numbers, and two special characters.

About This Task

After you enable **hsecure** and restart the system, change your password if you have an invalid-length password.

Procedure

1. At the CLI prompt, log on to the system.
2. Enter the password.

When you have an invalid-length password, the system displays the following message:

```
Your password is valid but less than mandatory 10 characters.  
Please change the password to continue.
```

3. When prompted, enter the new password.
4. When prompted, reenter the new password.

Example

Log on to the switch:

```
Login: rwa
```

Enter the password:

```
Password: ***
```

```
Your password is valid but less than mandatory 10 characters. Please  
chnage the password to continue.
```

Enter the new password:

```
Enter the new password: *****
```

Re-enter the new password:

```
Re-enter the new password: *****
```

```
Password successfully changed.
```

Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If

you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Change a password:

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|  
read-write-all}
```

3. Enter the old password.

4. Enter the new password.

5. Enter the new password a second time.

6. Configure password options:

```
password access-level WORD<2-8>
```

```
password aging-time day <1-365>
```

```
password default-lockout-time <60-65000>
```

```
password lockout WORD<0-46> [time <60-65000>]
```

```
password min-passwd-len <10-20>
```

```
password password-history <3-32>
```

Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Change a password:

```
Switch:1(config)#password smith read-write-all
```

Enter the old password:

```
Switch:1(config)#*****
```

Enter the new password:

```
Switch:1 (config) #*****
```

Enter the new password a second time:

```
Switch:1 (config) #*****
```

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1 (config) #access-level rwa aging-time 60
```

Variable Definitions

The following table defines parameters for the **cli password** command.

Variable	Value
<i>layer1 layer2 layer3 read-only read-write read-write-all</i>	Changes the password for the specific access level.
<i>WORD<1-20></i>	Specifies the user logon name.

The following table defines parameters for the **password** command.

Variable	Value
<i>access level WORD<2-8></i>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> • l1 • l2 • l3 • ro • rw • rwa
<i>aging-time day <1-365></i>	Configures the expiration period for passwords in days, from 1-365. The default is 90 days.
<i>default-lockout-time <60-65000></i>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60-65000 range. The default is 60 seconds. To configure this option to the default value, use the default operator with the command.
<i>lockout WORD<0-46> time <60-65000></i>	Configures the host lockout time. <ul style="list-style-type: none"> • <i>WORD<0-46></i> is the host IP address in the format a.b.c.d. • <i><60-65000></i> is the lockout-out time, in seconds, in the 60-65000 range. The default is 60 seconds.

Variable	Value
<code>min-passwd-len <10-20></code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the default operator with the command.
<code>password-history <3-32></code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the default operator with the command.

Configuring directed broadcast

A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. When you disable (or suppress) directed broadcasts on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling directed broadcasts protects hosts from possible denial-of-service (DOS) attacks. By default, this feature is enabled on the device.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure the switch to forward directed broadcasts for a VLAN:

```
ip directed-broadcast enable
```

Example

Enable directed broadcast on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip directed-broadcast enable
```

Display VLAN IDs with directed broadcast enabled:

```
Switch:1>show ip directed-broadcast vlan
```

```

                                Vlan Directed-Broadcast
=====
  VLAN ID  DIRECTED-BROADCAST
-----
      2           true
```

Variable Definitions

The following table defines parameters for the **ip directed-broadcast** command.

Variable	Value
<i>enable</i>	Enables the device to forward directed broadcast frames to the specified VLAN. The default setting for this feature is enabled.

Preventing certain types of DOS attacks

Protect the switch against IP packets with illegal IP addresses such as loopback addresses or a source IP address of ones, or Class D or Class E addresses from being routed. The switch supports high-secure configurable flag.

About This Task

Important

After you enable this flag, the desired behavior (not routing source packets with an IP address of 255.255.255.255) applies to all ports that belong to the same port.

Important

The setting to enable hsecure only takes effect for packets going to the CP; not to datapath traffic.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable high-secure mode:

```
high-secure [port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]] enable
```

Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# interface GigabitEthernet 1/16
```

```
Switch:1(config-if)# high-secure enable
```

Variable Definitions

The following table defines parameters for the **high-secure** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port on which you want to enable high-secure mode. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>enable</code>	Enables the high-secure feature that blocks packets with illegal IP addresses. This flag is disabled by default. Use the no operator to remove this configuration. To configure this option to the default value, use the default operator with the command.

Configuring port lock

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable port lock globally:

```
portlock enable
```
3. Enter GigabitEthernet Interface Configuration mode:

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
4. Lock a port:

```
lock [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
enable
```

Example

```
Switch:1> enable

Switch:1# configure terminal

Log on to GigabitEthernet Interface Configuration mode:

Switch:1(config)# interface GigabitEthernet 1/1

Lock port 1/1:

Switch:1(config-if)# lock port 1/1 enable

Unlock port 1/1:
```

```
Switch:1(config-if)# no lock port 1/1 enable
```

Variable Definitions

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **lock port** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port you want to lock. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. The default is disabled.

Unicast Reverse Path Forwarding configuration using CLI

This section provides CLI procedures for Unicast Reverse Path Forwarding configuration.

Enable urpf-mode Boot Flag

To configure Unicast Reverse Path Forwarding on a port or VLAN, you are required to enable the urpf-mode boot flag. If you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

About This Task

Use the following procedure to enable the urpf-mode boot flag. By default, urpf-mode is disabled.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable the urpf-mode boot flag:

```
boot config flags urpf-mode
```

- When you get the following prompt to reboot the switch, enter `y` to reboot.

The new setting requires a reboot to take effect!

The configuration will be saved and rebooted.

Are you sure you want to re-boot the switch (y/n)?

Note

If you enter `n`, the following message is displayed: Warning: Please save the configuration and reboot the switch for this configuration to take effect.

- Check the status of the urpf-mode boot flag:

```
show boot config flags
```

Example

Enable the urpf-mode boot flag:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# boot config flags urpf-mode

Configuring unicast reverse path forwarding on a port

About This Task

You can use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

Before You Begin

- You must enable the urpf-mode boot flag. See [Enable urpf-mode Boot Flag](#) on page 2978.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Set or change the urpf operating mode on a port:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

3. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode strict
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet

=====
                               Brouter Port Ip

Variable Definitions

The following table defines parameters for the **ip rvs-path-chk mode** and **ipv6 rvs-path-chk mode** commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

Configuring unicast reverse path forwarding on a VLAN

About This Task

Use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

Before You Begin

- You must enable the urpf-mode boot flag.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the VLAN Interface Configuration mode in CLI.

Important

You must assign a valid IP address to the selected port.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

- Set or change the urpf operating mode on a VLAN:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

- Verify the configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode exist-only
```

Verify the configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

```

Variable Definitions

The following table defines parameters for the **ip rvs-path-chk mode** and **ipv6 rvs-path-chk mode** commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

Viewing unicast reverse path forwarding configuration on a port

About This Task

Use the following procedure to view the status of the uRPF configuration on a port.

Before You Begin

- You must enable the urpf-mode boot flag.

Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.
- You must configure unicast reverse path forwarding on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Verify the configuration on the port:

For IPv4, enter: `show ip interface gigabitethernet`

For IPv6, enter: `show ipv6 interface gigabitethernet`

Example

Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/10
```

Verify the configuration on the port:

```
Switch:1(config-if)# show ip interface gigabitethernet

Configuring Digital Certificates using CLI

The following section provides procedures to configure digital certificates using CLI.

Configure Device Subject Parameters

About This Task

Use this procedure to configure the device subject parameters to identify the device, such as the name, Email ID, company, department, and location.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject parameters of the device:

```
certificate subject {[common-name WORD<0-64>] [e-mail WORD<0-254>]
[unit WORD<0-64>] [organization WORD<0-64>] [locality WORD<0-128>]
[province WORD<0-128>] [country WORD<2-2>]}
```

Example

Configuring subject parameters:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# certificate subject common-name Self e-mail example@company.com unit
Engineering organization Company locality SanFrancisco province California country US
```

Variable Definitions

The following table defines parameters for the **Certificate Subject** command.

Variable	Value
common-name WORD<0-64>	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
country WORD<2-2>	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.

Variable	Value
e-mail WORD<0-254>	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
locality WORD<0-128>	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
organization WORD<0-64>	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
province WORD<0-128>	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
unit WORD<0-64>	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.

Configure Subject Alternative Names

About This Task

Use this procedure to protect additional host names with a single certificate.

Note

The switch supports 100 subject alternative names.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a subject alternative name for the entity:

```
certificate subject-alternative-name <dns | e-mail | ip> WORD<1-255>
```
3. View the subject alternative names configured on the switch:

```
show certificate subject-alternative-name
```

Examples

Configure a subject alternative name for an email address and an IP address.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#certificate subject-alternative-name e-mail name@company.com
Switch:1(config)#certificate subject-alternative-name ip 192.0.2.22
```

View the configuration.

```
Switch:1>show certificate subject-alternative-name
=====
                        SAN Table
=====
TYPE      NAME
-----
e-mail    name@company.com
ip        192.0.2.22
```

Variable Definitions

The following table defines parameters for the **certificate subject-alternative-name** command.

Variable	Value
<dns e-mail ip>	Specifies the type of subject alternative name to add.
WORD<1-255>	Specifies the alternative name to add to the subject alternative name table.

Generate the Key Pair

About This Task

Use the following procedure to generate the private and public key pair for the specific cryptography type. By default, VOSS generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new key.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Generate the key pair:

```
certificate generate-keypair {type rsa size 2048}
```

Example

Generating the key pair:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-keypair type rsa size 2048
```

Variable Definition

The following table defines parameters for the **generate-keypair** command.

Variable	Value
type rsa	Specifies type of cryptography algorithm used to generate the key-pair. The switch uses only rsa as the cryptography algorithm type.
size 2048	Specifies the size or modulus of key-pair to be generated. The value should be 2048.

Configure a Trustpoint CA

About This Task

Use this procedure to configure the certificate authority and perform related actions. You can configure only one CA in a device at a time.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the trustpoint and associate it with the generated key pair:

```
certificate ca WORD<1-45> {[common-name WORD<0-64>] [key-name WORD<0-45>] [ca-url WORD<0-1000>] [use-post <true|false>]}
```

3. Configure an SHA-256 fingerprint to authenticate the received CA certificate:

```
certificate ca WORD<1-45> sha256-fingerprint WORD<64-64>
```

4. Configure the appropriate action:

- Configure trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca WORD<1-45> action caauth
```

- Generate certificate signing request to obtain identity certificate from configured trustpoint CA, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca WORD<1-45> action enroll [validity-days <7-1185>]
```

- Get the Certificate Revocation List from the CDP and store into a file:

```
certificate ca WORD<1-45> action get-crl
```

- Install the subject certificate obtained from the given trustpoint CA:

```
certificate ca WORD<1-45> action install
```

- Configure trustpoint and perform no other operation:

```
certificate ca WORD<1-45> action noop
```

- Release the locally stored certificate associated with the trustpoint CA post revocation:

```
certificate ca WORD<1-45> action remove
```

- Generate certificate renew request for given trustpoint CA, get the new digital certificate, and store it locally by replacing the old certificate with the new one:

```
certificate ca WORD<1-45> action renew [validity-days <7-1185>]
```

5. Install the Root Certificate Authority's certificate obtained offline:

```
certificate ca WORD<1-45> install-file {root-ca-filename WORD<1-80>}
```

6. Set the HTTP request type to support the type of CA:

```
certificate ca WORD<1-45> use-post <false | true>
```

Examples

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate ca ej common-name subca5 key-name rsa_2048
Switch:1(config)#certificate ca ej action enroll
Switch:1(config)#CP1 [07/21/16 12:22:11.992:CEST] 0x003a8604 00000000 GlobalRouter

```

Configure an encrypted fingerprint to validate the certificate:

```

Switch:1(config)#certificate ca ej sha256-fingerprint
EEA68F35CC6195CBB038073F520AA385A5A78F42

```

Variable Definitions

The following table defines parameters for the **certificate ca** command.

Variable	Value
<i>action caauth</i>	Authenticates the trustpoint CA by getting the certificate of the CA and stores the CA certificate locally.
<i>action enroll</i> <i>[validity-days <7-1185>]</i>	Generates certificate signing request to obtain identity certificate from configured trustpoint CA, gets the digital certificate, and stores it locally, associating with the trustpoint CA. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<i>action get-crl</i>	Gets the Certificate Revocation List from the CDP and stores into a file.
<i>action install</i>	Installs the subject certificate obtained from the given trustpoint CA.
<i>action noop</i>	Specifies that no operation should be performed after configuring trustpoint.
<i>action remove</i>	Releases the locally stored certificate associated with the trustpoint CA post revocation.
<i>action renew</i> <i>[challenge-password</i> <i>WORD<0-128>]</i>	Specifies the password. This password is provided offline by the CA during the end entity registration.
<i>action renew</i> <i>[validity-days <7-1185>]</i>	Generates certificate renewal request for given trustpoint CA, gets the digital certificate, and stores it locally by replacing the old certificate with the new one. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<i>ca WORD<1-45></i>	Specifies the name of the certificate authority. It should be alphanumeric and case-sensitive. The maximum length should be 45 characters.
<i>ca-url WORD<0-1000></i>	Specifies the trusted CA url.
<i>common-name</i> <i>WORD<0-64></i>	Specifies the name of the owner of the device or user.

Variable	Value
<code>key-name WORD<0-45></code>	Specifies the key pair generated by the command that was first associated with the CA trustpoint.
<code>install-file root-ca-filename WORD<1-80></code>	Installs the Root CA file obtained offline from the CA.
<code>sha256-fingerprint WORD<64-64></code>	Specifies an encrypted fingerprint of the expected certificate to match.
<code>use-post <false true></code>	Specify the HTTP request style. The default value is True. For example, True for EJBCA and False for Win2012 CA.

Install the Certificate

About This Task

Use this procedure to install one of the following:

- certificate authority (CA) certificate
- root CA certificate
- subject certificate
- Certificate Revocation List (CRL) file obtained offline from the CA

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Install the offline CA certificate:

```
certificate install-file offline-ca-filename WORD<1-80>
```
3. Install the CRL offline file:

```
certificate install-file offline-crl-filename WORD<1-80>
```
4. Install the root CA offline certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```
5. Install the subject offline certificate:

```
certificate install-file offline-subject-filename WORD<1-80> [relaxed]
```
6. (Optional) Install the subject offline certificate with PKCS12-format:

```
certificate install-file offline-subject-filename WORD<1-80> relaxed  
pkcs12-password WORD<1-128>
```

Variable Definitions

The following table defines parameters for the **certificate install-file** command.

Variable	Definition
<code>offline-ca-filename WORD<1-80></code>	Specifies the certificate authority (CA) file name obtained from the CA.
<code>offline-crl-filename WORD<1-80></code>	Specifies the CRL file obtained from the CA.
<code>offline-root-ca-filename WORD<1-80></code>	Specifies the root CA file name obtained from the CA.
<code>offline-subject-filename WORD<1-80></code>	Specifies the subject certificate file name obtained from the CA.
<code>relaxed [pkcs12-password WORD<1-128>]</code> Note: Exception: not supported on VSP 8600 Series or XA1400 Series.	Uses the relaxed mode for offline subject certificate installation for less restrictive consistency checks. You can also install a PKCS12 format certificate and secret key in relaxed mode. <code>WORD<1-128></code> is the password to extract the PKCS12 container. If you do not include this parameter, the supported format is Distinguished Encoding Rules (DER).

Generate the Certificate Signing Request

About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Generate certificate signing request:

```
certificate generate-csr [relaxed]
```

View the Certificate Details

About This Task

Use this procedure for the following tasks:

- Displaying the digital certificate for given certificate type or list all the certificate details from the local store for given certificate type.
- Displaying the CA details for a given trustpoint CA name or listing all the CA details from the local store if the CA name is not specified.
- Displaying the configured key details for given key name.
- Displaying the configured subject details.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Display the digital certificate for given certificate type:

```
show certificate cert-type [default-tls-certificate] [online-ca-cert]
| [online-subject-cert] | [offline-ca-cert] | [offline-subject-cert] |
[intermediate-ca-cert WORD<1-80>] | [root-ca-cert WORD<1-80>]]
```
3. Display the certificate authority details:

```
show certificate ca WORD<1-45>
```
4. Display the name and public key of all the key-pairs:

```
show certificate key-name
```
5. Display the details of the configured subject:

```
show certificate subject
```

Examples

Display the CA certificate details:

```
Switch:1>enable
Switch:1>show certificate ca
CA table entry
Name                : caica2
CommonName          : caica2
KeyName             : rsa_2048
CaUrl               : http://192.51.100.9:8080/ejbca/publicweb/apply/scep/test/
pkiclient.exe
UsePost             : 0
SubjectCertValidityDays : 365
Action              : no-op
LastActionStatus    : success
LastActionFailureReason :
CA-Auth Sha256Fingerprint :
```

Display the name and public key of all the key-pairs:

```
Switch:1>show certificate key-name

Key Name: rsa_2048
Public Key Value:
000000000000001020000000003010001000001000bcb8339f794b7ce8a90a7f3a238f07e176a48337

Variable Definitions

The following table defines parameters for the **show certificate** command.

Variable	Value
cert-type default-tls-certificate	Displays the default TLS certificate (self-signed).
cert-type online-ca-cert	Specifies Certificate Authority's Certificate obtained online from Certificate Authority.
cert-type online-subject-cert	Specifies subject certificate obtained online from Certificate Authority.

Variable	Value
cert-type offline-ca-cert	Specifies Certificate Authority's certificate obtained offline from Certificate Authority.
cert-type offline-subject-cert	Specifies subject certificate obtained offline from Certificate Authority.
cert-type intermediate-ca-cert [WORD<1-80>]	Specifies the intermediate certificate obtained offline from Certificate Authority.
cert-type root-ca-cert [WORD<1-80>]	Specifies root certificate obtained offline from Root Certificate Authority.
ca [WORD<1-45>]	Specifies name of the Certificate Authority. If the name is not specified, the command displays the CA details of all configured CA.

Digital certificate configuration examples

This section shows how to obtain an online CA signed certificate, remove the expired certificate, renew the certificate, and install an offline subject certificate.

Obtaining an online CA-signed subject certificate

Use the following procedure as an example to obtain an online CA signed subject certificate that the application can use.

About This Task

In the following commands, the variable `WORD<1-45>` refers to the name of the certificate authority and the variable `WORD<1-80>` refers to the certificate filename.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject:

```
certificate subject common-name scephub
certificate subject e-mail test@mocana.com
certificate subject unit Engineering
certificate subject organization "Mocana Corporation"
certificate subject locality "San Francisco"
certificate subject country US
certificate subject province California
```

Note

The values mentioned are for example only.

3. Generate the key pair:

```
certificate generate-keypair type rsa size 2048
```

- Configure the certificate authority (CA):

```
certificate ca ej common-name subca5
certificate ca ej key-name rsa_2048
certificate ca ej ca-url http://192.51.100.9:8080/ejbca/publicweb/apply/scep/test/
pkiclient.exe
certificate ca ej use-post true
```

Note

The values mentioned are for example.

- Copy and paste the Root CA certificate to: /intflash/.cert/.offlineRootCACert/.
- Install the Root CA certificate:

```
certificate ca WORD<1-45> install-file root-ca-filename WORD<1-80>
```

- Authenticate the CA:

```
certificate ca WORD<1-45> action caauth
```

- Enroll the subject certificate by the CA:

```
certificate ca WORD<1-45> action enroll
```

- Install the certificate:

```
certificate ca WORD<1-45> action install
```

- (Optional) If the certificate expires, remove the enrolled subject certificate:

```
certificate ca WORD<1-45> action remove
```

The certificate is removed from /intflash/.cert and /intflash/.cert/.installedCert/.

- (Optional) To obtain the new certificate before the old certificate expires, enter the following command to renew the certificate:

```
certificate ca WORD<1-45> action renew
```

The Certificate Authority generates a new certificate for the subject.

Installing an offline CA certificate

Use the following procedure as an example to install the offline CA certificate.

About This Task

In the following commands, the variable *WORD<1-80>* refers to the certificate filename.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the subject:

```
certificate subject common-name scep-sub
certificate subject e-mail test@mocana.com
certificate subject unit Engineering
certificate subject organization "Mocana Corporation"
certificate subject locality "San Francisco"
```

```
certificate subject country US
certificate subject province California
```

**Note**

The values mentioned are for example only.

3. Generate the certificate signing request using the command:

```
certificate generate-csr
```

4. Use the generated CSR file to enroll the certificate on the server.

5. Copy and paste the enrolled certificate along with Root to: /intflash/.cert/.offlineRootCACert/.

6. Install the Root CA certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

**Note**

If the subject certificate issuer is directly the Root, then Step 7 and 8 are optional. If the subject is issued by Intermediate CA, then Step 7 and 8 are mandatory, also in the certificate chain between Root and Subject, all the Intermediates must be installed using these steps.

7. Copy and paste the Intermediate CA certificate to: /intflash/.cert/.offlineCACert/.

8. Install the intermediate CA:

```
certificate install-file offline-ca-filename WORD<1-80>
```

9. Copy and paste the Offline subject certificate to: /intflash/.cert/.offlineCert/.

10. Install the offline subject filename:

```
certificate install-file offline-subject-filename WORD<1-80>
```

Configuring X.509 V3 certificates for SSH Two Factor Authentication

**Note**

DEMO FEATURE - Two-Factor Authentication-X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [VOSS Feature Support Matrix](#).

Use the following procedure as an example to configure the SSH server on the VOSS switch, and the SSH client Secure CRT for two factor authentication using X.509 V3 certificates.

Before You Begin

The following certificates must be loaded on the SSH server and SSH client:

- For the Secure CRT (SSH client):
 - subject certificate from the PIV card.
- For the VOSS switch (SSH server):
 - CAC-server.pem - the subject certificate
 - ca.cert.pem - the root CA certificate

- `Self-signedTrustAnchorCertificate.cer` - the root CA certificate that signed the intermediate certificate
- `RSA2048IssuingCACertificate.cer` - the intermediate certificate signed by the previous root CA that signed the subject certificate.

About This Task

Use the following steps as an example to configure the SSH server on the VOSS switch, the RADIUS Windows server, and the SSH client Secure CRT.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Ensure the switch is running in Enhanced Secure Mode:

```
Switch:1(config)#show boot config flags
flags enhancedsecure-mode true
```

Note

This shows a partial output of only the relevant entry.

3. Ensure the switch clock is synchronized:

```
Switch:1#show clock
System Clock time : Fri Oct 12 19:36:36 2018 UTC
```

4. Generate the key pair:

```
Switch:1(config)#certificate generate-keypair type rsa size 2048
Switch(config)#show certificate key-name
Key Name: rsa_2048
Public Key Value: ...
```

5. Configure the certificate subject parameters:

```
Switch:1(config)#certificate subject common-name CAC-server
Switch:1(config)#certificate subject e-mail user@companyname.com
Switch:1(config)#certificate subject unit CAC-project
Switch:1(config)#certificate subject organization Extreme
Switch:1(config)#certificate subject locality Salem
Switch:1(config)#certificate subject province New Hampshire
Switch:1(config)#certificate subject country US
Switch:1(config)#show certificate subject
Common-name : CAC-server
E-mail : jsmith@extremenetworks.com
Organizational unit : CAC-project
Organization : Extreme
Locality : Salem
State/Province : New Hampshire
Country : US
```

Note

The values mentioned are for example.

6. Generate the Certificate Signing Request (CSR):

```
Switch:1(config)#certificate generate-csr
```

7. Export the csr file from /intflash/.cert/.
8. Create a subject certificate using the exported csr file.
9. Import the root certificate .der file to /intflash/.cert/.offlineRootCACert.
10. Import the intermediate certificate .der file to /intflash/.cert/.offlineCACert.
11. Import the subject certificate .der file to /intflash/.cert/.offlineCert.
12. Install the Root certificate:

```
Switch:1(config)#certificate install-file offline-root-ca-filename
<SUBJECT_ROOT_CERTIFICATE_NAME>
Switch:1(config)#show certificate cert-type root-ca-cert
CERT STORE table entry
Certificate Type : Root CA Certificate
CommonName : ca_cert
VersionNumber : X.509 v3
SerialNumber : 00fb084e6b97f3f72a

```

Note

Disable all other SSH authentication methods except X.509 V3 on the VOSS switch because the SSH client Secure CRT always prefers SSH RSA over X.509 V3 authentication. You can also force Secure CRT to negotiate X.509 V3 SSH RSA only.

17. From the RADIUS server, configure a username that is the same as the principal-name from the PIV card certificate with an empty password, or with a specific password. Enable the network policy.
18. From the RADIUS server, configure one standard attribute and one Vendor-specific attribute with a username and password policy.
19. From the SSH client Secure CRT, import the External Root CA certificate `ca.cert.pem`.
20. Connect a card reader to your computer and insert the smart card.
21. From the SSH client Secure CRT, open an SSH session with the username from the subject certificate as configured on the RADIUS server. Select the proper certificate from the smart card.
22. Enter the PIN for the smart card.
The username is sent to the RADIUS server for authorization after you enter the PIN.
23. Enter the password for the cardholder user.

X.509 Authentication Username Option Example

Use the following procedure as an example to configure username authentication options using X.509 V3 certificates.

Procedure

1. Enable X.509 V3 authentication username override:

```
Switch:1(config)# ssh x509v3-auth username overwrite
```

The switch disregards the username sent by the SSH client and uses the principal name from the client's certificate for authentication. If RADIUS authentication is configured, the username is sent after you type the RADIUS password. For example, if you configure the SSH client with the username "John" and enable `x509v3-auth username overwrite` on the device, the switch sends the principal name `1403824387@mil` to the RADIUS server for authorization.

```

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb1

```

2. Enable X.509 V3 authentication username strip:

```
Switch:1(config)#ssh x509v3-auth username strip-domain
```

If x509v3-auth username strip-domain is configured, the switch sends the principal name without the domain to the RADIUS for authorization. The username is sent after you type the RADIUS password. For example: If you select principal name 1403824387@mil, the switch sends the principal name 1403824387 without the domain to the RADIUS server for authorization.

```

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129

```

3. Enable X.509 V3 authentication username use-domain:

```
Switch:1(config)ssh x509v3-auth username use-domain extreme.com
```

If you select the username as the principal name, the switch sends the principal name from the certificate with the domain configured on the switch to the RADIUS for authorization. The username is sent after typing the RADIUS password. For example: If you configure use-domain "extreme.com" on the switch and you configure the username to be the principal name 1403824387@mil, the switch sends the username 1403824387@extreme.com to the RADIUS server for authorization.

```

Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129

```

4. RADIUS server is not configured:

If the Radius server is not configured, the authorization fallbacks locally on the switch, for the username. You must configure the usernames on the switch. You are prompted for the password. For example: If you select the principal name 1403824387@mil, the switch authorizes locally the username as 1403824387@mil or 1403824387 if strip domain is enabled. You are prompted for the password.

Install Online Certificates for Fabric Extend with IPsec

Use the following procedure as an example to install subject certificates for switches that use Fabric Extend with IPsec. After you complete the certificate configuration, you must configure the IPsec authentication method for the Fabric Extend tunnel. For more information about IPsec configuration, see [IPsec configuration using CLI](#) on page 1723. For more information about Fabric Extend, see [Fabric Extend configuration using the CLI](#) on page 1020.

Note

The values mentioned are for example only.

Before You Begin

Configure the Fabric Extend tunnels between the branch and hub switches.

Procedure

1. Configure the CA instance:

```

Switch:1(config)#certificate ca aaa common-name CaAaa
Switch:1(config)#certificate ca aaa key-name rsa_2048
Switch:1(config)#certificate ca aaa ca-url http://192.0.2.9:8080/ejbca/publicweb/apply/
scep/test/pkiclient.exe
Switch:1(config)#certificate ca aaa use-post true
Switch:1(config)#certificate ca aaa sha256-fingerprint
EEA68F35CC6195CBB038073F520AA385A5A78F42

```

2. Authenticate the CA TrustPoint:

```

Switch:1(config)# certificate ca aaa action caauth
1 2020-06-10T15:07:16.814Z XA1440 CP1 - 0x003a863d - 00000000 GlobalRouter DIGITALCERT

```

4. Configure the IPsec authentication-method:

```
Switch:1(config-isis-1-192.0.2.74)#ipsec auth-method rsa-sig
```

Configure TCP Keepalive and TCP Timestamp

About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must perform a **config save** and **reboot** to apply the new configuration to all TCP connections.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the TCP keepalive interval:

```
sys control tcp-keepalive-interval <1-3600>
```
3. Configure the TCP keepalive probes:

```
sys control tcp-keepalive-probes <1-50>
```
4. Configure the TCP keepalive time:

```
sys control tcp-keepalive-time <5-65535>
```
5. Enable the TCP Timestamp:

```
sys control tcp-timestamp
```
6. Disable the TCP Timestamp:

```
no sys control tcp-timestamp
```
7. View the status of TCP Timestamp:

```
show sys control
```

Examples

Configure the TCP keepalive to interval 60 seconds, with 15 probes, and 120 seconds time:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control tcp-keepalive-interval 60
Switch:1(config)#sys control tcp-keepalive-probes 15
Switch:1(config)#sys control tcp-keepalive-time 120
```

Disable TCP Timestamp:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no sys control tcp-timestamp
```

Warning: Existing TCP connections won't be affected.
 A config save and reboot is required to apply this configuration for all TCP connections

Display the status of the TCP Timestamp:

```
Switch:1>show sys control
=====
                        System Control Settings
=====
                        tcp-timestamp : disable
                        tcp-keepalive-time : 120
```

```

tcp-keepalive-interval : 60
tcp-keepalive-probes : 15
mac-move-protection : on

```

Variable Definitions

The following table defines parameters for the **sys control** command.

Variable	Value
<i>tcp-keepalive-interval</i> <1-3600> Note: Exception: Not supported on VSP 8600 Series	Configure the TCP keepalive interval in seconds. The default is 10.
<i>tcp-keepalive-probes</i> <1-50> Note: Exception: Not supported on VSP 8600 Series	Configure the TCP keepalive probes. The default is 5.
<i>tcp-keepalive-time</i> <5-65535> Note: Exception: Not supported on VSP 8600 Series	Configure the TCP keepalive time in seconds. The default is 60.
<i>tcp-timestamp</i>	Enable or disable tcp-timestamp. Note: The timestamp is enabled by default. The system displays the following warning message when a new configuration is applied: Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.

Enable Authentication for Privileged EXEC Command Mode using CLI

With authentication enabled, you must enter a username and password to access Privileged EXEC command mode from User-EXEC command mode. The username and password is the same username and password you used to Telnet or SSH to the switch.

Note

When you enable authentication for the Privileged EXEC CLI command mode, the changes do not affect any existing CLI sessions. For the changes to take effect, you must first log out from your current CLI session and log back in on a new session.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable authentication for Privileged EXEC CLI command mode:
`sys priv-exec-password`
3. Verify the configuration:
`show sys priv-exec-password`

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#sys priv-exec-password
```

Enable MAC Move Protection on vIST

About This Task

Perform this procedure to enable MAC move protection on virtual interswitch trunk (vIST).

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable MAC move protection:
`sys control virtual-ist mac-move-protection`
3. Confirm the configuration:
`show sys control`

Examples

Enable MAC move protection on vIST:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control virtual-ist mac-move-protection
Switch:1>show sys control
=====
                        System Control Settings
=====
      tcp-timestamp : disable
      tcp-keepalive-time : 120
      tcp-keepalive-interval : 60
      tcp-keepalive-probes : 15
      mac-move-protection : on
```

Variable Definitions

The following table defines parameters for the **sys control virtual-ist** command.

Variable	Value
<i>mac-move-protection</i>	Enable MAC move protection on vIST. The default value is disabled.

Security Configuration using EDM

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using EDM](#) on page 3300.

Enable Port Lock

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Lock a Port

Before You Begin

- You must enable port lock before you lock or unlock a port.

About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. In the **LockedPorts** box, click the ellipsis (...) button.
5. Click the desired port or ports.
6. Click **Ok**.
7. In the **Port Lock** tab, click **Apply**.

Port Lock field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
Enable	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
LockedPorts	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

Change Passwords

About This Task

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

CLI Field Descriptions

The following table defines parameters for the **CLI** tab.

Name	Description
RWAUserName	Specifies the user name for the read-write-all CLI account.
RWAPassword	Specifies the password for the read-write-all CLI account.
RWEnable	Activates the read-write access. The default is enabled.
RWUserName	Specifies the user name for the read-write CLI account.
RWPassword	Specifies the password for the read-write CLI account.
RWL3Enable	Activates the read-write Layer 3 access. The default is enabled.
RWL3UserName	Specifies the user name for the Layer 3 read-write CLI account.
RWL3Password	Specifies the password for the Layer 3 read-write CLI account.
RWL2Enable	Activates the read-write Layer 2 access. The default is enabled.
RWL2UserName	Specifies the user name for the Layer 2 read-write CLI account.
RWL2Password	Specifies the password for the Layer 2 read-write CLI account.
RWL1Enable	Activates the read-write Layer 1 access. The default is enabled.
RWL1UserName	Specifies the user name for the Layer 1 read-write CLI account.
RWL1Password	Specifies the password for the Layer 1 read-write CLI account.
ROEnable	Activates the read-only CLI account. The default is enabled.
ROUserName	Specifies the user name for the read-only CLI account.
ROPassword	Specifies the password for the read-only CLI account.
MaxTelnetSessions	Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8.
MaxRloginSessions Note: Exception: only supported on VSP 8600 Series.	Specifies the maximum number of concurrent rlogin sessions in a range from 0–8. The default is 8.
Timeout	Specifies the number of seconds of inactivity for a Telnet or Rlogin session before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds. Note: rlogin is supported only on the VSP 8600 Series.

Name	Description
NumAccessViolations	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.
CustomBannerText Note: Exception: not supported on VSP 8600 Series.	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
CustomBannerEnable Note: Exception: not supported on VSP 8600 Series.	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

Configure Directed Broadcast on a VLAN

Configure directed broadcast on a VLAN to enable or disable directed broadcast traffic forwarding for an IP interface.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **Direct Broadcast** tab.
7. Select **DirectBroadcastEnable**.

Important

Configure multiple VLANs or IPs in the same subnet but in different systems simultaneously.

8. Click **Apply**.

Direct Broadcast field descriptions

Use the data in the following table to use the **Direct Broadcast** tab.

Name	Description
DirectBroadcastEnable	Specifies that an Isolated Routing Port (IRP) can forward directed broadcast traffic. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcast on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling this function protects a host from possible denial of service (DoS) attacks. With the feature enabled, the Control Processor (CP) does not receive a copy of the directed broadcast. As a result, the system does not respond to a subnet broadcast ping sent from a remote subnet. The default is disabled.

Unicast Reverse Path Forwarding configuration using EDM

This section provides EDM procedures for Unicast Reverse Path Forwarding configuration.

*Configure Reverse Path Checking on a Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

About This Task

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **Reverse Path Checking** tab.
5. Select the **Enable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
Enable	Enables reverse path checking on the selected port. The default is disabled.
Mode	Specifies the mode for reverse path checking. The modes are <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded. The default is exist-only.

*Configure Reverse Path Checking on an IPv6 Port***Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

About This Task

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click the **Reverse Path Checking** tab.
5. Select the **ReversePathCheckEnable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
ReversePathCheckEnable	Enables reverse path checking on the selected port. The default is disabled.
ReversePathCheckMode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded. <p>The default is exist-only.</p>

Configure Reverse Path Checking on a VLAN

Before You Begin

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

About This Task

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the VLAN on which you want to configure reverse path checking.
4. In the toolbar, click **IP**.
5. Click the **Reverse Path Checking** tab.
6. Select the **Enable** box to enable reverse path checking.
7. Select **exist-only** or **strict**.
8. Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
Enable	Enables reverse path checking on the selected VLAN.
Mode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded. <p>The default is exist-only.</p>

*Configure Reverse Path Checking on an IPv6 VLAN***Before You Begin**

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

About This Task

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Click the VLAN on which you want to configure reverse path checking.
5. Click **IPv6**.
6. Click the **Reverse Path Checking** tab.
7. Select the **ReversePathCheckEnable** box to enable reverse path checking.
8. Select **exist-only** or **strict**.

- Click **Apply**.

Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
ReversePathCheckEnable	Enables reverse path checking on the selected VLAN.
ReversePathCheckMode	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> • exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded. • strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded. <p>The default is exist-only.</p>

Digital certificate configuration using EDM

The following section provides procedures to configure digital certificates using EDM.

Configure Device Subject Parameters

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **Certificate**.
- Click the **Subject** tab.
- In the **CommonName** field, type the name of the subject.
- Complete the remaining optional configuration to customize the policy.
- Click **Apply**.

Subject field descriptions

Use the data in the following table to use the **Subject** tab.

Name	Description
CommonName	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
EmailAddress	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
OrganizationalUnit	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.
Organization	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
Locality	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
Province	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
Country	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
InstallFile	Installs the specific certificate file type obtained offline from the Certificate Authority.
InstallFileName	Specifies the certificate file name to install.
UninstallFile	Uninstalls the specific certificate file type obtained offline from the Certificate Authority.
UninstallFileName	Specifies the certificate file name to uninstall.
GenerateCsr	Generates the certificate signing request to obtain the offline subject certificate.

Generate the Key Pair

Use the following procedure to generate the private and public key pair for the specific cryptography type.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **Key-pair** tab.
4. Click **Insert**.
5. In the **Type** field, select the cryptography type.

This software supports RSA only.

6. In the **Size** field, enter the size of the key.
7. Click **Insert**.

Certificate key-pair field description

Use the data in the following table to use the **Certificate > Key-Pair** tab.

Name	Description
Type	Specifies the cryptography algorithm used to generate the key-pair.
Size	Specifies the size of the key-pair to be generated.
Name	Specifies the name of the key-pair generated for the subject. This name is auto-generated as the combination of key-type and key-size.

Configure the Certificate Authority

Use this procedure to configure the certificate authority (CA) and perform related actions. You can configure only one CA in a device at a time.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **CA** tab.
4. Click **Insert**.
5. In the **Name** field, type a user-defined name of the CA.
6. In the **CommonName** field, type the common name of the CA.
7. In the **KeyName** field, type the name of the associated key pair.
8. Complete the remaining optional configuration to customize the policy.
9. Click **Insert**.
10. (Optional) Click **Retry Action** if the trustpoint CA certificate authentication fails or takes time for authentication. This can be done only when the selected Action is **caauth**.

CA field descriptions

Use the data in the following table to use the **CA** tab.

Name	Description
Name	Specifies the user-defined name referring to the Certificate Authority issuing the Digital Certificate.
CommonName	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
KeyName	Specifies the name of the associated key pair.
CaUrl	Specifies the URL of the Certificate Authority issuing the Digital Certificate.

Name	Description
Action	Specifies the action the Certificate Authority can take: <ul style="list-style-type: none"> • noop — no operation • caauth — CA authentication • enroll — certificate enrolment request • renew — certificate renew request • remove — remove the subject certificate obtained online from the CA • install — install the subject certificate obtained online from the CA • getCrI — retrieve the Certificate Revocation List (CRL) from the CRL Distribution Point (CDP).
ActionChallengePassword	Specifies the challenge password required to perform the SCEP operation.
LastActionStatus	Specifies the status of the last action: <ul style="list-style-type: none"> • none - No action is performed yet • success - Execution of the action triggered is completed successfully • failed - Execution of the action triggered has failed • inProgress - Execution of the action triggered is in progress
LastActionFailureReason	Specifies the reason of failure for the last action performed by the Certificate Authority.
InstallRootCaFileName	Specifies the certificate file obtained offline from the Root Certificate Authority.
SubjectCertificateValidityDays	Specifies the number of days for which subject certificate will remain valid. The default value is 365 days.
UsePost	Specifies the HTTP request type: URL or POST. TRUE for EJBCA and FALSE for Win2012 CA
Sha256Fingerprint Note: Exception: not supported on VSP 8600 Series.	Specifies an encrypted fingerprint of the expected certificate to match.

View the Certificate Details

Use this procedure to:

- display the configured key details for given key name.
- display the digital certificate for the given certificate index or list all the certificate details from the local store if the certificate index is not specified.
- display the CA details for given trustpoint CA name or list all the CA details from the local store if the CA name is not specified.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **Certificate** tab.

Certificate field descriptions

Use the data in the following table to use the **Certificate** tab.

Name	Description
Type	Specifies the certificate type.
VersionNumber	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
SerialNumber	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
IssuerName	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
ValidStartPeriod	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
ValidEndPeriod	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.
CertificateSignatureAlgorithm	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
CertificateSignature	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
Subject	Specifies the details of the subject on its certificate as issued by Certificate Authority.
SubjectPublicKeyAlgorithm	Specifies the algorithm used to generate the public key of the subject for the certificate issued by the Certificate Authority.
SubjectPublicKey	Specifies the public key of the subject used for the Certificate Signing Request.
HasBasicConstraint	Specifies whether the certificate contains any basic certificate constraint or not.
HasKeyUsage	Specifies whether the certificate contains basic key usage constraint or not.
IsCa	Specifies whether the certificate is a ca certificate or not.

Name	Description
KeyUsage	Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> • bit 0 - digitalSignature • bit 1 - nonRepudiation • bit 2 - keyEncipherment • bit 3 - dataEncipherment • bit 4 - keyAgreement • bit 5 - keyCertSign • bit 6 - cRLSign • bit 7 - encipherOnly • bit 8 - decipherOnly
Status	Specifies the status of the certificate.
Installed	Specifies whether the certificate is installed or not.
CdpUrl	Specifies the CDP URL present in the Digital Certificate Extensions field.
OcspUrl	Specifies the OCSP URL present in the Digital Certificate AIA field.
ExtendedKeyUsage	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.

Install the Root CA Certificate

Use the following procedure to install the Root CA certificate obtained offline.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Diagnostics**.
2. Click **System Log**.
3. Click **Root Certificate Table** tab.
4. Click **Insert**.
5. In the **Filename** field, enter the filename obtained offline from the CA.
6. In the **Action** field, select the action.
7. Click **Insert**.

Root Certificate Table field description

Use the data in the following table to use the **System Log > Root Certificate Table** tab.

Name	Description
Filename	Specifies the certificate filename obtained offline from the Root Certificate Authority.
Action	<p>Specifies the action to be performed on Root CA.</p> <ul style="list-style-type: none"> noaction: No action is performed. install: Installs the Root CA certificate obtained offline. uninstall: Uninstalls the Root CA certificate. <p>The system displays the Conversion Fail if the execution of the action fails.</p>

View the Certificate Store

Use the following procedure to view the online, offline and root certificates in the local store.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **Certificate Store** tab.

Certificate Store field descriptions

Use the data in the following table to use the **Certificate Store** tab.

Name	Description
CommonName	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
Type	Specifies the certificate type.
VersionNumber	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
SerialNumber	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
IssuerName	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
ValidStartPeriod	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
ValidEndPeriod	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.
CertificateSignatureAlgorithm	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.

Name	Description
CertificateSignature	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
Subject	Specifies the details of the subject on its certificate as issued by Certificate Authority.
SubjectPublicKeyAlgorithm	Specifies the algorithm used to generate the subject's public key for the certificate issued by the Certificate Authority.
SubjectPublicKey	Specifies the public key of the subject used for Certificate Signing Request.
HasBasicConstraint	Specifies whether certificate contains basic certificate constraint.
HasKeyUsage	Specifies whether certificate contains basic key usage constraint.
IsCa	Specifies if the certificate is a CA certificate or not.
KeyUsage	Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> • bit 0 - digitalSignature • bit 1 - nonRepudiation • bit 2 - keyEncipherment • bit 3 - dataEncipherment • bit 4 - keyAgreement • bit 5 - keyCertSign • bit 6 - cRLSign • bit 7 - encipherOnly • bit 8 - decipherOnly
Status	Specifies the status of the certificate.
Installed	Specifies whether the certificate is installed or not.
CdpUrl	Specifies the CDP URL present in the Digital Certificate Extensions field.
OscpUrl	Specifies the OCSP URL present in the Digital Certificate AIA field.
ExtendedKeyUsage	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.
CaFileName	Specifies the certificate file obtained offline from the Root Certificate Authority.

Configure TCP Keepalive and TCP Timestamp

About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must save the configuration and reboot the switch to apply the new configuration to all TCP connections.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.
4. Configure the TCP timestamp by performing one of the following actions:
 - a. Select **TcpTimestamp** to enable the TCP timestamp.
 - b. Clear **TcpTimestamp** to disable the TCP timestamp.
5. In **KeepaliveTime**, enter a number in seconds.
6. In **KeepaliveInterval**, enter a number in seconds.
7. In **KeepaliveProbes**, enter a number of probes.
8. Select **Apply**.

System Control Field Descriptions

Use the data in the following table to use the **System Control** tab.

Name	Description
TcpTimestamp	Enables or disables the TCP timestamp. The timestamp is enabled by default. The system displays the following warning message when a new configuration is applied: Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.
PrivExecPasswordEnable	Enables authentication for Privileged EXEC CLI command mode. Authentication is disabled by default.
KeepaliveTime Note: Exception: Not supported on VSP 8600 Series.	Specify the TCP keepalive time in seconds. Range is 5 to 65535 and default is 60.

Name	Description
<p>KeepaliveInterval</p> <p>Note: Exception: Not supported on VSP 8600 Series.</p>	<p>Specify the TCP keepalive interval in seconds. Range is 1 to 3600 and the default is 10.</p>
<p>KeepaliveProbes</p> <p>Note: Exception: Not supported on VSP 8600 Series.</p>	<p>Specify the TCP keepalive probes. Range is 1 to 50 and the default is 5.</p>

Enable Authentication for Privileged EXEC Command Mode

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.
4. Select **PrivExecPasswordEnable**.

Service Level Agreement Monitor

[QoS tests](#) on page 3033

[Limitations](#) on page 3033

[SLA Mon configuration using CLI](#) on page 3033

[SLA Mon Configuration using EDM](#) on page 3036

Table 226: SLA Mon product support

Feature	Product	Release introduced
SLA Mon	5420 Series	Not supported
	5520 Series	VOSS 8.2.5
	VSP 4450 Series	VOSS 4.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 4.1
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	Not Supported

The switch supports the Service Level Agreement Monitor (SLA Mon) agent as part of the SLA Mon solution.

SLA Mon uses a server and agent relationship to perform end-to-end network Quality of Service (QoS) validation and to distribute monitoring devices. You can use the test results to target under-performing areas of the network for deeper analysis.

SLA Mon Server and Agent

The switch supports the SLA Mon agent. You must have an Avaya Diagnostic Server with SLA Mon technology in your network to use the SLA Mon feature. Most of the SLA Mon configuration occurs on the server; configuration on the SLA Mon agent is minimal.

The SLA Mon server initiates the SLA Mon functions on one or more agents, and the agents run specific QoS tests at the request of the server. Agents can exchange packets between one another to conduct the QoS tests.

SLA Mon can monitor a number of key items, including the following:

- network paths
- Differentiated Services Code Point (DSCP) markings
- loss
- jitter
- delay

The following figure shows an SLA Mon implementation.

Figure 229: SLA Monitor network

An SLA Mon agent remains dormant until it receives a User Datagram Protocol (UDP) discovery packet from a server. The agent accepts the discovery packet to register with an SLA Mon server. If the registration process fails, the agent remains dormant until it receives another discovery packet.

An agent can attempt to register with an SLA Mon server once every 60 seconds. After a successful registration, the agent reregisters with the server every 6 hours to exchange a new encryption key.

An agent only accepts commands from the SLA Mon server to which it is registered. An agent can use alternate SLA Mon servers to provide backup for time-out and communication issues with the primary SLA Mon server.

Note

If you configure the SLA Mon agent address under an IP address for a VLAN or router, you must remove the SLA Mon address before you can remove the IP address for the VLAN or router.

HA Support

SLA Monitor agent provides partial HA support. In HA mode, the agent startup and initialization occurs only on the master CP module. When reset occurs, the standby CP takes over the operations. Based on the SLAMon agent operation-mode, the agent on the standby CP restarts the initialization and registration and gets registered only when the server sends a discovery. The user configuration updates on the Master CP is saved on the Standby CP and used when the reset occurs.

QoS tests

SLA Mon uses two types of tests to determine QoS benchmarks:

- Real Time Protocol (RTP)

This test measures network performance — for example, jitter, delay, and loss — by injecting a short stream of UDP packets from source to destination (an SLA Mon agent).

- New Trace Route (NTR)

This test is similar to traceroute but also includes DSCP values at each hop in the path from the source to the destination. The destination does not need to be an SLA Mon agent.

Limitations

SLA Mon agent communications are IPv4-based. Agent communications do not currently support IPv6.

SLA Mon configuration using CLI

Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an SLA Mon with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

Before You Begin

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

Note

- If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you are configuring SLA Mon at the switch side for the first time, make sure you configure the SLA Mon agent address under an IP address for a VLAN or brouter, and you must remove the SLA Mon address before you can remove the IP address for the VLAN or brouter. To remove the SLA Mon address, first use the command **no slamon oper-mode enable**, followed by **slamon agent ip address 0.0.0.0**.

Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```
2. Configure the SLA Mon agent IP address:

Note

The SLA Mon Agent uses its own reserved Host IP address, reachable via the Switch VLAN IP interface of the same IP subnet.

- ```
slamon agent ip address {A.B.C.D} [vrf WORD<1-16>]
```
3. (Optional) Configure the UDP port for agent-server communication:  

```
slamon agent port <0-65535>
```
  4. (Optional) Restrict which servers an agent can use:  

```
slamon server ip address {A.B.C.D} [{A.B.C.D}]
```

```
slamon server port <0-65535>
```
  5. (Optional) Control the port used for Real Time Protocol (RTP) and New Trace Route (NTR) testing:  

```
slamon agent-comm-port <0-65535>
```
  6. (Optional) Install a Secure Socket Layer (SSL) certificate for the agent:  

```
slamon install-cert-file WORD<0-128>
```
  7. Enable the agent:  

```
slamon oper-mode enable
```
  8. Verify the agent configuration:  

```
show application slamon agent
```

## Example

Configure the SLA Mon agent IP address. Configure the agent so that it only accepts registration packets from a specific server communicating on a specific port. Finally, enable the SLA Mon agent, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#application
Switch:1(config-app)#slamon agent ip address 192.0.2.1
Switch:1(config-app)#slamon server ip address 192.0.2.24
Switch:1(config-app)#slamon server port 50011
Switch:1(config-app)#slamon oper-mode enable
Switch:1(config-app)#show application slamon agent
=====

SLAMon Configured Server Address: 192.0.2.24 0.0.0.0
SLAMon Configured Server Port: 50011 0
SLAMon Agent-To-Agent Communication Port: 50012
SLAMon Configured Agent-To-Agent Communication Port: 0
SLAMon Configured Agent Address Vrf Name:

```

### Note

The SLA Mon agent IP address given in this example is on the same subnet as VLAN120, as shown in the following example.

Show result of the SLA Mon agent IP address.

```

### What to Do Next

If you have configured SLA Mon, but the agent does not function as expected, use the **show khi performance pthread** `[{slot[-slot][, ...]}`] command to verify that the slamon task is running.

If the SLA Mon agent is not running, use the commands **no slamon oper-mode enable** and **slamon oper-mode enable** to start the agent.

If the agent task is running, perform typical troubleshooting steps to verify agent accessibility:

- Verify IP address assignment and port use.
- Ping the server IP address.
- Verify the server configuration.
- Use the **trace level 192 <0-4>** command to observe the status of the SLA Mon software module.

### Variable definitions

Use the data in the following table to use the **slamon** command.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>agent-comm-port</i><br><0-65535>                    | Configures the port used for RTP and NTR testing in agent-to-agent communication. The default port is 50012. If you configure this value to zero (0), the default port is used.                                                                                                                                           |
| <i>agent ip address</i><br>{A.B.C.D}                   | Configures the SLA Mon agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent ip address is a mandatory parameter. The default value is 0.0.0.0.                                                                                          |
| <i>agent port</i> <0-65535>                            | Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.                                                                                                                                          |
| <i>install-cert-file</i>                               | Installs an SSL certificate. <i>WORD</i> <0-128> specifies the file name and path of the certificate to install.<br>If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.                                                                                            |
| <i>oper-mode enable</i>                                | Enables the SLA Mon agent. The default is disabled.<br>If you disable the agent, it does not respond to discovery packets from a server.<br>If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets. |
| <i>server ip address</i><br>{A.B.C.D}<br>[ {A.B.C.D} ] | Restricts the SLA Mon agent to use the server at this IP address only. The default is 0.0.0.0, which means the agent can register with any server. You can specify a secondary server as well.                                                                                                                            |
| <i>server port</i> <0-65535>                           | Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic.<br>The server must use the same port.                                                                                                                   |
| <i>vrf</i> <i>WORD</i> <1-16>                          | Specifies the name of a VRF.                                                                                                                                                                                                                                                                                              |

## SLA Mon Configuration using EDM

### Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an Avaya Diagnostic Server with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

#### Before You Begin

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

## About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

### Note

If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you configure the SLA Mon agent address under an IP address for a VLAN or router, you must remove the SLA Mon address, before you can remove the IP address for the VLAN or router. To remove the SLA Mon address, first select disabled from the **Status** field, then configure the IP address in the **ConfiguredAgentAddr** field to 0.0.0.0.

## Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **SLA Monitor**.
3. Select the **SLA Monitor** tab.
4. For the status, select **enabled**.
5. In the **ConfiguredAgentAddr** field, enter the SLA Mon agent IP address
6. Configure optional parameters as required.
7. Select **Apply**.

### *SLA Monitor* field descriptions

Use the data in the following table to use the **SLA Monitor** tab.

| Name                            | Description                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b>                   | Enables or disables the SLA Mon agent. The default is disabled. If you disable the agent, it does not respond to discovery packets from a server.<br>If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets. |
| <b>CertFileInstallAction</b>    | Installs or uninstalls a Secure Sockets Layer (SSL) certificate file. The default is noAction.                                                                                                                                                                                                                                     |
| <b>CertFile</b>                 | Specifies the file name and path of the SSL certificate.<br>If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.                                                                                                                                                             |
| <b>ConfiguredAgentAddrType</b>  | Specifies the address type of the agent: IPv4.                                                                                                                                                                                                                                                                                     |
| <b>ConfiguredAgentAddr</b>      | Configures the agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent IP address is a mandatory parameter. The default value is 0.0.0.0.                                                                                                           |
| <b>ConfiguredAgentPort</b>      | Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.                                                                                                                                                   |
| <b>ConfiguredAgentVrfName</b>   | Specifies the name of a VRF.                                                                                                                                                                                                                                                                                                       |
| <b>ConfiguredServerAddrType</b> | Specifies the address type of the server: IPv4.                                                                                                                                                                                                                                                                                    |

| Name                               | Description                                                                                                                                                                                                                  |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConfiguredServerAddr</b>        | Restricts the SLA Mon agent to use the server at this IP address only. If the default of 0.0.0.0 is used, then the SLA Mon agent can register with any server.                                                               |
| <b>ConfiguredServerPort</b>        | Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.                         |
| <b>ConfiguredAltServerAddrType</b> | Specifies the address type of the secondary server: IPv4.                                                                                                                                                                    |
| <b>ConfiguredAltServerAddr</b>     | Configures a secondary server in the event that the primary server is unreachable.                                                                                                                                           |
| <b>ConfiguredAltServerPort</b>     | Restricts the SLA Mon agent to use this registration port on the secondary server only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port. |
| <b>SupportedApps</b>               | Shows the type of testing supported: Real Time Protocol (RTP) and New Trace Route (NTR).                                                                                                                                     |
| <b>AgentAddressType</b>            | Shows the SLA Mon agent address type.                                                                                                                                                                                        |
| <b>AgentAddress</b>                | Shows the configured SLA Mon agent IP address.                                                                                                                                                                               |
| <b>AgentPort</b>                   | Shows the configured SLA Mon agent port.                                                                                                                                                                                     |
| <b>RegisteredWithServer</b>        | Indicates if the SLA Mon agent has registered with a server.                                                                                                                                                                 |
| <b>RegisteredServerAddrType</b>    | Shows the address type for the registered server.                                                                                                                                                                            |
| <b>RegisteredServerAddr</b>        | Shows the IP address for the registered server.                                                                                                                                                                              |
| <b>RegisteredServerPort</b>        | Shows the port number for the registered server.                                                                                                                                                                             |
| <b>RegistrationTime</b>            | Shows the amount of time, in seconds, since the SLA Mon agent registered with the server.                                                                                                                                    |
| <b>AgentToAgentPort</b>            | Shows the port for SLA Mon agent-to-agent communication.                                                                                                                                                                     |
| <b>ConfiguredAgentToAgentPort</b>  | Configures the port used for RTP and NTR testing in SLA Mon agent-to-agent communication. The default port is 50012. If you configure this value as zero (0), the default port is used.                                      |

|                                                   | VSP 8200 Series | Not Supported      |
|                                                   | VSP 8400 Series | Not Supported      |
|                                                   | VSP 8600 Series | VSP 8600 6.2       |
|                                                   | XA1400 Series   | Not Supported      |

## sFlow Fundamentals

sFlow monitors traffic in a data network. Use sFlow to monitor routers and switches in the network, and capture traffic statistics about those devices. sFlow uses sampling to provide scalability for network-

wide monitoring, and therefore applies to high speed networks. The switch sends the sampled data as a User Datagram Protocol (UDP) packet to the specified host and port.

**Note**

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination. For more information, see [Common Elements Between sFlow and Application Telemetry](#) on page 318.

sFlow consists of the following:

- sFlow agent—Performs two types of sampling:
  - Flow samples: Flow sampling randomly samples an average of 1 out of n packets for each operation.
  - Counter samples: Counter sampling periodically polls and exports counters for a configured interface. This type of sampling uses a counter to determine if the packet is sampled. Each packet that an interface receives, and that a filter does not drop, reduces the counter by one. After the counter reaches zero, the sFlow agent takes a sample.

**Note**

Only generic interface counters and Ethernet interface counters are supported.

- sFlow datagrams—Supports both flow samples and counter samples. Datagrams can be sent from the front panel port or an out-of-band (OOB) port. Each datagram provides information about the sFlow version, the originating IP address of the device, a sequence number, the number of samples it contains, and one or more flow and/or counter samples.
- sFlow collector—Located on a central server and runs software that analyzes and reports on network traffic. Two sFlow collectors can be configured to be reachable over a management network or Shortest Path Bridging (SPB). The preferred network is SPB.

## Limitations

- Application-specific integrated circuit (ASIC) or Software Development Kit (SDK) limitation—To avoid wobbling, the counter interval for sFlow is 20 seconds. Minor wobbling can still occur even after configuring the counter interval due to the interaction between the sFlow agent counter export schedule and the frequency with which the switch ASIC SDK copies and caches counters from the ASIC.
- sFlow supports a maximum of two collectors.
- UDP datagram size and the collector buffer are restricted to 1400 bytes. sFlow sends datagrams to the collector when the buffer reaches the 1400-byte capacity or after a timeout of one second is triggered. The collector buffer size cannot be modified.
- The switch supports IPv4 collector IP addresses.
- VLAN counters/statistics are not supported.
- sFlow can be enabled only on the front panel ports.
- You cannot configure the sampling limit. The sampling limit applies system-wide rather than on a per port basis. Sampling rates differ depending on the hardware platform so any sampled packets beyond the limit are dropped. For more information about feature support, see [VOSS Release Notes](#).
- The switch supports only ingress sampling. The switch does not support egress sampling.

- The switch does not support enabling sFlow on a link aggregation group (LAG) interface. However, you can enable sFlow on the member interfaces of a LAG.
- The sFlow collector can be reachable through the Management VRF, the Global Routing Table (GRT) or if your switch supports doing so, through a user created VRF (virtual routing and forwarding). If the sFlow collector is hosted in either the GRT or a user created VRF, SPB reachability only supports using Layer 2 VSN or IP shortcuts to access the collector. Layer 3 VSNs are not supported in accessing the collector when it is hosted in the GRT or a User created VRF.
-  **Note**  
This restriction applies to the VSP 8600 only. Other platforms mirror copies to both destinations.

A packet can have only one mirror destination so you cannot configure sFlow and Port Mirroring on the same port.

- For Segmented Management Instance interfaces, sFlow is only supported on Segmented Management Instance OOB and on circuitless IP (CLIP) in GRT.

## Configuration considerations

- If the sFlow collector has two network interface controller (NIC) cards, to avoid dropped sFlow datagrams that are a result of reverse path checks, you can add a route to the agent-ip address for the NIC card on which the sFlow datagrams are received.
- First preference is always given to either the GRT or management VRF to where the sFlow agent IP address is configured. For example, if you configure the sFlow agent IP address as part of GRT, the GRT route to the collector is given preference over the management VRF. If the management network hosts a collector with a collector IP address that is reachable over SPB as a result of redistributing direct routes on a peer Backbone Edge Bridge (BEB) or in situations where the GRT has a default route (0.0.0.0) and the collector route is in the local management VRF, first preference is given to the VRF where you have configured the sFlow agent IP address.
- For Segmented Management Instance interfaces, preference for sFlow collector reachability checks is determined by agent-ip configuration. If you configure the sFlow agent IP address to Segmented Management Instance OOB, preference for route lookup is given to the management VRF. If no route is found, lookup occurs in GRT.

If you do not configure the agent-ip address to Segmented Management Instance OOB, preference for route lookup is given to GRT. If no route is found, lookup occurs in the management VRF.

After you configure the sFlow agent on the network device that you want to monitor, the system collects flow samples or counter samples, and exports these traffic statistics as sFlow datagrams to the sFlow collector on a server or appliance.

For example, after the buffers reach capacity or a timeout is triggered, an sFlow datagram, which is a UDP packet, sends the measurement information to the sFlow collector buffers. The UDP payload contains the sFlow datagram.

The following figure shows the sFlow agent on various routers and switches with sFlow datagrams being sent to the sFlow collector.

**Table 228: sFlow legend**

| Number | Description     |
|--------|-----------------|
| 1      | sFlow collector |
| 2      | sFlow datagrams |
| 3      | sFlow agents    |

As a general rule, drop action occurs after sampling completes. However, in situations related to Layer 1 errors such as, MTU exceeded packets, the drop action occurs before sampling begins. For errors such as, frame too long, packets are dropped due to the size of the frame being greater than the interface MTU. In this situation, the packets are dropped before sampling begins so only counter polling occurs. To enable trace, use **line-card 1 trace level 232 <0-4>**.

**Important**

The defined sampling rate, an average of 1 out of n packets/operations does not provide a 100% accurate result, but it does provide a result with quantifiable accuracy.

## sFlow Configuration Using CLI

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using CLI.

### Configuring the agent-ip and Enabling sFlow Globally

Configure the sFlow agent IPv4 address, and then enable sFlow before the system can monitor and capture traffic statistics to send to an sFlow collector. By default, sFlow is globally disabled.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the agent IPv4 address:  
`sflow agent-ip {A.B.C.D}`
3. Enable sFlow:  
`sflow enable`
4. Verify the global configuration:  
`show sflow`

#### Example

Globally enable sFlow, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow agent-ip 192.0.2.27
INFO: Please be aware that sFlow agent IP address is only supported in MGMT or GRT VRF.
Switch:1(config)#sflow enable
Switch:1(config)#show sflow
=====
 sFlow Global Configuration
=====
Global State : Enabled
Agent IP : 192.0.2.27
```

#### What to Do Next

After you configure the agent-ip and globally enable sFlow, proceed to configuring the sFlow collector.

### Variable Definitions

Use the data in the following table to use the **sflow agent-ip** command.

| Variable    | Definition                                                                                                                                                                                                                                      |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D. } | Specifies the agent-ip address (IPv4).<br><br><b>Note:</b><br>For Segmented Management Instance interfaces, you must configure the agent-ip address to the IP address of the Segmented Management Instance interface on which datagrams egress. |

## Configuring an sFlow Collector

Configure an sFlow collector to determine the device to which the sFlow agent sends sFlow datagrams. You can configure up to two collectors for each interface slot in the chassis.

### Before You Begin

- You must globally enable sFlow.

### About This Task

The sFlow datagrams that the agent sends to the collector are not encrypted. Use a VLAN to create a secure measurement network to route sFlow datagrams.

To further protect the sFlow collector, configure it to accept only sFlow datagrams, or to check sequence numbers and verify source addresses.

### Procedure

- Enter Global Configuration mode:  

```
enable

configure terminal
```
- Configure the collector information:  

```
sflow collector <1-2> address {A.B.C.D} [Owner WORD <1-20>] [port <1-65535>] [timeout <1-65535>]
```
- Verify the collector configuration:  

```
show sflow collector <1-2>
```

### Example

Configure collector ID, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#sflow collector 2 address 192.0.2.27 owner sflow2 port 6343 timeout 531
Switch:1(config)#show sflow collector
=====
```

| sFlow Collector Configuration Info |        |              |      |                |               |
|------------------------------------|--------|--------------|------|----------------|---------------|
| Id                                 | Owner  | Collector-IP | Port | Timeout (secs) | Reachable via |
| 1                                  | sflow1 | 192.0.2.26   | 6343 | 497            | 192.0.2.15    |
| 2                                  | sflow2 | 192.0.2.27   | 6343 | 531            | 192.0.2.16    |

All 2 out of 2 Total Num of sflow collector entries displayed

### What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

### Variable Definitions

Use the data in the following table to use the **sflow collector** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                     |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collector &lt;1-2&gt;</code>   | Specifies the id to export sFlow datagrams to the collector id.<br>Use the no operator to remove an sflow collector id and a collector name. no <code>sflow collector &lt;1-2&gt; owner WORD&lt;1-20&gt;</code><br>To configure the default value, enter <code>default sflow collector &lt;1-2&gt;</code> |
| <code>address {A.B.C.D.}</code>      | Specifies the collector IP address.<br>Use the no operator to remove an sflow collector address. no <code>sflow collector &lt;1-2&gt; address {A.B.C.D}</code>                                                                                                                                            |
| <code>owner WORD&lt;1-20&gt;</code>  | Specifies the sFlow collector name.                                                                                                                                                                                                                                                                       |
| <code>port &lt;1-65535&gt;</code>    | Specifies the destination UDP port. The default port is 6343.<br>To configure the default value, enter <code>default sflow collector &lt;1-2&gt; port</code>                                                                                                                                              |
| <code>timeout &lt;1-65535&gt;</code> | Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the collector sends data forever.<br>To configure the default value, enter <code>default sflow collector &lt;1-2&gt; timeout</code>                         |
| <code>vrf WORD&lt;1-16&gt;</code>    | Specifies the name of the VRF used to reach the collector.<br><br><b>Note:</b><br>This parameter is not supported on all hardware platforms.                                                                                                                                                              |

## Configuring the Packet Sampling Rate

Configure the packet sampling rate at port level to determine how many packets the system counts before it takes a sample. Configuring the sampling rate enables sFlow on the port.

### Before You Begin

- You must globally enable sFlow.

## About This Task

If you configure a conservative sampling rate to prevent overloading the sFlow agent, the result will reflect high values that do not reflect typical traffic levels.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the collector id:

```
sflow collector <1-2>
```

3. Configure the sampling rate:

```
sflow sampling-rate <1024-1000000>
```

4. Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

## Example

Configure sampling rates for ports 2/1, 2/2, 2/3, and 2/4.

```
Switch:1(config-if)#interface gigabitethernet 2/1,2/2
Switch:1(config-if)#sflow collector 1
Switch:1(config-if)#sflow sampling-rate 10000
Switch:1(config-if)#interface gigabitethernet 2/3
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 8192
Switch:1(config-if)#interface gigabitethernet 2/4
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 12001
Switch:1(config-if)#show sflow interface enabled
```

### sFlow Port Configuration Info

| Port | Packet-Sample-Rate | Max-Header-Size | Counter-interval<br>(in secs) | Collector-list |
|------|--------------------|-----------------|-------------------------------|----------------|
| 2/1  | 10000              | 128             | 0                             | 1              |
| 2/2  | 10000              | 128             | 0                             | 1              |
| 2/3  | 8192               | 128             | 0                             | 2              |
| 2/4  | 12001              | 128             | 0                             | 2              |

All 4 out of 4 Total Num of sflow port entries displayed

### Variable Definitions

Use the data in the following table to use the **sflow sampling-rate** and **show sflow interface** commands.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1024-1000000>                                        | Configures the packet sampling rate on a port. The default value is 0 (disabled). To configure the default value, enter <code>default sflow sampling-rate</code> .                                                                                                                                                                                            |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring sFlow Maximum Header Size

Configure the maximum header size on a single port or multiple ports.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the maximum-header size:

```
sflow max-header-size <64-256>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Example

For ports 1/1 to 1/10, configure the maximum header size, and then verify the configuration.

```
Switch:1(config-if)#interface gigabitethernet 1/1-1/10
Switch:1(config-if)#sflow max-header-size 255
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```
=====
sFlow Port Configuration Info
```

| Port | Packet-Sample-Rate | Max-Header-Size | Counter-interval<br>(in secs) | Collector-list |
|------|--------------------|-----------------|-------------------------------|----------------|
| 1/1  | 0                  | 255             | 525                           | 1,2            |
| 1/2  | 0                  | 255             | 525                           | 1,2            |
| 1/3  | 0                  | 255             | 525                           | 1,2            |
| 1/4  | 0                  | 255             | 525                           | 1,2            |
| 1/5  | 0                  | 255             | 525                           | 1,2            |
| 1/6  | 0                  | 255             | 525                           | 1,2            |
| 1/7  | 0                  | 255             | 525                           | 1,2            |
| 1/8  | 0                  | 255             | 525                           | 1,2            |
| 1/9  | 0                  | 255             | 525                           | 1,2            |
| 1/10 | 0                  | 255             | 525                           | 1,2            |

### Variable Definitions

Use the data in the following table to use the **max-header-size** command.

| Variable | Value                                                                                              |
|----------|----------------------------------------------------------------------------------------------------|
| <64-256> | Identifies the maximum number of bytes to be copied from the sampled packet.<br>Default 128 bytes. |

## Configuring the Counter Sampling Interval

Configure the counter sampling interval values at port level to determine how often the sFlow agent polls and exports counters for a configured interface.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the counter sampling interval:

```
sflow counter-interval <1-3600>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

## Example

Verify all slots use the default polling-interval configuration.

```
Switch:1(config-if)#sflow counter-interval 525
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```

### Variable Definitions

Use the data in the following table to use the **sflow counter-interval** and **show sflow interface** commands.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-3600>                                              | Specifies the polling interval for a slot.<br>Default value is 0 (disabled).                                                                                                                                                                                                                                                                                  |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing sFlow Statistics

Display statistics for sFlow datagrams.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- To enter User EXEC mode, log on to the switch.
- View sFlow statistics:

```
show sflow statistics [collector <1-2>]
```

**Example**

```
Switch:1>show sflow statistics

=====
sFlow Statistics Info
=====
Collector-id sFlow-Datagrams

1 1001
2 0

All 2 out of 2 Total Num of sflow statistics entries displayed
```

## Clearing sFlow Statistics

Use this procedure to clear the statistics for each collector.

**Before You Begin**

- You must globally enable sFlow.

**Procedure**

- Enter Privileged EXEC mode:
 

```
enable
```
- Clear sFlow statistics:
 

```
clear sflow statistics [collector <1-2>]
```
- Verify the collector information:
 

```
show sflow statistics [collector <1-2>]
```

**Example**

Clear the statistics for collector ID 1.

```
Switch:1>enable
Switch:1#clear sflow statistics collector 1
Switch:1#show sflow statistics collector 1

=====
sFlow Statistics Info
=====
Collector-id sFlow-Datagrams

1 0

All 1 out of 1 Total Num of sflow statistics entries displayed
```

## sFlow Configuration Using EDM

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using EDM.

## Enabling sFlow and Configuring the Agent IP Address

Use this procedure to enable sFlow and configure the sFlow agent IP address so the system can send packets to an sFlow collector.

### About This Task

Application Telemetry and sFlow both use the **sFlow Globals** tab.

### Before You Begin

You must enable sFlow before you enable Application Telemetry.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Globals** tab.
4. Check **AdminEnable** to enable sFlow.
5. In the **AgentAddress** field, enter the agent IPv4 address.
6. Click **Apply**.

### What to Do Next

After you configure the agent IP address and globally enable sFlow, proceed to configuring the sFlow collector.

#### *Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>      | Shows whether sFlow is enabled. By default, the check box is not enabled.                                                                                                                                                                                                                       |
| <b>AgentAddressType</b> | Specifies the collector IP address type. Only IPv4 collector addresses are supported.                                                                                                                                                                                                           |
| <b>AgentAddress</b>     | Specifies the agent IP address of an interface that exists in the local management VRF or GRT.<br><br><b>Note:</b><br>For Segmented Management Instance interfaces, you must configure AgentAddress to the IP address of the Segmented Management Instance interface on which datagrams egress. |

## Configuring an sFlow Collector

Use this procedure to configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

#### Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

### About This Task

#### Tip

You can configure the **Collector** tab to select only the columns you are interested in seeing. By default, the system does not display **AddressType** option. To make the **AddressType** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **AddressType** check box.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Collector** tab.
4. Configure the fields for Collector 1.
5. Click **Apply**.

### What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

#### *Collector Field Descriptions*

Use the data in the following table to use the **Collector** tab.

| Name           | Description                                                                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>   | Shows collector 1 and collector 2. The switch exports sFlow and Application Telemetry traffic to the collector.                                                                                 |
| <b>Owner</b>   | Specifies the sFlow collector name. The string length is 1 to 20 characters.                                                                                                                    |
| <b>Timeout</b> | Specifies the time remaining (in seconds) before the collector is released and stops sampling. The default timeout is 0, which means the timeout is not used and the switch sends data forever. |
| <b>Address</b> | Specifies the collector IP address. If the default address is set to 0.0.0.0, no traffic is sent.                                                                                               |
| <b>Port</b>    | Specifies the destination port. The default port is 6343.                                                                                                                                       |

| Name               | Description                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>IsReachable</b> | Shows whether the sFlow collector is reachable.                                                                    |
| <b>NextHop</b>     | If the collector is reachable, shows the name or address of the next hop through which the collector is reachable. |

## Configuring the Packet Samples and Counter Samples

Configure the packet sampling rate to determine how many packets the system counts before it takes a sample and configure the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. You can also configure the maximum header size on a single port or multiple ports.

Configuring the sampling rate enables sFlow on the port.

### Before You Begin

- You must globally enable sFlow.

### About This Task

#### Tip

You can configure the **Interfaces** tab to select only the columns you are interested in seeing. By default, the system does not display **Instances** option. To make the **Instances** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **Instances** check box.

### Procedure

- In the navigation pane, expand the **Configuration > Serviceability** folders.
- Click **Sflow**.
- Click the **Interfaces** tab.
- In the **DataSource** column, navigate to the slot and port where you want to configure sFlow, and configure the following:
  - PacketSamplingRate—Double-click the field, and enter a sampling rate value.
  - MaximumHeaderSize—Double-click the field, and enter a maximum header size value.
  - Interval—Double-click the field, and enter the counter sampling interval value in seconds.
- Click **Apply**.

### *Interfaces Field Descriptions*

Use the data in the following table to use the **Interfaces** tab.

| Name                      | Description                                                                                                                                                                               |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DataSource</b>         | Shows the slot and port for which traffic statistics are collected.<br>The field name is different on different hardware platforms.                                                       |
| <b>Instance</b>           | Shows the number of sFlow samplers associated with a specific datasource.<br><br><b>Note:</b><br>You must select this field for it to display on the Interfaces tab.                      |
| <b>Collectors</b>         | Shows the collectors that have been configured for the sFlow agent to send sFlow datagrams. Two collectors are supported.<br>The field name is different on different hardware platforms. |
| <b>PacketSamplingRate</b> | Specifies the packet sampling rate to determine how many packets the system counts before it take a sample.<br>The default is 0.                                                          |
| <b>MaximumHeaderSize</b>  | Specifies the maximum header size on a single port or multiple ports.<br>The default is 128 bytes.                                                                                        |
| <b>Interval</b>           | Specifies the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface.<br>The default is 0.                                |

## Displaying sFlow Statistics

Use the following procedure to display (true) sFlow statistics. Statistics for sFlow are cleared (false), by default.

### About This Task

#### Tip

You can configure the **Stats** tab to select only the columns you are interested in seeing. The system displays all the options, by default. To hide a column, click the down arrow on one of the menu headings, navigate to **Columns**, and select the check box for the column you want to hide.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Stats** tab.
4. In the **ClearStats** column, double-click the field, and select true or false from the list.
5. Click **Apply**.

*Stats Field Descriptions*

Use the data in the following table to use the **Statistics** tab.

| Name                 | Description                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------|
| <b>Index</b>         | Shows sFlow collector ID 1 and 2                                                                  |
| <b>DatagramCount</b> | Shows the number of datagrams that have been sent to the collector.                               |
| <b>ClearStats</b>    | Shows whether the sFlow statistics are displayed (true) or cleared (false). The default is false. |

## Configuring counter polling

### About This Task

Use this procedure to configure counter polling using the EDM.

This tab is not supported on all hardware platforms.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Counter Polling** tab.
4. In the **Index** column, navigate to the slot and port where you want to configure sFlow.
5. Double-click the **Interval** field and enter a value in seconds.
6. Click **Apply**.

*Counter Polling Field Descriptions*

Use the data in the following table to use the **Counter Polling** tab.

| Name            | Description                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>    | Identifies the source of the data for counter polling.                                                                                                         |
| <b>Receiver</b> | The sFlow receiver associated with the counter polling.                                                                                                        |
| <b>Interval</b> | The maximum number of seconds between successive samples of the counters associated with this data source. A sampling interval of 0 disables counter sampling. |

**Table 229: Simple Network Management Protocol product support**

| Feature                                                 | Product         | Release introduced |
|---------------------------------------------------------|-----------------|--------------------|
| Simple Network Management Protocol (SNMP) v1/2/3 (IPv4) | 5420 Series     | VOSS 8.4           |
|                                                         | 5520 Series     | VOSS 8.2.5         |
|                                                         | VSP 4450 Series | VSP 4000 4.0       |
|                                                         | VSP 4900 Series | VOSS 8.1           |
|                                                         | VSP 7200 Series | VOSS 4.2.1         |
|                                                         | VSP 7400 Series | VOSS 8.0           |
|                                                         | VSP 8200 Series | VSP 8200 4.0       |
|                                                         | VSP 8400 Series | VOSS 4.2           |
|                                                         | VSP 8600 Series | VSP 8600 4.5       |
|                                                         | XA1400 Series   | VOSS 8.0.50        |

**Table 229: Simple Network Management Protocol product support (continued)**

| Feature     | Product         | Release introduced |
|-------------|-----------------|--------------------|
| SNMP (IPv6) | 5420 Series     | VOSS 8.4           |
|             | 5520 Series     | VOSS 8.2.5         |
|             | VSP 4450 Series | VOSS 4.1           |
|             | VSP 4900 Series | VOSS 8.1           |
|             | VSP 7200 Series | VOSS 4.2.1         |
|             | VSP 7400 Series | VOSS 8.0           |
|             | VSP 8200 Series | VOSS 4.1           |
|             | VSP 8400 Series | VOSS 4.2           |
|             | VSP 8600 Series | VSP 8600 6.2       |
|             | XA1400 Series   | Not Supported      |

You can use the Simple Network Management Protocol (SNMP) to remotely collect management data and configure devices.

An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects to retrieve or modify.

## SNMPv3

The SNMP version 3 (v3) is the third version of the Internet Standard Management Framework and is derived from and builds upon both the original Internet Standard Management Framework SNMP version 1 (v1) and the second Internet Standard Management Framework SNMP version 2 (v2).

The SNMPv3 is not a stand-alone replacement for SNMPv1 or SNMPv2. The SNMPv3 defines security capabilities you must use in conjunction with SNMPv2 (preferred) or SNMPv1. The following figure shows how SNMPv3 specifies a user-based security model (USM) that uses a payload of either an SNMPv1 or an SNMPv2 Protocol Data Unit (PDU).

**Figure 230: SNMPv3 USM**

SNMPv3 is an SNMP framework that supplements SNMPv2 by supporting the following:

- New SNMP message formats
- Security for messages
- Access control
- Remote configuration of SNMP parameters

The recipient of a message can use authentication within the USM to verify the message sender and to detect if the message is altered. According to RFC2574, if you use authentication, the USM checks the entire message for integrity.

An SNMP entity is an implementation of this architecture. Each SNMP entity consists of an SNMP engine and one or more associated applications.

## SNMP Engine

An SNMP engine provides services for sending and receiving messages, authenticating and encrypting messages, and controlling access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity, which contains the SNMP engine.

## EngineID

Within an administrative domain, an EngineID is the unique identifier of an SNMP engine. Because there is a one-to-one association between SNMP engines and SNMP entities, the ID also uniquely and unambiguously identifies the SNMP entity within that administrative domain. The system generates an EngineID during the startup process. The SNMP engine contains a:

- [Dispatcher](#) on page 3059.
- [Message Processing Subsystem](#) on page 3059.
- [Security Subsystem](#) on page 3059.
- [Access Control Subsystem](#) on page 3060.

Automatic discovery of a Remote EngineID is performed so that Inform messages are populated properly and not rejected by the SNMP Manager. This automatic discovery is performed by the switch using a request to the Manager for a response that contains the EngineID. The switch then uses this Remote EngineID value to populate all subsequent Inform messages.

## Dispatcher

The dispatcher is part of an SNMP engine. You can use the dispatcher for concurrent support of multiple versions of SNMP messages in the SNMP engine through the following ways:

- To send and receive SNMP messages to and from the network.
- To determine the SNMP message version and interact with the corresponding message processing model.
- To provide an abstract interface to SNMP applications for delivery of a PDU to an application.
- To provide an abstract interface for SNMP applications to send a PDU to a remote SNMP entity.

## Message Processing Subsystem

The message processing subsystem prepares messages for sending and extracts data from received messages. The subsystem can contain multiple message processing models.

## Security Subsystem

The security subsystem provides the following features:

- Authentication
- Privacy
- Security

## Authentication

You can use authentication within the SNMPv3 to verify the message sender and whether the message is altered. If you use authentication, the integrity of the message is verified. The supported SNMPv3 authentication protocols are HMAC-MD5 and HMAC-SHA-96. By default, the switch uses HMAC-SHA1-96 with 160-bit key length.

## Privacy

SNMPv3 is an encryption protocol for privacy. Only the data portion of a message is encrypted; the header and the security parameters are not. The privacy protocol that SNMPv3 supports is CBC-DES Symmetric Encryption Protocol and Advanced Encryption Standard (AES).

## Security

The SNMPv3 security protects against:

- Modification of information—protects against altering information in transit.
- Masquerade—protects against an unauthorized entity assuming the identity of an authorized entity.

- Message stream modification—protects against delaying or replaying messages.
- Disclosure—protects against eavesdropping.

The SNMPv3 security also offers:

- Discovery procedure—finds the EngineID of an SNMP entity for a given transport address or transport endpoint address.
- Time synchronization procedure—facilitates authenticated communication between entities

The SNMPv3 does not protect against the following:

- Denial-of-service—prevention of exchanges between manager and agent.
- Traffic analysis—general pattern of traffic between managers and agents.

## Access Control Subsystem

SNMPv3 provides a group option for access policies.

The access policy feature in the switch determines the access level for the users connecting to the device with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), Telnet, and rlogin. The system access policy feature is based on the user access levels and network address. This feature covers services, such as TFTP, HTTP, SSH, rlogin, and SNMP. However, with the SNMPv3 engine, the community names do not map to an access level. The View-based Access Control Model (VACM) determines the access privileges.

### Note

Rlogin is only supported on VSP 8600 Series.

Use the configuration feature to specify groups for the SNMP access policy. You can use the access policy services to cover SNMP. Because the access restriction is based on groups defined through the VACM, the synchronization is made using the SNMPv3 VACM configuration. The administrator uses this feature to create SNMP users (USM community) and associate them to groups. You can configure the access policy for each group and network.

The following are feature specifications for the group options:

- After you enable SNMP service, this policy covers all users associated with the groups configured under the access policy. The access privileges are based on access allow or deny. If you select allow, the VACM configuration determines the management information base (MIB)-views for access.
- The SNMP service is disabled by default for all access policies.
- The access level configured under **access-policy policy <id>** does not affect SNMP service. The VACM configuration determines the SNMP access rights.

## User-Based Security Model

In a USM system, the security model uses a defined set of user identities for any authorized user on a particular SNMP engine. A user with authority on one SNMP engine must also have authorization on all SNMP engines with which the original SNMP engine communicates.

The USM provides the following levels of communication:

- NoAuthNoPriv—communication without authentication and privacy.
- AuthNoPriv—communication with authentication and without privacy.
- AuthPriv—communication with authentication and privacy.

The following figure shows the relationship between USM and VACM.

**Figure 231: USM association with VACM**

## View-Based Access Control

View-based Access Control Model (VACM) provides group access, group security levels, and context based on a predefined subset of MIB objects. These MIB objects define a set of managed objects and instances.

VACM is the standard access control mechanism for SNMPv3, and it provides:

- Authorization service to control access to MIB objects at the PDU level.
- Alternative access control subsystems.

The access is based on principal, security level, MIB context, object instance, and type of access requested (read or write). You can use the VACM MIB to define the policy and control remote management.

## SNMPv3 Encryption

A user-based security port for SNMPv3 is defined as a security subsystem within an SNMP engine. The switch USM uses HMAC-MD5-96 and HMAC-SHA-96 as the authentication protocols, and CBC-DES as the privacy protocol. Use USM to use other protocols instead of, or concurrently with, these protocols.

CFB128-AES-128, an AES-based Symmetric Encryption Protocol, is an alternative privacy protocol for the USM.

The AES standard is the current encryption standard, Federal Information Processing Standard 140-2 (FIPS 140-2), intended to be used by the U.S. Government organizations to protect sensitive information. The AES standard is also becoming a global standard for commercial software and hardware that uses encryption or other security features.

## The AES-Based Symmetric Encryption Protocol

This symmetric encryption protocol provides support for data confidentiality. The system encrypts the designated portion of the SNMP message and includes it as part of the transmitted message.

The USM specifies that the scoped PDU is the portion of the message that requires encryption. An SNMP engine that can legitimately originate messages on behalf of the appropriate user shares a secret value, in combination with a timeliness value and a 64-bit integer, used to create the (localized) encryption/decryption key and the initialization vector.

## The AES Encryption Key and Initialization Vector

The AES encryption key uses the first 128 bits of the localized key. The 128-bit Initialization Vector (IV) is the combination of the authoritative SNMP engine 32-bit `snmpEngineBoot`, the SNMP engine 32-bit `snmpEngineTime`, and a local 64-bit integer. The system initializes the 64-bit integer to a pseudo-random value at startup time.

## Data Encryption

The switch handles data encryption in the following manner:

1. The system treats data as a sequence of octets.
2. The system divides the plaintext into 128-bit blocks.

The first input block is the IV, and the forward cipher operation is applied to the IV to produce the first output block.

3. The system produces the first cipher text block by executing an exclusive-OR function on the first plaintext block with the first output block.
4. The system uses the cipher text block as the input block for the subsequent forward cipher operation.
5. The system repeats the forward cipher operation with the successive input blocks until it produces a cipher text segment from every plaintext segment.
6. The system produces the last cipher text block by executing an exclusive-OR function on the last plaintext segment of  $r$  bits ( $r$  is less than or equal to 128) with the segment of the  $r$  most significant bits of the last output block.

## Data Decryption

The switch handles data decryption in the following manner:

1. In CFB decryption, the IV is the first input block, the system uses the first cipher text for the second input block, the second cipher text for the third input block, and this continues until the system runs out of blocks to decrypt.
2. The system applies the forward cipher function to each input block to produce the output blocks.
3. The system passes the output blocks through an exclusive-OR function with the corresponding cipher text blocks to recover the plaintext blocks.
4. The system sends the last cipher text block (whose size  $r$  is less than or equal to 128) through an exclusive-OR function with the segment of the  $r$  most significant bits of the last output block to recover the last plaintext block of  $r$  bits.

## Trap Notifications

You configure traps by creating SNMP trap notifications, creating a target address to which you want to send the notifications, and specifying target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2205.

## SNMP Community Strings

---

For security reasons for SNMPv1 and SNMPv2, the SNMP agent validates each request from an SNMP manager before responding to the request by verifying that the manager belongs to a valid SNMP community. An SNMP community is a logical relationship between an SNMP agent and one or more SNMP managers (the manager software implements the protocols used to exchange data with SNMP agents). You define communities locally at the agent level.

The agent establishes one community for each combination of authentication and access control characteristics that you choose. You assign each community a unique name (community string), and all members of a community have the same access privileges, either read-only or read-write:

- Read-only: members can view configuration and performance information.
- Read-write: members can view configuration and performance information, and change the configuration.

By defining a community, an agent limits access to its MIB to a selected set of management stations. By using more than one community, the agent can provide different levels of MIB access to different management stations.

SNMP community strings are used when a user logs on to the device over SNMP, for example, using an SNMP-based management software. You set the SNMP community strings using CLI . If you have read/write/all access authority, you can modify the SNMP community strings for access to the device through Enterprise Device Manager (EDM).

You are provided with community strings for SNMPv1 and SNMPv2. If you want to use SNMPv3 only, you must disable SNMPv1 and SNMPv2 access by deleting the default community string entries and create the SNMPv3 user and group.[SNMPv3](#).

#### Note

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3.

If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

For more information on enhanced secure mode, see [Enhanced secure mode authentication access levels](#) on page 3272.

The following table lists the default community strings for SNMPv1 and SNMPv2.

| VRF                  | Default community string | Access       |
|----------------------|--------------------------|--------------|
| GlobalRouter VRF     | public                   | Read access  |
|                      | private                  | Write access |
| ManagementRouter VRF | public:512               | Read access  |
|                      | private:512              | Write access |

Community strings are encrypted using the AES encryption algorithm. The system does not display community strings on the device and are not stored in the configuration file.

#### Caution Security risk

For security reasons, as a best practice, set the community strings to values other than the factory defaults.

The switch handles community string encryption in the following manner:

- When the device starts up, community strings are restored from the hidden file.
- When the SNMP community strings are modified, the modifications are updated to the hidden file.
- Stale snmp-server community entries for different VRFs that the system displays it after reboot with no VRFs . On an node with any valid config file saved with more than the default vrf0 , snmp\_community entries for that VRF are created and maintained in a separate txt file, snmp\_comm.txt, on every boot. The node reads this file and updates the snmp communities available on the node. As a result for a boot with config having no VRFs, you may still see snmp\_community entries for VRFs other than the globalRouter vrf0.

## Hsecure with SNMP

If you enable hsecure, the system disables SNMPv1, SNMPv2 and SNMPv3. If you want to use SNMP, you must use the command **no boot config flag block-snmp** to re-enable SNMP.

## SNMPv3 support for VRF

---

Use Virtual Router Forwarding (VRF) to offer networking capabilities and traffic isolation to customers that operate over the same node (switch). Each virtual router emulates the behavior of a dedicated hardware router and is treated by the network as a separate physical router. You can use VRF Lite to perform the functions of many routers using a single router running VRF Lite. This substantially reduces the cost associated with providing routing and traffic isolation for multiple clients.

## SNMPv3 Remote Engine ID Discovery

---

The following sections contain information about SNMPv3 remote engine ID discovery.

### Traps and Informs

SNMPv3 supports two types of notifications, traps and informs.

Traps are unacknowledged notifications sent by agents to managers. Traps are generated by the agent, and the authoritative SNMP engine for a trap packet is the sending SNMP agent. Because the generator of the message and the authoritative engine are the same, there is no need for the SNMPv3 discovery process.

Informs are acknowledged notifications. An agent sends an inform notification and waits for acknowledgement. If the agent does not receive the acknowledgement within the configured timeout period, it resends the inform notification. The agent continues to resend the inform notification until a reply is received or until the maximum retry value is reached. For information about configuring an inform timeout period or configuring a maximum retry value, see [Configure SNMP settings](#) on page 3067.

### Remote Engine ID Discovery

Inform packets must contain the management (remote) SNMP engine ID. The agent generates informs, but the authoritative SNMP engine is the manager. To generate valid inform packets and avoid manual configuration of the manager SNMP engine ID, the agent must discover the SNMP engine ID of the manager.

The agent discovers the management SNMP Engine ID by sending a probe message to the manager. The manager response to the probe message is a report message that contains the SNMP engine ID of the authoritative SNMP engine. The agent stores the SNMP engine ID received from the manager in the engine table, and sends inform packets using the manager SNMP engine ID. If the manager SNMP

engine ID changes, the discovery process updates the manager SNMP engine ID value in the engine table.

**Note**

Remote engine ID discovery cannot use SNMP config files created in releases prior to VOSS 8.1. Config files must be saved in Release VOSS 8.1 or higher in order to be compatible with remote engine ID discovery.

## SNMP configuration using CLI

---

Configure the SNMP engine to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity.

- To perform the procedures in this section, you must log on to the Global Configuration mode in CLI. For more information about how to use CLI, see [CLI Procedures](#) on page 233.

This task flow shows you the sequence of procedures you perform to configure basic elements of SNMP when using CLI.

**Figure 232: SNMP configuration procedures**

## Configure SNMP settings

Configure Simple Network Management Protocol (SNMP) to define or modify the SNMP settings, and specify the security level for SNMP communications.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the generation of authentication traps:  

```
snmp-server authentication-trap enable
```

3. Configure the contact information for the system:

```
snmp-server contact WORD<0-255>
```

4. Configure the SNMP and IP sender flag to the same value:

**Note**

This step only applies to VSP 8600 Series.

```
snmp-server force-iphdr-sender enable
```

5. Send the configured source address (sender IP) as the sender network in the notification message:

**Note**

This step only applies to VSP 8600 Series.

```
snmp-server force-trap-sender enable
```

6. Create an SNMPv1 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]
```

7. Create an SNMPv2 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>] [filter WORD<1-32>]
```

8. Create an SNMPv3 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|authNoPriv|authPriv WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>]} [filter WORD<1-32>]
```

9. Configure the system location:

```
snmp-server location WORD<0-255>
```

10. Enable login-success traps:

```
snmp-server login-success-trap enable
```

11. Configure the system name:

```
snmp-server name WORD<0-255>
```

12. Create a new entry in the notify filter table:

```
snmp-server notify-filter WORD<1-32> WORD<1-32>
```

13. Configure the SNMP trap receiver and source IP addresses:

**Note**

This step only applies to VSP 8600 Series.

```
snmp-server sender-ip {A.B.C.D} {A.B.C.D}
```

## Example

Enable the generation of SNMP traps. Configure the contact information for the system. Configure the SNMP and IP sender flag to the same value. Configure hosts to receive SNMP notifications:

### Note

Exception: configuring the SNMP and IP sender flag to the same value only applies to VSP 8600 Series.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server authentication-trap enable
Switch:1(config)#snmp-server contact xxxx@company.com
Switch:1(config)#snmp-server force-iphdr-sender enable
Switch:1(config)#snmp-server host 192.0.2.16 port 1 v1 SNMPv1 filter SNMPfilterv1
```

## Variable Definitions

The following table defines parameters for the `snmp-server` command.

| Variable                                                                                                                                                                                                                                                                                                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Variable                                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>notify-filter WORD&lt;1-32&gt;<br/>WORD&lt;1-32&gt;</code>                                                | Creates a new entry in the notify filter table. The first WORD<1-32> specifies the filter profile name, and the second WORD<1-32> specifies the subtree object identifier (OID).                                                                                                                                                                                                                                                                                                                                           |
| <code>sender-ip {A.B.C.D}<br/>{A.B.C.D}</code><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | The first {A.B.C.D} configures the SNMP trap receiver and source IP addresses. Specify the IP address of the destination SNMP server that receives the SNMP trap notification in the first IP address.<br>The second {A.B.C.D} specifies the source IP address of the SNMP trap notification packet that is transmitted in the second IP address. If you set this to 0.0.0.0, the system uses the IP address of the local interface that is closest (from an IP routing table perspective) to the destination SNMP server. |

## Creating a user

Create a new user in the USM table to authorize a user on a particular SNMP engine.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Create a user on a remote system:  
`snmp-server user engine-id WORD<16-97> WORD<1-32> {md5 | sha } [aes | des ]`
3. Enter and confirm your password.
4. Create a user on the local system:  
`snmp-server user WORD<1-32> [notify-view WORD<0-32>] [read-view WORD<0-32>] [write-view WORD<0-32>] {md5 | sha} [aes | des ]`
5. Enter and confirm your password.
6. Add the user to a group:  
`snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des ]`
7. Enter and confirm your password.
8. Verify the configuration:  
`show snmp-server user`

### Example

Create a user named test1 on a remote system with MD5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user engine-id 0x80:00:08:E0:03:10:CD:AE:6B:D0:00 test1 md5
aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****
```

```

WARNING: For best security practices avoid the use
 of repeated patterns in passwords.

Switch:1(config)#show snmp-server user

Engine ID = 0x80:00:08:E0:03:10:CD:AE:6B:D0:00

=====

### Variable Definitions

The following table defines parameters for the `snmp-server user` command.

| Variable                                  | Value                                                                                                                                                                                                                 |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{aes des}</code>                    | Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des.<br><br><b>Important:</b><br>You must set authentication before you can set the privacy option. |
| <code>engine-id WORD&lt;16-97&gt;</code>  | Assigns an SNMPv3 engine ID. Use the <b>no</b> operator to remove this configuration.                                                                                                                                 |
| <code>group WORD&lt;1-32&gt;</code>       | Specifies the group access name.                                                                                                                                                                                      |
| <code>{md5 sha}</code>                    | Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.                                                                             |
| <code>notify-view WORD&lt;0-32&gt;</code> | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>read-view WORD&lt;0-32&gt;</code>   | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>write-view WORD&lt;0-32&gt;</code>  | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>user WORD&lt;1-32&gt;</code>        | Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the <b>no</b> operator to remove this configuration.                                      |

## Creating a new user group

Create a new user group to logically group users who require the same level of access. Create new access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

### Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new user group:

```
snmp-server group WORD <1-32> WORD<1-32> {auth-no-priv|auth-priv|no-
auth-no-priv} [notify-view WORD<1-32>] [read-view WORD<1-32>] [write-
view WORD<1-32>]
```

### Example

This example uses the following variable names:

- The new group name is *lan6grp*.
- The context of the group is *""*, which represents the Global Router (VRF 0).
- The security level is *no-auth-no-priv*.
- The access view name is *v1v2only* for all three views: **notify-view**, **read-view**, and **write-view**.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Create a new user group:

```
Switch:1(config)#snmp-server group lan6grp "" no-auth-no-priv notify-
view v1v2only read-view v1v2only write-view v1v2only
```

### Variable Definitions

The following table defines parameters for the `snmp-server group` command.

| Variable                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>auth-no-priv</code>                                | Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>auth-no-priv</code> parameter is included, it creates one entry for SNMPv3 access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>auth-priv</code>                                   | Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>auth-priv</code> parameter is included, it creates one entry for SNMPv3 access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>group WORD&lt;1-32&gt;<br/>WORD&lt;1-32&gt;</code> | The first <code>WORD&lt;1-32&gt;</code> specifies the group name for data access. The range is 1-32 characters. Use the <b>no</b> operator to remove this configuration.<br>The second <code>WORD&lt;1-32&gt;</code> specifies the context name. The range is 1-32 characters. If you use a particular group name value but with different context names, you create multiple entries for different contexts for the same group. You can omit the context name and use the default. If the context name value ends in the wildcard character (*), the resulting entries match a context name that begins with that context. For example, a context name value of <code>foo*</code> matches contexts starting with <code>foo</code> , such as <code>foo6</code> and <code>foofofum</code> . Use the <b>no</b> operator to remove this configuration. |
| <code>no-auth-no-priv</code>                             | Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>no-auth-no-priv</code> parameter is included, it creates 3 entries, one for SNMPv1 access, one for SNMPv2c access, and one for SNMPv3 access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>notify-view WORD&lt;1-32&gt;</code>                | Specifies the view name in the range of 0-32 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>read-view WORD&lt;1-32&gt;</code>                  | Specifies the view name in the range of 0-32 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>write-view WORD&lt;1-32&gt;</code>                 | Specifies the view name in the range of 0-32 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Creating a new entry for the MIB in the view table

Create a new entry in the MIB view table. The default Layer 2 MIB view cannot modify SNMP settings. However, a new MIB view created with Layer 2 permission can modify SNMP settings.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a new entry:
 

```
snmp-server view WORD<1-32> WORD<1-32>
```

### Example

```
Switch:1>enable

Switch:1#configure terminal
```

Create MIB views:

```
Switch:1 (config) snmp-server view 2 1.3.8.7.1.4
```

### Variable Definitions

The following table defines parameters for the `snmp-server view` command.

| Variable                      | Value                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------|
| The first <i>WORD</i> <1-32>  | Specifies the prefix that defines the set of MIB objects accessible by this SNMP entity. The range is 1-32 characters. |
| The second <i>WORD</i> <1-32> | Specifies a new entry with this group name. The range is 1-32 characters.                                              |

## Creating a community

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings to access the system using an SNMP-based management software.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a community:

```
snmp-server community WORD<1-32> [group WORD<1-32>] [index WORD<1-32>]
[secname WORD<1-32>]
```

#### Important

- The **group** parameter is only required if you created a new user group using the procedure in [Creating a new user group](#). If you use any of the default groups, the **secname** automatically links the community to its associated group so there is no need specify the group in this command.
- If you do create a new group, use the **snmp-server community** command to create an SNMP community with a new security name and link it to the new group you created. There is no separate command to create a security name (secname). You use the **snmp-server community** command. The security name is the key to link the community name to a group.
- You cannot use the @ character or the string :: when you create community strings.

### Example

In the following example, the community name is *anewcommunity*, the index is *third*, and the secname is *readview*. There is no group specified because this is a default public/read only group.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#snmp-server community anewcommunity index third secname
readview
```

### Variable Definitions

The following table defines parameters for the `snmp-server community` command.

| Variable                                    | Value                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>community</i><br><i>WORD&lt;1-32&gt;</i> | Specifies a community string. The range is 1-32 characters.                                                  |
| <i>group</i><br><i>WORD&lt;1-32&gt;</i>     | Specifies the group name. The range is 1-32 characters.                                                      |
| <i>index</i><br><i>WORD&lt;1-32&gt;</i>     | Specifies the unique index value of a row in this table. The range is 1-32 characters.                       |
| <i>secname</i><br><i>WORD&lt;1-32&gt;</i>   | Maps the community string to the security name in the VACM Group Member Table. The range is 1-32 characters. |

## Add a User to a Group

Add a user to a group to logically group users who require the same level of access.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new user group:

```
snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des]
```

3. Enter and confirm your password.

4. Verify the configuration:

```
show snmp-server group
```

### Example

Add a user to a group to logically group users who require the same level of access:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user test4 group grouptest4 md5 aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****
```

```
WARNING: For best security practices avoid the use
of repeated patterns in passwords.
```

```
Switch:1(config)#show snmp-server group
```

```

=====
```

### Variable Definitions

The following table defines parameters for the `snmp-server user` command.

| Variable                                  | Value                                                                                                                                                                                                                 |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{aes des}</code>                    | Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des.<br><br><b>Important:</b><br>You must set authentication before you can set the privacy option. |
| <code>engine-id WORD&lt;16-97&gt;</code>  | Assigns an SNMPv3 engine ID. Use the <b>no</b> operator to remove this configuration.                                                                                                                                 |
| <code>group WORD&lt;1-32&gt;</code>       | Specifies the group access name.                                                                                                                                                                                      |
| <code>{md5 sha}</code>                    | Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.                                                                             |
| <code>notify-view WORD&lt;0-32&gt;</code> | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>read-view WORD&lt;0-32&gt;</code>   | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>write-view WORD&lt;0-32&gt;</code>  | Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.                                       |
| <code>user WORD&lt;1-32&gt;</code>        | Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the <b>no</b> operator to remove this configuration.                                      |

## Blocking SNMP

Disable SNMP by using the SNMP block flag. By default, SNMP access is enabled.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Disable SNMP:  

```
boot config flags block-snmp
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Disable SNMP:

```
Switch:1(config)#boot config flags block-snmp
```

### Variable Definitions

The following table defines parameters for the `boot config flags` command.

| Variable                | Value                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>block-snmp</code> | Configures the block SNMP flag as active. Use the <b>no</b> operator to remove this configuration. The default is off. To set this option to the default value, use the <b>default</b> operator with the command. |

## View SNMP System Information

View SNMP system information to view trap and authentication profiles.

For a comprehensive set of SNMP-related `show` commands, see [VOSS Command Line Interface Commands Reference](#).

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View SNMP system information:

```
show snmp-server
```

### Example

```
Switch:1>show snmp-server

 trap-sender :
force-trap-sender : FALSE
force-iphdr-sender : FALSE
 contact: none
 location : none
 name : Switch:1
AuthenticationTrap : false
LoginSuccessTrap : false
```

#### Note

The `trap-sender`, `force-trap-sender`, and `force-iphdr-sender` only applies to VSP 8600 Series.

## SNMP configuration using Enterprise Device Manager

Configure SNMP to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects with Enterprise Device Manager (EDM).

The following task flow shows you the sequence of procedures you perform to configure basic elements of SNMP using EDM.

**Figure 233: SNMP configuration using Enterprise Device Manager procedures**

## Create a User

### About This Task

Create a new user in the USM table to authorize a user on a particular SNMP engine.

#### Note

In EDM, to create new SNMPv3 users you must use the **CloneFromUser** option. However, you cannot clone the default user, named initial. As a result, you must first use CLI to configure at least one user, and then you can use EDM to create subsequent users with the **CloneFromUser** option.

## Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **USM Table**.
3. Click **Insert**.
4. In the **EngineID** box, use the default Engine ID provided or type an administratively-unique identifier to an SNMP engine.
5. In the **User Name** box, type a name.
6. From the **CloneFromUser** list, select a security name from which the new entry copies authentication data and private data, if required.
7. From the **Auth Protocol** list, select an authentication protocol.
8. In the **Cloned User's Auth Password** box, type the authentication password of the cloned user.
9. In the **New User's Auth Password** box, type an authentication password for the new user.
10. From the **Priv Protocol** list, select a privacy protocol.
11. In the **Cloned User's Priv Password** box, type the privacy password of the cloned user.
12. In the **New User's Priv Password** box, type a privacy password for the new user.
13. Click **Insert**.

### Caution Security risk

To ensure security, change the GroupAccess table default view after you set up a new user in the USM table. This prevents unauthorized people from accessing the system using the default user logon. Also, change the Community table defaults, because the community name is used as a community string in SNMPv1/v2 PDU.

## USM Table field descriptions

Use the data in the following table to use the **USM Table** tab and the **Insert USM Table** dialog box. The system displays some fields only on the Insert USM Table dialog box.

| Name                               | Description                                                                                                                                                                                                         |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EngineID</b>                    | Specifies an administratively-unique identifier to an SNMP engine.                                                                                                                                                  |
| <b>UserName</b>                    | Creates the new entry with this security name. The name is used as an index to the table. The range is 1–32 characters.                                                                                             |
| <b>SecurityName</b>                | Identifies the name on whose behalf SNMP messages are generated.                                                                                                                                                    |
| <b>Clone From User</b>             | Specifies the security name from which the new entry must copy privacy and authentication parameters. The range is 1–32 characters. The system displays this option only in the <b>Insert USM Table</b> dialog box. |
| <b>Auth Protocol</b><br>(Optional) | Assigns an authentication protocol (or no authentication) from a list. If you select an authentication protocol, you must enter an old AuthPass and a new AuthPass.                                                 |
| <b>Cloned User's Auth Password</b> | Specifies the current authentication password of the cloned user. The system displays this option only in the <b>Insert USM Table</b> dialog box.                                                                   |
| <b>New User's Auth Password</b>    | Specifies the authentication password of the new user. The system displays this option only in the <b>Insert USM Table</b> dialog box.                                                                              |

| Name                               | Description                                                                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Priv Protocol</b><br>(Optional) | Assigns a privacy protocol (or no privacy) from a list. If you select a privacy protocol, you must enter an old PrivPass and a new PrivPass. |
| <b>Cloned User's Priv Password</b> | Specifies the current privacy password of the cloned user. The system displays this option only in the <b>Insert USM Table</b> dialog box.   |
| <b>New User's Priv Password</b>    | Specifies the privacy password of the new user. The system displays this option only in the <b>Insert USM Table</b> dialog box.              |

## Create a New Group Membership

### About This Task

Create a new group membership to logically group users who require the same level of access.

#### Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Membership** tab.
4. Click **Insert**.
5. From the **SecurityModel** options, select a security model.
6. In the **SecurityName** box, type a security name.
7. In the **GroupName** box, type a group name.
8. Click **Insert**.

### **Group Membership** field descriptions

Use the data in the following table to use the **Group Membership** tab.

| Name                 | Description                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>SecurityModel</b> | Specifies the security model to use with this group membership.                                                                       |
| <b>SecurityName</b>  | Specifies the security name assigned to this entry in the View-based Access Control Model (VACM) table. The range is 1-32 characters. |
| <b>GroupName</b>     | Specifies the name assigned to this group in the VACM table. The range is 1-32 characters.                                            |

## Create Access for a Group

### About This Task

Create access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Access Right** tab.
4. Click **Insert**.
5. In the **GroupName** box, type a VACM group name.
6. In the **ContextPrefix** box, select a VRF instance. This is an optional step.
7. From the **SecurityModel** options, select a model.
8. From the **SecurityLevel** options, select a security level.
9. In the **ContextMatch** option, select a value to match the context name. This value is **exact** by default.
10. (Optional) In the **ReadViewName** box, type the name of the MIB view that forms the basis of authorization when reading objects. This is an optional step.
11. (Optional) In the **WriteViewName** box, type the name of the MIB view that forms the basis of authorization when writing objects. This is an optional step.
12. (Optional) In the **NotifyViewName** box, type MIB view that forms the basis of authorization for notifications. This is an optional step.
13. Click **Insert**.

### **Group Access Right** field descriptions

Use the data in the following table to use the **Group Access Right** tab.

| Name                 | Description                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupName</b>     | Specifies the name of the new group in the VACM table. The range is 1–32 characters.                                                                                                                                    |
| <b>ContextPrefix</b> | Specifies if the contextName must match the value of the instance of this object exactly or partially. The range is an SnmpAdminString, 1–32 characters.                                                                |
| <b>SecurityModel</b> | Specifies the authentication checking to communicate to the switch. The security models are: <ul style="list-style-type: none"> <li>• SNMPv1</li> <li>• SNMPv2</li> <li>• USM</li> </ul>                                |
| <b>SecurityLevel</b> | Specifies the minimum level of security required to gain the access rights allowed. The security levels are: <ul style="list-style-type: none"> <li>• noAuthNoPriv</li> <li>• authNoPriv</li> <li>• authpriv</li> </ul> |

| Name                  | Description                                                                                                                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ContextMatch</b>   | Specifies if the prefix and the context name must match. If the value is exact, all rows where the contextName exactly matches vacmAccessContextPrefix are selected. If you do not select exact, all rows where the contextName with starting octets that exactly match vacmAccessContextPrefix are selected. |
| <b>ReadViewName</b>   | Identifies the MIB view of the SNMP context to which this conceptual row authorizes read access. The default is the empty string.                                                                                                                                                                             |
| <b>WriteViewName</b>  | Identifies the MIB view of the SNMP context to which this conceptual row authorizes write access. The default is the empty string.                                                                                                                                                                            |
| <b>NotifyViewName</b> | Identifies the MIB view of the SNMP context to which this conceptual row authorizes access for notifications. The default is the empty string.                                                                                                                                                                |

## Create Access Policies for SNMP Groups

### About This Task

Create an access policy to determine the access level for the users who connect to the switch with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), Telnet, and rlogin.

#### Note

Rlogin is only supported on VSP 8600 Series.

You only need to create access policies for SNMP groups if you have the access policy feature enabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies-SNMP Groups** tab.
4. Select **Insert**.
5. Enter an **ID**.
6. In the **Name** box, type a name.
7. From the **Model** options, select a security model.
8. Select **Insert**.

### **Access Policies – SNMP Groups** field descriptions

The following table defines parameters for the **Access Polices-SNMP Groups** tab.

| Name         | Description                                                                    |
|--------------|--------------------------------------------------------------------------------|
| <b>Id</b>    | Specifies the ID of the group policy.                                          |
| <b>Name</b>  | Specifies the name assigned to the group policy. The range is 1–32 characters. |
| <b>Model</b> | Specifies the security model {SNMPv1 SNMPv2c USM}.                             |

## Assign MIB View Access for an Object

### About This Task

Create a new entry in the MIB View table.

You cannot modify SNMP settings with the default Layer 2 MIB view. However, you can modify SNMP settings with a new MIB view created with Layer 2 permissions.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **MIB View** tab.
4. Click **Insert**.
5. In the **ViewName** box, type a view name.
6. In the **Subtree** box, type a subtree.
7. In the **Mask** box, type a mask.
8. From the **Type** options, select whether access to the MIB object is granted.
9. Click **Insert**.

### *MIB View field descriptions*

Use the data in the following table to use the **MIB View** tab.

| Name                   | Description                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>ViewName</b>        | Creates a new entry with this group name. The range is 1-32 characters.                                                           |
| <b>Subtree</b>         | Specifies a valid object identifier that defines the set of MIB objects accessible by this SNMP entity, for example, 1.3.6.1.1.5. |
| <b>Mask</b> (optional) | Specifies a bit mask with vacmViewTreeFamilySubtree to determine whether an OID falls under a view subtree.                       |
| <b>Type</b>            | Determines whether access to a MIB object is granted (included) or denied (excluded). The default is included.                    |

## Create a Community

### About This Task

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings for access to the switch using an SNMP-based management software.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Community Table**.
3. Click **Insert**.
4. In the **Index** box, type an index.

5. In the **Name** box, type a name that is a community string.
6. In the **SecurityName** box, type a security name.
7. In the **ContextName** box, type the context name.
8. Click **Insert**.

### **Community Table** field descriptions

Use the data in the following table to use the **Community Table** tab.

| Name                   | Description                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>           | Specifies the unique index value of a row in this table. The range is 1–32 characters.                                                       |
| <b>Name</b>            | Specifies the community string for which a row in this table represents a configuration.                                                     |
| <b>SecurityName</b>    | Specifies the security name in the VACM group member table to which the community string is mapped. The range is 1–32 characters.            |
| <b>ContextEngineID</b> | Indicates the location of the context in which management information is accessed when using the community string specified in <b>Name</b> . |
| <b>ContextName</b>     | Specifies the context in which management information is accessed when you use the specified community string.                               |

## View All Contexts for an SNMP Entity

### About This Task

View contexts to see the contents of the context table in the View-based Access Control Model (VACM). This table provides information to SNMP command generator applications so that they can properly configure the VACM access table to control access to all contexts at the SNMP entity.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **Contexts** tab.

### **Contexts** field descriptions

Use the data in the following table to use the **Contexts** tab.

| Variable           | Value                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ContextName</b> | Shows the name identifying a particular context at a particular SNMP entity. The empty contextName (zero length) represents the default context. |

## Showing SNMP Statistics

### About This Task

Display SNMP statistics to monitor the number of specific error messages, such as the number of messages that were delivered to SNMP but were not allowed.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **General**.
3. Click the **SNMP** tab.

### **SNMP** Field Descriptions

Use the data in the following table to display SNMP statistics.

| Name                       | Description                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OutTooBig</b>           | Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is tooBig.                                 |
| <b>OutNoSuchNames</b>      | Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status is noSuchName.                                   |
| <b>OutBadValues</b>        | Shows the number of SNMP PDUs that SNMP protocol entity generated and for which the value of the error-status field is badValue.                                   |
| <b>OutGenErrors</b>        | Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is genErr.                                 |
| <b>InBadVersions</b>       | Shows the number of SNMP messages that were delivered to the SNMP protocol entity and were for an unsupported SNMP version.                                        |
| <b>InBadCommunityNames</b> | Shows the number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to the entity.                                  |
| <b>InBadCommunityUsers</b> | Shows the number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message. |
| <b>InASNParseErrs</b>      | Shows the number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP messages.                                              |
| <b>InTooBig</b>            | Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.                         |
| <b>InNoSuchNames</b>       | Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.                     |
| <b>InBadValues</b>         | Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is badValue.                       |

| Name               | Description                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InReadOnlys</b> | Shows the number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "read-only". It is a protocol error to generate an SNMP PDU that contains the value "read-only" in the error-status field; this object is provided as a means of detecting incorrect implementations of the SNMP. |
| <b>InGenErrors</b> | Shows the number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "genErr."                                                                                                                                                                                                               |

## Spanning Tree Fundamentals

**Table 230: Spanning Tree Protocol product support**

| Feature                                                                                                                        | Product         | Release introduced |
|--------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|
| Spanning Tree Protocol (STP): <ul style="list-style-type: none"><li>• Multiple STP (MSTP)</li><li>• Rapid STP (RSTP)</li></ul> | 5420 Series     | VOSS 8.4           |
|                                                                                                                                | 5520 Series     | VOSS 8.2.5         |
|                                                                                                                                | VSP 4450 Series | VSP 4000 4.0       |
|                                                                                                                                | VSP 4900 Series | VOSS 8.1           |
|                                                                                                                                | VSP 7200 Series | VOSS 4.2.1         |
|                                                                                                                                | VSP 7400 Series | VOSS 8.0           |
|                                                                                                                                | VSP 8200 Series | VSP 8200 4.0       |
|                                                                                                                                | VSP 8400 Series | VOSS 4.2           |
|                                                                                                                                | VSP 8600 Series | VSP 8600 4.5       |
|                                                                                                                                | XA1400 Series   | VOSS 8.0.50        |

The switch supports Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

## Spanning Tree

Spanning Tree protocols detect and eliminate logical loops in a bridged or switched network. If multiple paths exist, the spanning Tree algorithm configures the network so that a bridge or device uses the root bridge path based on hop counts. Although link speed is taken into account, the path is based on the root bridge rather than on an optimized path. If that path fails, the protocol automatically reconfigures the network and makes another path active, thereby sustaining network operations. The switch

supports RSTP and MSTP but can downgrade a port automatically if it receives an STP Bridge Protocol Data Unit (BPDU) from a switch that runs STP.

**Note**

Spanning Tree is disabled on all Switched UNI (S-UNI) ports. The ports will move into forwarding state as soon as the physical port or VLACP or LACP comes up on the port. If the platform VLAN is associated to the S-UNI Service Instance Identifier (I-SID), then the S-UNI ports added to the platform VLAN will become the member of MSTP instances associated with the platform VLAN. To enable SLPP on the S-UNI ports, the platform VLAN must be associated with the S-UNI I-SID.

## Spanning Tree Groups

Spanning Tree Groups (STGs) represent logical topologies. A topology is created based on bridge configuration values such as root bridge priority. In the case of multiple STGs, you can map a VLAN to the most appropriate logical topology in the physical network.

The switch supports Spanning Tree modes RSTP and MSTP. The default Spanning Tree mode is MSTP. The default STG is 0. In RSTP mode, all VLANs run in the default STG. In MSTP mode, you can create additional STGs by using the VLAN create command. The switch supports up to 64 STGs.

Although STP and MSTP are variations of the same Spanning Tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the Spanning Tree groups running on a chassis configured with STP. MSTP Spanning Tree groups are not the same as STP Spanning Tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.

The root bridge for Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP) is determined by comparing attributes of each bridge in the network.

The protocol considers bridge priority first. If more than one bridge has the same priority, then the protocol must consider the bridge ID. The bridge with the lowest ID becomes the root bridge. For MSTP, this bridge is called the Common and Internal Spanning Tree (CIST) Root because it is the root of the entire physical network.

In MSTP mode, you can create additional Spanning Tree instances, by using the VLAN command. These instances, known as Multiple Spanning Tree Instances (MSTIs), can assign different priorities to switches. The MSTIs have different link costs or port priorities and as a result create separate logical topologies.

MSTP also allows the creation of MSTP regions. A region is a collection of switches sharing the same view of physical and logical topologies. For switches to belong to the same region, the following attributes must match:

- MSTP configuration ID selector
- MSTP configuration name
- MSTP configuration revision number
- VLAN instance mapping

Links connecting sections are called boundary ports. In a region, the boundary switch that contains the boundary port providing the shortest external path cost to the CIST Root is the CIST Regional Root.

## STGs and VLANs

When you map VLANs to STGs, be aware that all links on the bridge belong to all STGs. Because each Spanning Tree group can differ in its decision to make a link forwarding or blocking, you must ensure that the ports you add to a VLAN are in the expected state.

Untagged ports can only belong to one VLAN and therefore can only belong to one STG. Tagged ports can belong to multiple VLANs and therefore to multiple STGs.

## BPDUs handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

### Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

## BPDUs Guard

**Table 231: Bridge Protocol Data Unit (BPDU) Guard product support**

| Feature                                | Product         | Release introduced |
|----------------------------------------|-----------------|--------------------|
| Bridge Protocol Data Unit (BPDU) Guard | 5420 Series     | VOSS 8.4           |
|                                        | 5520 Series     | VOSS 8.2.5         |
|                                        | VSP 4450 Series | VOSS 6.0           |
|                                        | VSP 4900 Series | VOSS 8.1           |
|                                        | VSP 7200 Series | VOSS 6.0           |
|                                        | VSP 7400 Series | VOSS 8.0           |
|                                        | VSP 8200 Series | VOSS 6.0           |
|                                        | VSP 8400 Series | VOSS 6.0           |
|                                        | VSP 8600 Series | VSP 8600 6.2       |
|                                        | XA1400 Series   | Not Supported      |

The switch supports Bridge Protocol Data Unit (BPDU) Guard for STGs, RSTP, and MSTP.

### Overview

Spanning Tree eliminates loops in a network. A bridge that participates in spanning tree uses BPDUs to exchange information with other bridges. The bridges select a single bridge as the root bridge based on the BPDU information exchange. The bridge with the lowest priority becomes the root bridge. If all bridges share the same priority, the bridge with the lowest bridge ID becomes the root bridge. This process is the root selection process.

After you add a new bridge to the network, or remove an existing bridge, the bridges repeat the root selection process, and then select a new root bridge.

To ensure the correct operation of Spanning Tree in the network, BPDU Guard protects the stability of the Root Bridge by dropping stray, unexpected, or unwanted BPDU packets entering a port, and immediately shutting down those ports for a specified time period. BPDU Guard is normally enabled on access ports connecting to end user devices such as servers that are not expected to operate Spanning Tree.

Use BPDU Guard to achieve the following results:

- Block the root selection process after an edge device, such as a laptop that uses Linux with STP enabled, is added to the network. Blocking the root selection process prevents unknown devices from influencing the spanning tree topology.
- Block BPDU flooding of the switch from an unknown device.

### Operation

You can enable or disable BPDU Guard on an individual port basis, regardless of the spanning tree state. Each port uses a timer to determine port-state recovery.

After you enable BPDU Guard on a port and the port receives a BPDU, the following actions occur:

1. The guard disables the port.
2. The switch generates an SNMP trap and alarm, and the following log message:

```
BPDU Guard - Port <slot/port> is being shutdown by BPDU Guard, timeout
<time_seconds>
```

3. The port timer begins.
4. The port remains in the disabled state until the timer expires.

If you disable BPDU Guard before the timer expires, the timer stops and the port remains in the disabled state. You must manually enable the port.

BPDU Guard is enabled at the interface level. You can configure the BPDU Guard timer for each port, for 10 to 65535 seconds. If you set the port timer to zero, it will not expire.

## Rapid Spanning Tree Protocol and Multiple Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP or IEEE 802.1w) reduces the recovery time after a network breakdown. It also maintains backward compatibility with IEEE 802.1d (the spanning tree implementation prior to RSTP). In certain configurations, the recovery time of RSTP can be reduced to less than 1 second. RSTP also reduces the amount of flooding in the network by enhancing the way Topology Change Notification (TCN) packets are generated.

With Multiple Spanning Tree Protocol (MSTP or IEEE 802.1s), you can configure multiple instances or Spanning Tree groups on the same device. Each instance or Spanning Tree group can include one or more VLANs.

By using RSTP and MSTP, the switch achieves the following:

- reduces convergence time after a topology change (from 30 seconds to less than 1 or 2 seconds)
- eliminates unnecessary flushing of the MAC database and the flooding of traffic to the network
- creates backward compatibility with classic 802.1d switches
- creates support for 64 instances of spanning tree in MSTP mode

The following sections relate to RSTP and MSTP:

- [RSTP interoperability with STP](#) on page 3092
- [Differences in port roles for STP and RSTP](#) on page 3092
- [Port roles: root forwarding role](#) on page 3093
- [Port roles: designated forwarding role](#) on page 3093
- [Port roles: alternate blocking role](#) on page 3093
- [Edge port](#) on page 3094
- [Path cost values](#) on page 3094
- [RSTP negotiation process](#) on page 3094

#### *RSTP interoperability with STP*

RSTP provides a parameter called ForceVersion to provide backward compatibility with standard STP. A user can configure a port in either STP-compatible mode or RSTP mode:

- An STP-compatible port transmits and receives only STP Bridge Protocol Data Units (BPDUs). An RSTP BPDU that the port receives in this mode is discarded.
- An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.

#### **Note**

You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Before implement MSTP or RSTP you must be aware of the following:

- The default mode is MSTP. A special boot configuration flag identifies the mode.
- You can lose your configuration if you change the spanning tree mode from MSTP to RSTP and the configuration file contains VLANs configured with MSTI greater than 0. RSTP only supports VLANs configured with the default instance 0.
- For best interoperability results, contact your vendor representative.

#### *Differences in port roles for STP and RSTP*

RSTP is an enhanced version of STP. These two protocols have almost the same parameters.

The following table lists the differences in port roles for STP and RSTP. STP supports two port roles, while RSTP supports four port roles.

**Table 232: Differences in port roles for STP and RSTP**

| Port Role  | STP | RSTP | Description                                                                                                                                                                                                                       |
|------------|-----|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Root       | Yes | Yes  | This port receives a better BPDU than its own and has the best path to reach the Root. The root port is in Forwarding state. The root port and designated ports can be in the Discarding state before they go to root forwarding. |
| Designated | Yes | Yes  | This port has the best BPDU on the segment. The designated port is in the Forwarding state.                                                                                                                                       |
| Alternate  | No  | Yes  | This port receives a better BPDU than its own BPDU, and a root port exists within the same device. The alternate port is in the Discarding state.                                                                                 |
| Backup     | No  | Yes  | This port receives a better BPDU than its own BPDU, and this BPDU is from another port within the same device. The backup port is in the Discarding state.                                                                        |

*Port roles: root forwarding role*

MSTP and RSTP root forwarding roles are as follows:

- The port that receives the best path BPDU on a device is the root port, and is referred to as a Root Forwarding (RF) port. This is the port that is the closest to the root bridge in terms of path cost.
- The spanning tree algorithm elects a single root bridge in a bridged network. With MSTP, a root bridge is selected for the Common and Internal Spanning Tree (CIST). A root bridge is selected for the region, and a root bridge is selected for each spanning tree instance.
- The root bridge is the only bridge in a network that does not have root ports; all ports on a root bridge are Designated Forwarding (DF).
- Only one path towards a root bridge can exist on a given segment; otherwise, loops can occur.

*Port roles: designated forwarding role*

MSTP and RSTP designated forwarding roles are as follows:

- All bridges connected on a segment monitor the BPDUs of all other bridges. The bridge that sends the best BPDU is the root bridge for the segment.
- The corresponding port on the bridge is referred to as a Designated Forwarding Port.

*Port roles: alternate blocking role*

MSTP and RSTP alternate blocking roles are as follows:

- A blocked port is defined as not being the designated or root port. An alternate port provides an alternate path to the root and can replace the root port if it fails.

- An alternate blocked port is a port that is blocked because it received better path cost BPDUs from another bridge.

*Port roles: backup blocking role*

MSTP and RSTP backup blocking roles are as follows:

- A backup port receives the more useful BPDUs from the bridge on which the port exists.

*Edge port*

RSTP uses a parameter called the edge port. After a port connects to a nonswitch device, such as a PC or a workstation, it must be configured as an edge port. An active edge port enters the forwarding state without delay. An edge port becomes a nonedge port if it receives a BPDU.

*Path cost values*

RSTP and MSTP path cost values support a wide range of link speeds. The following table lists the path cost values.

**Table 233: Path cost values**

| Link speed                     | Value       |
|--------------------------------|-------------|
| Less than or equal to 100 Kbps | 200 000 000 |
| 1 Mbps                         | 20 000 000  |
| 10 Mbps                        | 2 000 000   |
| 100 Mbps                       | 200 000     |
| 1 Gbps                         | 20 000      |
| 10 Gbps                        | 2000        |
| 100 Gbps                       | 200         |
| 1 Tbps                         | 20          |
| 10 Tbps                        | 2           |

*RSTP negotiation process*

The following section describes the negotiation process between switches that takes place before PCs can exchange data (see the following figure).

**Figure 234: RSTP negotiation process**

After turning on, all ports assume the role of designated ports. All ports are in the discarding state except edge ports. Edge ports go directly into the forwarding state without delay.

Unit A port 1 and Unit B port 1 exchange BPDUs. Unit A knows that it is the root and that Unit A port 1 is the designated port. Unit B learns that Unit A has higher priority. Unit B port 1 becomes the root port. Both Unit A port 1 and Unit B port 1 are still in the discarding state.

Unit A starts the negotiation process by sending a BPDU with the proposal bit set.

Unit B receives the proposal BPDU and configures its nonedge ports to discarding state. This operation occurs during the synchronization process.

Unit B sends a BPDU to Unit A with the agreement bit set.

Unit A configures port 1 to the forwarding state, and Unit B configures port 1 to the forwarding state. PC 1 and PC 2 can now communicate. The negotiation process now moves on to Unit B port 3 and its partner port. PC 3 cannot exchange data with either PC 1 or PC 2 until the negotiation process between Unit B and Unit C finishes.

The RSTP convergence time depends on how quickly the switches can exchange BPDUs during the negotiation process, and on the number of switches in the network.

## Spanning Tree Configuration Using CLI

### Important

The switch supports up to 64 STGs on a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

## Configuring Spanning Tree

Configure the STP mode to configure the spanning tree mode on the device.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the STP mode:  

```
boot config flags spanning-tree-mode {rstp|mstp}
```

### Example

Configure the STP mode:

```
Switch:1(config)#boot config flags spanning-tree-mode mstp
```

```
Warning: Please save the configuration and reboot the switch
```

```
for this to take effect.
```

```
Warning: Please carefully save your configuration files before
```

```
starting configuring the switch in RSTP or MSTP mode.
```

### Variable Definitions

Use the data in the following table to use the **boot config flags spanning-tree-mode** command.

| Variable         | Value                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------|
| <i>rstp mstp</i> | Specifies the Spanning Tree modes: Rapid Spanning Tree Protocol (RSTP) or Multiple Spanning Tree Protocol (MSTP). |

## Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[, ...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BPDU Guard for the port:

```
spanning-tree bpduguard enable
```

3. (Optional) Configure the timer for port-state recovery:

```
spanning-tree bpduguard timeout <0, 10-65535>
```

4. (Optional) Enable BPDU Guard on an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]} enable
```

5. (Optional) Configure the timer for port-state recovery for an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]} timeout <0-65535>
```

6. Verify the configuration:

```
show spanning-tree bpduguard [GigabitEthernet {slot/port[/sub-port] [-slot/port[/subport]] [, ...]}] [{slot/port[/sub-port] [-slot/port[/subport]] [, ...]}]
```

### Example

Enable BPDU Guard on port 1/8, and specify a timer value of 200 seconds. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#spanning-tree bpduguard enable
Switch:1(config-if)#spanning-tree bpduguard timeout 200
Switch:1(config-if)#show spanning-tree bpduguard 1/8
```

```
=====
 Bpdu Guard
=====
```

| Port | PORT  | PORT        | TIMER   | BPDU  | BPDU        |        |
|------|-------|-------------|---------|-------|-------------|--------|
| NUM  | MLTID | ADMIN_STATE | TIMEOUT | COUNT | ADMIN_STATE | ORIGIN |
| 1/8  | Up    | Up          | 200     | 0     | Enabled     | CONFIG |

### Variable Definitions

Use the data in the following table to use the **spanning-tree bpduguard** commands.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                                     | Enables BPDU Guard on the port. The default is disabled.                                                                                                                                                                                                                                                                                                      |
| <i>port {slot/port[/sub-port] [-slot/port[/subport]] [, ...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>timeout &lt;0, 10-65535&gt;</i>                                | Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value from 10 to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.                                                                     |

Use the data in the following table to use the **show spanning-tree bpduguard** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring Rapid Spanning Tree Protocol

Configure Rapid Spanning Tree Protocol (RSTP) to reduce the recovery time after a network breakdown.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure RSTP:

```
spanning-tree rstp [forward-time <400-3000>] [group-stp enable]
[hello-time <100-1000>] [max-age <600-4000>] [pathcost-type <bits16|
bits32>] [priority <0-61440>] [tx-holdcount <1-10>] [version <rstp|
stp-compatible>]
```

### Example

Configure RSTP:

```
Switch:1(config)# spanning-tree rstp forward-time 1000 hello-time 200
max-age 4000 pathcost-type bits16 priority 4096 tx-holdcount 10 version
rstp group-stp enable
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

| Variable                             | Value                                                                                                                                                               |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>forward-time &lt;400-3000&gt;</i> | Configures the RSTP forward delay for the bridge in hundredths of a second.                                                                                         |
| <i>group-stp enable</i>              | Enables or disables RSTP for a specific STG. Enter the <b>no</b> form of the command to disable RSTP for the STG ( <b>no spanning-tree rstp group-stp enable</b> ). |
| <i>hello-time &lt;100-1000&gt;</i>   | Assigns the RSTP hello time delay for the bridge in hundredths of a second.                                                                                         |
| <i>max-age &lt;600-4000&gt;</i>      | Assigns the RSTP maximum age time for the bridge in hundredths of a second.                                                                                         |

| Variable                                   | Value                                                                      |
|--------------------------------------------|----------------------------------------------------------------------------|
| <code>pathcost-type {bits16 bits32}</code> | Assigns the RSTP default pathcost version. The default is 32 bits.         |
| <code>priority &lt;0-61440&gt;</code>      | Assigns the RSTP bridge priority.                                          |
| <code>tx-holdcount &lt;1-10&gt;</code>     | Assigns the RSTP transmit hold count from 1 to 10. The default value is 6. |
| <code>version {rstp/stp-compatible}</code> | Sets the version to RSTP or STP compatible.                                |

## Configuring Rapid Spanning Tree Protocol for a port

Configure RSTP to reduce the recovery time after a network breakdown.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure RSTP:

```
spanning-tree rstp cost <1-200000000> edge-port <false|true> p2p
<auto|force-false|force-true> priority <0-240> protocol-migration
<false|true> stp enable
```

### Example

Configure RSTP:

```
Switch:1(config-if)# spanning-tree rstp cost 100 edge-port true p2p auto
priority 32 protocol-migration true stp enable
```

*Variable Definitions*

Use the data in the following table to use the **spanning-tree rstp** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cost &lt;1-200000000&gt;</code>                | Specifies the contribution of this port to the path cost.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>edge-port &lt;false true&gt;</code>            | Configures the edge-port value for the port. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>p2p &lt;auto force-false force-true&gt;</code> | Specifies the point-to-point status of the LAN segment attached to this port. A value of force-true indicates that this port is treated as if it connects to a point-to-point link. A value of force-false indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means. |
| <code>priority &lt;0-240&gt;</code>                  | Assigns the RSTP bridge priority in a range of 0-240. The value has to increment in steps of 16.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>protocol-migration &lt;false true&gt;</code>   | If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.                                                                                                                                                            |
| <code>stp enable</code>                              | Configures STP for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configuring the Rapid Spanning Tree Protocol version

Perform this procedure to specify the RSTP mode.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure Rapid Spanning Tree Protocol version:
 

```
spanning-tree rstp version {rstp|stp-compatible}
```

### Example

Configure Rapid Spanning Tree Protocol version:

```
Switch:1(config)# spanning-tree rstp version rstp
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree rstp version** command.

| Variable                                  | Value                                                               |
|-------------------------------------------|---------------------------------------------------------------------|
| <i>rstp version {rstp stp-compatible}</i> | Sets the version to RSTP or to STP compatible. The default is RSTP. |

## Viewing the global RSTP configuration information

View the global RSTP configuration information to display the Rapid Spanning Tree Protocol (RSTP) configuration details.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View global RSTP configuration information:

```
show spanning-tree rstp config
```

### Example

View global RSTP configuration information:

```
Switch:1> show spanning-tree rstp config
```

```

=====
 RSTP Configuration
=====
Rstp Module Status : Enabled
Priority : 32768 (0x8000)
Stp Version : rstp Mode
Bridge Max Age : 20 seconds
Bridge Hello Time : 2 seconds
Bridge Forward Delay Time : 15 seconds
Tx Hold Count : 6
PathCost Default Type : 32-bit
=====

```

## Viewing RSTP statistics

Perform this procedure to view RSTP statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RSTP statistics:

```
show spanning-tree rstp statistics
```

### Example

View RSTP statistics:

```
Switch:1> show spanning-tree rstp statistics
```

```

=====
 RSTP Statistics
=====
Rstp UP Count : 1
Rstp Down Count : 0
Count of Root Bridge Changes : 0
Stp Time since Topology change: 0 day(s), 00H:00M:00S
Total No. of topology changes : 0

```

## Viewing the RSTP status

View the RSTP status to display the RSTP related status information for the selected bridge.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status:  

```
show spanning-tree rstp status
```

### Example

View the RSTP status:

```
Switch:1> show spanning-tree rstp status
```

```

=====
 RSTP Status Information
=====
Designated Root : 80:00:00:24:7f:9f:60:00
Stp Root Cost : 0
Stp Root Port : cpp
Stp Max Age : 20 seconds
Stp Hello Time : 2 seconds
Stp Forward Delay Time : 15 seconds

```

## Viewing the RSTP Configuration Information

View the RSTP configuration information to display the RSTP-related port level configuration details.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RSTP configuration information:  

```
show spanning-tree rstp port config {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]
```

### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

View RSTP configuration information:

```
Switch:1>show spanning-tree rstp port config 1/1
```

```

=====
 RSTP Port Configurations
=====
Port Number : 1/1
Port Priority : 128 (0x80)
Port PathCost : 200000000
Port Protocol Migration : False
Port Admin Edge Status : False
Port Oper Edge Status : False
Port Admin P2P Status : Auto
Port Oper P2P Status : False
Port Oper Protocol Version : Rstp
=====

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port config** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing the RSTP Status for a Port

View the RSTP status for a port to display the RSTP-related status information for a selected port.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status for a port:

```
show spanning-tree rstp port status {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

#### Note

If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

View the RSTP status for a port:

```
Switch:1>show spanning-tree rstp port status 1/2
```

```

=====
 RSTP Port Status
 (Port Priority Vector)
=====
Port Number : 1/2
Port Designated Root : 80:00:00:24:7f:9f:60:00
=====

```

```

Port Designated Cost : 0
Port Designated Bridge : 80:00:00:24:7f:9f:60:00
Port Designated Port : 80:c1

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port status** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing RSTP information for a selected port

View the RSTP information for a selected port to display the RSTP-related configuration information for the selected port.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View the RSTP information for a selected port:
 

```
show spanning-tree rstp port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

### Example

View the RSTP information for a selected port:

```
Switch:1# show spanning-tree rstp port statistics 1/4
```

```

=====
 RSTP Port Statistics

```

*Variable definitions*

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port statistics` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

**Viewing the RSTP role**

View the RSTP role to display the RSTP information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP role:

```
show spanning-tree rstp port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

**Example**

View the RSTP role:

```
Switch:1> show spanning-tree rstp port role 1/3
```

```

=====

*Variable definitions*

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port role` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Viewing spanning tree configuration

Perform this procedure to view configuration and status information for spanning tree in your network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View spanning tree configuration information:  

```
show spanning-tree config
```
3. View spanning tree status information:  

```
show spanning-tree status
```

### Example

View spanning tree configuration information:

```
Switch:1> show spanning-tree config
```

```

## Configuring Multiple Spanning Tree Protocol

Use the following procedure to configure the Multiple Spanning Tree Protocol.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure MSTP:  

```
spanning-tree mstp
```

## Example

Configure Multiple Spanning Tree Protocol to configure the MSTP configuration version.

```
Switch:1(config)# spanning-tree mstp forward-time 500 max-age 3000 max-
hop 200 pathcost-type bits32 priority 8192 tx-holdcount 10 version mstp
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

| Variable                                                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>forward-time</i> <400-3000>                                                                                           | Configures the MSTP forward delay for the bridge from 400 to 3000 hundredths of a second.                                                                                                                                                                                                                                                                                                           |
| <i>max-age</i> <600-4000>                                                                                                | Assigns the MSTP maximum age time for the bridge from 600 to 4000 one hundredths of a second.                                                                                                                                                                                                                                                                                                       |
| <i>max-hop</i> <100-4000>                                                                                                | Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.                            |
| <i>msti</i> <1-63> <i>priority</i> <0-65535>                                                                             | Assigns the MSTP MSTI instance parameter.                                                                                                                                                                                                                                                                                                                                                           |
| <i>pathcost-type</i> { <i>bits16</i>   <i>bits32</i> }                                                                   | Assigns the MSTP default pathcost type to either 16 bits or 32 bits. The default is 32 bits.                                                                                                                                                                                                                                                                                                        |
| <i>priority</i> <0-61440>                                                                                                | Assigns the MSTP bridge priority in a range of 0 to 61440 in steps of 4096.                                                                                                                                                                                                                                                                                                                         |
| <i>region</i> [ <i>config-id-sel</i> <0-255>]<br>[ <i>region-name</i> <WORD 1-32>]<br>[ <i>region-version</i> <0-65535>] | Assigns the MSTP region commands: <ul style="list-style-type: none"> <li>• <i>config-id-sel</i>—Assigns the MSTP region configuration ID number. The range is 0 to 255.</li> <li>• <i>region-name</i>—Assigns the MSTP region name. The character string can be a range of 1 to 32 characters</li> <li>• <i>region-version</i>—Assigns the MSTP region version. The range is 0 to 65535.</li> </ul> |

| Variable                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tx-holdcount &lt;1-10&gt;</code>          | Assigns the MSTP transmit hold count. The range is 1 to 10. The default value is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>version {mstp rstp stp-compatible}</code> | Assigns the bridge version. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode. |

## Configuring MSTP MSTI options

Use the following procedure to configure MSTP multiple spanning tree instance (MSTI) options.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure MSTP MSTI:

```
spanning-tree mstp msti <1-63> priority <0-65535>
```

### Example

Configure MSTP MSTI:

```
Switch:1(config)# spanning-tree mstp msti 62 priority 4096
```

*Variable Definitions*

Use the data in the following table to use the **spanning-tree mstp msti <1-63> priority <0-65535>** command.

| Variable  | Value                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-63>    | Specifies the instance ID.                                                                                                                                                                                                                                                                                                                                              |
| <0-65535> | Specifies the priority value. Enter values in increments of 4096: <ul style="list-style-type: none"> <li>• 4096</li> <li>• 8192</li> <li>• 12288</li> <li>• 16384</li> <li>• 20480</li> <li>• 24576</li> <li>• 28672</li> <li>• 32768</li> <li>• 36864</li> <li>• 40960</li> <li>• 45056</li> <li>• 49152</li> <li>• 53248</li> <li>• 57344</li> <li>• 61440</li> </ul> |

## Configuring Ethernet MSTP

Configure Ethernet MSTP on a port to enable this feature.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP:

```
spanning-tree mstp [cost <1-200000000>] [edge-port <false|true>]
[force-port-state enable] [hello-time <100-1000>] [msti <1-63>] [p2p
{auto|force-false|force-true}] [port {slot/port[/sub-port]}] [priority
<0-240>] [protocol-migration <false|true>]
```

## Example

Configure Ethernet MSTP:

```
Switch:1(config)# spanning-tree mstp cost 1 edge-port true force-port-
state enable hello-time 100 p2p auto priority 2 protocol-migration true
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cost</i> <1-200000000>                | Configures the path cost for a port. Valid values are 1 to 200000000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>edge-port</i> <false true>            | Enables or disables the port as an edge port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>force-port-state enable</i>           | Enables STP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>hello-time</i> <100-1000>             | Configures the hello-time for a port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>msti</i> <1-63>                       | Configures the port MSTP MSTI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>p2p</i> {auto force-false force-true} | Enables or disables point-to-point for a port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| {slot/port[/sub-port]}                   | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>priority</i> <0-240>                  | Configures priority for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>protocol-migration</i> {false true}   | If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode. |

## Configuring Ethernet MSTP MSTI

Use the following procedure to configure the Ethernet MSTP MSTI parameters on a port.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP MSTI:

```
spanning-tree mstp msti <1-63> [cost <1-200000000>] [force-port-state
enable] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
[priority <0-240>]
```

**Example**

Configure Ethernet MSTP MSTI:

```
Switch(config-if)# spanning-tree mstp msti 62 priority 32
```

*Variable Definitions*

Use the data in the following table to use the **spanning-tree mstp msti <1-63>** command.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-63>                                                       | Specifies the instance ID.                                                                                                                                                                                                                                                                                                                                    |
| <i>cost &lt;1-200000000&gt;</i>                              | Configures the path cost for the port                                                                                                                                                                                                                                                                                                                         |
| <i>force-port-state enable</i>                               | Enables MSTI learning for the port.                                                                                                                                                                                                                                                                                                                           |
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>priority &lt;0-240&gt;</i>                                | Configures the priority for the port. Enter the priority value (0-240) as increments of 16.                                                                                                                                                                                                                                                                   |

**Viewing MSTP configurations**

View the MSTP configurations to display the MSTP-related bridge-level VLAN and region information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.

2. View the MSTP configurations:

```
show spanning-tree mstp config
```

### Example

View the MSTP configurations:

```
Switch:1> show spanning-tree mstp config
```

```

=====
 MSTP Configurations
=====
Mstp Module Status : Enabled
Number of Msti Supported : 64
Cist Bridge Priority : 32768 (0x8000)
Stp Version : Mstp Mode
Cist Bridge Max Age : 20 seconds
Cist Bridge Forward Delay : 15 seconds
Tx Hold Count : 3
PathCost Default Type : 32-bit
Max Hop Count : 2000
Msti Config Id Selector : 0
Msti Region Name : 00:15:e8:9e:10:01
Msti Region Version : 0

```

## Viewing MSTP status

View the MSTP status to display the MSTP-related status information known by the selected bridge.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the MSTP status:

```
show spanning-tree mstp status
```

### Example

View the MSTP status:

```
Switch:1> show spanning-tree mstp status
```

```

=====

Cist Max Age : 20 seconds
Cist Forward Delay : 15 seconds
=====

```

## Viewing MSTP Port Information

View the MSTP port information to display the MSTP, CIST port, and MSTI port information maintained by every port of the common spanning tree.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the MSTP port information:

```
show spanning-tree mstp port role [slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]]
```

#### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

View the MSTP port information:

```
Switch:1> show spanning-tree mstp port role 1/3
```

```

=====
 CIST Port Roles and States
=====
Port-Index Port-Role Port-State PortSTPStatus PortOperStatus

1/3 Disabled Discarding Enabled Disabled

```

## Viewing MSTP MSTI Information

View MSTP MSTI information to ensure the feature is configured correctly for your network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show MSTI information:

```
show spanning-tree mstp msti [config <1-63>] [port <config {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | role {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | statistics {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}]
```

#### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

Show MSTI information:

```
Switch:1>show spanning-tree mstp msti config 62
```

```
=====
 MSTP Instance Status
=====
Instance Id : 62

### Variable Definitions

Use the data in the following table to use the **show spanning-tree mstp msti** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>config</i> [ <i>&lt;1-63&gt;</i> ] | Shows the configuration for one or all MSTP instance IDs.                                                                                                                                                                                                                                                                          |
| <i>port</i>                           | Shows the configuration, role, or statistics information of a MSTP port. <ul style="list-style-type: none"> <li>config {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</li> <li>role {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</li> <li>statistics {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</li> </ul> |

## Viewing MSTP statistics

View MSTP MSTI information to ensure the feature is configured correctly for your network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show MSTP statistics:

```
show spanning-tree mstp statistics
```

### Example

Show MSTP statistics:

```
Switch:1>show spanning-tree mstp statistics
```

```

=====
 MSTP Bridge Statistics
=====
Mstp UP Count : 1
Mstp Down Count : 0
Region Config Change Count : 4
Time Since Topology Change : 0 seconds
Topology Change Count : 0
New Root Bridge Count : 1
=====

```

## Configuring tc-receive-alarm-threshold

### About This Task

You can establish a threshold rate for receiving TC/TCN packets by configuring values for count and interval. If the threshold rate is exceeded, you receive a warning message. Use the following procedure to configure values for **tc-receive-alarm-threshold count** and **tc-receive-alarm-threshold interval**.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure a value for count:
 

```
spanning-tree tc-receive-alarm-threshold count <1-1000>
```
3. Configure a value for interval:
 

```
spanning-tree tc-receive-alarm-threshold interval <1-15>
```

### Example

Configure count and interval values:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spanning-tree tc-receive-alarm-threshold count 3
Switch:1(config)#spanning-tree tc-receive-alarm-threshold interval 2

```

Display the alarm threshold configuration:

```

Switch:1#show spanning-tree tc-receive-alarm-threshold
=====
 Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval : 2 minutes
Count : 3

```

*Variable definitions*

Use the data in the following table to use the **tc-receive-alarm-threshold** command.

| Variable        | Value                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------|
| count <1-1000>  | Specifies the number of packets used to establish the threshold rate. The default is 2.          |
| interval <1-15> | Specifies the time interval (in minutes) used to establish the threshold rate. The default is 1. |

## Displaying the tc-receive-alarm-threshold configuration

### About This Task

You can configure a threshold rate for receiving TC/TCN packets. If the threshold is exceeded, you receive a warning message. Use the following procedure to display the tc-receive-alarm-threshold configuration.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the tc-receive-alarm-threshold configuration:
 

```
show spanning-tree tc-receive-alarm-threshold
```

### Example

```
Switch:1(config)#show spanning-tree tc-receive-alarm-threshold
```

```

=====
 Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval : 1 minutes
Count : 2

```

## Spanning Tree Configuration Using EDM

This section describes how to create, manage, and monitor spanning tree groups (STG). It also describes how to configure the Rapid Spanning Tree Protocol (RSTP) and the Multiple Spanning Tree Protocol (MSTP) using Enterprise Device Manager (EDM).

### Important

The switch supports up to 64 STGs in a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MTSI 62 cannot be used by other VLANs or MSTIs.

## Configuring the Spanning Tree mode

Configure the Spanning Tree mode to change the mode to MSTP or RSTP mode.

### Important

After you change the mode, restart the system for the changes to take effect.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **Globals**.
3. Select the required spanning tree mode.
4. Click **Apply**.

The system notifies you that the setting takes effect after you save the configuration and restart the server.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                         | Description                                                                    |
|------------------------------|--------------------------------------------------------------------------------|
| <b>SpanningTreeAdminMode</b> | Configures the spanning tree mode as either RSTP or MSTP. The default is MSTP. |
| <b>SpanningTreeOperMode</b>  | Specifies the current mode of the spanning tree.                               |

## Restarting the switch

Restart the switch so that changes to the bootconfig parameters (or other parameters) take effect. For example, you must restart the device to enable a change to the Spanning Tree mode.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Edit**.
2. Click **Chassis**.
3. In the System tab, locate the **ActionGroup1** box.
4. Select **saveRuntimeConfig**.
5. Click **Apply**.
6. In the **ActionGroup4** box, select **softReset**.
7. Click **Apply**.

## Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

### About This Task

To configure multiple ports simultaneously, select more than one port in the Device Physical View tab. The system displays **BPDU Guard** tab as a table-based tab.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **Interface** tab.

5. Select **BpduGuardAdminEnabled** to enable BPDU Guard for the port.
6. (Optional) Type a value in **BpduGuardTimeout** to configure the timer for port-state recovery
7. Click **Apply**.

### **Interface** Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                                                          | Description                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                                                  | Displays the index of the port, written in the slot/port[/sub-port] format.                                                                                                                                                                                                                                           |
| <b>Name</b>                                                   | Configures the name of the port.                                                                                                                                                                                                                                                                                      |
| <b>Descr</b>                                                  | Displays the description of the port. A textual string containing information about the interface.                                                                                                                                                                                                                    |
| <b>Type</b>                                                   | Displays the type of connector plugged in the port.                                                                                                                                                                                                                                                                   |
| <b>Mtu</b>                                                    | Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. |
| <b>PhysAddress</b>                                            | Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address (e.g., a serial line), this object should contain an octet string of zero length.                         |
| <b>VendorDescr</b>                                            | Displays the vendor of the connector plugged in the port.                                                                                                                                                                                                                                                             |
| <b>DisplayFormat</b>                                          | Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port                                                                                                                                                                  |
| <b>AdminStatus</b>                                            | Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                                                             |
| <b>OperStatus</b>                                             | Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.                                                                                                                                       |
| <b>LicenseControlStatus</b>                                   | Shows the port license status.                                                                                                                                                                                                                                                                                        |
| <b>Note:</b><br>Exception: only supported on VSP 7200 Series. |                                                                                                                                                                                                                                                                                                                       |
| <b>ShutdownReason</b>                                         | Indicates the reason for a port state change.                                                                                                                                                                                                                                                                         |
| <b>LastChange</b>                                             | Displays the timestamp of the last change.                                                                                                                                                                                                                                                                            |
| <b>LinkTrap</b>                                               | Enable or disable link trapping.                                                                                                                                                                                                                                                                                      |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoNegotiate</b>       | Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>AutoNegAd</b>           | Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select <b>default</b> , all capabilities supported by the hardware are advertised. |
| <b>AdminDuplex</b>         | Configures the administrative duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OperDuplex</b>          | Indicates the operational duplex setting for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>AdminSpeed</b>          | Configures the administrative speed for the port.<br><br><b>Important:</b><br>If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.                                                                                                                                                                                                                                                                                                                                                           |
| <b>OperSpeed</b>           | Indicates the operational speed for the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>QoSLevel</b>            | Selects the Quality of Service (QoS) level for this port. The default is level1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DiffServ</b>            | Enables the Differentiated Service feature for this port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Layer3Trust</b>         | Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Layer2Override8021p</b> | Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>MltId</b>               | Shows the MLT ID associated with this port. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Locked</b>              | Shows if the port is locked. | <b>BpduGuardTimeout</b>                    | Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires.<br>You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.                                                                                                                        |
| <b>BpduGuardAdminEnabled</b>               | Enables BPDU Guard on the port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                            |
| <b>ForwardErrorCorrection</b>              | Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> <li>• CL 91</li> <li>• CL 108</li> <li>• CL 74</li> <li>• disable</li> <li>• auto</li> </ul> The disable option disables this configuration on the port.                                                                                                                                 |
| <b>ForwardErrorCorrectionApplicability</b> | Displays whether FEC is applicable on the interface.                                                                                                                                                                                                                                                                                                                                                                |
| <b>OperAutoNegotiate</b>                   | Shows the operational state of Auto-Negotiation.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OperForwardErrorCorrection</b>          | Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.                                                                                                                                                             |
| <b>IsPortShared</b>                        | Indicates whether the port is combo or not. <ul style="list-style-type: none"> <li>• portShared—Combo port.</li> <li>• portNotShared—Not a combo port.</li> </ul>                                                                                                                                                                                                                                                   |
| <b>PortActiveComponent</b>                 | Specifies whether the copper port is active or fabric port is active if port is a combo port. <ul style="list-style-type: none"> <li>• fixed port—Copper port is active.</li> <li>• gbic port—Fabric port is active.</li> </ul>                                                                                                                                                                                     |
| <b>Action</b>                              | Performs one of the following actions on the port <ul style="list-style-type: none"> <li>• none - none of the following actions</li> <li>• flushMacFdb - flush the MAC forwarding table</li> <li>• flushArp - flush the ARP table</li> <li>• flushIp - flush the IP route table</li> <li>• flushAll - flush all tables</li> <li>• triggerRipUpdate — manually triggers a RIP update</li> </ul> The default is none. |
| <b>Result</b>                              | Displays the result of the selected action. The default is none.                                                                                                                                                                                                                                                                                                                                                    |

| Name                                                                                                                         | Description                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>AutoSense</b></p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series and XA1400 Series.</p>               | <p>Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.</p>                                                                                                                        |
| <p><b>AutoSenseKeepAutoConfig</b></p> <p><b>Note:</b><br/>Exception: not supported on VSP 8600 Series and XA1400 Series.</p> | <p>Retains the Auto-sense configuration if you disable Auto-sense on the port. ## Configuring RSTP global parameters

Perform this procedure to configure the RSTP global parameters.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Configure the parameters as required.
4. Click **Apply**.

**Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PathCostDefault</b>    | Specifies the version of the spanning tree default path costs that are used by this bridge. A value of 8021d1998 indicates the use of the 16-bit default path costs from IEEE Std. 802.1d-1998. A value of stp8021t2001 indicates the use of the 32-bit default path costs from IEEE Std. 802.1t. |
| <b>TxHoldCount</b>        | Specifies the value used by the port transmit state machine to limit the maximum transmission rate. The default is 3.                                                                                                                                                                             |
| <b>Version</b>            | Specifies the version of STP that the bridge currently runs. The value stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use.                                 |
| <b>EnableStp</b>          | Indicates whether the spanning tree protocol is active in this STG. The default is enabled.                                                                                                                                                                                                       |
| <b>Priority</b>           | Specifies the RSTP bridge priority.                                                                                                                                                                                                                                                               |
| <b>BridgeMaxAge</b>       | Specifies the value that all bridges use for MaxAge while this bridge acts as the root.                                                                                                                                                                                                           |
| <b>BridgeHelloTime</b>    | The value that all bridges use for HelloTime while this bridge acts as the root.                                                                                                                                                                                                                  |
| <b>BridgeForwardDelay</b> | Specifies the value that all bridges use for forward delay while this bridge acts as the root.                                                                                                                                                                                                    |
| <b>DesignatedRoot</b>     | Specifies the unique bridge identifier of the bridge recorded as the root in the configuration BPDUs transmitted by the designated bridge for the segment to which the port is attached.                                                                                                          |
| <b>RootCost</b>           | Specifies the cost of the path to the root from this bridge.                                                                                                                                                                                                                                      |
| <b>RootPort</b>           | Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.                                                                                                                                                                                      |
| <b>MaxAge</b>             | Specifies the maximum age of Spanning Tree Protocol information in hundredths of a second learned from the network on any port before the port is discarded.                                                                                                                                      |
| <b>HelloTime</b>          | Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on any port while it is the root of the spanning tree (or trying to become the root).                                                                                   |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ForwardDelay</b>             | Specifies a time value, measured in hundredths of a second, controls how fast a port changes its spanning state after moving towards the forwarding state. The value determines how long the port stays in each of the listening and learning states, which precede the forwarding state. This value is also used after a topology change is detected, and is underway, to age all dynamic entries in the forwarding database. |
| <b>RstpUpCount</b>              | Specifies the number of times the RSTP module is enabled. A trap is generated on the occurrence of this event.                                                                                                                                                                                                                                                                                                                 |
| <b>RstpDownCount</b>            | Specifies the number of times the RSTP module is disabled. A trap is generated on the occurrence of this event.                                                                                                                                                                                                                                                                                                                |
| <b>NewRootIdCount</b>           | Specifies the number of times this bridge detects a root identifier change. A trap is generated on the occurrence of this event.                                                                                                                                                                                                                                                                                               |
| <b>TimeSinceTopology Change</b> | Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.                                                                                                                                                                                                                                                                                       |
| <b>TopChanges</b>               | Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.                                                                                                                                                                                                                                                                                                       |

## Configuring RSTP ports

Configure RSTP to reduce the recovery time after a network breakdown.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Click the **RSTP Ports** tab.
4. Use the fields in the **RSTP Ports** tab to configure the RSTP ports.
5. Click **Apply**.

### **RSTP Ports** field descriptions

Use the data in the following table to use the **RSTP Ports** tab.

| Name            | Description                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------|
| <b>Port</b>     | Specifies a unique value, greater than zero, indicating the port number.                                    |
| <b>Priority</b> | Specifies the value of the priority field.                                                                  |
| <b>PathCost</b> | Specifies the contribution of this port to the path cost of paths towards the root that includes this port. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ProtocolMigration</b> | Specifies a port to transmit RSTP BPDUs if operating in RSTP mode. Any other operation on this object has no effect, and RSTP mode returns false if read.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>AdminEdgePort</b>     | Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OperEdgePort</b>      | Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgePort and is configured to false on reception of a BPDU.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AdminPointToPoint</b> | Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it is connected to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means. |
| <b>OperPointToPoint</b>  | Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminPointToPoint object.                                                                                                                                                                                                                                                                                        |
| <b>OperVersion</b>       | Indicates if the port is in MSTP mode, RSTP mode or STP-compatible mode. MSTP mode transmits MST BDUs, RSTP mode transmits RST BPDUs and STP-compatible transmits Config/TCN BPDUs.                                                                                                                                                                                                                                                                                                                                                                                            |

## Viewing RSTP port status

View the RSTP port status to ensure proper functioning of RSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. In the RSTP tab, click the **RSTP Status** tab.

**RSTP Status** field descriptions

Use the data in the following table to use the **RSTP Status** tab.

| Name                      | Description                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b>               | Specifies a unique value, greater than zero, indicating the port number.                                                                                                                                                                                                         |
| <b>State</b>              | Specifies the current state of the port as defined by application of the Spanning Tree Protocol. This state controls what action a port takes on reception of a frame.                                                                                                           |
| <b>Role</b>               | Indicates the current port role assumed by this port.                                                                                                                                                                                                                            |
| <b>OperVersion</b>        | Indicates whether the port is operationally in the RSTP- or STP-compatible mode; that is, whether the port transmits RSTP BPDUs or Config/TCN BPDUs.                                                                                                                             |
| <b>EffectivePortState</b> | Specifies the effective operational state of the port. This object is configured to true if the port is operationally up in the Interface Manager, and if Force Port State for this port and the specified port state is enabled. Otherwise, this object is configured to false. |

## Viewing RSTP Status Statistics

**About This Task**

You can view status statistics for Rapid Spanning Tree Protocol (RSTP).

**Procedure**

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **RSTP**.
3. In the **RSTP Status** tab, select a port, and then click **Graph**.

**RSTP Status** Field Descriptions

The following table describes the **RSTP Status** fields.

| Name                     | Description                                                     |
|--------------------------|-----------------------------------------------------------------|
| <b>RxRstBpduCount</b>    | Specifies the number of RSTP BPDUs this port received.          |
| <b>RxConfigBpduCount</b> | Specifies the number of configuration BPDUs this port received. |
| <b>RxTcnBpduCount</b>    | Specifies the number of TCN BPDUs this port received.           |
| <b>TxRstBpduCount</b>    | Specifies the number of RSTP BPDUs this port transmitted.       |
| <b>TxConfigBpduCount</b> | Specifies the number of Config BPDUs this port transmitted.     |
| <b>TxTcnBpduCount</b>    | Specifies the number of TCN BPDUs this port transmitted.        |

| Name                             | Description                                                                                                                                                                                         |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InvalidRstBpduRxCount</b>     | Specifies the number of invalid RSTP BPDUs this port received. A trap is generated on the occurrence of this event.                                                                                 |
| <b>InvalidConfigBpduRx Count</b> | Specifies the number of invalid configuration BPDUs this port received. A trap is generated on the occurrence of this event.                                                                        |
| <b>InvalidTcnBpduRxCount</b>     | Specifies the number of invalid TCN BPDUs this port received. A trap is generated on the occurrence of this event.                                                                                  |
| <b>ProtocolMigrationCount</b>    | Specifies the number of times this port migrated from one STP protocol version to another. The relevant protocols are STP-Compatible and RSTP. A trap is generated on the occurrence of this event. |

## Viewing Port Spanning Tree Statistics

View port spanning tree statistics to manage network performance.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Spanning Tree** tab.

### **Spanning Tree** Field Descriptions

The following table describes parameters on the **Spanning Tree** tab.

| Name                  | Description                                                    |
|-----------------------|----------------------------------------------------------------|
| <b>InConfigBpdus</b>  | The number of Config BPDUs received.                           |
| <b>InTcnBpdus</b>     | The number of Topology Change Notifications BPDUs received.    |
| <b>InBadBpdus</b>     | The number of unknown or malformed BPDUs received.             |
| <b>OutConfigBpdus</b> | The number of Config BPDUs transmitted.                        |
| <b>OutTcnBpdus</b>    | The number of Topology Change Notifications BPDUs transmitted. |

## Configuring MSTP global parameters

Configure the global MSTP parameters to determine how MSTP operates for the system. Interface-level parameters override global settings.

### Before You Begin

- The system must be in MSTP mode.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.

3. Click the **Globals** tab.
4. Configure MSTP as required.
5. Click **Apply**.

### **Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PathCostDefaultType</b>    | Specifies the version of the spanning tree default path costs to be used by this bridge. A value of 8021d1998 denotes the use of the 16-bit default path costs from IEEE 802.1d-1998. A value of stp8021t2001 denotes the use of the 32-bit default path costs from IEEE 802.1t.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>TxHoldCount</b>            | Specifies the value used by the port transmit state to limit the maximum transmission rate. The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>MaxHopCount</b>            | Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second.<br>The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>NoOfInstancesSupported</b> | Indicates the maximum number of spanning tree instances supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>MstpUpCount</b>            | The number of times the MSTP module is enabled. A trap is generated on the occurrence of this event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>MstpDownCount</b>          | The number of times the MSTP module is disabled. A trap is generated on the occurrence of this event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ForceProtocolVersion</b>   | Specifies the version of Spanning Tree Protocol that the bridge currently runs. stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use; and mstp indicates that the multiple spanning tree protocol as specified in IEEE 802.1s is in use.<br>Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.<br>The default is MSTP. |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BrgAddress</b>         | Specifies the MAC address used by this bridge if it must be referred to in a unique fashion. This should be the numerically smallest MAC address of all ports that belong to this bridge. If concatenated with MstCistBridgePriority or MstBridgePriority, a unique bridge identifier is formed, which is used in the STP.                                                                       |
| <b>Root</b>               | Specifies the bridge identifier of the root of the common spanning tree as determined by the STP by this node. This value is used as the CIST root identifier parameter in all configuration bridge PDUs originated by this node.                                                                                                                                                                |
| <b>RegionalRoot</b>       | Specifies the bridge identifier of the root of the multiple spanning tree region as determined by the STP as executed of this node. This value is used as the common and internal spanning tree (CIST) regional root identifier parameter in all configuration bridge PDUs originated by this node.                                                                                              |
| <b>RootCost</b>           | Specifies the cost of the path to the CIST root from this bridge.                                                                                                                                                                                                                                                                                                                                |
| <b>RegionalRootCost</b>   | Specifies the cost of the path to the CIST regional root from this bridge.                                                                                                                                                                                                                                                                                                                       |
| <b>RootPort</b>           | Specifies the port number of the port which offers the lowest path cost from this bridge to the CIST root bridge.                                                                                                                                                                                                                                                                                |
| <b>BridgePriority</b>     | Specifies the value of the writable portion of the bridge identifier comprising the first two octets. The values you enter for bridge priority must be in steps of 4096. The default is 32768.                                                                                                                                                                                                   |
| <b>BridgeMaxAge</b>       | Specifies the value that all bridges use for MaxAge while this bridge acts as the root. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 2000.                                                                                                           |
| <b>BridgeForwardDelay</b> | Specifies the value that all bridges use for forward delay if this bridge acts as the root. Note that 802.1d specifies that the range for this parameter is related to the value of BridgeMaxAge. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 1500. |
| <b>HoldTime</b>           | Determines the interval length in hundredths of a second during which no more than two configuration bridge PDUs can be transmitted by this node.                                                                                                                                                                                                                                                |

| Name                            | Description                                                                                                                                                                                                                                                                     |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxAge</b>                   | Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the value that this bridge currently uses.                                                                                                 |
| <b>ForwardDelay</b>             | Specifies the time value, measured in units of hundredths of a second, that controls how fast a port changes its spanning state after moving towards the forwarding state. This value determines how long the port stays in a particular state before moving to the next state. |
| <b>TimeSinceTopology Change</b> | Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.                                                                                                                                        |
| <b>TopChanges</b>               | Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.                                                                                                                                                        |
| <b>NewRootBridgeCount</b>       | Specifies the number of times this bridge detects a root bridge change for Common Spanning Tree. A trap is generated on the occurrence of this event.                                                                                                                           |
| <b>RegionName</b>               | Specifies the name for the region configuration. By default, the region name is equal to the bridge MAC Address.                                                                                                                                                                |
| <b>RegionVersion</b>            | Specifies the version of the MST region.                                                                                                                                                                                                                                        |
| <b>ConfigIdSel</b>              | Specifies the configuration identifier format selector used by the bridge. This has a fixed value of 0 to indicate RegionName. RegionVersions are specified as in the standard.                                                                                                 |
| <b>ConfigDigest</b>             | Specifies the configured MD5 digest value for this region, which must be 16 octets long.                                                                                                                                                                                        |
| <b>RegionConfigChange Count</b> | Specifies the number of times a region configuration identifier change is detected. A trap is generated on the occurrence of this event.                                                                                                                                        |

## Configuring CIST ports for MSTP

Configure Common and Internal Spanning Tree (CIST) ports to configure ports for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **CIST Port** tab.

#### Note

The MSTP, CIST Port tab contains information for each port that is common to all bridge and spanning tree instances.

4. Use the fields in the **CIST Port** box to configure the MSTP CIST port.
5. Click **Apply**.

### **CIST Port** field descriptions

Use the data in the following table to use the **CIST Port** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b>             | Specifies the port number of the port for which this entry contains spanning tree information.                                                                                                                                                                                                                                                                                                                                |
| <b>PathCost</b>         | Specifies the contribution of this port to the path cost of paths towards the CIST root that includes this port.                                                                                                                                                                                                                                                                                                              |
| <b>Priority</b>         | Specifies the four most significant bits of the port identifier of the spanning tree instance which are modified by setting the CistPortPriority value. The values that are configured for port priority must be in steps of 16.<br>Although port priority values can range from 0 to 255, only the following values are used: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240.<br>The default is 128. |
| <b>DesignatedRoot</b>   | Specifies the unique bridge identifier of the bridge recorded as the CIST root in the configuration BPDUs transmitted.                                                                                                                                                                                                                                                                                                        |
| <b>DesignatedCost</b>   | Specifies the path cost of the designated port of the segment that connects to this port.                                                                                                                                                                                                                                                                                                                                     |
| <b>DesignatedBridge</b> | Specifies the unique bridge identifier of the bridge which that port considers to be the designated bridge for the ports segment.                                                                                                                                                                                                                                                                                             |
| <b>DesignatedPort</b>   | Specifies the port identifier of the port on the designated bridge for this port segment.                                                                                                                                                                                                                                                                                                                                     |
| <b>RegionalRoot</b>     | Specifies the unique bridge identifier of the bridge recorded as the CIST regional root identifier in the configuration BPDUs transmitted.                                                                                                                                                                                                                                                                                    |
| <b>RegionalPathCost</b> | Specifies the contribution of this port to the path cost of paths towards the CIST regional root that include this port.                                                                                                                                                                                                                                                                                                      |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ProtocolMigration</b> | Indicates the protocol migration state of this port. If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port.<br>An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode. |
| <b>AdminEdgeStatus</b>   | Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OperEdgeStatus</b>    | Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgeStatus and is configured to false on reception of a BPDU.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>AdminP2P</b>          | Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it connects to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.                                                                                              |
| <b>OperP2P</b>           | Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminP2P object.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>HelloTime</b>         | Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OperVersion</b>        | Indicates whether the port is operationally in the MSTP mode, the RSTP mode, or the STP-compatible mode; that is, whether the port transmits MST BPDUs, RST BPDUs, or Config/TCN BPDUs.<br>Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network. |
| <b>EffectivePortState</b> | Specifies the effective operational state of the port for CIST. This is true only if the port is operationally up at the interface and protocol levels for CIST. This is configured to false for all other conditions.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>State</b>              | Specifies the current state of the port as defined by the common spanning tree protocol. It can be disabled, discarding, learning, or forwarding.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ForcePortState</b>     | Specifies the current state of the port. You can change the port to either Disabled or Enabled for the base spanning tree instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SelectedPortRole</b>   | Specifies the selected port role of the port for this spanning tree instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>CurrentPortRole</b>    | Specifies the current port role of the port for this spanning tree instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configuring MSTI bridges for MSTP

Perform this procedure to configure multiple spanning tree instance (MSTI) bridges for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Bridges** tab.

#### Note

The systems generates MSTI bridge instances after you create a VLAN in MSTP mode.

4. Use the fields in the **MSTI Bridges** box to configure the MSTP bridge.
5. Click **Apply**.

**MSTI Bridges** field descriptions

Use the data in the following table to use the **MSTI Bridges** tab.

| Name                           | Description                                                                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Instance</b>                | Specifies the spanning tree instance to which this information belongs.                                                                                                                          |
| <b>RegionalRoot</b>            | Specifies the MSTI regional root identifier value for the instance. This value is used as the MSTI regional root identifier parameter in all configuration bridge PDUs originated by this node.  |
| <b>Priority</b>                | Specifies the writable portion of the MSTI bridge identifier comprising the first two octets. The values that are configured for bridge priority must be in steps of 4096. The default is 32768. |
| <b>RootCost</b>                | Specifies the cost of the path to the MSTI regional root as seen by this bridge.                                                                                                                 |
| <b>RootPort</b>                | Specifies the port number of the port that offers the lowest path cost from this bridge to the MSTI region root bridge.                                                                          |
| <b>TimeSinceTopologyChange</b> | Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for this spanning tree instance.                                                  |
| <b>TopChanges</b>              | Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for this spanning tree instance.                                                                  |
| <b>NewRootCount</b>            | Specifies the number of times this bridge detects a root bridge change for this spanning tree instance. A trap is generated on the occurrence of this event.                                     |
| <b>InstanceUpCount</b>         | Specifies the number of times a new spanning tree instance is created. A trap is generated on the occurrence of this event.                                                                      |
| <b>InstanceDownCount</b>       | Specifies the number of times a spanning tree instance is deleted. A trap is generated on the occurrence of this event.                                                                          |

## Configuring MSTI ports for MSTP

Perform the following procedure to configure MSTI ports for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.

- Click the **MSTI Port** tab.

**Note**

Port members you select on the VLAN, the system displays **Basic** tab in the **MSTI Port** tab.

- Use the fields in the **MSTI Port** box to configure the MSTP.
- Click **Apply**.

**MSTI Port** field descriptions

Use the data in the following procedure to use the **MSTI Port** tab.

| Name                    | Description                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b>             | Specifies the port number of the port for which this entry contains spanning tree information.                                                                                                                                                                                |
| <b>Instance</b>         | Specifies the spanning tree instance to which the information belongs.                                                                                                                                                                                                        |
| <b>PathCost</b>         | Specifies the contribution of this port to the path cost of paths towards the MSTI root that includes this port.                                                                                                                                                              |
| <b>Priority</b>         | Specifies the four most significant bits of the port identifier for a given spanning tree instance can be modified independently for each spanning tree instance supported by the bridge. The values configured for port priority must be in steps of 16. The default is 128. |
| <b>DesignatedRoot</b>   | Specifies the unique bridge identifier of the bridge recorded as the MSTI regional root in the configuration BPDUs transmitted.                                                                                                                                               |
| <b>DesignatedBridge</b> | Specifies the unique bridge identifier of the bridge that this port considers to be the designated bridge for the port segment.                                                                                                                                               |
| <b>DesignatedPort</b>   | Specifies the port identifier of the port on the designated bridge for this port segment.                                                                                                                                                                                     |
| <b>State</b>            | Specifies the current state of the port, as defined by the MSTP. A port which is in forwarding state in one instance can be in discarding (blocking) state in another instance.                                                                                               |
| <b>ForcePortState</b>   | Specifies the current state of the port, that is changed to either disabled or enabled for the specific spanning tree instance.                                                                                                                                               |
| <b>DesignatedCost</b>   | Specifies the path cost of the designated port of the segment connected to this port.                                                                                                                                                                                         |

| Name                      | Description                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CurrentPortRole</b>    | Specifies the current port role of the port for this spanning tree instance.                                                                                                                                                                              |
| <b>EffectivePortState</b> | Specifies the effective operational state of the port for a specific instance. This is configured to true if the port is operationally up at the interface and protocol levels for the specific instance. This is configured to false at all other times. |

## Viewing VLAN and Spanning Tree CIST Statistics

### About This Task

View CIST port statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **CIST Port** tab.
4. Select a port, and then click **Graph**.

### CIST Field Descriptions

The following table describes parameters on the **CIST** tab.

| Name                            | Descriptions                                                                      |
|---------------------------------|-----------------------------------------------------------------------------------|
| <b>ForwardTransitions</b>       | Specifies the number of times this port has transitioned to the forwarding state. |
| <b>RxMstBpduCount</b>           | Specifies the number of MSTP BPDUs received on this port.                         |
| <b>RxRstBpduCount</b>           | Specifies the number of RSTP BPDUs received on this port.                         |
| <b>RxConfigBpduCount</b>        | Specifies the number of configuration BPDUs received on this port.                |
| <b>RxTcnBpduCount</b>           | Specifies the number of TCN BPDUs received on this port.                          |
| <b>TxMstBpduCount</b>           | Specifies the number of MSTP BPDUs transmitted from this port.                    |
| <b>TxRstBpduCount</b>           | Specifies the number of RSTP BPDUs transmitted from this port.                    |
| <b>TxConfigBpduCount</b>        | Specifies the number of configuration BPDUs transmitted from this port.           |
| <b>TxTcnBpduCount</b>           | Specifies the number of TCN BPDUs transmitted from this port.                     |
| <b>InvalidMstBpduRxCount</b>    | Specifies the number of Invalid MSTP BPDUs received on this port.                 |
| <b>InvalidRstBpduRxCount</b>    | Specifies the number of Invalid RSTP BPDUs received on this port.                 |
| <b>InvalidConfigBpduRxCount</b> | Specifies the number of invalid configuration BPDUs received on this port.        |

| Name                          | Descriptions                                                                                                                                                                                                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InvalidTcnBpduRxCount</b>  | Specifies the number of invalid TCN BPDUs received on this port. The number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP/MSTP. A trap is generated on the occurrence of this event. |
| <b>ProtocolMigrationCount</b> | Specifies the number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP. A trap is generated on the occurrence of this event.                                                             |

## Viewing VLAN and Spanning Tree MSTI Statistics

### About This Task

View multiple spanning tree instance (MSTI) port statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.
4. Select a port, and then click **Graph**.

### MSTI Field Descriptions

The following table describes parameters on the **MSTI** tab.

| Name                      | Description                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>ForwardTransitions</b> | Specifies the number of times this port has transitioned to the forwarding state for this specific instance. |
| <b>ReceivedBPDUs</b>      | Specifies the number of BPDUs received by this port for this spanning tree instance.                         |
| <b>TransmittedBPDUs</b>   | Specifies the number of BPDUs transmitted on this port for this spanning tree instance.                      |
| <b>InvalidBPDUsRcvd</b>   | Specifies the number of invalid BPDUs received on this port for this spanning tree instance.                 |

## SPB-PIM Gateway fundamentals

This section provides conceptual content to help you configure and customize SPB-PIM Gateway (SPB-PIM GW) on the switch.

### IP Multicast over Fabric Connect in Protocol Independent Multicast networks

IP Multicast over Fabric Connect provides simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

#### *IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect).

Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VXLAN, Multi-tenant IP multicast.

**Important**

Sources must be IGMP enabled to support discovery functions specific to the multicast applications in use.

*IP Multicast over Fabric Connect restrictions*

- IP Multicast over Fabric Connect cannot connect to an IP Multicast router outside the SPB network.
- You can only deploy IP Multicast over Fabric Connect in environments where there are no multicast routers between the edge of the SPB network and the IP Multicast hosts that connect to the network.
- An existing network which is Protocol Independent Multicast (PIM) based cannot participate in the SPB network either by connecting to SPB originated streams or by injecting PIM network streams into the SPB network.
- In certain environments it is not possible to deploy an SPB network all the way to the point where the SPB network directly connects to an IGMP edge.

You encounter these restrictions during the following typical deployment scenarios:

- **Scenario 1:** You deployed IP Multicast using PIM and want to expand the network by deploying SPB for the new portion of the network. You want multicast applications to work across the old and new portion of the network.
- **Scenario 2:** Multicast traffic is exchanged between independent network operators at the boundary between their networks. PIM is the multicast routing protocol. A network operator wants to upgrade or replace the existing network to an SPB network. The inter-domain multicast traffic exchanges with other networks should not be disrupted.

The following figure shows the traditional Multicast over Fabric Connect environment with no PIM routers.

**Figure 235: IP Multicast over Fabric Connect streams**

In the above figure, sources and receivers on the edges of the SPB network are IGMP hosts and sources of multicast data. Hence, the traditional Multicast over Fabric Connect host-to-host deployment works.

The following figure shows the traditional Multicast over Fabric Connect environment with PIM routers.

**Figure 236: IP Multicast over Fabric Connect Streams**

In the above figure, sources and receivers on the edges of the SPB network, which are IGMP or source hosts can communicate over the SPB network. Sources and receivers connected to PIM routers cannot participate in the SPB network.

## SPB-PIM Gateway

Multicast over Fabric Connect cannot connect to a PIM router that is external to the SPB network. When a receiver joins the SPB network for a specific group, the receiver must receive multicast streams in the neighboring multicast domains (PIM network). Similarly, a receiver in the neighboring multicast domain (PIM network) must receive multicast streams from sources in the SPB network. SPB-PIM Gateway (SPB-PIM GW) provides multicast inter-domain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this inter-domain communication across a special gateway VLAN. The gateway VLAN communicates with the PIM network through a subset of the full protocol messaging required for RFC 4601 compliance of a PIM interface, and translates the PIM network requirements into SPB language and vice versa.

SPB-PIM GW provides the following functionality:

- One or more SPB domains can share streams with one or more PIM domains.
- SPB-PIM GW can connect two independent SPB domains. The independent SPB domains connected by SPB-PIM GW share a subset of multicast streams without a PIM network in between.

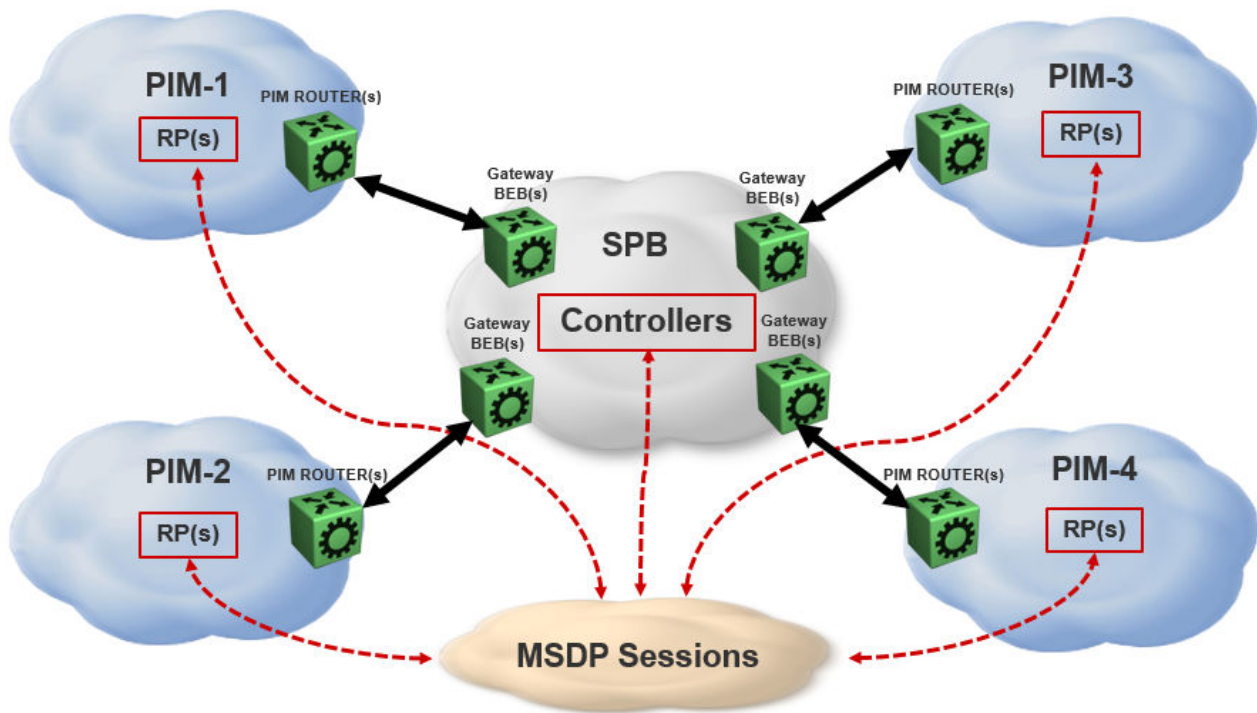

SPB-PIM GW is supported in the GRT and in VRFs.

*Multicast over Fabric Connect with SPB-PIM GW*

In a Multicast over Fabric Connect environment with SPB-PIM GW, the SPB network connects sources and receivers from one or more PIM networks. The multicast traffic is then delivered across the domain boundaries through a path that transports the multicast traffic.

Multicast over Fabric Connect with SPB-PIM GW functionality consists of SPB nodes, which act as SPB-PIM Controller nodes and SPB-PIM Gateway nodes. The SPB Controller uses the Multicast Source Discovery Protocol (MSDP) to discover foreign sources.

The following figure shows the Multicast over Fabric Connect environment with SPB-PIM GW.

**Figure 237: Multicast over Fabric Connect with SPB-PIM GW**

**SPB-PIM GW components**

SPB-PIM GW has two functional components:

- SPB-PIM Gateway Controller Nodes (Controller), which are used for multicast source discovery.
- SPB-PIM Gateway Nodes (Gateway), on which the SPB-PIM Gateway interfaces reside.

**Note**  
The Controller and Gateway can reside in a single node.

The following figure shows the SPB-PIM GW components.

**Figure 238: SPB-PIM GW components**

*SPB-PIM Gateway Controller Node*

SPB-PIM Gateway Controller Node (Controller) shares stream information between the local SPB domain and a foreign domain. The foreign domain is the PIM network Rendezvous point (RP) or another SPB domain Controller.

The Controller functionality is outlined below:

- The Controller discovers PIM sources for a specific multicast group and distributes them to the Gateways.

**Note**

PIM source discovery is either through MSDP or static configuration of foreign streams at the Controller.

- The Controller advertises local SPB originated streams through MSDP to another PIM domain or another SPB domain.
- The Controller references the Unicast IP route table to determine which Gateway has the best route to the PIM source. The Controller then assigns the stream to the selected Gateway.

The Controller Node has the following components:

- Source Discovery (MSDP and static configuration)
- Gateway Selection Controller

### Source Discovery (MSDP and static configuration)

MSDP resides in the Controller BEB or Controller BCB and PIM network RP that wish to advertise multicast source information between domains.

You can implement SPB-PIM GW under the following scenarios:

- The multicast source resides in the Protocol Independent Sparse Module (PIM-SM) domain. The multicast source must be discovered by MSDP residing on the Gateway Controller in the SPB domain.
- The multicast source resides in the SPB domain. The multicast source must be advertised to the neighboring PIM domain through MSDP peers.

For more information on MSDP, see [MSDP overview](#) on page 3148.

#### Note

You can also configure multicast sources statically on the Controller. Static configuration is useful for SSM multicast group range streams in the foreign domain, which are not advertised by MSDP. Static configuration is also useful for when two SPB domains are connected through a PIM Gateway, and want to only advertise a subset of streams to each other, without enabling MSDP.

### Gateway Selection Controller

The Gateway Selection Controller resides in the Controller BEB or Controller BCB node in the SPB network. The Gateway Selection Controller receives source information from MSDP or through static configuration. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VRF ID of the stream
- RP of the source (optional)

Gateway Selection Controller finds the best BEB (Gateway Node) in the SPB network through which the sender sends traffic to group G. The Gateway Selection Controller performs the following tasks:

- The Gateway Selection Controller uses Layer 3 reachability information to reach S, which is retrieved from the ISIS IP Shortcuts (IPSC) database.
- The VSN identifier (I-SID) is determined by using the VRF ID provided by MSDP.
- The Gateway Selection Controller uses the VRF ID and searches the IP shortcut database to determine which Gateway is closest to S.

#### Note

If multiple BEBs have a route to S, the BEB with the lowest Layer 3 metric is selected as the Gateway.

#### Note

If a Gateway link fails or the cost of the route changes, the selection process identifies the link failure as a route change and selects another best Gateway BEB.

The selected Gateway BEB for a stream must satisfy the following criteria:

- The selected Gateway BEB for a stream must announce a route to the source of the foreign stream through ISIS.

#### Note

Among all the routes to the source of the foreign stream announced by different BEBs through ISIS, the route announced by the selected Gateway has the longest prefix match and has the lowest external route metric.

- If multiple BEBs meet the Gateway selection criteria, a deterministic hash function of system ID, source IP address, and group IP address is used. The deterministic hash function is computed for each of the BEBs that meet the Gateway selection criteria. The BEB that generates the lowest hash value is selected as the Gateway for the stream.

The result of the Gateway selection process is saved in the Gateway assignment table. The Gateway assignment table consists of VSN identifier or I-SID, S, G, and the selected Gateway BEB. Having only one selected Gateway BEB ensures that traffic from source S is drawn into the SPB network by only one BEB, the selected Gateway BEB. The selection Controller then distributes the Gateway assignment table information to all the Gateway nodes.

### *SPB-PIM Gateway Node*

The SPB-PIM Gateway Node (Gateway) has the following components:

- Gateway Selection Agent
- SPB-PIM Gateway interface

#### **Gateway Selection Agent**

The Gateway Selection Agent (Agent) resides in the Gateway BEB Node in the SPB network. The Gateway BEB has connections into the foreign network over SPB-PIM Gateway Interfaces. The Agent receives foreign network source information from the Controller BEB or the Controller BCB Node. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VSN identifier (I-SID)
- Gateway assigned to the stream

The Agent interacts with SPB-PIM Gateway interface and creates the multicast path. The Agent receives foreign source information from the Controller and creates a foreign source address (SA) cache after validating the reachability to S. The Agent interacts with the SPB-PIM Gateway interface to validate that the next-hop ip address toward the source is a valid PIM adjacency. The foreign SA cache includes the following components:

- Source IP address (information received from the Gateway Controller)
- Group IP address (information received from the Gateway Controller)
- Ingress port (The port through which S is accessible)
- Upstream IP address (The next-hop IP address, which is also the PIM neighbor across the SPB-PIM Gateway interface which is used to reach S as indicated by the unicast routing entry)
- Ingress VLAN ID

If multiple next-hops are available, then the first valid PIM neighbor next-hop is used for the upstream.

**Note**

If the Agent receives the same source information from multiple Controllers, then the Agent takes action only for the information received from the preferred Controller. The Controller with the lowest system ID is the preferred Controller.

**SPB-PIM Gateway interface**

The SPB-PIM Gateway interface provides inter-domain multicast services. The SPB-PIM Gateway interface connects senders and receivers of multicast streams across a PIM Domain and a SPB network boundary over a Gateway interface. The SPB-PIM Gateway interface provides the following functionality:

- PIM HELLO exchanges
- Issuing Joins and Leaves
- Process received Joins and Leaves
- Implements the Gateway assignment table by acting as the Ingress BEB for streams for which the SPB-PIM Gateway interface is the selected Gateway
- Enforces the Gateway assignment table and does not forward streams for which the SPB-PIM Gateway interface is not the selected Gateway
- Forwards local and remote SPB streams to satisfy stream requests from neighboring multicast domains
- SPB-PIM Gateway Interfaces supports both SM and SSM multicast group range joins and prunes. \*G joins are only supported in SM group range.

The PIM Gateway interface resides in the SPB-PIM Gateway Node (Gateway). The SPB-PIM Gateway interface connects to a PIM router in a PIM network or to another Gateway BEB in an SPB network. Local hosts (IGMP member hosts and multicast data source hosts) are not supported on SPB-PIM Gateway interfaces, only PIM Routers or another SPB BEB with SPB-PIM Gateway interface configured. Multicast data from local source hosts and IGMP reports from local hosts are dropped. An SPB Node must be configured as a SPB-PIM Gateway Node if the SPB Node is connected to a foreign PIM network or a foreign SPB network. A single Gateway Node can have multiple SPB-PIM Gateway interfaces. The SPB-PIM Gateway interface can be a VLAN or a brouter port, can reside on an MLT and is fully virtualized. The SPB-PIM Gateway interface is a translation mechanism between the PIM protocol and SPB TLVs.

**Note**

- Only PIM protocol messages are communicated over the SPB-PIM Gateway interface
- Only SPB TLVs are communicated over Fabric Connect over SPB
- The SPB-PIM Gateway interface is the only component that handles the translation mechanism

The SPB-PIM Gateway interface communicates with the PIM router through the standard PIM protocol messaging HELLO, JOIN, and PRUNE. The SPB-PIM Gateway interface then forms a normal PIM adjacency with the PIM router or another SPB Gateway Node. The SPB-PIM Gateway Interface processes received SG joins and prunes, \*G joins and prunes, and SG-RPT joins and prunes. The SPB-PIM Gateway interface transmits SG joins and prunes, but never \*G joins. The SPB-PIM Gateway Interface does not have RP capabilities, and therefore has no need for group-to-RP mapping configurations. A \*G

JOIN received on a SPB-PIM Gateway Interface is accepted if the destination IP is the IP address of the interface or of a neighbor on the interface if the neighbor is learned on another port in the interface. However, the RP address within the \*G JOIN message is ignored by the SPB-PIM Gateway Interface.

## MSDP overview

MSDP enables advertisement of multicast source information between different PIM-SM domains. This function of MSDP in SPB-PIM GW topologies is to advertise multicast source information between SPB domains and PIM domains. MSDP routers in a PIM-SM or SPB domain have a peering relationship with MSDP peers in another domain. The peering relationship is a TCP connection in which the control information is exchanged. The TCP connection between peers uses the underlying unicast routing system.

### *Source Active messages*

In a PIM domain, MSDP enabled routers are RPs. MSDP routers form adjacencies through TCP port 639 to share multicast source information. This functionality is similar to the Border Gateway Protocol (BGP). When an MSDP router receives multicast source information, the routers use reachability information to perform Reverse Path Forwarding (RPF) checks. The reachability information is exchanged through BGP or any other unicast routing protocol.

When a RP router learns of a new (S,G), the RP router saves the (S,G) information and the RP address in the MSDP Source Active (SA) local cache. The RP router learns the new (S,G) through a directly connected source or PIM register message. The RP router then sends an SA update message which contains (S,G,RP) information to the MSDP peers. The MSDP peers broadcast the SA to RPs in their local domains and to their MSDP peers in other PIM-SM domains.

#### **Note**

A PIM domain is a set of routers in a single Autonomous System (AS), which uses the same RP for any given multicast group.

When an SPB-PIM Gateway Controller in the SPB domain learns of a new (S,G) in its own domain, the Controller saves the (S,G) information in the local SA cache. The Controller learns the new (S,G) through a directly connected source or Intermediate-System-to-Intermediate-System (IS-IS). The controller sends an SA update message to the MSDP peers in the PIM domain. SA uses the CLIP address configured on the controller as the RP address.

#### **Note**

Configure CLIP before you enable MSDP. Peer connections use the CLIP address as the local address.

### *Reverse Path Forwarding check*

When an MSDP peer receives the SA from a peer, the MSDP performs an RPF check. The RPF check ensures that the SA received from the MSDP peer is the closest to the originating RP. An RPF check prevents SA loops.

#### **Note**

This RPF check is different from the multicast routing RPF check.

If the RPF checks pass, then the receiving MSDP enabled router saves the SA information in the SA foreign cache and makes it available to the local domain. Each MSDP peer floods the SA information away from the originating RP. The flooding process is called peer RPF flooding.

### *SA redistribution and filtering*

Redistribution and filtering is used to control SA flooding. The MSDP redistribute policy is applied on the MSDP node that originates the SAs to control which SAs are advertised on all MSDP peers. An SA filter is applied to a specific MSDP peer in the inbound direction or outbound directions or both inbound and outbound direction on any MSDP router. Filtering is multicast group based.

When configuring MSDP redistribution, use prefix lists to create the route policies. When a route policy is created it must match the group prefix with the name of the prefix list created for the group address. If deny action is set for the lists in the route-policy, the policy blocks the matching groups from all the sources. If permit action is set for the lists in the route-policy, the policy accepts the matching groups from all the sources. MSDP redistribution does not refer to the redistribution of SPB domain sources to MSDP. MSDP redistribution refers to SAs which needs to be redistributed to other MSDP peers.

#### **Note**

MSDP redistribution is applied globally to all MSDP peers. SA filtering is used to filter SAs on a peer-to-peer level.

### *MSDP and SPB-PIM GW*

The SPB-PIM GW functional component for MSDP resides in the SPB-PIM Gateway Controller node (Controller).

#### **Overview**

Controllers from an SPB network discover sources through MSDP sessions with RPs from a PIM network. Once the SA packet is received at the MSDP module of the Controller, the IP routing table is examined to determine which peer is the next hop towards the originating RP of the SA message. Once the SA RPF test passes, the SA packet is saved in the foreign cache and passed to the Controller.

The Controller nodes also distribute the sources from an SPB domain to a PIM domain through an MSDP session with RPs in the PIM network. Similar to RP, when a Controller in the SPB domain learns of a new (S,G), through a directly connected source or ISIS, the Controller saves the new (S,G) in its local SA cache. The Controller then transmits an SA update message for this source to its MSDP peers in the PIM domain. The Controller that sends the SA to the MSDP is viewed as the RP (circuitless IP interface is used).

#### **MSDP as part of SPB-PIM GW**

MSDP does not work with the traditional PIM implementation. MSDP communicates only with the Controller and should be configured as an IP endpoint.

MSDP configuration considerations:

- A circuitless IP interface (CLIP) is used in the context of global router or VRF, hence at least one CLIP in each VRF should be configured.
- MSDP should use a single CLIP address as the source for establishing all MSDP connections in the same VRF.
- For SPB sources, this CLIP is used as the RP in all SA messages advertised.

- MSDP source IP address should be one of the CLIP interfaces pre-configured on the global router or VRF.
- The originator-id should be configured before enabling MSDP.

**Note**

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

For more information on MSDP configuration, see [Multicast Source Discovery Protocol configuration](#) on page 3151.

### *Full mesh group*

MSDP mesh groups are full mesh of MSDP peers and is a subset of MSDP speakers. MSDP mesh groups are used for SA flooding which is similar to the BGP route reflector concept. MSDP floods the SA to all the members of the mesh group when:

- The MSDP peers are fully meshed
- The MSDP enabled router learns a new SA from a non-member of its mesh group
- The SA passes the RPF check

The receiving routers accept the SA and forwards it only to any non-mesh Group MSDP peers.

The SPB-PIM Gateway is deployed in two models:

- Model 1: All multicast networks have peering agreements with one another. The full mesh MSDP is setup.
- Model 2 : An inter-domain multicast provider exists. All multicast networks setup MSDP peering with the provider.

The controllers relay SA messages between individual networks.

#### Note

Consider the following when you deploy SPB-PIM Gateway:

- Use mesh group of MSDP peers (PIM RP's and SPB-PIM Gateway Controller nodes) to avoid flooding and RPF failure.

#### Note

Since MSDP uses CLIP interface in its peering relation, the MSDP peer may not fall in any of the RFC rules and the MSDP SA messages will be rejected.

- Controllers from the same SPB network must not have MSDP sessions with each other, regardless of whether mesh groups are used or not.
- When using mesh groups, all Controllers within one SPB domain should peer with the same set of RPs and Controllers in adjacent domains, ie, one Controller should not peer with an RP that the other Controllers do not peer with.

## Multicast Source Discovery Protocol configuration

This section provides procedures to configure Multicast Source Discovery Protocol (MSDP) using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

### Basic MSPD configuration using the CLI

This section provides procedures to configure Basic MSDP using the command line interface (CLI).

#### *Configuring the MSDP originator ID*

Configure the originator ID to set the Rendezvous Point (RP) address inside the Source Active (SA) message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

#### Note

To delete the originator ID, you must first disable MSDP.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Configure the MSDP originator ID:

```
ip msdp originator-id {A.B.C.D}
```

#### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
Switch:1(config)#ip msdp originator-id 2.0.2.2
```

### Variable definitions

The following table defines parameters for the **ip msdp originator-id** command.

| Variable  | Value                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies the MSDP source IP address. The IP address must be one of the CLIP interfaces configured on the global router or a VRF. |

### Configuring MSDP on a VRF

Create an MSDP instance on a user defined VRF to allow further configuration to take place. This command does not exist in the Global Configuration mode because the MSDP instance for a default VRF is created by default.

#### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
 

```
enable
configure terminal
router vrf WORD<1-16>
```
2. Create the MSDP instance:
 

```
ip msdp
```

### Enabling MSDP globally

Enable or disable MSDP globally on the device to allow further configuration to take place.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Enable MSDP globally on the switch:
 

```
ip msdp enable
```

### Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

#### Important

Do not enable more than 20 active peers.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```
