In the preceding figure, all routers use PIM-SSM. The source connects to Router A on VLAN 10. All routers and receiver hosts connect on the same extended VLAN, VLAN 20. All routers have a receiver in VLAN 20. Router D is the PIM DR for VLAN 20 and the source host is not on VLAN 20. PIM-SSM does not require a Rendezvous Point (RP).

In this topology, each router receives an IGMP membership report from its local receiver host, and then sends a PIM SG join message towards the source on VLAN 20. VLAN flooding propagates the PIM SG join message through to Router A, the PIM DR for the source VLAN 10. Each router from Router D to Router A records a PIM join on the port on which the join message was received, and then sends out its own join message toward the source. Data then flows from the source to the receiver, as long as a join exists on those ports.

Because all routers are in the same VLAN 20, they receive joins from one another due to flooding in the VLAN. For example, Router D receives join messages from Router C on its port 'b', and Router C receives join messages from Router B on its port toward Router B. On VSP 9000 Series routers, PIM join suppression is always enabled. In accordance with the PIM protocol rules, suppression causes Router D to stop sending a join towards the source because it receives a join for the same group and same RP on the port (port b) of the upstream neighbor (the router towards the source). Router D does not need to send a redundant join on the same VLAN. Router D stops sending a join, and the join that is recorded on port c of Router C eventually times out and is removed from the egress list of the (s,g) multicast route entry on Router C. This removal causes Router C to stop forwarding multicast traffic to Router D, and to the receiver (R1).

The purpose of join suppression is to suppress joins on a shared VLAN, such that if all routers on the shared VLAN want to receive data from the same RP and group, then only one of them needs to send the join on the VLAN. One join is enough to pull the data from the source router to the shared VLAN for all routers to receive. The other routers can suppress sending their own joins when they see such a join on the port toward the upstream router. In this way, less protocol message congestion exists in the shared VLAN. In the following figure, Router D sends the initial join message, which is seen by Router B and Router C. Router B and Router C suppress their own join messages. Router A (the PIM DR for the source VLAN 10) sends the data to VLAN 20, which is received by Routers B, C, and D due to the shared (non-extended) VLAN topology, and traffic is forwarded to all receiver hosts.

The extended VLAN topology looks exactly like the non-extended shared VLAN topology to the router, which cannot distinguish between the two.

In the current release, you cannot disable join suppression on a router. This enhancement will be added in a future release. Until this enhancement is included, you can perform the following actions:

1. Avoid this type of extended VLAN topology, and instead use Layer 3 routing between the routers. Do not extend VLAN 20 throughout, but rather, create a different VLAN between each router.
2. Configure the PIM DR for VLAN 20 to be the router closer to the source (Router B) so that any join received on the VLAN 20 DR (Router B) will be recorded as an IGMP local leaf on VLAN 20 as opposed to a PIM join, which does not time out until the receiver host stops sending IGMP membership reports.

### PIM-SM Design and the BSR Hash Algorithm

To optimize the flow of traffic down the shared trees in a network that uses a BSR to dynamically advertise candidate RPs, consider the hash function. The BSR uses the hash function to assign multicast group addresses to each C-RP.

The BSR distributes the hash mask used to compute the RP assignment. For example, if two RPs are candidates for the range 239.0.0.0 through 239.0.0.127, and the hash mask is 255.255.255.252, that range of addresses is divided into groups of four consecutive addresses and assigned to one or the other C-RP.

The following figure illustrates a suboptimal design where Router A sends traffic to a group address assigned to RP D. Router B sends traffic assigned to RP C. RP C and RP D serve as backups for each other for those group addresses. To distribute traffic, it is desirable that traffic from Router A use RP C and that traffic from Router B use RP D.

While still providing redundancy in the case of an RP failure, you can ensure that the optimal shared tree is used by using the following methods.

1. Use the hash algorithm to proactively plan the group-address-to-RP assignment.

Use this information to select the multicast group address for each multicast sender on the network and to ensure optimal traffic flows. This method is helpful for modeling more complex redundancy and failure scenarios, where each group address has three or more C-RPs.

2. Allow the hash algorithm to assign the blocks of addresses on the network, and then view the results using the command **show ip pim active-rp**.

Use the command output to assign multicast group addresses to senders that are located near the indicated RP. The limitation to this approach is that while you can easily determine the current RP for a group address, the backup RP is not shown. If more than one backup for a group address exists, the secondary RP is not obvious. In this case, use the hash algorithm to reveal which of the remaining C-RPs take over for a particular group address in the event of primary RP failure.

The hash algorithm works as follows:

1. For each C-RP router with matching group address ranges, a hash value is calculated according to the formula:

$$\text{Hash value [G, M, C(i)]} = \{1\ 103\ 515\ 245 * [(1\ 103\ 515\ 245 * (G\&M) + 12\ 345) \text{ XOR } C(i)] + 12\ 345\} \text{ mod } 2^{31}$$

The hash value is a function of the group address (G), the hash mask (M), and the IP address of the C-RP C(i). The expression (G&M) guarantees that blocks of group addresses hash to the same value for each C-RP, and that the size of the block is determined by the hash mask.

For example, if the hash mask is 255.255.255.248, the group addresses 239.0.0.0 through 239.0.0.7 yield the same hash value for a given C-RP. Thus, the block of eight addresses are assigned to the same RP.

2. The C-RP with the highest resulting hash value is chosen as the RP for the group. In the event of a tie, the C-RP with the highest IP address is chosen.

This algorithm runs independently on all PIM-SM routers so that every router has a consistent view of the group-to-RP mappings.

### Candidate RP Considerations

The C-RP priority parameter determines an active RP for a group. The hash values for different RPs are only compared for RPs with the highest priority. Among the RPs with the highest priority value and the same hash value, the C-RP with the highest RP IP address is chosen as the active RP.

You cannot configure the C-RP priority. Each RP has a default C-RP priority value of 0, and the algorithm uses the RP if the group address maps to the grp-prefix that you configure for that RP. If a different router in the network has a C-RP priority value greater than 0, the switch uses this part of the algorithm in the RP election process.

Currently, you cannot configure the hash mask used in the hash algorithm. Unless you configure a different PIM BSR in the network with a nondefault hash mask value, the default hash mask of 255.255.255.252 is used. Static RP configurations do not use the BSR hash mask; they use the default hash mask.

For example:

RP1 = 128.10.0.54 and RP2 = 128.10.0.56. The group prefix for both RPs is 238.0.0.0/255.0.0.0. Hash mask = 255.255.255.252.

The hash function assigns the groups to RPs in the following manner:

The group range 238.1.1.40 to 238.1.1.51 (12 consecutive groups) maps to 128.10.0.56. The group range 238.1.1.52 to 238.1.1.55 (4 consecutive groups) maps to 128.10.0.54. The group range 238.1.1.56 to 238.1.1.63 (8 consecutive groups) maps to 128.10.0.56.

### **PIM-SM RP Selection Algorithm Inconsistency between Platforms**

In topologies where VOSS platforms are interoperating with ERS or VSP 9000 Series platforms, the selection of the RP from multiple candidate RPs may produce different results on VOSS than it does on ERS or VSP 9000 Series. VOSS platforms conform to PIM RFC 4601, while ERS and VSP 9000 Series platforms conform to RFC 2362. RFC 4601 is not backward compatible with RFC 2362 regarding how it defines the selection algorithm for an RP, specifically when there are several candidate RPs for the same group, but with different prefix lengths. Both RFCs have the RP selection mechanism based on a specific hash function, common to all routers in PIM domain, however there are differences in determining the pool of candidate RPs to which the hash function will be applied. In RFC 4601, only the RP of the group range with the longest prefix match for the group range will be chosen to apply the hash function and thus participate in the actual election. In RFC 2362, longest prefix match is not part of the selection criteria, and therefore ERS/VSP 9000 Series could potentially choose a different RP, since they will apply the hash function on a different pool of candidate RPs. This would cause inconsistencies in the PIM-SM network.

In order to work around this issue, please define RP group ranges with the same prefix length, such that the next RFC-defined match rule will be applied equally across all platforms in the network.

### **PIM-SM Receivers and VLANs**

Some designs cause unnecessary traffic flow on links in a PIM-SM domain. In these cases, traffic is not duplicated to the receivers, but wastes bandwidth.

The following figure shows such a situation. Switch B is the DR between switches A and B. Switch C is the RP. A receiver R is on the VLAN (V1) that connects switches A and B. A source sends multicast data to the receiver.

IGMP reports that the messages that the receiver sends are forwarded to the DR, and both A and B create (\*,G) records. Switch A receives duplicate data through the path from C to A, and through the second path from C to B to A. Switch A discards the data on the second path (assuming the upstream source is A to C).

To avoid this waste of resources, do not place receivers on V1. This configuration guarantees that no traffic flows between B and A for receivers attached to A. In this case, the existence of the receivers is only learned through PIM join messages to the RP [for (\*,G)] and of the source through SPT joins.

### PIM Network with Non-PIM Interfaces

For proper multicast traffic flow in a PIM-SM domain, as a general rule, enable PIM-SM on all interfaces in the network (even if paths exist between all PIM interfaces). Enable PIM on all interfaces because PIM-SM relies on the unicast routing table to determine the path to the RP, BSR, and multicast sources. Ensure that all routers on these paths have PIM-SM enabled interfaces.

The following figure provides an example of this situation. If A is the RP, then initially the receiver receives data from the shared tree path (that is, through switch A).

If the shortest path from C to the source is through switch B, and the interface between C and B does not have PIM-SM enabled, then C cannot switch to the SPT. C discards data that comes through the

shared path tree (that is, through A). The simple workaround is to enable PIM on VLAN1 between C and B.

### Source Filtering

The system can report interest in receiving packets from only a specific source address (INCLUDE), from all but specific source addresses (EXCLUDE), or sent to specific multicast addresses. IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

#### *Protocol Independent Multicast-Source Specific Multicast guidelines*

PIM-Source Specific Multicast (SSM) is a one-to-many model that uses a subset of the PIM-SM features. In this model, members of an SSM group can only receive multicast traffic from a specific source or sources, which is more efficient and puts less load on multicast routing devices.

IGMPv3 supports PIM-SSM by enabling a host to selectively request traffic from individual sources within a multicast group. The system can report interest in receiving packets from only specific source addresses (INCLUDE). IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

### IGMPv2 SSM extensions

VSP 4450 Series processes messages according to the following rules:

- After IGMPv3 receives an IGMPv2 report in the SSM range, the system translates the report to an IGMPv3 report message.
- After an IGMPv2 router sends queries on an IGMPv3 interface, the switch downgrades this interface to IGMPv2 (backward compatibility).

This can cause traffic interruption, but the switch recovers quickly.

### PIM-SSM design considerations

Use the following information when you design an SSM network:

- If you configure SSM, it affects SSM groups only. The switch handles other groups in sparse mode (SM) if a valid RP exists on the network.
- You can configure PIM-SSM only on switches at the edge of the network. Core switches use PIM-SM if they do not have receivers for SSM groups.
- For networks where group addresses are already in use, you can change the SSM range to match the groups.
- One switch has a single SSM range.
- You can have different SSM ranges on different switches.

Configure the core switches that relay multicast traffic so that they cover all of these groups in their SSM range, or use PIM-SM.

- One group in the SSM range can have multiple sources for a given SSM group.

### *Multicast for Multimedia*

The switch provides a flexible and scalable multicast implementation for multimedia applications. Several features are dedicated to multimedia applications and in particular to television distribution.

#### **Join and leave performance**

For TV applications, you can attach several TVs directly to the switch, or through an IGMP-capable Ethernet switch. Base this implementation on IGMP; the set-top boxes use IGMP reports to join a TV channel and IGMP leaves to exit the channel. After a viewer changes channels, the switch issues an IGMPv2 leave for the old channel (multicast group), and sends a membership report for the new channel. If viewers change channels continuously, the number of joins and leaves can become large, particularly if many viewers attach to the switch.

The switch supports more than a thousand joins and leaves per second, which is well adapted to TV applications.

#### **Important**

For IGMPv3, ensure a join rate of 1000 per second or less. This ensures the timely processing of join requests.

If you use the IGMP proxy functionality at the receiver edge, you reduce the number of IGMP reports received by switch. This provides better overall performance and scalability.

## Fast Leave

IGMP Fast Leave supports two modes of operation: single-user mode and multiple-user mode.

In single-user mode, if more than one member of a group is on the port and one of the group members leaves the group, everyone stops receiving traffic for this group. Single-user mode does not send a group-specific query before the effective leave takes place.

Multiple-user mode allows several users on the same port or VLAN. If one user leaves the group and other receivers exist for the same stream, the stream continues. The switch tracks the number of receivers that join a given group. For multiple-user mode to operate properly, do not suppress reports. This ensures that the switch properly tracks the correct number of receivers on an interface.

The Fast Leave feature is particularly useful in IGMP-based TV distribution where only one receiver of a TV channel connects to a port. If a viewer changes channels quickly, you create considerable bandwidth savings if you use Fast Leave.

You can implement Fast Leave on a VLAN and port combination; a port that belongs to two different VLANs can have Fast Leave enabled on one VLAN (but not on the other). Thus, with the Fast Leave feature enabled, you can connect several devices on different VLANs to the same port. This strategy does not affect traffic after one device leaves a group to which another device subscribes. For example, you can use this feature when two TVs connect to a port through two set-top boxes, even if you use the single-user mode.

To use Fast Leave, you must first enable explicit host tracking. IGMP uses explicit host tracking to track all source and group members. Explicit host tracking is disabled by default. For configuration information, see [Configuring Fast Leave Mode](#) on page 1600.

## Last member query interval tuning

If an IGMPv2 host leaves a group, it notifies the router by using a leave message. Because of the IGMPv2 report suppression mechanism, the router cannot access information of other hosts that require the stream. Thus, the router broadcasts a group-specific query message with a maximum response time equal to the last member query interval (LMQI).

Because this timer affects the latency between the time that the last member leaves and the time the stream actually stops, you must properly tune this parameter. This timer can especially affect TV delivery or other large-scale, high-bandwidth multimedia applications. For instance, if you assign a value that is too low, this can lead to a storm of membership reports if a large number of hosts are subscribed. Similarly, assigning a value that is too high can cause unwanted high-bandwidth stream propagation across the network if users change channels rapidly. Leave latency also depends on the robustness value, so a value of 2 equates to a leave latency of twice the LMQI.

Determine the proper LMQI value for your particular network through testing. If a very large number of users connect to a port, assigning a value of 3 can lead to a storm of report messages after a group-specific query is sent. Conversely, if streams frequently start and stop in short intervals, as in a TV delivery network, assigning a value of 10 can lead to frequent congestion in the core network.

Another performance-affecting factor that you need to be aware of is the error rate of the physical medium. For links that have high packet loss, you can find it necessary to adjust the robustness variable to a higher value to compensate for the possible loss of IGMP queries and reports.

In such cases, leave latency is adversely affected as numerous group-specific queries are unanswered before the stream is pruned. The number of unanswered queries is equal to the robustness variable (default 2). The assignment of a lower LMQL can counterbalance this effect. However, if you configure the LMQL too low, it can actually exacerbate the problem by inducing storms of reports on the network. LMQL values of 3 and 10, with a robustness value of 2, translate to leave latencies of 6/10 of a second and 2 seconds, respectively.

When you choose an LMQL, consider all of these factors to determine the best configuration for the given application and network. Test that value to ensure that it provides the best performance.

**Important**

In networks that have only one user connected to each port, use the Fast Leave feature instead of LMQL, because no wait is required before the stream stops. Similarly, the robustness variable does not affect the Fast Leave feature, which is an additional benefit for links with high loss.

*Layer 3 switch clustering and multicast SMLT*

Switch clustering is the logical aggregation of two nodes to form one logical entity known as the switch cluster. The two peer nodes in a switch cluster connect using a virtual interswitch trunk (vIST). The vIST exchanges forwarding and routing information between the two peer nodes in the cluster. This section provides guidelines for switch clusters that use multicast and Split Multilink Trunking (SMLT).

**General guidelines**

The following list identifies general guidelines to follow if you use multicast and switch clustering:

- Enable Protocol Independent Multicast - Sparse Mode (PIM-SM) on the vIST VLAN for fast recovery of multicast. A unicast routing protocol is not required.
- Enable Internet Group Management Protocol (IGMP) snooping and proxy on the edge switches.

The following figure shows multicast behavior in an SMLT environment. The configuration in the following figure provides fast failover if the switch or rendezvous point (RP) fails.

**Figure 146: Multicast behavior in SMLT environment**

In Multicast behavior in SMLT environment the following actions occur:

1. The multicast server sends multicast data towards the source designated router (DR).
2. The source DR sends register messages with encapsulated multicast data towards the RP.
3. After the client sends IGMP membership reports towards the multicast router, the router creates a (\*,G) entry.
4. The RP sends join messages towards the source DR on the reverse path.
5. After the source DR receives the join messages, it sends native multicast traffic.
6. After SW\_B or SW\_D receives multicast traffic from upstream, it forwards the traffic on the vIST as well as on the SMLT link. Other aggregation switches drop multicast traffic received over the vIST at

gress. This action provides fast failover for multicast traffic. Both SW\_D and SW\_E (Aggregation switches) have similar (S,G) records.

- In case of SW\_D or RP failure, SW\_B changes only the next-hop interface towards SW\_E. Because the circuitless IP (CLIP) RP address is the same, SW\_B does not flush (S,G) entries and achieves fast failover.

### Multicast triangle topology

A triangle design is an SMLT configuration that connects edge switches or SMLT clients to two aggregation switches. Connect the aggregation switches together with a vIST that carries all the SMLT trunks configured on the switches.

The switch supports the following triangle configurations:

- a configuration with Layer 3 PIM-SM routing on both the edge and aggregation switches
- a configuration with Layer 2 snooping on the client switches and Layer 3 routing with PIM-SM on the aggregation switches

To avoid using an external query device to provide correct handling and routing of multicast traffic to the rest of the network, use the triangle design with IGMP Snoop at the client switches. Use multicast routing at the aggregation switches as shown in the following figure.

**Figure 147: Multicast routing using PIM-SM**

Client switches run IGMP Snoop or PIM-SM, and the aggregation switches run PIM-SM. This design is simple and, for the rest of the network, PIM-SM performs IP multicast routing. The aggregation switches are the query devices for IGMP, so an external query device is not required to activate IGMP membership. These switches also act as redundant switches for IP multicast.

Multicast data flows through the vIST link when receivers are learned on the client switch and senders are located on the aggregation switches, or when sourced data comes through the aggregation switches. This data is destined for potential receivers attached to the other side of the vIST. The data

does not reach the client switches through the two aggregation switches because only the originating switch forwards the data to the client switch receivers.

#### Note

Always place multicast receivers and senders on the core switches on VLANs different from those that span the vIST.

The following figure shows a switch clustering configuration with a single switch cluster core and dual-connected edge devices. This topology represents different VLANs spanning from each edge device and those VLANs routed at the switch cluster core. You can configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster core.

**Figure 148: Multicast SMLT triangle**

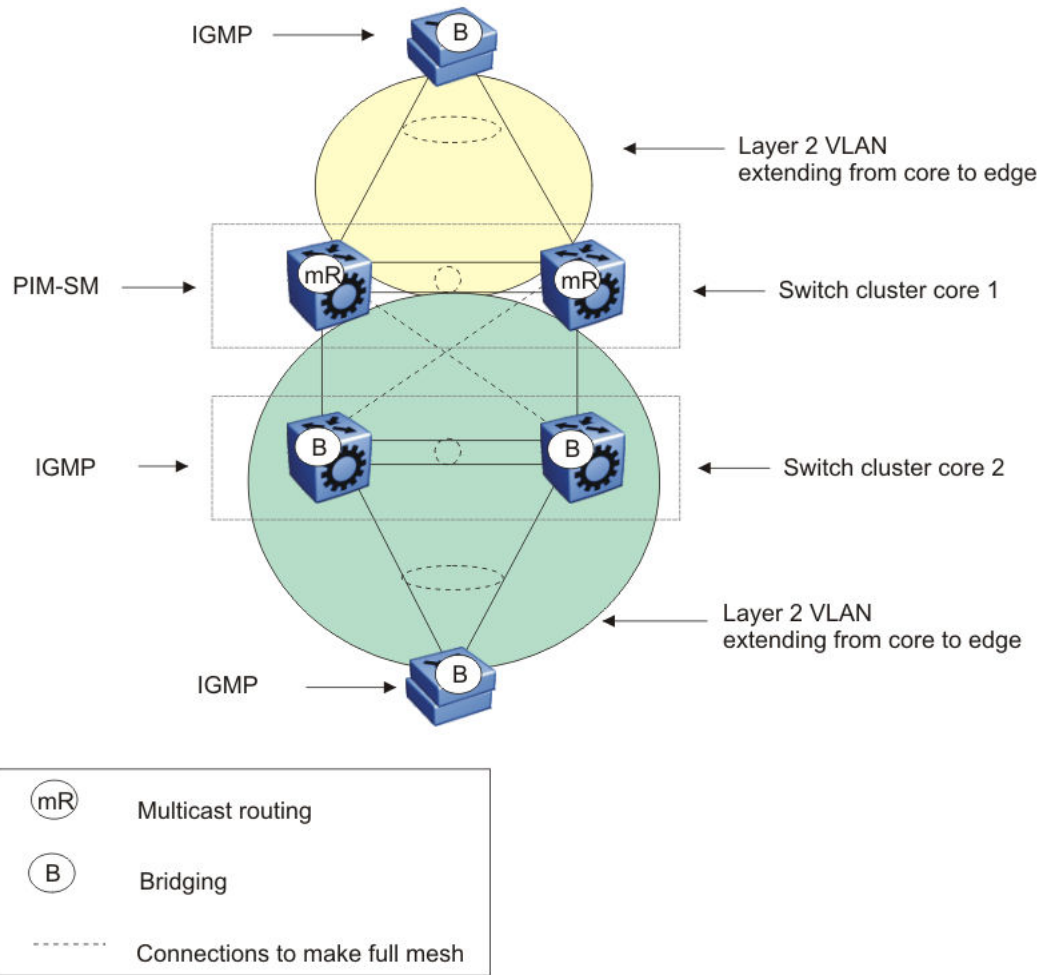

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either Virtual Router Redundancy Protocol (VRRP) BackupMaster or Routed SMLT (RSMLT) Layer 2 Edge on the switch cluster core.

#### Square and full-mesh topology multicast guidelines

A square design connects a pair of aggregation switches to another pair of aggregation switches. A square design becomes a full-mesh design if the aggregation switches are connected in a full-mesh. The switch supports Layer 3 IP multicast (PIM-SM only) over a full-mesh SMLT or RSMLT configuration.

In a square design, configure all switches with PIM-SM. Place the bootstrap router (BSR) and RP in one of the four core switches; and place the RP closest to the source. If using PIM-SM over a square or full-mesh configuration, enable the **multicast smlt-square** flag.

The following three figures show switch clustering configurations with two-switch cluster cores and dual-connected edge devices.

**Figure 149: Multicast SMLT square 1**

In the preceding figure, only one of the switch cluster cores performs Layer 3 multicast routing while the other is strictly Layer 2. Configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster cores.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster core.

**Figure 150: Multicast SMLT square 2**

In the preceding figure, both of the switch cluster cores performs Layer 3 multicast routing, while the edge devices are Layer 2 IGMP.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

**Figure 151: Multicast SMLT square 3**

In the preceding figure, both of the switch cluster cores and the edge devices perform Layer 3 multicast routing.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

### SMLT and multicast traffic issues

If PIM-SM or other multicast protocols are used in an SMLT environment, enable the protocol on the vST. Routing protocols in general are not run over an vST but multicast routing protocols are an exception. When using PIM-SM and a unicast routing protocol, ensure the unicast route to the BSR and RP has PIM-SM active and enabled. If multiple OSPF paths exist and PIM-SM is not active on each pair, the BSR is learned on a path that does not have PIM-SM active. The following figure demonstrates this issue.

**Figure 152: Unicast route example**

The network configuration in the preceding figure is as follows:

- 5510A is on VLAN 101.
- 5510B is on VLAN 102.
- Switch B is the BSR.
- Switch A and Switch B have OSPF enabled.
- PIM is enabled and active on VLAN 101.
- PIM is either disabled or passive on VLAN 102.

In this example, the unicast route table on Switch A learns the BSR on Switch B through VLAN 102 using OSPF. The BSR is either not learned or does not provide the RP to Switch A.

## Protocol Independent Multicast over IPv6

**Table 120: PIM over IPv6 product support**

| Feature       | Product         | Release introduced |
|---------------|-----------------|--------------------|
| PIM over IPv6 | 5420 Series     | VOSS 8.4           |
|               | 5520 Series     | VOSS 8.2.5         |
|               | VSP 4450 Series | VOSS 5.1           |
|               | VSP 4900 Series | VOSS 8.1           |
|               | VSP 7200 Series | VOSS 5.1           |
|               | VSP 7400 Series | VOSS 8.0           |
|               | VSP 8200 Series | VOSS 5.1           |
|               | VSP 8400 Series | VOSS 5.1           |
|               | VSP 8600 Series | Not Supported      |
|               | XA1400 Series   | Not Supported      |

Several multicast protocols are used to enable IP multicast.

Hosts use the Internet Group Management Protocol (IGMP) for IPv4 and Multicast Listener Discovery (MLD v1/v2) for IPv6 to report multicast group memberships of directly attached multicast listeners to neighboring multicast routers. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4.

Routers use Protocol Independent Multicast-Sparse Mode (PIM-SM) and PIM source Specific Mode (SSM) to exchange multicast routing information. The PIM-SM protocol is the multicast routing protocol that uses the underlying unicast routing information base to build unidirectional shared trees to group members rooted at the RP per group, and creates shortest-path trees (SPT) per source. The router forwards multicast packets along these trees. PIM-SSM does not require RP and only supports SPT.

PIM over IPv6 uses the IPv6 unicast routing table for reverse path information about source and RP.

### Note

IPv4 and IPv6 multicast streams cannot interact. To configure an end-to-end PIM IPv6 network, all nodes from sender to receiver must support PIM IPv6.

### *PIM-SM over IPv6 features*

The following are features of PIM-SM over IPv6:

- Compliant with RFC 4601
- Multicast networks built by PIM IPv4 and PIM IPv6 do not overlap
- IPv4 receiver hosts cannot receive data from IPv6 source hosts and vice versa
- IPv4 and IPv6 multicast protocols can be enabled at the same time on the same VLAN
- PIM IPv4 and PIM IPv6 can be configured on the same VLAN
- PIM IPv4 and PIM IPv6 must be configured separately
- Supports sparse and ssm modes

### *Operational note for PIM-SM over IPv6*

The following are operational considerations when deploying PIM-SM over IPv6:

- You can only configure PIM-SM if you configure the `spbm_config_mode` boot flag to false
- The following HELLO messages options are not supported:
  - GENid
  - DR priority
  - LAN-PRUNE delay
  - T-bit
- IPv6 multicast is not supported over SPBM
- IPv6 multicast routing is not virtualized, it is supported only on GRT
- IPv6 multicast configuration on SMLT VLAN is not supported. vIST peers cannot form PIM-SM over IPv6 neighbor adjacencies. Senders and receivers on the vIST peers (SMLT and non-SMLT) cannot communicate. MLT and LACP is supported.
- The switch does not support the following features:
  - Static entries
  - Bootstrap message (BSR)
  - Anycast RP
  - Virtual PIM neighbors
  - Fast join prune
  - Software forwarding
  - Passive PIM interfaces
  - IP mroute stream limit
  - Bidirectional PIM
  - Multicast Border Router (PMBR)
  - VRF support for PIM (GRT only)
  - IGMP and PIM mtrace capability
  - High Availability (HA)

### *IPv6 interface multiple addresses*

IPv6 interfaces can have multiple addresses associated with them. A router running PIM for IPv6 has a network unique domain-wide reachable IPv6 VLAN address used for multiple hop messages. A link local address is associated with the VLAN. The link local address is a non-routable unicast IPv6 address used as source address (primary interface address) for transmitting different types of PIM messages.

## IP multicast configuration and DvR

Configuration of IPv4 multicast is supported only on the Controller nodes of a DvR domain. You cannot configure IP multicast on the DvR Leaf nodes. The following sections detail IP multicast configuration support on DvR enabled nodes (Controllers or Leaf nodes).

For more information on DvR, see [Distributed Virtual Routing \(DvR\) Fundamentals](#) on page 681.

*Multicast configuration that is pushed from DvR Controllers to DvR Leaf nodes*

When you perform the following multicast configuration on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- IP multicast over Fabric Connect
- IGMP Layer 2 Querier parameters, such as the IGMP Layer 2 Querier version, query interval, query maximum response time, robustness value, last member query interval and compatibility mode
- Enabling and clearing of multicast route statistics

*Multicast configuration that is not supported on DvR enabled Layer 2 VSNs*

- IGMP Snooping on DvR enabled Layer 2 VSNs
- SPB-PIM Gateway

For more information on SPB-PIM Gateway, see [SPB-PIM Gateway configuration](#) on page 3172.

## IP multicast basic configuration using CLI

---

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts subscribe to multicast services using a host membership protocol. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

## Configuring IP multicast in SMLT topologies

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

### Before You Begin

SPBM must not be enabled on the vIST peers or any router that participates in the PIM network.

### About This Task

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable the boot flag:

```
no boot config flags spbm-config-mode
```

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-mode
is changed to disable, removes SPBM configurations from the
configuration file.
```

3. Save the configuration and, then reboot the switch.

### Important

Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.

4. Create the vIST VLAN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

```
interface vlan <1-4059>
```

```
ip address <A.B.C.D/X>
```

5. Configure the vIST peer address and VLAN:

```
virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
```

6. Configure the SMLT MLT:

```
mlt <1-512> enable
```

```
mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

```
interface mlt <1-512>
```

```
smlt
```

- Configure the vIST MLT:

```
mlt <1-512> enable

mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}

mlt <1-512> encapsulation dot1q

interface mlt <1-512>

virtual-ist enable
```

#### Note

The **virtual-ist enable** command enables Simplified vIST and is only available when the **spbm-config-mode** boot flag is disabled.

- Create a customer VLAN and assign the SMLT MLT ID:

```
vlan create <2-4059>

vlan mlt <1-4059> <1-512>

interface vlan <1-4059>

ip address <A.B.C.D/X>
```

- Configure PIM or IGMP Snooping on the SMLT VLAN:

```
interface vlan <1-4059>

ip pim enable or ip igmp snooping
```

- Configure PIM on the vIST VLAN:

```
interface vlan <1-4059>

ip pim enable
```

- Enable PIM globally:

```
ip pim enable
```

#### Note

You can also configure other global PIM attributes such as **ip pim join-prune-interval**.

### Example

```
enable
configure terminal
no boot config flags spbm-config-mode
```

Save the configuration and reboot the switch.

```
virtual-ist peer-ip 198.51.100.0 vlan 50

mlt 3 enable
mlt 3 member 1/35,1/36
interface mlt 3
smlt
```

```
exit
mlt 5 enable
mlt 5 member 2/15,2/17
mlt 5 encapsulation dot1q
interface mlt 5
virtual-ist enable
exit
vlan create 50 type port-mstprstp 0
interface vlan 50
ip address 198.51.100.0 255.255.255.0 1
exit
vlan create 100
vlan mlt 100 3
interface vlan 100
ip address 192.0.2.0 255.255.255.0 2
exit
interface vlan 100
ip pim enable (or ip igmp snooping)
exit
interface vlan 50
ip pim enable
exit
ip pim enable
```

## Configuring PIM-SM globally

Configure PIM-SM to enable or disable PIM-SM globally on the switch and change default global parameters.

### About This Task

PIM-SM is the default mode so you do not need to configure the PIM mode.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable PIM-SM:  
`ip pim enable`
3. Configure the time between bootstrap messages:  
`ip pim bootstrap-period <5-32757>`
4. Configure the timeout to discard data:  
`ip pim disc-data-timeout <5-65535>`
5. Enable the fast join prune interval:  
`ip pim fast-joinprune`
6. Configure the forward cache timeout:  
`ip pim fwd-cache-timeout <10-86400>`
7. Configure the interval for join and prune messages:  
`ip pim join-prune-interval <1-18724>`
8. Specify how long to suppress register messages:  
`ip pim register-suppression-timeout <6-65535>`

- Specify how often the candidate-redirect point (C-RP) sends advertisements:

```
ip pim rp-c-adv-timeout <5-26214>
```

- Configure the polling interval for the routing table manager (RTM):

```
ip pim unicast-route-change-timeout <2-65535>
```

- Verify the configuration changes:

```
show ip pim
```

### Example

Verify the configuration changes:

```
Switch:1(config)#show ip pim
```

```

## Enabling or disabling IPv6 PIM-SM globally

### About This Task

Use this procedure to enable or disable IPv6 PIM-SM globally. By default, IPv6 PIM-SM is disabled.

### Procedure

- Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
- Enable IPv6 PIM-SM:
 

```
ipv6 pim enable
```
- Disable IPv6 PIM-SM:
 

```
no ipv6 pim enable
```
- Set IPv6 PIM-SM status to default:
 

```
default ipv6 pim enable
```

## Configuring global IPv6 PIM-SM properties

## About This Task

Use this procedure to configure the global IPv6 PIM-SM parameters on the switch.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the timeout to discard data:  

```
ipv6 pim disc-data-timeout <5-65535>
```
3. Configure the forward cache timeout:  

```
ipv6 pim fwd-cache-timeout <10-86400>
```
4. Configure the interval for join and prune messages:  

```
ipv6 pim join-prune-interval <1-18724>
```
5. Specify how long to suppress register messages:  

```
ipv6 pim register-suppression-timeout <10-65535>
```
6. Configure the polling interval for the routing table manager (RTM):  

```
ipv6 pim unicast-route-change-timeout <2-65535>
```
7. Configure the PIM mode:  

```
ipv6 pim mode <sparse> <ssm>
```
8. Verify the configuration changes:  

```
show ipv6 pim
```

## Example

Verify the configuration changes:

```
Switch:1(config)#show ipv6 pim
=====
                          Pim General Group - GlobalRouter
=====
PimStat           : disabled
Mode              : sparse
StaticRP          : disabled
FwdCacheTimeout  : 210
DiscDataTimeout  : 60
RegSupprTimeout  : 60
UniRouteChangeTimeout : 5
JoinPruneInt     : 60
```

### Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

| Variable                                | Value                                                                                                                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| disc-data-timeout <5-65535>             | Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message.<br>The default value is 60. |
| enable                                  | Enables PIM globally on the switch.<br>The default is disabled.                                                                                                                                                                                                                                    |
| fwd-cache-timeout <10-86400>            | Specifies the forward cache timeout value.<br>The default value is 120.                                                                                                                                                                                                                            |
| join-prune-interval <1-18724>           | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The default value is 60.                                                                                                                                            |
| mode <sparse> <ssm>                     | Configures PIM mode on the switch.<br>The default value is sparse.                                                                                                                                                                                                                                 |
| register-suppression-timeout <10-65535> | Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP.<br>The default value is 60.                                                                                       |
| static-rp                               | Add new static-rp entries and enable static-rp.                                                                                                                                                                                                                                                    |
| unicast-route-change-timeout <2-65535>  | Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM.<br>The default value is 5.                                                                                                                                                             |

## Configure PIM on a VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you configure PIM on a VLAN.
- The interface uses a valid IP address.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Create a PIM interface on a VLAN:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

5. Verify the configuration:

```
show ip pim interface vlan [<1-4059>]
```

### Example

Configure the interval for join and prune messages, the time between hello messages, and then verify the configuration.

```
Switch:1(config-if)#ip pim join-prune-interval 60
Switch:1(config-if)#ip pim hello-interval 30
Switch:1>show ip pim interface vlan 10
=====
Vlan Ip Pim
=====
VLAN-ID    PIM-ENABLE MODE    HELLOINT  JPINT    CBSRPREF    INTF TYPE
-----
10         enable    sparse    30        60        -1 (disabled) active
```

## Configuring PIM on a port

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you configure it on an interface.
- The interface uses a valid IP address.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port:

```
ip pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ip pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ip pim hello-interval <0-18724>
```

### Example

Configure the interval for join and prune messages and the time between hello messages:

```
Switch(config-if)#ip pim join-prune-interval 60
Switch(config-if)#ip pim hello-interval 30
```

## Configuring IPv6 PIM on a port or VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- Enable IPv6 interface.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port or VLAN:

```
ipv6 pim enable
```

This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

```
ipv6 pim join-prune-interval <1-18724>
```

4. Configure the time between hello messages:

```
ipv6 pim hello-interval <0-18724>
```

### Example

```
Switch:1(config-if)#ipv6 pim join-prune-interval 60
Switch:1(config-if)#ipv6 pim hello-interval 30
```

### Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

| Variable                             | Value                                                                                                                                                           |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>hello-interval</i> <0-18724>      | Specifies the duration in seconds before the PIM router sends out the next hello message to neighboring switches.<br>The default value is 30 seconds.           |
| <i>join-prune-interval</i> <1-18724> | Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors.<br>The default value is 60 seconds. |

## Configuring SSM globally

Configure SSM to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Before You Begin

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using CLI](#) on page 2784. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2451.
- Enable PIM globally.

### About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure PIM-SSM:
 

```
ip pim mode ssm
```

## Configuring IPv6 SSM globally

Configure IPv6 SSM to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 2794. For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2492.

- Enable IPv6 PIM globally.

### About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model which requires only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure IPv6 PIM-SSM:

```
ipv6 pim mode ssm
```

## Configuring IGMP on a VLAN

Configure IGMP for each interface to change default multicasting operations.

### Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

For more information on DvR, see .

### Before You Begin

- For PIM interfaces, you must enable PIM globally and on the VLAN. For snooping interfaces, do not enable PIM.

## Procedure

1. Enter VLAN Interface Configuration mode:  

```
enable  
  
configure terminal  
  
interface vlan <1-4059>
```
2. Enable IGMP v2-v3 compatibility mode:  

```
ip igmp compatibility-mode
```
3. Configure the system to downgrade the version of IGMP:  

```
ip igmp dynamic-downgrade-version
```
4. Configure message intervals and response times:  

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]  
[query-max-response <0-255>]
```
5. Configure expected packet loss and IGMP version:  

```
ip igmp robust-value <2-255> [version <1-3>]
```
6. Add multicast router ports:  

```
ip igmp mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
7. Enable proxy-snoop:  

```
ip igmp proxy
```
8. Enable router alert:  

```
ip igmp router-alert
```
9. Enable snooping:  

```
ip igmp snooping
```
10. Enable SSM-snooping:  

```
ip igmp ssm-snoop
```

## Example

Enter VLAN Interface Configuration Mode for VLAN 10:

```
Switch:1(config)# interface vlan 10
```

Configure the last member query interval to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp last-member-query-interval 15
```

Configure the query interval to 100 seconds.

```
Switch:1(config-if)# ip igmp query-interval 100
```

Configure the query maximum response time to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp query-max-response 15
```

Configure the robustness value to 4 seconds.

```
Switch:1(config-if)# ip igmp robust-value 4
```

Enable proxy snoop for the VLAN.

```
Switch:1(config-if)# ip igmp proxy
```

Enable snoop for the VLAN.

```
Switch:1(config-if)# ip igmp snooping
```

Enable support for SSM on the snoop interface.

```
Switch:1(config-if)# ip igmp ssm-snoop
```

Enable IGMPv3.

```
Switch:1(config-if)# ip igmp version 3
```

### Variable Definitions

Use the definitions in the following table to use the **ip igmp** command.

| Variable                                                                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list WORD&lt;1-64&gt;<br/>{A.B.C.D/X} &lt;eny-tx deny-rx <br/>deny-both allow-only-tx <br/>allow-only-rx allow-only-<br/>both&gt;</i> | Specifies the name of the access list from 1-64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                |
| <i>compatibility-mode</i>                                                                                                                       | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br>default ip igmp compatibility-mode<br>, or use the no option to disable compatibility mode:<br>no ip igmp compatibility-mode                                                                                                                                                                                                                                    |
| <i>dynamic-downgrade-version</i>                                                                                                                | Configures the version of IGMP to handle older query messages if the system downgrades. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br>default ip igmp dynamic-downgrade-version<br>or use the no option to disable downgrade:<br>no ip igmp dynamic-downgrade-version |
| <i>igmpv3-explicit-host-tracking</i>                                                                                                            | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>immediate-leave</i>                                                                                                                          | Enables fast leave on a VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Variable                                                                                                                                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                                                                           | Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                     |
| <code>last-member-query-interval &lt;0-255&gt;</code>                                                                                                                                                | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3-10 (equal to 0.3 - 1.0 seconds). |
| <code>mrdisc [maxadvertinterval &lt;2-180&gt;] [maxinitadvertinterval &lt;2-180&gt;] [maxinitadvertisements &lt;2-15&gt;] [minadvertinterval &lt;3-180&gt;] [neighdeadinterval &lt;2-180&gt;]</code> | Configures the multicast router discovery options to enable the automatic discovery of multicast capable routers. The default parameter values are: <ul style="list-style-type: none"> <li>• maxadvertinterval: 20 seconds</li> <li>• maxinitadvertinterval: 2 seconds</li> <li>• maxinitadvertisements: 3</li> <li>• minadvertinterval: 15 seconds</li> <li>• neighdeadinterval: 60 seconds</li> </ul>                                                             |
| <code>mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                                                                                           | Adds multicast router ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |
| <code>proxy</code>                                                                                                                                                                                   | Activates the proxy-snoop option globally for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>query-interval &lt;1-65535&gt;</code>                                                                                                                                                          | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.                                                                                                                                                                                                                                                                                                                                             |
| <code>query-max-response &lt;0-255&gt;</code>                                                                                                                                                        | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). <p><b>Important:</b><br/>You must configure this value lower than the query-interval.</p>                                                                                      |
| <code>robust-value &lt;2-255&gt;</code>                                                                                                                                                              | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.                                                                                                                                                                                                                                                                                                           |

| Variable                                                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>router-alert</code>                                                                                                | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <code>snoop-querier</code>                                                                                               | Enables the IGMP Layer 2 Querier feature on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>snoop-querier-addr {A.B.C.D}</code>                                                                                | Specifies the IGMP Layer 2 Querier source IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>snooping</code>                                                                                                    | Activates the snoop option for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>ssm-snoop</code>                                                                                                   | Activates support for PIM-SSM on the snoop interface.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>static-group {A.B.C.D} {A.B.C.D} {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static blocked]</code>     | Configures IGMP static members to add members to a snoop group.<br><code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group.<br><code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry.<br><code>[static blocked]</code> configures the route to static or blocked.                                                                                                                                  |
| <code>stream-limit stream-limit-max-streams &lt;0-65535&gt;</code>                                                       | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |
| <code>stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams &lt;0-65535&gt;</code> | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4.                                                                                                                                                                                                                                                                                                  |
| <code>version &lt;1-3&gt;</code>                                                                                         | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).                                                                                                                                                                                                                                                                                                                        |

## Configuring IGMP ports

Configure IGMP for each interface to change default multicasting operations.

### Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

For more information on DvR, see .

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IGMP v2-v3 compatibility mode:

```
ip igmp compatibility-mode
```

3. Configure the system to downgrade the version of IGMP:

```
ip igmp dynamic-downgrade-version
```

4. Configure message intervals and response times:

```
ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]
[query-max-response <0-255>]
```

5. Configure expected packet loss and IGMP version:

```
ip igmp robust-value <2-255> [version <1-3>]
```

6. Configure IGMP for a specific port:

```
ip igmp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. Enable router alert:

```
ip igmp router-alert
```

## Example

Configure message intervals and response times:

```
Switch(config-if)#ip igmp last-member-query-interval 30 query-interval 60 query-max-response 90
```

Configure expected packet loss and IGMP version:

```
Switch(config-if)#ip igmp robust-value 2 version 3
```

Configure IGMP for a specific port:

```
Switch(config-if)#ip igmp port 1/4
```

Enable router alert:

```
Switch(config-if)#ip igmp router-alert
```

## Variable definitions

Use the definitions in the following table to use the **ip igmp** command.

| Variable                                                                                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list WORD&lt;1-64&gt;<br/>{A.B.C.D/X} &lt;eny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both&gt;</i> | Specifies the name of the access list from 1–64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                |
| <i>compatibility-mode</i>                                                                                                        | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br>default ip igmp compatibility-mode<br>, or use the no option to disable compatibility mode:<br>no ip igmp compatibility-mode                                                                                                                                                                                                                                    |
| <i>dynamic-downgrade-version</i>                                                                                                 | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br>default ip igmp dynamic-downgrade-version<br>or use the no option to disable downgrade:<br>no ip igmp dynamic-downgrade-version |
| <i>igmpv3-explicit-host-tracking</i>                                                                                             | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>immediate-leave</i>                                                                                                           | Enables fast leave on a port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Variable                                                                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>last-member-query-interval</code><br><0-255>                                                      | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3-10 (equal to 0.3 - 1.0 seconds).                     |
| <code>port {slot/port[/sub-port]</code><br><code>[-slot/port[/sub-port]]</code><br><code>[,...]}</code> | Configures IGMP for a specific port.<br>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                      |
| <code>query-interval</code> <1-65535>                                                                   | Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.                                                                                                                                                                                                                                                                                                                                                                    |
| <code>query-max-response</code> <0-255>                                                                 | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the query-interval.                                                                                                              |
| <code>robust-value</code> <2-255>                                                                       | Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.                                                                                                                                                                                                                                                                                                                                  |
| <code>router-alert</code>                                                                               | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul> |
| <code>stream-limit stream-limit-max-streams</code> <0-65535>                                            | Configures multicast stream limitation on a port to limit the number of concurrent multicast streams on the port. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |
| <code>version</code> <1-3>                                                                              | Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).                                                                                                                                                                                                                                                                                                                        |

## Configuring IGMP on a VRF

You configure IGMP on a VRF instance the same way you configure IGMP for the Global Router, except that you must use VRF Router Configuration mode.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Enable SSM dynamic learning:

```
ip igmp ssm dynamic-learning
```

3. Configure the range group:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter y to continue.

4. Enable the SSM map table for all static entries:

```
ip igmp ssm-map all
```

5. Create a static entry for a specific group:

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

6. Enable the generation of IGMP traps:

```
ip igmp generate-trap
```

7. Enable the generation of IGMP log messages:

```
ip igmp generate-log
```

8. Configure the fast leave mode:

```
ip igmp immediate-leave-mode {multiple-user|one-user}
```

### Example

For the VRF Red context, configure a new IP multicast group address and create an SSM map table entry for the multicast group and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ip igmp ssm group-range 232.1.1.10/32
```

```
WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(router-vrf)#ip igmp ssm-map 232.1.1.10 192.32.99.151
Switch:1(router-vrf)#ip igmp ssm-map all
```

### Variable definitions

Use the definitions in the following table to use the `ip igmp` command on a VRF.

| Variable                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>generate-log</code>                                  | Enables the generation of IGMP log messages. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>generate-trap</code>                                 | Enables the generation of IGMP traps. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>immediate-leave-mode {multiple-user one-user}</code> | <ul style="list-style-type: none"> <li>multiple-user: Removes (from the group) the IGMP member who sent the leave message. The default is multiple-user.</li> <li>one-user: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member.</li> </ul>                                                                                                                                                                                        |
| <code>ssm dynamic-learning</code>                          | Enables dynamic learning from IGMPv3 reports. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>ssm group-range {A.B.C.D/X}</code>                   | Changes the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0.                                                                                                                       |
| <code>ssm-map &lt;all   {A.B.C.D} {A.B.C.D} enable</code>  | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group. Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

## Viewing IP Multicast Threshold Exceeded Statistics

This procedure only applies to VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

```
show sys stats ipmc-threshold-exceeded-cnt
```

### Example

```
Switch:1>show sys stats ipmc-threshold-exceeded-cnt
SourceGroupThresholdExceeded : 7372
EgressStreamThresholdExceeded : 7331
```

## IP multicast basic configuration using EDM

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts use a host membership protocol to subscribe to multicast services. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

## Configuring multicast on the switch

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

### Before You Begin

SPBM must not be enabled on the vIST peers or any router participating in the PIM network.

### Procedure

1. In the navigation pane, expand the **Configuration > Edit > Chassis** folders.
2. Click the **Boot Config** tab.
3. Clear the **EnableSpbmConfigMode** to disable the boot flag.

The system responds with these messages:

```
Warning: Please save the configuration and reboot the switch for this
to take effect.
```

```
Warning: Please carefully save your configuration file before
rebooting the switch. Saving configuration file when spbm-config-mode
is changed to disable, removes SPBM configurations from the
configuration file.
```

4. Click **Apply**.
5. Save the configuration, and then reboot the switch.

#### Important

Any change to the **EnableSpbmConfigMode** boot flag requires a reboot for the change to take effect.

6. Configure the *SMLT* MLT:
  - a. Expand the following folders: **Configuration > VLAN > MLT/LACP**.
  - b. Click the **MultiLink/LACP Trunks** tab.
  - c. Click **Insert**.
  - d. In the **Id** box, type the ID number of the MLT.
  - e. In the **PortMembers** box, click the (...) button.
  - f. In the **Port Editor: PortMembers** dialog box, select the desired ports.

- g. Click **Ok**
- h. Click **Insert**.

The switch adds the SMLT MLT to the MultiLink/LACP Trunks tab in the MLT\_LACP box.

7. Configure the *vIST* MLT:
  - a. Repeat steps 6a to 6g to configure the MLT.
  - b. Click **MitVistEnable** to enable Simplified vIST.

#### Note

The **MitVistEnable** field enables Simplified vIST and is only available when the **EnableSpbmConfigMode** boot flag is disabled.

- c. Click **Insert**.
8. Create the *vIST* VLAN:
  - a. Expand the following folders: **Configuration > VLAN > VLANs**
  - b. In the **Basic** tab, click **Insert**.
  - c. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
  - d. In the **MstpInstance** box, click the down arrow, and then choose an MSTI instance from the list.
  - e. In the **Type** box, select **byPort**.
  - f. Click **OK**.
  - g. Click **Insert**.
  - h. Select the vIST VLAN from the list of VLANs, and then click **IP**.
  - i. Click **Insert**.
  - j. Configure the IP address for the vIST VLAN.
9. Repeat Step 8 to create an *SMLT* VLAN and assign the SMLT MLT ID to it. Do not use the vIST MLT ID.
10. Configure PIM or IGMP Snooping on the *SMLT* VLAN:
  - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
  - b. To enable IGMP Snooping, select the SMLT VLAN from the list of VLANs and click **IP > IGMP**. Select **SnoopEnable** and click **Apply**.
11. Configure PIM on the *SMLT* VLAN:
  - a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP > PIM**. Select **Enable** and click **Apply**.
12. Click **IP > PIM > Globals** to enable PIM globally.
13. Select the **Enable** check box, and then click **Apply**.

## Enabling PIM-SM globally

Enable PIM-SM to offer multicasting services. After you enable PIM-SM globally and on a particular interface, the IGMP parameters take effect.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Globals** tab.

4. Click **sm** (sparse mode).
5. Select the **Enable** check box.
6. Click **Apply**.

### **Globals** field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mode</b>               | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).                                                                                                                                                                                                                                                                                                                                    |
| <b>Enable</b>             | Enables or disables PIM.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>JoinPruneInterval</b>  | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1-18724 and the default is 60 seconds.                                                                                                                                                                                                                                         |
| <b>RegisterSuppTimer</b>  | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 6-65535 and the default is 60 seconds.                                                                                                                                                               |
| <b>UniRouteChgTimeOut</b> | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2-65535 and the default is 5 seconds.<br><br><b>Important:</b><br>If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| <b>DiscardDataTimeOut</b> | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5-65535 and the default is 60 seconds.                                                                                                                           |
| <b>CRPADVTimeOut</b>      | Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR). The range is from 5-26214 and the default is 60 seconds.                                                                                                                          |
| <b>BootStrapPeriod</b>    | Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages. The range is from 5-32757 and the default is 60 seconds.                                                                                                                                                                                                                                                                    |
| <b>StaticRP</b>           | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.                                                                                                                                                                                                                      |
| <b>FwdCacheTimeOut</b>    | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10-86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.                                                                                                                                          |
| <b>FastJoinPrune</b>      | Enables or disables the PIM fast join prune feature.                                                                                                                                                                                                                                                                                                                                                                               |

## Enabling IPv6 PIM-SM globally

Enable IPv6 PIM-SM to offer multicasting services. After you enable IPv6 PIM-SM globally and on a particular interface, the MLD parameters take effect.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select the **Enable** check box.
5. Click **sm** (sparse mode).
6. Click **Apply**.

### *Globals* field descriptions

Use the descriptions in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>             | Enables or disables PIM.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Mode</b>               | Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).                                                                                                                                                                                                                                                                                                                                    |
| <b>RegisterSuppTimer</b>  | Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 10–65535 and the default is 60 seconds.                                                                                                                                                              |
| <b>UniRouteChgTimeOut</b> | Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds.<br><br><b>Important:</b><br>If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch. |
| <b>DiscardDataTimeOut</b> | Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds.                                                                                                                           |
| <b>StaticRP</b>           | Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.                                                                                                                                                                                                                      |
| <b>FwdCacheTimeOut</b>    | Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.                                                                                                                                          |
| <b>JoinPruneInterval</b>  | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1–18724 and the default is 60 seconds.                                                                                                                                                                                                                                         |

## Enabling PIM on a port

Enable PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you enable it on an interface.
- The interface uses a valid IP address.

### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Select the **Enable** check box.
6. Click **Apply**.

### *PIM* field descriptions

Use the data in the following table to use the **PIM** tab.

| Name                     | Description                                                                                                                                                                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>            | Enables (true) or disables (false) PIM for the specified port.                                                                                                                                                                                                     |
| <b>Mode</b>              | Displays the mode currently running on the routing switch.                                                                                                                                                                                                         |
| <b>IntfType</b>          | Indicates the interface type as active or passive.                                                                                                                                                                                                                 |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds.                                                                                    |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds.                                                                         |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a candidate BSR (C-BSR). The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

## Enabling IPv6 PIM on a port

Enable IPv6 PIM for each interface to enable the interface to perform multicasting operations.

### About This Task

You can also right-click the port and use the **Edit IPv6** shortcut menu to reach this same tab.

### Before You Begin

- You must enable IPv6 interface before you enable PIM on a port.

## Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IPv6**.
4. Click the **PIM** tab.
5. Select **Enable**.
6. Click **Apply**.

### *PIM* field descriptions

Use the data in the following table to use the **PIM** tab.

| Name                     | Description                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>           | Specifies the IPv6 address of the PIM interface.                                                                                                                                           |
| <b>NetMask</b>           | Specifies the network mask for the IPv6 address of the PIM interface.                                                                                                                      |
| <b>Enable</b>            | Enables (true) or disables (false) PIM for the specified port.                                                                                                                             |
| <b>Mode</b>              | Displays the mode currently running on the routing switch.                                                                                                                                 |
| <b>DR</b>                | Specifies the designated router on this PIM interface.                                                                                                                                     |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds.            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds. |
| <b>OperState</b>         | Specifies the current operational state of this PIM interface.                                                                                                                             |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                           |

## Enabling SSM globally

Enable Source Specific Multicast (SSM) to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

### Before You Begin

- Configure a unicast protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see [RIP configuration using EDM](#) on page 2799. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2517.

- Enable PIM globally.

**Important**

After you enable PIM in SSM mode, the IGMP parameters take effect. To take full advantage of SSM, enable IGMPv3 if hosts that attach to the switch run IGMPv3 or configure the SSM table.

**About This Task**

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

**Procedure**

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Click **ssm** (source specific multicast).
5. Select the **Enable** check box.
6. Click **Apply**.

The system displays the following message:

```
Are you sure you want to change the PIM mode? The traffic will not be
stopped immediately. All Static Source Group entries in the SSM range
will be deleted. Do you wish to continue?
```

7. Click **Yes**.

## Enabling IPv6 SSM globally

Enable Source Specific Multicast (SSM) to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the IPv6 PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

**Before You Begin**

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using EDM](#) on page 2809. For more information about OSPFv3, [OSPFv3 Configuration using EDM](#) on page 2550.

- Enable PIM globally.

**Important**

After you enable IPv6 PIM in SSM mode, the MLD parameters take effect. To take full advantage of SSM, enable MLDv2 if hosts that attach to the switch run MLDv2.

## About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select the **Enable** check box.
5. Click **ssm** (source specific multicast).
6. Click **Apply**.

The system displays the following message:

```
Warning: RP entries in the SSM range will be deleted
```

```
Do you wish to continue? (y/n)?
```

7. Click **Yes**.

## Enabling PIM on a VLAN interface

Configure PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable PIM globally before you enable it on an interface.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Select the **Enable** check box.
8. Click **Apply**.

### *PIM* field descriptions

Use the descriptions in the following table to use the **PIM** tab.

| Name            | Description                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>   | Enables (true) or disables (false) PIM.                                                                                      |
| <b>Mode</b>     | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field. |
| <b>IntfType</b> | Specifies the type of interface: active or passive.                                                                          |

| Name                     | Description                                                                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724.                                                                            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724.                                                                 |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. The range is -1-255. |

## Enabling IPv6 PIM on a VLAN interface

Configure IPv6 PIM for each interface to enable the interface to perform multicasting operations.

### Before You Begin

- You must enable IPv6 PIM globally before you enable it on an interface.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Basic** tab.
- Select the VLAN ID that you want to configure with PIM.
- Click **IPv6**.
- Click the **PIM** tab.
- Select the **Enable** check box.
- Click **Apply**.

### *PIM* field descriptions

Use the descriptions in the following table to use the **PIM** tab.

| Name                 | Description                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>       | Specifies the interface index for PIM.                                                                                                                                  |
| <b>Address</b>       | Specifies the IPv6 address of the PIM interface.                                                                                                                        |
| <b>Netmask</b>       | Specifies the network mask for the IPv6 address of the PIM interface.                                                                                                   |
| <b>Enable</b>        | Enables (true) or disables (false) PIM.                                                                                                                                 |
| <b>Mode</b>          | Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field.                                            |
| <b>DR</b>            | Specifies the designated router on this PIM interface.                                                                                                                  |
| <b>HelloInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724. |

| Name                     | Description                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724. |
| <b>OperState</b>         | Specifies the current operational state of this PIM interface.                                                                                                                     |
| <b>Type</b>              | Specifies the type of interface.                                                                                                                                                   |

## Configuring IGMP parameters on a port

Configure IGMP for each interface to enable the interface to perform multicasting operations.

### Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **IGMP** tab.
5. Edit the appropriate values.

#### Note

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

For information on DvR, see .

#### Note

To use the fast leave feature on IGMP, enable explicit-host-tracking.

6. Click **Apply**.

**IGMP** field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>            | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The range is from 1–65535 and the default is 125.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>QueryMaxResponseTime</b>     | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval.                                                                                                                                                                                                      |
| <b>Robustness</b>               | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                      |
| <b>LastMembQueryIntvl</b>       | Configures the maximum response time (in 1/10 seconds) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, Use values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>SnoopEnable</b>              | Enables snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SsmSnoopEnable</b>           | Enables SSM snoop. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ProxySnoopEnable</b>         | Enables proxy snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Version</b>                  | Configures the version of IGMP (1, 2 or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>FastLeaveEnable</b>          | Enables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams this port permits. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Current Number Of Stream</b> | Displays the current number of streams. This variable is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FastLeavePortMembers</b>     | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopMRouterPorts</b>          | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| <b>RouterAlertEnable</b>          | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br>To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                    |
| <b>DynamicDowngradeEnable</b>     | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.                                                                                                      |
| <b>CompatibilityModeEnable</b>    | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.                                                                                                                                                                                                                                                                                                                                                              |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                       |

## Configuring IGMP parameters on a VLAN

Configure IGMP for each interface to enable the interface to perform multicasting operations.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Select **IGMP**.

7. Configure the relevant variables.

#### Note

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

Configuration of IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

8. Click **Apply**.

#### **IGMP** field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1-65535 and the default is 125.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1.<br>Smaller values allow a router to prune groups faster. The range is from 0-255 and the default is 100 tenths of a second (equal to 10 seconds.)<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval.                                                                                                                                                                                                             |
| <b>Robustness</b>           | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2-255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                                |
| <b>LastMembQueryIntvl</b>   | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0-255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopEnable</b>                | Enables snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SsmSnoopEnable</b>             | Enables SSM snoop. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ProxySnoopEnable</b>           | Enables proxy snoop on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Version</b>                    | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                                                                                                                                    |
| <b>FastLeaveEnable</b>            | Enables or disables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>StreamLimitEnable</b>          | Enables or disables stream limitation on this VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Maximum Number Of Stream</b>   | Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Current Number Of Stream</b>   | Displays the current number of streams. This value is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>FastLeavePortMembers</b>       | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SnoopMRouterPorts</b>          | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this field only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| <b>RouterAlertEnable</b>          | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br>To maximize network performance, configure this parameter according to the version of IGMP currently in use: <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                 |
| <b>DynamicDowngradeEnable</b>     | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.                                                                                                   |
| <b>CompatibilityModeEnable</b>    | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.                                                                                                                                                                                                                                                                                                                                                           |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                    |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopQuerierEnable</b> | Enables snoop querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups. Enable Layer 2 Querier on only one node in the VLAN. |
| <b>SnoopQuerierAddr</b>   | Specifies the pseudo IP address of the IGMP snoop querier. The default IP address is 0.0.0.0.                                                                                                                                                                                                                                                                                                                                                                           |

## Multicast Listener Discovery

**Table 121: Multicast Listener Discovery product support**

| Feature                            | Product         | Release introduced |
|------------------------------------|-----------------|--------------------|
| Multicast Listener Discovery (MLD) | 5420 Series     | VOSS 8.4           |
|                                    | 5520 Series     | VOSS 8.2.5         |
|                                    | VSP 4450 Series | VOSS 5.1           |
|                                    | VSP 4900 Series | VOSS 8.1           |
|                                    | VSP 7200 Series | VOSS 5.1           |
|                                    | VSP 7400 Series | VOSS 8.0           |
|                                    | VSP 8200 Series | VOSS 5.1           |
|                                    | VSP 8400 Series | VOSS 5.1           |
|                                    | VSP 8600 Series | Not Supported      |
|                                    | XA1400 Series   | Not Supported      |

### MLD Fundamentals

MLD is an asymmetric protocol. It specifies separate behaviors for multicast address listeners (that is, hosts or routers that listen to multicast packets) and multicast routers. Each multicast router learns, for each directly attached link, which multicast addresses and which sources have listeners on that link. The information that MLD gathers is provided to the multicast routing protocols that the router uses. This information ensures that multicast packets arrive at all links where listeners require such packets.

A multicast router can itself be a listener of one or more multicast addresses; that is, the router performs both the multicast router role and the multicast address listener part of the protocol. The router collects the multicast listener information needed by the multicast routing protocol and informs itself and other neighboring multicast routers of the listening state.

IPv6 routers use MLD to discover:

- The presence of multicast listeners on directly attached links
- Multicast addresses required by neighboring nodes

### MLD versions

The purpose of the MLD protocol in the IPv6 multicast architecture is to allow an IPv6 router to discover the presence of multicast listeners on directly-attached links and to discover which multicast addresses are of interest to neighboring nodes. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4. The MLD implementation described in this document is based on the MLDv2 standard, which is a backward-compatible update to the MLDv1 standard.

There are three versions of IGMP, and two versions of MLD. IGMPv2 is equivalent in function to MLDv1 and IGMPv3 is equivalent to MLDv2.

### MLD Querier

MLD Querier is similar to IGMP querier. A multicast query router communicates with hosts on a local network by sending MLD queries. This router periodically sends a general query message to each local network of the router. This is standard multicast behavior.

#### Note

Queries are sent only if PIM is enabled globally and on the interface. PIM and snooping cannot be enabled at the same time.

Each VLAN using MLD multicast must have a router performing multicast queries. Networks with no stand-alone devices currently have no capability for implementing the pruning of multicast traffic. A dedicated querier must be available on the network.

There are several behavioral differences between a traditional query router and a switch or stack using the MLD Querier functionality. The following are the differences:

- There is no election process. When a switch or stack restarts, queries are sent as part of MLD startup. This process stops other devices from sending queries while they detect the new device starting up. The last active device sending queries on the network is the active one. This is not the case with Layer 3 MLD behavior.
- If the current active device stops sending queries, a timeout period must elapse before another device takes over. This can result in an ageout of groups, and subsequent flooding, before a new query is sent and the pruning process restarts. This occurs only during the transition between active query devices. Once the new device is established, queries are sent as configured in the Query Interval and Robust Values fields.
- Multiple active query devices are not supported. Enabling multiple devices establishes one active device and other devices listening to take over should the active device fail.

The querier version is determined by the received query version and establishes the interface operational version. By default, the interface operational version is MLDv1. If the interface operational version is downgraded from MLDv2 to MLDv1 (when operational version is MLDv2 and a MLDv1 query is received), then all MLDv2 listeners (registered by MLDv2 reports) are removed and all incoming MLDv2 reports are dropped.

### MLD snooping

MLD snooping is an IPv6 multicast constraining mechanism running on Layer 2 devices. When MLD snooping is enabled on a VLAN, the switch examines the MLD messages between hosts and multicast routers and learns which hosts are interested in receiving traffic for a multicast group. Based on the

learning, the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

The following figure shows an example of this scenario. On the left side of the figure, IPv6 multicast packets are transmitted when MLD snooping is not enabled. All the hosts that are interested and not interested receive the IP Multicast traffic consuming bandwidth. Whereas, on the right side of the figure, when MLD snooping is enabled and IPv6 multicast packets are transmitted, only the interested hosts receive the IP multicast packets.

**Figure 153: IPv6 multicast packet transmission when MLD snooping is enabled and not enabled**

The following figure shows IPv6 multicast packets transmitted when MLD v2 snooping is enabled and not enabled.

**Figure 154: IPv6 multicast packet transmission when MLD v2 snooping is enabled and not enabled**

### MLD snooping configuration guidelines and restrictions

You can perform the following configurations to manage and control IPv6 multicast groups using the MLD snooping feature:

- Enable or disable MLD snooping on each VLAN. MLD snooping can be enabled on a maximum of 512 VLANs.
- Enable IGMP snooping and MLD snooping on the same VLAN.

### Limitations

Following are the limitations for MLD snooping configuration:

- The maximum (S,G,V) entries supported in the IPv6 multicast routing table (L3\_ENTRY\_IPV6\_MULTICAST) is 512.

MLD snooping shares the (S,G,V) entries with IGMP snooping, where the (S,G,V) entries number = (G,V) MLD\_V1 type entries number + (S,G,V) MLD\_V2 type entries number + (\*,G,V) MLD\_V2 type entries number + number of groups without (\*,G,V) registered listeners.

- IPv6 MLD proxy functionality is not supported.

- Multicast Flood Control (MFC) is not supported.
- Static mrouter ports cannot be configured.
- IPv6 MLD send query functionality is not supported.
- Configure static router ports is not supported.

## MLD Configuration Using the CLI

### *Configuring MLD trap generation*

#### **About This Task**

Use this procedure to enable MLD traps.

#### **Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MLD trap generation:  
`ipv6 mld generate-trap`
3. Disable MLD trap generation:  
`no ipv6 mld generate-trap`
4. Set MLD trap enable status to default:  
`default ipv6 mld generate-trap`

### *Configuring MLD log status*

#### **About This Task**

Use this procedure to enable MLD traps.

#### **Procedure**

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MLD log status:  
`ipv6 mld generate-log`
3. Disable MLD log status:  
`no ipv6 mld generate-log`
4. Set MLD log enable status to default:  
`default ipv6 mld generate-log`

### *Configuring MLD version*

## About This Task

Use this procedure to configure MLD version.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MLD version:

```
ipv6 mld version <1-2>
```

#### Note

For MLD to function correctly, the MLD version must be the same on all routers in the network.

3. Set MLD version to default:

```
default ipv6 mld version
```

### Variable Definitions

The following table describes the variables for the **ipv6 mld version** command.

| Variable | Value                                                     |
|----------|-----------------------------------------------------------|
| <1-2>    | Indicates the version of MLD that runs on this interface. |

*Configuring the MLD last listener query interval*

## About This Task

Use this procedure to configure the last listener query interval in seconds for the MLD interface.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the last listener query interval:

```
ipv6 mld last-listener-query-interval <0-60>
```

3. Set the last listener query interval to its default value:

```
default ipv6 mld last-listener-query-interval
```

**Variable Definitions**

The following table describes the variables for the **ipv6 mld last-listener-query-interval** command.

| Variable | Value                                                  |
|----------|--------------------------------------------------------|
| <0-60>   | Indicates the last listener query interval in seconds. |

*Configuring the MLD query interval***About This Task**

Use this procedure to configure the query interval for the MLD interface.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query interval for the MLD interface:

```
ipv6 mld query-interval <1-65535>
```

- Set the query interval to its default value:  

```
default ipv6 mld query-interval
```

### Variable Definitions

The following table describes the variables for the **ipv6 mld query-interval** command.

| Variable  | Value                                                                               |
|-----------|-------------------------------------------------------------------------------------|
| <1-65535> | Indicates the frequency at which MLD host query packets transmit on this interface. |

*Configuring the MLD query maximum response time*

### About This Task

Use this procedure to configure the query maximum response time for mld interface.

### Procedure

- Enter Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
```

```
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the query maximum response time for mld interface:  

```
ipv6 mld query-max-response-time <0-60>
```
- Set the query maximum response time to its default value:  

```
default ipv6 mld query-max-response-time
```

### Variable Definitions

The following table describes the variables for the **ipv6 mld query-max-response-time** command.

| Variable | Value                                                          |
|----------|----------------------------------------------------------------|
| <0-60>   | Indicates the query maximum response interval time in seconds. |

*Configuring the MLD robustness*

## About This Task

The robustness value allows the tuning for the expected packet loss on a link. If a link expects packet loss, increase the robustness variable value.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the MLD robustness:

```
ipv6 mld robust-value <2-255>
```

3. Set the MLD robustness to its default value:

```
default ipv6 mld robust-value
```

## Variable Definitions

The following table describes the variables for the **ipv6 mld robust-value** command.

| Variable | Value                                                    |
|----------|----------------------------------------------------------|
| <2-255>  | Specifies a numerical value for MLD snooping robustness. |

### *Enabling MLD snooping on a VLAN*

## About This Task

Use this procedure to enable MLD snooping on a VLAN.

## Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable MLD snooping:

```
ipv6 mld snooping
```

3. Set the MLD snooping to its default value:

```
default ipv6 mld snooping
```

*Enabling MLD ssm-snooping on a VLAN***About This Task**

Use this procedure to enable IPv6 MLD ssm-snooping on a VLAN.

**Procedure**

1. Enter VLAN Interface Configuration mode:  

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable MLD snooping:  

```
ipv6 mld ssm-snoop
```
3. Set the MLD snooping to its default value:  

```
default ipv6 mld ssm-snoop
```

*Display MLD Snooping Configuration Status***About This Task**

Use this procedure to display information about the MLD snooping configuration for the switch.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display the switch MLD snooping configuration status:  

```
show ipv6 mld snooping
```

**Example**

```
Switch:1#show ipv6 mld snooping
=====
                        Mld Snooping - GlobalRouter
=====
IFINDEX SNOOP   SSM   ACTIVE   MROUTER
          ENABLE SNOOP  MROUTER  EXPIRATION
          ENABLE PORTS   TIME
-----
V666    False   False  NONE     0
1 out of 1 entries displayed
```

*Display MLD Snooping Tracing Information***About This Task**

Use this procedure to display MLD snooping tracing information.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```

2. Display the MLD snooping tracing information:

```
show ipv6 mld snoop-trace
```

### Example

```
Switch:1#show ipv6 mld snoop-trace
=====
Mld Snoop Trace - GlobalRouter
=====

```

### Display MLD Interface Information

#### About This Task

Use this procedure to display MLD snooping interface parameters.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display MLD interface information:

```
show ipv6 mld interface [gigabitethernet {slot/port[/sub-port}}] [vlan
<1-4059>]
```

#### Examples

```
Switch:1#show ipv6 mld interface

### Variable Definitions

The following table describes the variables for the **show ipv6 mld interface** command.

| Variable                                | Value                                                       |
|-----------------------------------------|-------------------------------------------------------------|
| vlan <1-4059>                           | Displays MLD snooping information for the configured VLANs. |
| gigabitEthernet {slot/port [/sub-port]} | Displays MLD snooping information on a specific interface.  |

### Displaying MLD system parameters

#### About This Task

Use this procedure to display information about the MLD traps and logs.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the system parameters:  
show ipv6 mld sys

#### Example

```
Switch:1#show ipv6 mld sys
=====
Mld System Parameters - GlobalRouter
=====
generate-trap : disable
generate-log : disable
```

### Display MLD Cache Information

#### About This Task

Use this procedure to display the learned multicast groups in the cache.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the learned multicast groups in the cache:  
show ipv6 mld cache

#### Example

```
Switch:1#show ipv6 mld cache
=====
MLD Cache Information
=====
```

```

```

### View IPv6 MLD Host Cache

View the learned multicast group addresses in the host cache.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv6 MLD host cache:  

```
show ipv6 mld-host-cache
```
3. View IPv6 MLD host cache for a management interface:  

```
show ipv6 mld-host-cache mgmtEthernet [mgmt]
```

#### Note

This step only applies to VSP 8600 Series.

### Example

```
Switch:1#show ipv6 mld-host-cache
=====
MLD Cache Information
=====

mgmt      ff02::1:ff4c:9400                          enabled
mgmt      ff02::1                                    enabled
```

## MLD Configuration Using EDM

### Configuring MLD globally

#### About This Task

Use the following procedure to configure MLD parameters for the switch.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Globals** tab.
4. Configure the MLD global parameters as required.
5. On the toolbar, click **Apply** to save the changes.
6. On the toolbar, click **Refresh** to update the changes.

#### Globals field description

Use the data in the following table to use the **Globals** tab.

| Field        | Description                    |
|--------------|--------------------------------|
| GenerateTrap | Enables MLD to generate traps. |
| GenerateLog  | Enables MLD to generate logs.  |

*Viewing the MLD SSM global information***Procedure**

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Ssm Globals** tab.

**Ssm Globals field description**

Use the data in the following table to use the **Ssm Globals** tab.

| Field      | Description                   |
|------------|-------------------------------|
| RangeGroup | Specifies the ssm range.      |
| RangeMask  | Specifies the ssm range mask. |

*MLD interface configuration*

Configure the interfaces so that the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

**Configuring an MLD interface**

Perform this procedure to change the configuration of existing MLD interfaces.

**Procedure**

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Interfaces** tab.
4. On the toolbar, click **Insert**.
5. Configure the MLD interface parameters.
6. Click **Insert**.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

## MLD interfaces field description

Use the data in the following table to use the **Interfaces** tab.

| Field         | Description                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| IfIndex       | Specifies the internetwork layer interface value of the interface for which MLD is enabled.                              |
| QueryInterval | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version       | Indicates the MLD version.                                                                                               |
| Querier       | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                         |

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QueryMaxResponseDelay  | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.                                                                                                                                                                                                                                                                                   |
| Joins                  | Specifies the number of times a group membership has been added on this interface.                                                                                                                                                                                                                                                                                                                  |
| Groups                 | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                      |
| Robustness             | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                                |
| LastListenQueryIntvl   | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60.<br>This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable            | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                   |
| FlushAction            | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>flushGrpMember</li> <li>flushMrouter</li> <li>flushSender</li> </ul>                                                                                                                                                                                                                                 |
| SsmEnable              | Indicates if ssm is enabled.                                                                                                                                                                                                                                                                                                                                                                        |
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                                                                                                                                                                                                                  |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                                                                                                                                                                                                          |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                                                                                                                                                                                                             |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>snoop</li> <li>pim</li> <li>snoopSpb</li> <li>routerSpb</li> <li>dvmrp</li> <li>none</li> </ul>                                                                                                                                                                                                    |

### Configuring MLD on a port

Configure the MLD on a port.

## Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IPv6**.
4. Click the **MLD** tab.
5. Configure the MLD interface parameters.
6. On the toolbar, click **Apply** to save the changes.
7. On the toolbar, click **Refresh** to update the changes.

## MLD field description

Use the data in the following table to use the **MLD** tab.

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| QueryInterval         | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535.                                                                                                                                                                                                                                                                            |
| Version               | Indicates the MLD version.                                                                                                                                                                                                                                                                                                                                                                          |
| Querier               | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                    |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.                                                                                                                                                                                                                                                                                   |
| Joins                 | Specifies the number of times a group membership has been added on this interface.                                                                                                                                                                                                                                                                                                                  |
| Groups                | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                      |
| Robustness            | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                                |
| LastListenQueryIntvl  | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60.<br>This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable           | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                   |
| FlushAction           | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>• flushGrpMember</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                           |

| Field                  | Description                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SsmEnable              | Indicates if ssm is enabled.                                                                                                                                                                                 |
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                           |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                   |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                      |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>• snoop</li> <li>• pim</li> <li>• snoopSpb</li> <li>• routerSpb</li> <li>• dvmrp</li> <li>• none</li> </ul> |

## Configuring MLD on a VLAN

### About This Task

Configure MLD on a VLAN.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Select a VLAN from the list.
4. Click the **IPv6** tab.
5. Click the **MLD** tab.
6. Configure the MLD interface parameters.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

MLD field description

Use the data in the following table to use the **MLD** tab.

| Field                 | Description                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|
| QueryInterval         | Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535. |
| Version               | Indicates the MLD version.                                                                                               |
| Querier               | Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.                         |
| QueryMaxResponseDelay | Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.        |

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Joins                  | Specifies the number of times a group membership has been added on this interface.                                                                                                                                                                                                                                                                                                               |
| Groups                 | Specifies the current number of entries for this interface in the cache table.                                                                                                                                                                                                                                                                                                                   |
| Robustness             | Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.                                                                                                                                                                                             |
| LastListenQueryIntvl   | Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group. |
| SnoopEnable            | Indicates if snooping is enabled.                                                                                                                                                                                                                                                                                                                                                                |
| FlushAction            | Specifies the MLD flush action as one of the following: <ul style="list-style-type: none"> <li>flushGrpMember</li> <li>flushMrouter</li> <li>flushSender</li> </ul>                                                                                                                                                                                                                              |
| SsmEnable              | Indicates if ssm is enabled.                                                                                                                                                                                                                                                                                                                                                                     |
| NewQuerier             | Specifies the IPv6 address of the new MLD querier.                                                                                                                                                                                                                                                                                                                                               |
| DynamicDowngradeEnable | Enables dynamic downgrade of the MLD version when older version query message is received.                                                                                                                                                                                                                                                                                                       |
| OperVersion            | Specifies the operational version of the MLD running on this interface.                                                                                                                                                                                                                                                                                                                          |
| McastMode              | Specifies the MLD interface mode as one of the following: <ul style="list-style-type: none"> <li>snoop</li> <li>pim</li> <li>snoopSpb</li> <li>routerSpb</li> <li>dvmrp</li> <li>none</li> </ul>                                                                                                                                                                                                 |

### Configuring MLD snooping

#### About This Task

Use the following procedure to enable MLD snooping on the switch.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click **Snooping** tab.
4. Select a value, double-click the cell in **SnoopEnable** column, select **True** or **False**.
5. Select a value, double-click the cell in **SsmEnable** column, select **True** or **False**.
6. Click **Apply**.

### Snooping field description

Use the data in the following table to use the **Snooping** tab.

| Field       | Description                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IfIndex     | Specifies the interface on which you enabled MLD snooping. It specifies the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.                       |
| SnoopEnable | Indicates the status of MLD snooping on the specified interface: <ul style="list-style-type: none"> <li>• True – MLD snooping is enabled</li> <li>• False – MLD snooping is disabled</li> </ul> |
| SsmEnable   | Indicates the status of SSM on the specified interface: <ul style="list-style-type: none"> <li>• True – SSM is enabled</li> <li>• False – SSM is disabled</li> </ul>                            |

*Viewing the MLD snoop trace information*

### About This Task

Use this procedure to display information about the multicast groups traversing the snoop enabled router.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Snoop Trace** tab.

### Snoop Trace field description

Use the data in the following table to use the **Snoop Trace** tab.

| Field   | Description                                                            |
|---------|------------------------------------------------------------------------|
| GrpAddr | Specifies the IP multicast address of the group traversing the router. |
| SrcAddr | Specifies the IP source address of the multicast group address.        |

| Field   | Description                                                 |
|---------|-------------------------------------------------------------|
| OutVlan | Specifies the egress VLAN ID for the multicast group.       |
| OutPort | Specifies the egress port of the multicast group.           |
| InVlan  | Specifies the ingress VLAN ID for the multicast source.     |
| InPort  | Specifies the ingress port for the multicast group.         |
| Type    | Specifies the port type on which the snoop entry is learnt. |

### Viewing the MLD cache information

#### About This Task

Use this procedure to display information about the learned multicast groups in the cache.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Cache** tab.

#### MLD cache field description

Use the data in the following table to use the **Cache** tab.

| Field        | Description                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address      | The IPv6 multicast group address for which this entry contains information.                                                                                                               |
| IfIndex      | Indicates the internetwork-layer interface for which this entry contains information for an IPv6 multicast group address.                                                                 |
| LastReporter | Indicates the source IPv6 address of the last membership report received for this IPv6 Multicast group address on this interface. If membership report is not received, the value is 0::0 |
| ExpiryTime   | Indicates the minimum amount of time remaining before the entry ages out.                                                                                                                 |

### Viewing the MLD V2 cache information

#### About This Task

Use this procedure to display information about the MLDv2 corresponding to each interface, port and multicast group paired on a router.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.

3. Click the **V2 Cache** tab.

### V2 Cache field description

Use the data in the following table to use the **V2 Cache** tab.

| Field             | Description                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupAddress      | Specifies the multicast group address that others want to join. A group address can be the same for many incoming ports.                                                                                                                                                 |
| Ifindex           | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.                                                                                                                                                    |
| InPort            | Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.                                                                                                                                                    |
| Version1HostTimer | Specifies the time remaining until the local router assumes that there are no more MLDv1 members on the IP subnet attached to the interface. This is applicable only for MLDv1 hosts. Upon receiving an MLDv1 report, this value is reset to the group membership timer. |
| SourceFilterMode  | Specifies the current group state applicable on MLDv2 compatible nodes.                                                                                                                                                                                                  |

### Viewing IPv6 MLD host cache

View the learned multicast group addresses in the host cache.

#### Note

Not all hardware platforms include a dedicated, physical management interface. For more information about supported interfaces, see your hardware documentation.

### Procedure

1. In the navigation tree, expand the **Configuration > IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Host Cache** tab.

### MLD host cache field descriptions

Use the data in the following table to use the **Host Cache** tab.

| Name                        | Description                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------|
| <b>Ifindex</b>              | Shows the index value that uniquely identifies the interface to which this entry applies. |
| <b>GrpAddress</b>           | Shows the IP address for the multicast group.                                             |
| <b>GrpLocallyRegistered</b> | Shows the Group Locally Registered for an IPv6 MLD host-cache entry.                      |

| Name                   | Description                                                             |
|------------------------|-------------------------------------------------------------------------|
| <b>GrpLastReporter</b> | Shows the Group Last Reporter address for an IPv6 MLD host-cache entry. |
| <b>GrpUpTime</b>       | Shows the Group Uptime for an IPv6 MLD host-cache entry.                |
| <b>GrpExpiryTime</b>   | Shows the Group Expiry Time for an IPv6 MLD host-cache entry.           |
| <b>GrpFilterMode</b>   | Shows the Group Filter Mode for an IPv6 MLD host-cache entry.           |

*Viewing the MLD source information*

### About This Task

Use this procedure to display information about the MLD source.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Source** tab.

### Source field description

Use the data in the following table to use the **Source** tab.

| Field         | Description                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------|
| GroupAddress  | Specifies the IPv6 multicast group address for which this entry contains information.                          |
| Ifindex       | Specifies the interface for which this entry contains information for an IP multicast group address.           |
| InPort        | Identifies a physical interface or logical interface (VLAN), which has received group reports for this source. |
| HostAddress   | Specifies the host address to which this entry corresponds.                                                    |
| MemberAddress | Specifies the IPv6 address of a member that has sent source specific report wishing to join this source.       |
| Expire        | Specifies the state of this entry.                                                                             |
| Mode          | Specifies the current member state. This is applicable to MLDv2 compatible nodes.                              |
| MemberExpire  | Specifies the time until the member for this source expires.                                                   |

*Viewing the MLD sender information***About This Task**

Use this procedure to display information about the multicast senders.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Sender** tab.

**Source field description**

Use the data in the following table to use the **Sender** tab.

| Field      | Description                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| GrpAddr    | Specifies the IPv6 multicast group address.                                                                                                          |
| Ifindex    | Specifies the interface index of the sender.                                                                                                         |
| MemberAddr | Specifies the IPv6 host address.                                                                                                                     |
| Action     | Specifies the MLD action as one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushEntry</li> <li>• flushGrp</li> </ul> |
| Port       | Specifies the MLD sender port.                                                                                                                       |

*Viewing the MLD group information***About This Task**

Use this procedure to display information about the groups configured in this device.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Group** tab.

**Group field description**

Use the data in the following table to use the **Group** tab.

| Field       | Description                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| IPv6Address | Specifies the multicast group address that others want to join to. A group address can be the same for many incoming ports. |
| Members     | Specifies the IP address of a source that has sent group report wishing to join this group.                                 |

| Field      | Description                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------|
| InPort     | Identifies a physical interface or a logical interface which has received group reports from various sources.    |
| Expiration | Specifies the time left before group report expires on this port. This is updated upon receiving a group report. |
| IfIndex    | Identifies a physical interface or a logical interface which has received group reports from various sources.    |

## PIM Configuration Using the CLI

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

### Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### Before You Begin

For an IPv4 PIM configuration using the CLI:

- Configure an IPv4 interface.

For more information, see [IP routing configuration using the CLI](#) on page 1820.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using CLI](#) on page 2784. For more information about OSPF, see [OSPF configuration using CLI](#) on page 2451.

- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- You must first configure and enable PIM on an IP interface, which can be circuitless, before you can utilize that interface as a candidate rendezvous point (RP). To configure PIM-SM RP for an IP interface, see [Configuring a candidate rendezvous point](#) on page 1565.
- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using the CLI:

- Configure an IPv6 interface.

For more information, see [Configure an IPv6 Interface](#) on page 1899.

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see [RIPng Configuration using CLI](#) on page 2794. For more information about OSPFv3, see [OSPFv3 Configuration using CLI](#) on page 2492.

- Enable IPv6 PIM-SM globally
- Enable IPv6 PIM-SM on individual interfaces.

## Changing the interface status to passive

Change the PIM interface status to passive to deny PIM control traffic on the interface.

### Before You Begin

- The PIM interface is disabled.

### About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a passive interface and enable it simultaneously:

```
ip pim passive
```

3. Create a passive interface in the disabled state:

```
ip pim interface-type passive
```

You must manually enable the interface.

4. Enable a disabled interface:

```
ip pim enable
```

*Variable definitions*

Use the data in the following table to use the **ip pim** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>active</i>  | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |
| <i>passive</i> | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Changing the interface status to active

Change the PIM interface status to active to allow PIM control traffic on the interface.

### Before You Begin

- The PIM interface is disabled.

### About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an active interface in the disabled state:

```
ip pim interface-type active
```

You must manually enable the interface.

3. Create an active interface and enable it simultaneously:

```
ip pim active
```

OR

```
ip pim enable
```

The second command enables an active interface only if this is the first PIM interface you create on the port or VLAN or you created an active interface in the disabled state. If you already created a passive interface in the disabled state, the second command enables that passive interface.

*Variable definitions*

Use the data in the following table to use the **ip pim** command.

| Variable       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>active</i>  | Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |

This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the PIM virtual neighbor:
 

```
ip pim virtual-neighbor <A.B.C.D> <A.B.C.D>
```

### Example

Configure the PIM virtual neighbor:

```
Switch:1(config)#ip pim virtual-neighbor 192.0.2.0 198.51.100.0
```

*Variable definitions*

Use the definitions in the following table to use the `ip pim virtual-neighbor` command.

| Variable                         | Value                                                                                                                                    |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{A.B.C.D} {A.B.C.D}</code> | The first IP address indicates the IP address of the selected interface. The second IP address indicates the IP address of the neighbor. |

## Configuring a candidate rendezvous point

Configure a candidate rendezvous point (C-RP) to serve as backup to the RP router.

### About This Task

You can configure only one interface on the switch for multiple groups. You cannot configure multiple interfaces for multiple groups.

With the mask value, you can configure a C-RP router for several groups in one configuration.

For example, if you use a C-RP configuration with a group address of 224.0.0.0 and a group mask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Add a candidate rendezvous point:
 

```
ip pim rp-candidate group <A.B.C.D> <A.B.C.D> rp <A.B.C.D>
```
3. Remove a candidate rendezvous point:
 

```
no ip pim rp-candidate group <A.B.C.D> <A.B.C.D>
```
4. Display information about the candidate rendezvous points for the PIM-SM domain:
 

```
show ip pim rp-candidate
```

### Example

Add a candidate rendezvous point:

```
Switch:1(config)#ip pim rp-candidate group 224.1.1.0 255.255.255.0 rp 198.51.100.0
```

### Variable definitions

Use the definitions in the following table to use the `ip pim rp-candidate` command.

| Variable                                               | Value                                                                                                                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>group {A.B.C.D}</code><br><code>{A.B.C.D}</code> | Specifies the IP address and the address mask of the multicast group. After the IP address and group mask are combined, it identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <code>rp {A.B.C.D}</code>                              | Specifies the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.                                                                                                     |

## Configuring static RP

Configure a static RP to ignore the bootstrap router (BSR) mechanism and use the statically configured RPs.

### Before You Begin

- Enable PIM-SM globally.

### About This Task

Static RP-enabled switches use this feature to communicate with switches from other vendors that do not use the BSR.

#### Important

You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.

All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable static RP:

```
ip pim static-rp
```

The system displays the following message:

```
WARNING: RP information learnt dynamically through BSR functionality will be lost.
Do you wish to enable Static RP? (y/n) ?
```

3. Enter `y`.
4. Configure a static RP entry:

```
ip pim static-rp {A.B.C.D/X} {A.B.C.D}
```
5. Configure all the switches in the network (including switches from other vendors) to map to the same RP.

6. Display information about the candidate rendezvous points for the PIM-SM domain:

```
show ip pim static-rp
```

### Example

Configure a static RP:

```
Switch:1(config)# ip pim static-rp 239.255.0.0/255.255.0.0 198.51.100.0
```

### Variable definitions

Use the definitions in the following table to use the **ip pim static-rp** command.

| Variable    | Value                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Specifies the IP address and address mask of the multicast group. When combined, the IP address and address mask identify the range of the multicast addresses that the RP handles. |
| {A.B.C.D}   | Specifies the IP address of the static RP.                                                                                                                                          |

## Configuring IPv6 PIM static RP

On IPv6 PIM BSR mechanism is not supported so static RP must be configured.

### Before You Begin

Enable IPv6 PIM-SM globally.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Enable static RP:
 

```
ipv6 pim static-rp
```
3. Configure an IPv6 static RP entry:
 

```
ipv6 pim static-rp WORD<0-255> WORD<0-255>
```
4. Configure all the switches in the network (including switches from other vendors) to map to the same RP.
5. Display information about the candidate rendezvous points for the PIM-SM domain:
 

```
show ipv6 pim static-rp
```

### Variable Definitions

The following table describes the variables for the **ipv6 pim static-rp** command.

| Variable    | Value                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<0-255> | Specifies the IPv6 address and address mask of the multicast group. When combined, the IPv6 address and address mask identify the range of the multicast addresses that the RP handles. |
| WORD<0-255> | Specifies the IPv6 address of the static RP.                                                                                                                                            |

## Configuring a candidate BSR on a port

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

### Before You Begin

- Static RP is disabled.

### About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a candidate BSR:

```
ip pim bsr-candidate preference <0-255>
```

### Example

Configure a candidate BSR:

```
Switch:1(config-if)#ip pim bsr-candidate preference 2
```

*Variable definitions*

Use the definitions in the following table to use the **ip pim bsr-candidate** command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference &lt;0-255&gt;</code> | Activates the C-BSR on this interface and configures its preference value, from 0-255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. To set this option to the default value, use the <b>default</b> operator with the command. |

## Configuring a candidate BSR on a VLAN

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

### Before You Begin

- Static RP is disabled.

### About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

### Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure a candidate BSR on a VLAN:
 

```
ip pim bsr-candidate preference <0-255>
```

### Example

Configure a candidate BSR on a VLAN:

```
Switch:1(config-if)#ip pim bsr-candidate preference 5
```

### Variable definitions

Use the definitions in the following table to use the `ip pim bsr-candidate` command.

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference &lt;0-255&gt;</code> | Activates the C-BSR on this interface and configures its preference value, from 0-255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

### About This Task

#### Important

The following command also activates full-mesh configurations.

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable square-SMLT:

```
multicast smlt-square
```

## PIM Configuration Using EDM

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

#### Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

## Before You Begin

For an IPv4 PIM configuration using EDM:

- Configure an IP interface.

For more information, see [IP routing configuration using Enterprise Device Manager](#) on page 1848.

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

For more information about RIP, see [RIP configuration using EDM](#) on page 2799. For more information about OSPF, see [OSPF configuration using EDM](#) on page 2517.

- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- Configure one or more rendezvous points (RP) for the groups that multicast applications use in the network.

### Important

If you configure the rendezvous point (RP) to be the address of a circuitless IP (CLIP) interface, then you must first configure and enable PIM on the CLIP interface before you can utilize that interface as a candidate RP. To configure a PIM-SM RP for a circuitless IP interface, see [Configuring a candidate RP](#) on page 1581.

- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using EDM:

- Configure an IPv6 interface. For more information, see [Configure an IPv6 Interface](#) on page 1933.
- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM. For more information about RIPng, see [RIPng Configuration using EDM](#) on page 2809. For more information about OSPFv3, see [OSPFv3 Configuration using EDM](#) on page 2550.
- Enable IPv6 PIM-SM globally.
- Enable IPv6 PIM-SM on individual interfaces.

## Enabling static RP

Enable static RP to avoid the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.

7. Click **Apply**.

The system displays the following message:

```
RP information learnt dynamically through BSR functionality will be
lost. Do you wish to enable Static RP?
```

8. Click **Yes**.

## Enabling IPv6 static RP

Use this procedure to enable IPv6 static RP.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.
8. Click **Yes**.

## Configuring a static RP

Configure a static RP to ignore the BSR mechanism and use the statically configured RPs only. A static RP-enabled switch uses this feature to communicate with switches from other vendors that do not use the BSR mechanism.

### Before You Begin

- Before you can configure a static RP, you must enable the following:
  - PIM-SM
  - static RP

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

**Static RP field descriptions**

Use the descriptions in the following table to use the **Static RP** tab.

| Name                | Description                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.      |
| <b>GroupMask</b>    | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| <b>Address</b>      | Configures the IP address of the static RP.                                                                                                                               |
| <b>Status</b>       | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP and is invalid otherwise.        |

*Job aid*

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

**Configuring an IPv6 static RP entry**

Configure an IPv6 static RP to use the statically configured RPs. A static RP-enabled switch uses this feature to elect the active RP only from the statistically configured switches, without any relation to the RP information of other switches.

**Before You Begin**

- Before you can configure a static RP, you must enable the following:
  - IPv6 PIM-SM
  - IPv6 static RP

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.

2. Click **IPv6 PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

### **Static RP** field descriptions

Use the descriptions in the following table to use the **Static RP** tab.

| Name                | Description                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Configures the IPv6 address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.    |
| <b>GroupMask</b>    | Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles. |
| <b>Address</b>      | Configures the global IPv6 address of the static RP.                                                                                                                      |
| <b>Status</b>       | Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP.                                 |

### *Job aid*

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

## Viewing the active RP

Perform this procedure to show information about the active RP for all the running multicast groups on the switch.

### **Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.

3. Click the **Active RP** tab.

#### Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

| Name                | Description                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IP address of the multicast group.                                                            |
| <b>Address</b>      | Shows the IP address of the RP router. This address must be one of the local PIM-SM enabled interfaces. |
| <b>Priority</b>     | Shows the priority of the RP.                                                                           |

## Viewing the IPv6 active RP

Perform this procedure to show information about the IPv6 active RP for all the running multicast groups on the switch.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Active RP** tab.

#### Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

| Name                | Description                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IPv6 address of the multicast group.                                                                                                                                                                                                                                              |
| <b>Address</b>      | Shows the IPv6 address of the RP router. This address can be one of the local PIM-SM enabled interfaces or any reachable global IPv6 address configured using the <b>static-rp</b> CLI command.<br><br><b>Note:</b><br>IPv6 link local address is always used as the PIM interface address. |
| <b>Priority</b>     | Shows the priority of the RP.                                                                                                                                                                                                                                                               |

## Configuring a candidate bootstrap router

Configure routers as candidate bootstrap routers (C-BSR) to provide backup protection in case the primary BSR fails. PIM-SM cannot operate without a BSR. A PIM-SM domain can use only one active BSR.

## About This Task

The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

## Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Click **Enable**.
6. In the **CBSRPreference** box, type the preference.

The C-BSR with the highest BSR-preference and address becomes the active BSR. The default is -1, which indicates that the current interface is not a C-BSR.

7. Click **Apply**.

## Viewing current BSR information

View the current BSR information to review the configuration.

### Before You Begin

- You must disable static RP.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Current BSR** tab.

### *Current BSR field descriptions*

Use the descriptions in the following table to use the **Current BSR** tab.

| Name                  | Description                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address</b>        | Shows the IP address of the current BSR for the local PIM domain.                                                                                                                            |
| <b>FragmentTag</b>    | Shows a randomly generated number that distinguishes fragments that belong to different bootstrap messages. Fragments that belong to the same bootstrap message carry the same fragment tag. |
| <b>HashMask</b>       | Shows the mask used in the hash function to map a group to one of the C-RPs from the RP set. The hashmask allows a small number of consecutive groups to always hash to the same RP.         |
| <b>Priority</b>       | Shows the priority of the current BSR. The C-BSR with the highest BSR priority and address (referred to as the preferred BSR) is elected as the BSR for the domain.                          |
| <b>BootStrapTimer</b> | Shows the bootstrap timer. After the bootstrap timer expires, the BSR sends out bootstrap messages.                                                                                          |

## Changing VLAN interface type

Change the state (active or passive) of PIM on a VLAN interface.

### Before You Begin

- Before you change the state of PIM on a VLAN interface, you must first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Clear the **Enable** check box.
8. Click **Apply**.
9. Select **active** or **passive**.
10. Reenable PIM on the VLAN interface.
11. Click **Apply**.

## Editing PIM interface parameters

Edit PIM parameters for an interface to customize the PIM configuration.

### Before You Begin

- Before you change the state (active or passive) of a PIM interface, first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name           | Description                                                                    |
|----------------|--------------------------------------------------------------------------------|
| <b>IfIndex</b> | Shows the interface Index. This variable is a read-only field.                 |
| <b>Address</b> | Shows the IP address of the PIM interface. This variable is a read-only field. |

| Name                     | Description                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NetMask</b>           | Shows the network mask for the IP address of the PIM interface. This variable is a read-only field.                                                                                                                           |
| <b>Mode</b>              | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field.                                                                                                          |
| <b>InterfaceType</b>     | Specifies if the interface is active or passive.                                                                                                                                                                              |
| <b>DR</b>                | Shows the router with the highest IP address on a LAN designated to perform these tasks.                                                                                                                                      |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.                                                                            |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds.                                                                  |
| <b>CBSRPreference</b>    | Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is -1, which indicates that the current interface is not a C-BSR. |
| <b>OperState</b>         | Indicates the status of PIM on this interface: Up or Down.                                                                                                                                                                    |

## Editing IPv6 PIM interface parameters

Edit the IPv6 PIM parameters for an interface to customize the IPv6 PIM configuration.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name           | Description                                                                                                          |
|----------------|----------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b> | Shows the interface Index. This variable is a read-only field.                                                       |
| <b>Address</b> | Shows the IPv6 address of the PIM interface. This variable is a read-only field.                                     |
| <b>NetMask</b> | Shows the network mask for the IPv6 address of the PIM interface. This variable is a read-only field.                |
| <b>Enable</b>  | Shows the configured mode of this PIM interface. sparseDense mode is valid only for PIMv1.                           |
| <b>Mode</b>    | Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field. |

| Name                     | Description                                                                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DR</b>                | Shows the router with the highest IPv6 address on a LAN designated to perform these tasks.                                                                   |
| <b>HelloInterval</b>     | Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.           |
| <b>JoinPruneInterval</b> | Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. |
| <b>OperState</b>         | Indicates the status of PIM on this interface: Up or Down.                                                                                                   |
| <b>Type</b>              | Specifies the interface type.                                                                                                                                |

## Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Virtual Neighbors** tab.
4. Click **Insert**.
5. Specify the IP address of the virtual neighbor.
6. Specify the interface index for the PIM interface.
7. Click **Insert**.

### *Virtual Neighbors* field descriptions

Use the descriptions in the following table to use the **Virtual Neighbors** tab.

| Name           | Description                                    |
|----------------|------------------------------------------------|
| <b>Address</b> | Specifies the IP address of the neighbor.      |
| <b>Ifindex</b> | Specifies the IP address of the PIM interface. |

## Viewing PIM-SM neighbor parameters

View PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Neighbors** tab.

**Neighbors** field descriptions

Use the descriptions in the following table to use the **Neighbors** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Address</b>    | Shows the IP address of the PIM neighbor.                                                   |
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>UpTime</b>     | Shows the time since this neighbor became a neighbor of the local router.                   |
| <b>ExpiryTime</b> | Shows the time remaining before the neighbor expires.                                       |

## Viewing IPv6 PIM-SM neighbor parameters

View IPv6 PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbors** tab.

**Neighbors** field descriptions

Use the descriptions in the following table to use the **Neighbors** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Address</b>    | Shows the IPv6 address of the PIM neighbor.                                                 |
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>UpTime</b>     | Shows the time since this neighbor became a neighbor of the local router.                   |
| <b>ExpiryTime</b> | Shows the time remaining before the neighbor expires.                                       |

## Viewing IPv6 Neighbor Secondary Address

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbor Secondary Address** tab.

**Neighbor Secondary Address** field descriptions

Use the descriptions in the following table to use the **Neighbor Secondary Address** tab.

| Name              | Description                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor. |
| <b>Type</b>       | Shows the address type of this PIM neighbor.                                                |
| <b>Primary</b>    | The primary IPv6 address of this PIM neighbor.                                              |
| <b>SecAddress</b> | The secondary IPv6 address of this PIM neighbor.                                            |

## Viewing RP set parameters

View the RP set to see a list of rendezvous point addresses. The BSR constructs this list from C-RP advertisements, and then distributes it to all PIM routers in the PIM domain for the BSR. View the parameters for troubleshooting purposes.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **RP Set** tab.

**RP Set** field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name                | Description                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Shows the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.                                                                                |
| <b>GroupMask</b>    | Shows the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.                                                                           |
| <b>Address</b>      | Shows the IP address of the C-RP router.                                                                                                                                                                                                                         |
| <b>HoldTime</b>     | Shows the time specified in a C-RP advertisement that the BSR uses to time out the RP. After the BSR receives an advertisement for the RP, it restarts the timer. If no advertisement arrives before the timer expires, the BSR removes that RP from the RP set. |
| <b>ExpiryTime</b>   | Shows the time remaining before this C-RP router times out.                                                                                                                                                                                                      |

## Configuring a candidate RP

Configure a C-RP router to add it to the RP Set.

### About This Task

You can configure only one interface on a switch for multiple groups; that is, you cannot configure multiple interfaces for multiple groups.

Using the GroupMask value, you can configure a candidate RP for several groups in one configuration. For example, if you use a C-RP configuration with a GroupAddress value of 224.0.0.0 and a GroupMask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **PIM**.
3. Click the **Candidate RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

### **Candidate RP** field descriptions

Use the descriptions in the following table to use the **Candidate RP** tab.

| Name                    | Description                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>     | Configures the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.      |
| <b>GroupMask</b>        | Configures the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router. |
| <b>InterfaceAddress</b> | Configures the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.                                                                              |

## Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

### About This Task

#### Important

The following configuration also activates full-mesh configurations.

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**

2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select **MulticastSquareSmltEnable**.  
Clear this check box if you want to disable square-SMLT globally.
5. Click **Apply**.

## Viewing IPv6 RP set parameters

View the IPv6 RP set to see a list of rendezvous point addresses. View the parameters for troubleshooting purposes.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **RP Set** tab.

### *RP Set* field descriptions

Use the descriptions in the following table to use the **RP Set** tab.

| Name                | Description                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Specifies the IPv6 address of the multicast group. When combined with the group mask, this value identifies a group prefix for which the address is a static RP.    |
| <b>GroupMask</b>    | Specifies the address mask of the multicast group. When combined with the group address, this value identifies a group prefix for which the address is a static RP. |
| <b>Address</b>      | Specifies the IPv6 address of the static RP.                                                                                                                        |
| <b>HoldTime</b>     | Specifies the hold time of the static RP. The value is 0.                                                                                                           |
| <b>ExpiryTime</b>   | Specifies the minimum time remaining before the static RP is down. The value is 0.                                                                                  |

## Viewing IPv6 Mroute interface information

Use the following procedure to view IPv6 Mroute information for an interface.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Interfaces** tab.

**Interfaces** field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>  | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                                                                                                            |
| <b>Ttl</b>      | Displays the datagram time-to-live (TTL) threshold for the interface. IPv6 multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.                                                                  |
| <b>Protocol</b> | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>other(1): none of the following</li> <li>local(2): manually configured</li> <li>netmgmt(3): configured by a network management protocol</li> <li>pimSparseMode(8): PIM-SMv2</li> <li>igmpOnly(10)</li> <li>pimSsmMode(11)</li> <li>spb</li> </ul> |

## Viewing IPv6 Mroute next hop information

Use the following procedure to view IPv6 Mroute next hop information.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Next Hop** tab.

**Next Hop** field descriptions

Use the data in the following table to use the **Next Hop** tab.

| Name              | Description                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>      | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                       |
| <b>Source</b>     | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                |
| <b>SourceMask</b> | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                       |
| <b>IfIndex</b>    | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                               |
| <b>Address</b>    | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b>             | Displays whether the outgoing interface and next hop represented by this entry currently forward IPv6 datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.                                                                                                                                  |
| <b>ExpiryTime</b>        | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                            |
| <b>ClosestMemberHops</b> | Displays the minimum number of hops between this router and members of the IPv6 multicast group reached through the next hop on this outgoing interface. IPv6 multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop.                                                              |
| <b>Protocol</b>          | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## Configuring resource usage counter for IPv6 Mroute

Configure the resource usage counters to query the number of ingress and egress IPv6 multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

### Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

**Resource Usage** field descriptions

Use the data in the following table to use the **Resource Usage** tab.

| Name                          | Description                                                                                                                                |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ingress Records In-Use</b> | Displays the number of ingress records (source or group) traversing the switch.                                                            |
| <b>Egress Records In-Use</b>  | Displays the number of egress records traversing the switch.                                                                               |
| <b>Ingress Threshold</b>      | Configures the ingress threshold level (0–32767).                                                                                          |
| <b>Egress Threshold</b>       | Configures the egress threshold level (0–32767).                                                                                           |
| <b>SendTrapAndLog</b>         | Sends both trap and log notification messages after the number of streams exceeds a threshold level.                                       |
| <b>SendTrapOnly</b>           | Sends only trap notification messages after the number of streams exceeds a threshold level. You can configure only one notification type. |
| <b>LogMsgOnly</b>             | Sends only log notification messages after the number of streams exceeds a threshold level.                                                |

## Viewing IPv6 multicast route information

Use the following procedure to view IPv6 Mroute route information.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Route** tab.

**IPv6 Multicast Route** field descriptions

Use the data in the following table to use the **Route** tab.

| Name                    | Description                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>            | Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                        |
| <b>Source</b>           | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface. |
| <b>SourceMask</b>       | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.        |
| <b>UpStreamNeighbor</b> | Shows the address of the upstream neighbor from which the IPv6 datagrams from these sources are received.                                                                                   |
| <b>IfIndex</b>          | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                |

| Name              | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ExpiryTime</b> | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                            |
| <b>Protocol</b>   | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## IGMP Configuration Using the CLI

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

### Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

### Before You Begin

- Complete one of the following tasks:
  - Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
  - Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

### Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Configuring IGMP on a VRF](#) on page 1520.

## Configuring multicast stream limitation on an Ethernet port

Configure multicast stream limitation on an Ethernet port to limit the number of concurrent multicast streams on the port. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the port drops joins to new streams. A service provider uses this feature to control the

overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

#### Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

3. If stream-limit is already enabled on the interface, change the maximum number of allowed streams:

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```

4. Display multicast stream limitation information for the ports on a specific interface:

```
show ip igmp stream-limit interface
```

### Example

Enable multicast stream limitation on the Ethernet port and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

#### Variable definitions

Use the data in the following table to use the **ip igmp stream-limit-max-streams** command.

| Variable  | Value                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------|
| <0-65535> | Configures the maximum number of allowed streams on this port. The range is from 0-65535 and the default is 4. |

## Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

## About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops joins to new streams. A service provider uses this feature to control the overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

### Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

## Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Enable multicast stream limitation and configure the maximum number of allowed streams:
 

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```
3. If stream-limit is already enabled on the VLAN, change the maximum number of allowed streams:
 

```
ip igmp stream-limit stream-limit-max-streams <0-65535>
```
4. Display multicast stream limitation information for the ports on a specific interface:
 

```
show ip igmp stream-limit port
```

## Example

Enable multicast stream limitation and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

### Variable definitions

Use the data in the following table to use the **ip igmp stream-limit** command.

| Variable  | Value                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------|
| <0-65535> | Configures the maximum number of allowed streams on this VLAN. The range is from 0-65535 and the default is 4. |

## Configuring VLAN multicast stream limitation members

Configure multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN.

**Procedure**

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Configure multicast stream limitation members on a VLAN:
 

```
ip igmp stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-
port]][,...]} enable max-streams <0-65535>
```

**Example**

Enable multicast stream limitation on ports 2/3 to 2/8 and configure the maximum allowed number of streams to 6 for this interface.

```
Switch:1(config-if)# ip igmp stream-limit-group 2/3-2/8 max-streams 6
```

*Variable definitions*

Use the data in the following table to use the **ip igmp stream-limit-group** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-65535>                                            | Configures the maximum number of allowed streams for the specified ports on this VLAN. The range is from 0-65535 and the default is 4.                                                                                                                                                                                                                        |
| {slot/port[/sub-port] [-slot/port[/sub-port]][,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

**Configuring multicast router discovery options**

Configure the multicast router discovery options to enable the automatic discovery of multicast-capable routers.

**About This Task****Important**

The switch does not support the Multicast Router Discovery (MRDISC) protocol on brouter ports.

**Procedure**

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable multicast router discovery:  

```
ip igmp mrdisc
```
3. Configure the maximum advertisement intervals between successive advertisements:  

```
ip igmp mrdisc maxadvertinterval <2-180> maxinitadvertinterval <2-180>
```
4. Configure the maximum advertisements after initialization:  

```
ip igmp mrdisc maxinitadvertisements <2-15>
```
5. Configure the minimum advertisement interval between successive advertisements:  

```
ip igmp mrdisc minadvertinterval <3-180>
```
6. Configure the time allowed before a neighbor is declared dead:  

```
ip igmp mrdisc neighdeadinterval <2-180>
```

### Example

Configure the maximum advertisement intervals between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc maxadvertinterval 30 maxinitadvertinterval 5
```

Configure the maximum advertisements after initialization:

```
Switch:1(config-if)#ip igmp mrdisc maxinitadvertisements 8
```

Configure the minimum advertisement interval between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc minadvertinterval 30
```

Configure the time allowed before a neighbor is declared dead:

```
Switch:1(config-if)#ip igmp mrdisc neighdeadinterval 60
```

### Variable definitions

Use the data in the following table to use the **ip igmp mrdisc** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>maxadvertinterval</i> <2-180>     | Configures the maximum number (in seconds) between successive advertisements.<br>For this change to take effect, you must save the configuration, and then reset the switch.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 20.        |
| <i>maxinitadvertinterval</i> <2-180> | Configures the maximum number (in seconds) between successive initial advertisements.<br>For this change to take effect, you must save the configuration, and then reset the switch.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 2. |

| Variable                                        | Value                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>maxinitadvertisements &lt;2-15&gt;</code> | Configures the maximum number of initial multicast advertisements after initialization.<br>For this change to take effect, you must save the configuration, and then reset the switch.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 3.   |
| <code>minadvertinterval &lt;3-180&gt;</code>    | Configures the minimum number (in seconds) between successive advertisements.<br>For this change to take effect, you must save the configuration, and then reset the switch.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 15.            |
| <code>neighdeadinterval &lt;2-180&gt;</code>    | Configures the multicast router discovery dead interval—the number of seconds the multicast route neighbors for the switch must wait before assuming that the multicast router is down.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 60. |

## Configure Explicit Host Tracking

Configure explicit host tracking to track all the source and group members.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure explicit host tracking:

```
ip igmp igmpv3-explicit-host-tracking
```

3. Display all the tracked members for a specific group:

```
show ip igmp group group <A.B.C.D> tracked-members [member-subnet  
<A.B.C.D/X>] [source-subnet <A.B.C.D/X>] [port {slot/port[/sub-port] [-  
slot/port[/sub-port]] [,...]}] [vlan <1-4059>]
```

4. Display the IGMPv3 specific data:

```
show ip igmp group group <A.B.C.D> detail port {{slot/port[/sub-port]  
[-slot/port[/sub-port]] [,...]} vlan <1-4059>
```

*Examples*

Configure explicit host tracking:

```
Switch:1(config-if)#ip igmp igmpv3-explicit-host-tracking
```

Display all the tracked members:

```
Switch:1#show ip igmp group
```

```
=====
                          Igmp Group - GlobalRouter
=====
```

| GRPADDR   | INPORT   | MEMBER   | EXPIRATION | TYPE    | L2ISID |
|-----------|----------|----------|------------|---------|--------|

```
-----
4 out of 4 group Receivers displayed

Total number of unique groups 2
```

Display all the tracked members for a specific group:

```
Switch:1(config-if)#show ip igmp group group 232.1.1.1 tracked-members
```

```
=====
                          Members of Channels/Groups - GlobalRouter
=====
```

| INTERFACE    | CHANNEL/GROUP | MEMBER          | MEMBER_MODE | EXP |
|--------------|---------------|-----------------|-------------|-----|
| Vlan333-2/30 | */232.1.1.1   | 133.133.133.200 | IS_EXCLUDE  | 205 |

Note:

The "\*" attached to the interface (if any) indicates that the interface has explicit host tracking disabled.

Display IGMPv3 specific data:

```
Switch:1(config-if)#show ip igmp group group 232.32.32.10 detail
```

```
=====
                          Igmp Group Detail - GlobalRouter

V1 Host Timer:            Not Running
Interface Group Include Source List:
  Source Address  Expires
  133.133.133.200 114
```

*Variable definitions*

Use the data in the following table to use the **ip igmp igmpv3-explicit-host-tracking** command.

| Variable                      | Value                                                                   |
|-------------------------------|-------------------------------------------------------------------------|
| <i>explicit-host-tracking</i> | Enables explicit host tracking on IGMPv3. The default state is disable. |
| <i>&lt;A.B.C.D&gt;</i>        | Specifies the IP address of the group of the tracked member.            |

## Configuring IGMP static members

Configure IGMP static members to add members to a snoop group. You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams are always forwarded to the multicast router within the VLAN, in addition to the ports in this static entry.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure interface static members:

```
ip igmp static-group {A.B.C.D} {A.B.C.D} {port {slot/port[/sub-port]} [-slot/port[/sub-port]] [, ...]} [static|blocked]
```

### Example

Configure interface static members:

```
Switch:1(config-if)#ip igmp static-group 239.1.1.1 239.1.2.1 port 2/1 static
```

*Variable definitions*

Use the data in the following table to use the **ip igmp static-group** command.

| Variable                   | Value                                                           |
|----------------------------|-----------------------------------------------------------------|
| <i>{A.B.C.D} {A.B.C.D}</i> | Indicates the IP address range of the selected multicast group. |
| <i>port</i>                | Adds ports to a static group entry                              |

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Creates a static group entry. Specifies the port or list of ports that is a member of the VLAN interface being configured to which you want to redirect the multicast stream for this multicast group.<br>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>&lt;static blocked&gt;</code>                                | Configures the route to static or blocked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Configuring SSM dynamic learning and range group

Configure SSM dynamic learning and a range group to enable the IGMPv3 dynamic learning feature and to extend the default SSM range of 232/8 to include an IP multicast address. As new SSM channels are learned, the system displays them in the SSM channel table.

### Before You Begin

- To define the range group, you must first disable PIM.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

- Enter Global Configuration mode:  

```
enable

configure terminal
```
- Enable SSM dynamic learning:  

```
ip igmp ssm dynamic-learning
```
- Configure the range group:  

```
ip igmp ssm group-range <A.B.C.D/X>
```

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter `y` to continue.

## Example

Define the SSM range group address (234.0.0.0) and mask (255.0.0.0). Enable dynamic learning from IGMPv3 reports.

```
Switch:1(config)#ip igmp ssm group-range 234.0.0.0/255.0.0.0

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(config)#ip igmp ssm dynamic-learning
```

### Variable definitions

Use the data in the following table to use the **ip igmp ssm** command.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

## Changing the SSM range group

Change the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address.

### Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

### About This Task

#### Important

This procedure reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), it also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable PIM:

```
no ip pim enable
```

If you forget to disable PIM, the system displays the following error message:

```
Error: PIM is enabled in SSM mode, disable PIM
```

3. Delete each entry in the SSM channel table:

```
no ip igmp ssm-map [all] [{A.B.C.D} enable]
```

If you forget to delete the SSM channels, the system displays the following error message:

```
Error: SSM source group table not empty
```

4. Configure the new IP multicast group address:

```
ip igmp ssm group-range {A.B.C.D/X}
```

The system displays the following message:

```
Warning: Changing the SSM range will cause all spb-multicast and spb-
pim-gw enabled interfaces to be internally bounced. Do you wish to
continue? (y/n) ? (y/n)?
```

Enter y to continue.

5. Enable PIM:

```
ip pim enable
```

### Example

Configure the new IP multicast group address:

```
Switch:1(config)#ip igmp ssm group-range 232.0.0.0/16
```

```
WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
```

### Variable definitions

Use the data in the following table to use the **ip igmp ssm group-range** and **ip igmp ssm** commands.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X} | Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0. |

## Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a

consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple sources to the same group for both static source group and an SSM map.

### About This Task

The consistency check applies to all SSM map entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenable it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the SSM map table for all static entries:  

```
ip igmp ssm-map all
```
3. Create a static entry for a specific group:  

```
ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
```

### Example

Create an SSM map table entry for the multicast group 234.0.1.0 and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1(config)#ip igmp ssm-map 234.0.1.0 192.32.99.151
Switch:1(config)#ip igmp ssm-map all
```

#### Variable definitions

Use the data in the following table to use the **ip igmp ssm-map** command.

| Variable                         | Value                                                                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{A.B.C.D} {A.B.C.D}</code> | Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group.                         |
| <code>{A.B.C.D} enable</code>    | Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry. |

## Configuring multicast access control for an IGMP Ethernet port

Configure multicast access control for an IGMP Ethernet port to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> {A.B.C.D/X} <deny-tx|deny-rx|deny-both|
allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64>> {A.B.C.D/X} mode <deny-tx|deny-rx|
deny-both|allow-only-tx|allow-only-rx|allow-only-both>
```

### Variable definitions

Use the data in the following table to use the **ip igmp access-list** command

| Variable                                                                       | Value                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D/X}</i>                                                             | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| <i>deny-tx deny-rx deny-both  allow-only-tx allow-only-rx  allow-only-both</i> | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                                                                                                     |
| <i>mode</i>                                                                    | Changes the access control group configuration.                                                                                                                                                                                                                                              |
| <i>WORD&lt;1-64&gt;</i>                                                        | Specifies the name of the access list from 1–64 characters.                                                                                                                                                                                                                                  |

## Configuring multicast access control for a VLAN

Configure multicast access control for an IGMP VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure multicast access control:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] <deny-tx|deny-rx|deny-both|
allow-only-tx|allow-only-rx|allow-only-both>
```

3. Change an existing access list:

```
ip igmp access-list WORD<1-64> [A.B.C.D/X] mode <deny-tx|deny-rx|deny-
both|allow-only-tx|allow-only-rx|allow-only-both>
```

### Variable definitions

Use the data in the following table to use the **ip igmp access-list** command.

| Variable                                                              | Value                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X}                                                           | Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. |
| deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both | Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic                                                                                                                                     |
| mode                                                                  | Changes the access control group configuration.                                                                                                                                                                                                                                              |
| WORD<1-64>                                                            | Specifies the name of the access list from 1-64 characters.                                                                                                                                                                                                                                  |

## Configuring Fast Leave Mode

Configure fast (immediate) leave mode to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces. Normal IGMP behavior is skipped. Fast leave mode provides one command that controls all IGMP fast leave enabled interfaces.

### Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode for IGMPv3. For more information on enabling explicit-host-tracking, see [Configure Explicit Host Tracking](#) on page 1592.

### About This Task

If a single user connects to an interface, you do not need to track if other users exist on the interface to perform the fast leave. In cases like this, you must change the mode to one-user.

#### Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- View the current fast leave mode:

```
show ip igmp sys
```

#### Note

This command is not supported on a node configured as the DvR Leaf within a DvR domain.

- Configure fast leave mode:

```
ip igmp immediate-leave-mode <multiple-user|one-user>
```

### Example

Change the mode to one-user.

```
Switch:1(config)#ip igmp immediate-leave-mode one-user
```

#### Variable definitions

Use the data in the following table to use the **ip igmp immediate-leave-mode** command.

| Variable                      | Value                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>multiple-user one-user</i> | <i>multiple-user</i> removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This configuration is the default.<br><i>one-user</i> removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process. |

## Enabling fast leave mode on a port

Enable fast (immediate) leave mode to specify if a port receives a leave message from a member of a group. If you enable fast leave mode on a port, it uses the global fast leave mode configuration.

### Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Enable fast leave:

```
ip igmp immediate-leave
```

## Configuring IGMP fast leave members on a VLAN

Configure IGMP fast leave members on a VLAN to specify fast leave capable ports.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable fast leave on the VLAN:

```
ip igmp immediate-leave
```

3. Configure fast leave members on a VLAN:

```
ip igmp immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

### Variable definitions

Use the data in the following table to use the **ip igmp immediate-leave-members** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Enable IGMP Layer 2 Querier

When no multicast router exists in your network, you can use IGMP Layer 2 Querier to allow the Layer 2 switch to act as a multicast router so that the system can participate in multicast environments where multicast routing is not required.

### Before You Begin

- You must enable IGMP snooping.

### About This Task

When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.

By default, IGMP Layer 2 Querier is disabled.

Enable Layer 2 Querier on only one node in the VLAN.

On Shortest Path Bridging (SPB) Customer VLANs (CVLAN), IGMP Querier is enabled automatically when you enable snooping on the VLAN.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable IGMP Layer 2 Querier:

```
ip igmp snoop-querier
```

### What to Do Next

You must enable the IGMP Layer 2 Querier address. See [EnablingIGMPLayer2QuerierAddress](#)

## Enable IGMP Layer 2 Querier Address

To use the IGMP Layer 2 Querier feature you must designate the IGMP Layer 2 Querier source IP address, the address the system uses in the query message.

### Before You Begin

- Enable IGMP Layer 2 Querier.

### About This Task

You must configure the IGMP Layer 2 Querier address to an IP address in the IP subnet that IGMP hosts, and to which IGMP snoopers in the VLAN belong.

The default IP address is 0.0.0.0 when the IGMP Layer 2 Querier is disabled.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```

3. Verify the configuration:

```
show ip igmp snooping [vrf WORD<1-16>] [vrfids WORD<0-512>
```

### Example

Enable the IGMP Layer 2 Querier feature for VLAN 4, and configure the querier address. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 4
```

```

Switch:1(config-if)#ip igmp snoop-querier

## IGMP configuration using EDM

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

### Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration > Edit > Chassis** and click on the **Boot Config** tab.

### Before You Begin

- Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
- Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM), or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

### Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see [Select and Launch a VRF Context View](#) on page 3832.

## Enabling IGMP snoop on a VLAN

Enable IGMP snooping on a VLAN to optimize the multicast data flow for a group within a VLAN to only those that are members of the group that uses IGMP snoop.

### About This Task

The switch listens to group reports from each port and builds a database of multicast group members for each port. The switch suppresses the reports heard by not forwarding them to other hosts, forcing the members to continuously send their own reports.

The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. The switch multicasts data only to the participating group members and to the multicast routers within the VLAN.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. Select the **ProxySnoopEnable** check box.
9. For SteamLimtEnable, select **enable**.
10. Click **Apply**.

## Configuring IGMP interface static members

Configure IGMP interface static members to add members to a snoop group.

### About This Task

You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams always forward to the multicast router within the VLAN, in addition to the ports in this static entry.

#### Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Static** tab.
4. Click **Insert**.
5. Type the appropriate information.
6. Click **Insert**.

**Static** field descriptions

Use the data in the following table to use the **Static** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>          | Shows the interface where the IGMP entry is enabled.                                                                                                                                                                                                                                                                                     |
| <b>GrpAddr</b>          | Indicates the start of the IP multicast address range of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message. |
| <b>ToGrpAddr</b>        | Indicates the end of the IP multicast address range of the multicast stream. If an address is not entered, the IP address in the GrpAddr field is the single address.                                                                                                                                                                    |
| <b>MemberPorts</b>      | Specifies the ports to which you want to redirect the multicast stream for this multicast group. The ports must be member ports of the VLAN.                                                                                                                                                                                             |
| <b>NotAllowedToJoin</b> | Specifies the ports that do not receive the multicast stream for this multicast group.                                                                                                                                                                                                                                                   |

## Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) or multiple groups to different sources for both static source group and an SSM channel.

### Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

### About This Task

The consistency check applies to all SSM channel entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenabling it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Map** tab.
4. Select **Insert**.

5. Type the IP address for the multicast group and source.
6. Select **Insert**.

You can change the default status of an SSM map from enable to disable in the **AdminState** field.

### **Ssm Map** field descriptions

Use the data in the following table to use the **Ssm Map** tab.

| Name                  | Description                                                                                                                                                                                                                       |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpMulticastGrp</b> | Specifies an IP multicast address that is within the SSM range.                                                                                                                                                                   |
| <b>IpSource</b>       | Specifies the IP address of the source that sends traffic to the group.                                                                                                                                                           |
| <b>LearningMode</b>   | Displays whether the entry is statically configured (Static) or dynamically-learned from IGMPv3 (Dynamic). This variable a read-only field.                                                                                       |
| <b>Activity</b>       | Displays the current activity of the selected (S,G) entry. True indicates that traffic is flowing to the switch, otherwise, the system displays it false. This variable a read-only field.                                        |
| <b>AdminState</b>     | Configures the administrative state for the selected static entry. This state determines whether the switch uses the static entries. Configure this field to enable (default) to use the entry or disable to save for future use. |

## Configure SSM Range and Global Parameters

Configure the SSM range parameter to extend the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without changing their group configurations.

### Before You Begin

- To change the RangeGroup configuration, you must first disable PIM.
- To change the RangeGroup configuration, you must delete all entries in the SSM channel table before you configure the new IP multicast group address.

### About This Task

The other global parameters enable the IGMPv3 dynamic learning feature and configure the administrative state for all the entries in the SSM channel table.

#### Important

If you change the RangeGroup configuration, the switch reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), this procedure also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Ssm Global** tab.
4. Configure the appropriate fields.
5. Select **Apply**.

### *Ssm Global* field descriptions

Use the data in the following table to use the **SsmGlobal** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DynamicLearning</b>   | Activates the dynamic learning of SSM channel (S,G) pairs from IGMPv3 reports. As new SSM channels are learned, the system displays them in the SSM channel table.                                                                                                                                                                                                                                                                                                   |
| <b>RangeGroup</b>        | Configures the IP multicast group address. The lowest group address is 224.0.0.0 and the highest is 239.255.255.255. The default is 232.0.0.0.                                                                                                                                                                                                                                                                                                                       |
| <b>RangeMask</b>         | Configures the address mask of the multicast group. The default is 255.0.0.0.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SsmMapAdminAction</b> | Configures the administrative state, which determines whether the switch uses the table entries: <ul style="list-style-type: none"> <li>• <b>enableAll</b>—Globally activates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries.</li> <li>• <b>disableAll</b>—Globally inactivates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries.</li> </ul> |

## Configuring multicast stream limitation on an interface

Configure multicast stream limitation to limit the number of concurrent multicast streams on the interface. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific interface and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the interface drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit** tab.
4. To change the status of an interface, double-click on the **StreamLimitEnable** field for the interface, and then select **enable** or **disable** from the menu. If the interface is enabled, you can edit the **Maximum Number of Stream** field.

- Click **Apply**.

### **StreamLimit** field descriptions

Use the data in the following tab to use the **StreamLimit** tab.

| Name                            | Description                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>                | Displays the slot and port number or VLAN ID for this interface.                                                     |
| <b>StreamLimitEnable</b>        | Enables or disables stream limitation on this interface.                                                             |
| <b>Maximum Number Of Stream</b> | Configures the maximum number of streams allowed on this interface. The range is from 0–65535, and the default is 4. |
| <b>Current Number Of Stream</b> | Displays the current number of streams received on this interface. This value is a read-only value.                  |

## Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific VLAN and control access to multicast streams.

### About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Basic** tab.
- Select a VLAN.
- Click **IP**.
- Click the **IGMP** tab.
- For StreamLimitEnable, select **enable**.
- Configure the maximum number of streams.
- Click **Apply**.

## Configuring multicast stream limitation on a port

Configure multicast stream limitation to limit the number of concurrent multicast streams on the port. Limit the number of streams to protect the bandwidth on a specific port and control access to multicast streams.

### Procedure

- On the Device Physical View tab, select a port.
- In the navigation pane, expand the following folders: **Configuration > Edit > Port**.

3. Click **IP**.
4. Click the **IGMP** tab.
5. In the StreamLimitEnable field, select the **Enable** option button.
6. Configure the maximum number of streams.
7. Click **Apply**.

## Configuring multicast stream limitation members

Configure multicast stream limitation members on ports of the specified interface to configure the maximum number of streams on the interface.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click **Insert**.
5. Type the number of the VLAN to which you want to add a member or click **Vlan** to select an ID from the list.
6. Type the number of the slot and port that you want to add as a member or click **Port**, and then select one from the graphic display. If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

#### Important

You must select one of the ports in the VLAN that you selected in step 4.

7. Type a maximum number of streams or accept the default of 4.
8. Click **Insert**.

### **StreamLimit Members** field descriptions

Use the data in the following table to use the **StreamLimit Members** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b> | Displays the ID of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Port</b>    | Lists each slot and port number for this interface with stream limitation enabled.<br>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

| Name              | Description                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxStreams</b> | Configures the maximum number of allowed streams for this specific port. The number of allowed streams cannot exceed the maximum number for the interface. The range is from 0-65535 and the default is 4. |
| <b>NumStreams</b> | Displays the current number of streams received on this interface. This value is a read-only value.                                                                                                        |

## Deleting multicast stream limitation member

Delete a multicast stream limitation member from an interface to remove it from the configuration.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click on the row that lists the member you want to delete.
5. Click **Delete**.

## Configuring the IGMP interface

Configure the IGMP interface to change global IGMP values for the interface. Use the Interface tab to view or edit the IGMP interface table.

### About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but PIM-SM is not enabled, the system displays the interface as notInService in the Status field.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **IGMP**.
3. Click the **Interface** tab.
4. Edit the appropriate information.
5. Click **Apply**.

**Interface** Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                     |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                            |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                      |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                            |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                               |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                       |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1.<br>Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval. |
| <b>WrongVersionQueries</b>  | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                       |
| <b>Joins</b>                | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                 |
| <b>Robustness</b>           | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.<br>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastMembQueryIntvl</b>          | <p>Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.</p> <p>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0-255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)</p> |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>FlushAction</b>                 | <p>Configures the flush action to one of the following:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RouterAlertEnable</b>           | <p>Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.</p> <p><b>Important:</b><br/>To maximize network performance, configure this parameter according to the version of IGMP currently in use.</p> <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                             |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierAddr</b>            | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ExplicitHostTrackingEnable</b>  | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>McastMode</b>                   | <p>Indicates the protocol configured on the VLAN.</p> <ul style="list-style-type: none"> <li>• snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>• snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>• pim — Indicates PIM is enabled.</li> <li>• routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul>                                                                                                                                                                                    |

| Name                             | Description                                                                                                                                                                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ExtnUpnpFilterEnable</b>      | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                   |
| <b>ExtnUpnpFilterAddress</b>     | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                              |
| <b>ExtnUpnpFilterAddressMask</b> | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                       |
| <b>SnoopOrigin</b>               | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul> |

## Configuring IGMP sender entries

Configure IGMP sender entries to identify a source that sends multicast data to a multicast group.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Sender** tab.
4. Change the appropriate options.
5. Click **Apply**.

### *Sender* field descriptions

Use the data in the following table to use the **Sender** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>    | Specifies the interface where you enabled the IGMP entry.                                                                                                                                                                                                                                                                |
| <b>GrpAddr</b>    | Specifies the multicast group address of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message. |
| <b>MemberAddr</b> | Specifies the IP address of a host.                                                                                                                                                                                                                                                                                      |
| <b>Action</b>     | Flushes an entry or a group.                                                                                                                                                                                                                                                                                             |
| <b>TPort</b>      | Identifies the T port.                                                                                                                                                                                                                                                                                                   |

| Name          | Description                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------|
| <b>State</b>  | Indicates whether a sender exists because of an IGMP access filter. The options are filtered and not filtered. |
| <b>L2lsid</b> | Specifies the Layer 2 I-SID of the C-VLAN.                                                                     |

## Configuring Fast Leave Mode

Configure fast leave mode to control all IGMP fast leave enabled interfaces.

### Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode. To enable explicit-host-tracking, see [Configuring IGMP parameters on a port](#) on page 1531 and [Configuring IGMP parameters on a VLAN](#) on page 1533.

### About This Task

Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Use this global parameter to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces.

#### Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

- In the navigation pane, expand the following folders: **Configuration > IP**.
- Click **IGMP**.
- Click the **Global** tab.
- Select the mode.
- Click **Apply**.

**Global** field descriptions

Use the data in the following table to use the **Global** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FastLeaveMode</b> | Configures the mode to one of the following values: <ul style="list-style-type: none"> <li>multipleUser: Removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This value is the default.</li> <li>oneUser: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process.</li> </ul> |
| <b>GenerateTrap</b>  | Generates a trap. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>GenerateLog</b>   | Generates a log message. The default is disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring multicast access control for an interface

Configure multicast access control for a selected IGMP interface or VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Access Control** tab.
4. Click **Insert**.
5. Type the number of the slot and port or VLAN ID that you want to add as a member or click the appropriate button, and then select one from the graphic display.
6. Click the ellipsis button (...) next to **PrefixListId**.
7. Select a prefix list ID.
8. Click **OK**.
9. Type the host address and host mask.
10. Select the action mode that you want for the specified host.
11. Click **Insert**.

**Access Control** field descriptions

Use the data in the following table to use the **Access Control** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Specifies the interface where the IGMP entry is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>PrefixListId</b>   | Specifies a numeric string that identifies the prefix list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>HostAddr</b>       | Specifies the IP address of the host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>HostMask</b>       | Specifies the subnet mask that determines the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>PrefixListName</b> | Specifies the name of the prefix list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ActionMode</b>     | Specifies the action for the host identified by HostAddr. The options include the following: <ul style="list-style-type: none"> <li>denied IP multicast transmitted traffic (deny-tx).</li> <li>denied IP multicast received traffic (deny-rx).</li> <li>denied both IP multicast transmitted and received traffic (deny-both).</li> <li>allowed IP multicast transmitted traffic (allow-only-tx).</li> <li>allowed IP multicast received traffic (allow-only-rx).</li> <li>allowed both IP multicast transmitted and received traffic (allow-only-both).</li> </ul> |

## Viewing IGMP cache information

View IGMP cache information to view the group for which members exist on a specific interface.

**About This Task**

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

**Procedure**

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**
3. Click the **Cache** tab.

**Cache** field descriptions

Use the data in the following table to use the **Cache** tab.

| Name           | Description                                                                         |
|----------------|-------------------------------------------------------------------------------------|
| <b>Address</b> | Shows the IP multicast group address for this entry that contains this information. |
| <b>IfIndex</b> | Shows the interface from which the corresponding multicast group address is heard.  |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastReporter</b>      | Shows the IP address of the source of the last membership report received for this IP multicast group address on this interface. If no membership report is received, the object uses the value 0.0.0.0.                                                                                                                                                             |
| <b>ExpiryTime</b>        | Shows the amount of time (in seconds) that remain before this entry ages out.                                                                                                                                                                                                                                                                                        |
| <b>Version1HostTimer</b> | Shows the time that remains until the local router assumes that no IGMPv1 members exist on the IP subnet attached to the interface. Upon hearing IGMPv1 membership report, this value resets to the group membership timer. When the time that remains is nonzero, the local router ignores IGMPv2 leave messages for this group that it receives on this interface. |
| <b>Type</b>              | Shows the type of IGMP entry.                                                                                                                                                                                                                                                                                                                                        |
| <b>StaticPorts</b>       | Shows the static ports associated with the entry.                                                                                                                                                                                                                                                                                                                    |

## Viewing IGMPv3 cache

View the IGMPv3 specific data corresponding to each interface, port, and multicast group pair on a router.

### About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **IGMPv3 Cache** tab to view the IGMPv3 cache information.

### **IGMPv3 Cache** field descriptions

Use the data in the following table to use the **IGMPv3 Cache** tab.

| Name                   | Description                                                                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>    | Specifies the Multicast group Address (Class D) that others want to join. A group address can be the same for many incoming ports.                                                      |
| <b>IfIndex</b>         | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.                                                  |
| <b>InPort</b>          | An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.                                                  |
| <b>ModeExpiryTimer</b> | Represents the time remaining before the interface EXCLUDE state expires and the interface state transitions to INCLUDE mode. This value is applicable only to IGMPv3-compatible nodes. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Version1HostTimer</b> | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 1 members on the IP subnet attached to this interface. This entry only applies to IGMPv1 hosts. Upon hearing any IGMPv1 report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 Leave messages for this group that it receives on this interface. |
| <b>Version2HostTimer</b> | Specifies the time remaining until the local router assumes that there are no longer any IGMP version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 membership report, this value is reset to the group membership timer. Assuming no IGMPv1 hosts have been detected, the local router does not ignore any IGMPv2 Leave messages for this group that it receives on this interface.                 |
| <b>SourceFilterMode</b>  | Specifies the current group state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.                                                                                                                                                                                                                                                                                                |

## Viewing and editing multicast router discovery information

View multicast router discovery information to view the current configuration.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Multicast Router Discovery** tab.
4. To edit the current configuration, double-click the value, make the change, and then click **Apply**.

### **Multicast Router Discovery** field descriptions

Use the data in the following table to use the **Multicast Router Discovery** tab.

| Name                | Description                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>    | Shows the interface where IGMP is enabled.                                                                                                                                                                                                               |
| <b>MrdiscEnable</b> | Enables (true) or disables (false) the router interface to listen for multicast router discovery messages to determine where to send multicast source data and IGMPv2 reports. If you enable snoop, you automatically enable multicast router discovery. |

| Name                               | Description                                                                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DiscoveredRouterPorts</b>       | Lists ports that the Multicast Router Discovery (MRDISC) protocol discovers.<br><br><b>Important:</b><br>The switch does not support the MRDISC protocol on brouter ports.                                                        |
| <b>MaxAdvertiseInterval</b>        | Shows the maximum time allowed between sending router advertisements from the interface, in seconds. The range is from 2–180 seconds. The default is 20 seconds.                                                                  |
| <b>MinAdvertiseInterval</b>        | Shows the minimum time allowed between sending unsolicited router advertisements from the interface, in seconds. This value must be more than 3 seconds but no greater than the value assigned to the MaxAdvertiseInterval value. |
| <b>MaxInitialAdvertiseInterval</b> | Configures the maximum number (in seconds) of multicast advertisement intervals that you can configure on the switch.                                                                                                             |
| <b>MaxInitialAdvertisements</b>    | Configures the maximum number of initial multicast advertisements that you can configure on the switch.                                                                                                                           |
| <b>NeighborDeadInterval</b>        | Shows the time interval (in seconds) before the router interface drops traffic after a user leaves the multicast group.                                                                                                           |

## Viewing the IGMP router source list

View the source list entries corresponding to each interface and multicast group pair on a router.

### About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Igmp Router Source List** tab to view the IGMPv3 cache information.

### *Igmp router source list* field descriptions

Use the data in the following table to use the **Igmp Router Source List** tab.

| Name                | Description                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b> | Specifies the IP multicast group address for which this entry contains information.                                                        |
| <b>IfIndex</b>      | Specifies the interface for which this entry contains information for an IP multicast group address.                                       |
| <b>InPort</b>       | Specifies a unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports for this source. |

| Name                 | Description                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HostAddress</b>   | Specifies the host address to which this entry corresponds.                                                                                                                                 |
| <b>MemberAddress</b> | Specifies the IP Address of a member that has sent source specific report wishing to join this source.                                                                                      |
| <b>Expire</b>        | This value indicates the relevance of the source list entry, where a non-zero value indicates this is an INCLUDE state value, and a zero value indicates this to be an EXCLUDE state value. |
| <b>Mode</b>          | Specifies the current member state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.                                                     |
| <b>MemberExpire</b>  | This value indicates the time until the member for this source expires.                                                                                                                     |

## Viewing IGMP snoop information

View information about IGMP snoop to see the current configuration.

### About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop** tab.

### *Snoop field descriptions*

Use the data in the following table to use the **Snoop** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>            | Shows the VLAN ID for the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SnoopEnable</b>          | Shows the status of IGMP snoop. IGMP snoop works only if a multicast router exists in the VLAN.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SsmSnoopEnable</b>       | Shows the status of SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ProxySnoopEnable</b>     | Indicates whether the IGMP report proxy feature is enabled. If you enable this feature, the switch forwards reports from hosts to the multicast router once for each group for each query interval, or after new group information is available. If you disable this feature, the switch forwards all reports from different hosts to multicast routers, and can forward more than one group report for the same multicast group for each query interval. The default is enabled. |
| <b>FastLeaveEnable</b>      | Shows the status of fast leave for this port.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FastLeavePortMembers</b> | Lists ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopMRouterPorts</b>       | Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router.<br><br><b>Important:</b><br>Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms. |
| <b>SnoopActiveMRouterPorts</b> | Shows the active multicast router ports. Active multicast router ports are ports that directly attach to a multicast router. These ports include the querier port and all ports in the forwarding state that you configure as well as those that were dynamically learned through receiving queries.                                                                                                                                                                                                |
| <b>SnoopMRouterExpiration</b>  | Indicates the time that remains before the multicast router ages out. If the switch does not receive queries before this time expires, it flushes out all group memberships known to the VLAN. The query maximum response interval (obtained from the queries received) is used as the timer resolution.                                                                                                                                                                                            |

## View IGMP Snoop Trace Information

View the multicast group trace to track the data flow path of multicast streams.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **IGMP**.
3. Click the **Snoop Trace** tab.

### **Snoop Trace** Field Descriptions

Use the data in the following table to use the **Snoop Trace** tab.

| Name           | Description                                                           |
|----------------|-----------------------------------------------------------------------|
| <b>GrpAddr</b> | Displays the IP multicast address of the group traversing the router. |
| <b>SrcAddr</b> | Displays the IP source address of the multicast group.                |
| <b>OutVlan</b> | Displays the egress VLAN ID for the multicast group.                  |
| <b>InPort</b>  | Displays the ingress port for the multicast group.                    |
| <b>InVlan</b>  | Displays the ingress VLAN ID for the multicast group.                 |
| <b>OutPort</b> | Displays the egress port of the multicast group.                      |
| <b>Type</b>    | Displays the port type on which the snoop entry is learned.           |

## View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

### About This Task

#### Note

The following procedure displays the dynamically learned IGMP groups. **IP > IGMP > Static** displays statically configured IGMP groups. This is in contrast to the CLI command **show ip igmp group**, which displays both dynamically learned and statically configured IGMP groups, and the CLI command **show ip igmp static**, which displays only the statically configured groups.

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Groups** tab.

### *Groups* Field Descriptions

Use the data in the following table to use the **Groups** tab.

| Name              | Description                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddress</b>  | Shows the multicast group address (Class D). A group address can be the same for many incoming ports.                              |
| <b>Members</b>    | Shows the IP address of the host that issues the membership report to this group.                                                  |
| <b>InPort</b>     | Shows the port that receives the group membership report.                                                                          |
| <b>IfIndex</b>    | Shows a unique value that identifies a physical interface or a logical interface (VLAN) that receives the membership report.       |
| <b>Expiration</b> | Shows the time left before the group report expires on this port. This variable is updated after the port receives a group report. |

## Route management using the CLI

With multicast route commands, you can configure and view IP multicast routing parameters on the switch.

### Configuring multicast stream limits

Limit the number of multicast streams to protect the CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

## About This Task

You can enable or disable the mroute stream limit for the entire device or for individual ports when the switch is operating. If you enable the mroute stream limit for the device and for an individual port, only the periodic check is performed for that port.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable stream limitation globally:  
`ip mroute stream-limit`
3. Enter GigabitEthernet Interface Configuration mode.  
`interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}`
4. Enable stream limits:  
`ip mroute stream-limit`
5. For Gigabit Ethernet interfaces, configure the maximum number of streams and the interval at which to sample:  
`ip mroute max-allowed-streams <1-32768> max-allowed-streams-timer-  
check <1-3600>`
6. Show the mroute stream limit configuration:  
`show ip mroute interface gigabitethernet [{slot/port[/sub-port] [-slot/  
port[/sub-port]] [,...]]`

## Example

```
Switch:1(config)#ip mroute stream-limit
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#ip mroute stream-limit
Switch:1(config-if)#ip mroute max-allowed streams 1000 max-allowed-streams-timer-check 20
```

### Variable definitions

Use the data in the following table to use the **interface** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                             | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

Use the data in the following table to use the **ip mroute** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max-allowed-streams <1-32768>            | Configures the maximum number of streams on the specified port. The port is shut down if the number of streams exceeds this limit. The value is a number between 1-32768. The default value is 1984 streams. To configure this option to the default value, use the <b>default</b> operator with the command.                      |
| max-allowed-streams-timer-check <1-3600> | Configures the sampling interval, which checks if the number of ingress multicast streams to the CPU is under a configured limit or if the port needs to shut down. The range is between 1-3600. The default value is 10 seconds. To configure this option to the default value, use the <b>default</b> operator with the command. |

## Configuring multicast static source groups

Configure static source group entries in the Protocol Independent Multicast (PIM) multicast routing table. The PIM cannot prune these entries from the distribution tree.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

### About This Task

Even if no receivers exist in the group, the multicast stream for a static source group entry remains active.

The maximum number of static source groups must not exceed 1024.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a static source group entry:

```
ip mroute static-source-group <A.B.C.D> <A.B.C.D/X>
```

### Example

Create a static source group for two multicast groups: 224.32.2.1 and 226.50.2.2. The static source group for group 224.32.2.1 is for a source subnet 10.10.10.0/24. The static source group for group 226.50.2.2 is for the host 20.20.20.100/32.

```
Switch:1(config)# ip mroute static-source-group 224.32.2.1 10.10.10.0/24
Switch:1(config)# ip mroute static-source-group 226.50.2.2 20.20.20.100/32
```

### Variable definitions

Use the definitions in the following table to use the **ip mroute static-source-group** command.

| Variable         | Value                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>A.B.C.D</i>   | Specifies the IP address of the multicast group. Use the <b>no</b> operator to later remove this configuration.                                                                                                                                                                |
| <i>A.B.C.D/X</i> | Specifies the multicast source IP address and subnet mask for the static source group entry. You cannot create duplicate groups. How you configure the source address depends on the protocol and mode you use. Use the <b>no</b> operator to later remove this configuration. |

## Configuring IP multicast software forwarding

When you use the IP multicast software forwarding feature you can avoid initial data loss experienced by multicast applications; this is suitable for low bandwidth conditions.

When you configure the IP multicast software forwarding feature the system forwards the initial packets of an IP multicast data stream it receives and creates a corresponding hardware record for subsequent packets.

By default, multicast software forwarding is disabled.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB

Multicast. If you enable IP multicast software forwarding, the hardware continues to forward IP multicast traffic. The software only forwards initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only.

If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding and packet suppression by the hardware is disabled.

If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

### Important

To avoid overloading the CPU, ensure that you do not use the IP multicast software forwarding feature for video multicast applications.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable software forwarding:  
multicast software-forwarding
3. Show the software forwarding configuration:  
show multicast software-forwarding

### Example

```
Switch:1#show multicast software-forwarding
=====
                        Mcast Software Forwarding - GlobalRouter
=====
McastSoftwareForwarding      :enabled
```

## Configuring the resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

After you configure the counter thresholds for ingress and egress records, if the record usage exceeds the threshold, you receive notification by a trap on the console, a logged message, or both.

If you do not configure the thresholds, the system displays only the ingress and egress records currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the thresholds:

```
ip mroute resource-usage egress-threshold <0-32767> ingress-threshold <0-32767>
```

3. Configure one of the following notification methods:

- Configure a log-only notification method:

```
ip mroute resource-usage log-msg
```

- Configure a trap-only notification method:

```
ip mroute resource-usage trap-msg
```

- Configure both notification methods:

```
ip mroute resource-usage log-msg trap-msg
```

### Example

Configure the egress threshold to 200.

```
Switch:1(config)# ip mroute resource-usage egress-threshold 200
```

Configure the ingress threshold to 100.

```
Switch:1(config)# ip mroute resource-usage ingress-threshold 100
```

Enable the log message notification method.

```
Switch:1(config)# ip mroute resource-usage log-msg
```

### Variable definitions

Use the data in the following table to use the **ip mroute resource-usage** command.

| Variable                                       | Value                                                                                                                                                                                                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>egress-threshold &lt;0-32767&gt;</code>  | Configures the egress record threshold (S,G). The system sends a notification message after the number of streams exceeds a threshold level.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 0. |
| <code>ingress-threshold &lt;0-32767&gt;</code> | Configures the ingress record threshold. The system sends a notification message after the number of streams exceeds a threshold level.<br>To configure this option to the default value, use the <b>default</b> operator with the command. The default is 0.      |

## Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

### About This Task

#### Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure a prefix list:
 

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [le <0-32>]
```
- (Optional) Rename an existing prefix list:
 

```
ip prefix-list WORD<1-64> name WORD<1-64>
```
- Display the prefix list:
 

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [WORD <1-64>]
```

## Example

Configure a prefix-list. Display the prefix list.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list LIST1 47.17.121.50/255.255.255.0
Switch:1(config)#show ip prefix-list LIST1
=====
                        Prefix List - GlobalRouter
=====
      PREFIX              MASKLEN FROM TO
-----
List 1      LIST1:
      47.17.121.50      24      24      24
1 Total Prefix List entries configured
-----
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range
```

### Variable definitions

The following table defines parameters for the **ip prefix-list** command.

| Variable        | Value                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D/X}     | Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d/x</li> <li>a.b.c.d/x.x.x.x</li> <li>default</li> </ul> |
| ge <0-32>       | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                    |
| le <0-32>       | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                    |
| name WORD<1-64> | Renames the specified prefix list. The name length is 1-64 characters.                                                                                                       |
| WORD<1-64>      | Specifies the name for a new prefix list.                                                                                                                                    |

The following table defines parameters for the **show ip prefix-list** command.

| Variable       | Value                                                  |
|----------------|--------------------------------------------------------|
| {A.B.C.D}      | Specifies the prefix to include in the command output. |
| vrf WORD<1-16> | Specifies the name of the VRF.                         |

| Variable                              | Value                                                                |
|---------------------------------------|----------------------------------------------------------------------|
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the ID of the VRF and is an integer in the range of 0-512. |
| <code>WORD&lt;1-64&gt;</code>         | Specifies a prefix list, by name, to use for the command output.     |

The following table defines parameters for the **show ip prefix-list** command output.

| Variable | Value                                             |
|----------|---------------------------------------------------|
| PREFIX   | Indicates the member of a specific prefix list.   |
| MASKLEN  | Indicates the prefix mask length in bits.         |
| FROM     | Indicates the prefix mask starting point in bits. |
| TO       | Indicates the prefix mask endpoint in bits.       |

## Route management using EDM

View or edit interface configuration information for Layer 3 IP multicast protocols on the switch.

### View Multicast Route Information

View multicast route information for troubleshooting purposes.

This tab shows multicast routing information for IP datagrams from a particular source and addressed to a particular IP multicast group address.

#### About This Task

##### Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

#### Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Select the **Routes** tab.

**Routes** field descriptions

Use the data in the following table to use the **Routes** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>            | Displays the IP multicast group address for this entry that contains multicast routing information.                                                                                                                                                                                                                                                                                |
| <b>Source</b>           | Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.                                                                                                                                                                                                                 |
| <b>SourceMask</b>       | Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.                                                                                                                                                                                                                                                          |
| <b>UpstreamNeighbor</b> | Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.                                                                                                                                                                                                                            |
| <b>Interface</b>        | Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.                                                                                                                                                                                                                                 |
| <b>ExpiryTime</b>       | Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                                                                 |
| <b>Protocol</b>         | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb (12)</li> <li>• spbpimgw(13)</li> </ul> |

## View Multicast Next-Hop Information

View all multicast next-hop information.

This tab shows information about the next hops used by outgoing interfaces to route IP multicast datagrams. Each entry is one in a list of next hops on outgoing interfaces for particular sources that send to a particular multicast group address.

**About This Task**

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Next Hops** tab.

**Next Hops** field descriptions

Use the data in the following table to use the **Next Hops** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>             | Displays the IP multicast group for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                                                                                                                    |
| <b>Source</b>            | Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                           |
| <b>SourceMask</b>        | Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.                                                                                                                                                                  |
| <b>ReceiverPort</b>      | Displays the receiver port for this next hop.                                                                                                                                                                                                                                                                                                         |
| <b>OutInterface</b>      | Displays the interface slot and portnumber or VLAN ID for the outgoing interface for this next hop.                                                                                                                                                                                                                                                   |
| <b>Address</b>           | Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface.                                                                                            |
| <b>State</b>             | Displays whether the outgoing interface and next hop represented by this entry currently forward IP datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.                                                                                                                                    |
| <b>UpTime</b>            | Displays the up time for this entry.                                                                                                                                                                                                                                                                                                                  |
| <b>ExpiryTime</b>        | Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                            |
| <b>ClosestMemberHops</b> | Displays the minimum number of hops between this router and members of the IP multicast group reached through the next hop on this outgoing interface. IP multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop.                                                                  |
| <b>Protocol</b>          | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |
| <b>Pkts</b>              | Displays the number of next hop packets.                                                                                                                                                                                                                                                                                                              |

## View Multicast Interface Information

View multicast interface information to verify the multicast configuration.

This tab shows multicast routing information specific to interfaces.

## About This Task

You can view multicast interface information for a Layer 3 VSN the same way you view the Global Router except that you must first launch the appropriate VRF context.

### Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Interfaces** tab.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Displays the slot and port number or VLAN ID for this entry.                                                                                                                                                                                                                                                                                          |
| <b>Ttl</b>       | Displays the datagram time-to-live (TTL) threshold for the interface. IP multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.                                                                                  |
| <b>Protocol</b>  | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb</li> </ul> |

## Adding new static source groups

Add a new static source group to create an entry that the switch cannot prune from the distribution tree. An attempt to add a duplicate of an existing source-group entry results in an error message.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-SM
  - PIM-SSM

### About This Task

### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Click **Insert**.
5. Complete the information in the dialog box.
6. Click **Insert**.

## Editing static source groups

Configure static source-group entries in the PIM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers exist in the group, the multicast stream for a static source-group entry stays active.

### Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The maximum number of static source groups must not exceed 1024.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Edit the required information.
5. Click **Apply**.

**Static Source Group** field descriptions

Use the data in the following table to use the **Static Source Group** tab.

| Name                 | Description                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GroupAddress</b>  | Configures the multicast group IP address for this static source-group entry.                                                                              |
| <b>SourceSubnet</b>  | Configures the multicast source address for this static source-group entry. How you configure the source address depends on the protocol and mode you use. |
| <b>SrcSubnetMask</b> | Configures the subnet mask of the source for this static source-group entry.                                                                               |

## Configuring IP multicast software forwarding

Configure IP multicast software forwarding to enable the system to initially forward IP multicast data until a hardware record is created. The system forwards the initial packets of a stream it receives and creates a corresponding hardware record for subsequent packets. The advantage of this feature is that it avoids initial data loss experienced by multicast applications and is most suited for low bandwidth.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware still forwards IP multicast traffic. The software forwards only initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only. If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding. If you enable software forwarding, packet suppression by the hardware is disabled. If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

By default, the feature is disabled.

#### Important

To avoid overloading the CPU, do not use the IP multicast software forwarding feature for video multicast applications.

If you configure multicast software forwarding from within a VRF context, the configuration applies to the Global Router and all VRF contexts. You cannot change the multicast software forwarding configuration for individual VRF contexts.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.

2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select the **SWForwardingEnable** check box.
5. Click **Apply**.

### **Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                      | Description                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>SWForwardingEnable</b> | Enables the system to initially forward IP multicast data until a hardware record is created. The default is disabled. |
| <b>StatsEnabled</b>       | Enables or disables multicast route statistics. The default is disabled.                                               |
| <b>StatsClear</b>         | Clears multicast route statistics.                                                                                     |

## Configuring mroute stream limit

Limit the number of multicast streams to protect a CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

### **Procedure**

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Select the **Mroute Stream Limit** tab.
5. Select the **StreamLimitEnable** box.
6. Edit other fields as required.
7. Click **Apply**.

### **Mroute Stream Limit** field descriptions

Use the data in the following table to use the **Mroute Stream Limit** tab.

| Name                     | Description                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>StreamLimitEnable</b> | Enables or disables mroute stream limit on the port.                                                                      |
| <b>StreamLimit</b>       | Specifies the maximum number of multicast streams allowed to enter the CPU through this port.                             |
| <b>StreamTimerCheck</b>  | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through this port. |

## Configuring Mroute Stream Limit on an Extreme Integrated Application Hosting Port

### About This Task

Perform this procedure to limit the number of multicast streams to protect a Central Processing Unit (CPU) from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization, or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Insight Port**.
2. Select the Extreme Integrated Application Hosting (IAH) port you want to configure.
3. Select the **Mroute Stream Limit** tab.
4. Select **StreamLimitEnable**.
5. Configure other fields as required.
6. Select **Apply**.

### *Mroute Stream Limit* Field Descriptions

Use data in the following table to configure the **Mroute Stream Limit** tab.

| Name                     | Description                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>StreamLimitEnable</b> | Enables or disables mroute stream limit on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.                              |
| <b>StreamLimit</b>       | Specifies the maximum number of multicast streams allowed to enter the CPU through the IAH port. The default value is 1984.                             |
| <b>StreamTimerCheck</b>  | Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through the IAH port. The default is 10 seconds. |

## Configuring resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

### About This Task

#### Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

#### Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Select the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

### *Resource Usage* field descriptions

Use the data in the following table to use the **Resource Usage** tab.

| Name                          | Description                                                                                                                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Egress Records In-Use</b>  | Displays the number of egress records traversing the switch.                                                                                                                                           |
| <b>Ingress Records In-Use</b> | Displays the number of ingress records (source or group) traversing the switch.                                                                                                                        |
| <b>Egress Threshold</b>       | Configures the egress threshold level (0-32767).                                                                                                                                                       |
| <b>Ingress Threshold</b>      | Configures the ingress threshold level (0-32767).                                                                                                                                                      |
| <b>SendTrapOnly</b>           | Sends only trap notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. You can configure only one notification type. |
| <b>SendTrapAndLog</b>         | Sends both trap and log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.                                       |
| <b>LogMsgOnly</b>             | Sends only log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.                                                |

## Multicast route statistics configuration using the CLI

The following sections provide procedural information you can use to configure multicast route statistics using the Command Line Interface (CLI).

### Enabling IP multicast route statistics

Enable the collection and display of IP multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

#### Note

When you enable IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the collection of IP multicast route statistics.  

```
ip mroute stats enable
```
3. (Optional) Set the IP multicast route statistics to default.  

```
default ip mroute stats enable
```
4. (Optional) Disable the collection of IP multicast route statistics.  

```
no ip mroute stats enable
```
5. View the IP multicast route statistics.  

```
show ip mroute stats [WORD<3-160> {A.B.C.D[,E.F.G.H][,...]}]
```

### Note

The maximum number of multicast group IP addresses is 10.

## Example

Enable the collection of IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip mroute stats enable
```

View the IP multicast route statistics:

```
Switch:1#show ip mroute stats

=====
                          Multicast Stats
=====
-----
                          Statistics : Enabled
```

View the statistics for the multicast group IP address 225.0.0.1:

```
Switch:1#show ip mroute stats 225.0.0.1

=====
                          Multicast Stats - GlobalRouter
=====
-----
GroupAddress      SourceCounter      IngressPackets      IngressBytes      AverageSize
-----
225.0.0.1         1                  30452198             3897881344        128
```

View the statistics for multiple (up to a maximum of 10) group IP addresses.

```
Switch:1#show ip mroute stats
225.0.0.1,225.0.0.2,225.0.0.3,225.0.0.4,225.0.0.5,225.0.0.6,225.0.0.7,225.0.0.8,225.0.0.9,
225.0.0.10
```

```

225.0.0.10        1                   32446203             4153113984        128

```

### Variable definitions

Use the data in the following table to use the **show ip mroute stats** command.

| Variable                                 | Definition                                                                                                                                                                                                                        |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<3-160><br>{A.B.C.D[,E.F.G.H][,...]} | Specifies the multicast group IP address for which to display statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses.<br>You can specify a maximum of 10 groups. |

## Clearing IP multicast route statistics

Use this procedure to clear the IP multicast route statistics. This resets the IP multicast statistics counters.

### Note

When you clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the IP multicast route statistics:  
clear ip mroute stats

### Example:

Clear the IP multicast route statistics:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ip mroute stats

```

## Monitoring IP multicast route statistics

Use this procedure to monitor the IP multicast route statistics at regular intervals.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Monitor the IP multicast route statistics:

```
monitor ip mroute stats WORD<7-160> {A.B.C.D[,E.F.G.H] [,...]}
```

#### Note

You can monitor a maximum of 10 group IP addresses.

### Example:

Monitor the IP multicast route statistics for the group IP address 225.0.0.1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>en
Switch:1#monitor ip mroute stats 225.0.0.1

                          MULTICAST STATISTIC

| Variable                                 | Definition                                                                                                                                                                                                    |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<7-160><br>{A.B.C.D[,E.F.G.H][,...]} | Specifies the multicast group IP address for which to monitor statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

## Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable the collection of IPv6 multicast route statistics.  
ipv6 mroute stats enable
3. (Optional) Set the IPv6 multicast route statistics to default:  
default ipv6 mroute stats
4. (Optional) Disable the collection of IPv6 multicast route statistics.  
no ipv6 mroute stats
5. View the IPv6 multicast route statistics.  
show ipv6 mroute stats [WORD<7-400> {Ipv6address[,Ipv6address][,...]}]

#### Note

The maximum number of multicast group IP addresses is 10.

### Example:

Enable collection of IPv6 multicast route statistics:

```

Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ipv6 mroute stats enable

```

View the IPv6 multicast route statistics:

```
Switch:1#show ipv6 mroute stats

*Variable definitions*

Use the data in the following table to use the **show ipv6 mroute stats** command

| Variable                                                    | Definition                                                                                                                                                                                                                        |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<7-400><br>{ Ipv6address [, Ipv6address]<br>[ , ... ] } | Specifies the multicast group IP address for which to display statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses.<br>You can specify a maximum of 10 groups. |

## Clearing IPv6 multicast route statistics

Use this procedure to clear the IPv6 multicast route statistics. This resets the IP multicast statistics counters.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the IPv6 multicast route statistics:  
clear ipv6 mroute stats

*Example:*

Clear the IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ipv6 mroute stats
```

## Monitoring IPv6 multicast route statistics

Use this procedure to monitor IPv6 multicast route statistics at regular intervals.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Monitor IPv6 multicast route statistics:  
monitor ipv6 mroute stats WORD<7-400> {Ipv6address[,Ipv6address]  
[,...]}

#### Note

You can monitor a maximum of 10 group IP addresses.

*Example:*

Monitor the IPv6 multicast route statistics for the group IPv6 address FF05::1. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>enable
Switch:1#monitor IPv6 mroute stats FF05::1

### Variable definitions

Use the data in the following table to use the **monitor ipv6 mroute stats** command:

| Variable                                               | Definition                                                                                                                                                                                                    |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORD<7-400><br>{Ipv6address[, Ipv6address]<br>[, ...]} | Specifies the multicast group IP address for which to monitor statistics.<br>The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10. |

## Multicast route statistics configuration using EDM

The following sections provide procedural information you can use to configure multicast route statistics using the Enterprise Device Manager (EDM).

## Enabling IP multicast route statistics

Use this procedure to enable IP multicast route statistics.

### Note

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**
2. Click **Multicast**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

### *Globals* Field Definitions

Use the data in the following table to use the **Globals** tab.

| Field        | Description                                                 |
|--------------|-------------------------------------------------------------|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear   | Clears the multicast route statistics.                      |

## Viewing IP multicast route statistics

Use this procedure to view IP multicast route statistics.

### Before You Begin

- You must enable the collection of multicast statistics.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Stats** tab to view the statistics.

### *Stats* Field Definitions

Use the data in the following table to use the **Stats** tab.

| Field         | Description                                                                 |
|---------------|-----------------------------------------------------------------------------|
| GroupAddress  | Specifies the multicast group IP address for which to show statistics.      |
| SourceCounter | Specifies the number of sources associated with the multicast route record. |
| Pkts          | Specifies the number of packets received for the associated IP address.     |

| Field             | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bytes             | Specifies the number of bytes received for the associated IP address.                                                                                                                                          |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

## Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

### **Globals** Field Definitions

Use the data in the following table to use the **Globals** tab.

| Field        | Description                                                 |
|--------------|-------------------------------------------------------------|
| StatsEnabled | Displays whether the multicast route statistics is enabled. |
| StatsClear   | Clears the multicast route statistics.                      |

## Viewing IPv6 multicast route statistics

Use this procedure to view IPv6 multicast route statistics.

### Before You Begin

- You must enable the collection of multicast statistics.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Stats** tab to view the statistics.

**Stats** Field Definitions

Use the data in the following table to use the **Stats** tab.

| Field             | Description                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GroupAddress      | Specifies the multicast group IP address for which to show statistics.                                                                                                                                         |
| SourceCounter     | Specifies the number of sources associated with the multicast route record.                                                                                                                                    |
| Pkts              | Specifies the number of packets received for the associated IP address.                                                                                                                                        |
| Bytes             | Specifies the number of bytes received for the associated IP address.                                                                                                                                          |
| AverageSizePerPkt | Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte. |

|                                          | VSP 8600 Series | Not Supported      |
|                                          | XA1400 Series   | Not Supported      |

## IP Multicast over Fabric Connect Fundamentals

### *IP Multicast over Fabric Connect*

Extreme Networks is leading the industry with a new approach to transporting IP multicast using IP Multicast over Fabric Connect. IP Multicast over Fabric Connect greatly simplifies multicast deployment, with no need for any multicast routing protocols such as Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM). A BEB can forward a multicast stream anywhere in an SPBM network where IS-IS advertises the stream to the rest of the fabric.

The advantage of this solution over traditional approaches is the simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

You can compare the quick convergence times for IP Multicast over Fabric Connect to Interior Gateway Protocols like Open Shortest Path First (OSPF) combined with PIM-SM or PIM-SSM. OSPF combined with PIM-SM or PIM-SSM can have recovery times that are sub optimal with convergence times that take tens of seconds. PIM experiences longer convergence times, in part, because unicast IP routing protocols must converge before PIM can converge. PIM also maintains the network state for every multicast group and uses a mechanism based on each hop to update the network about state changes, which affects scalability.

IP Multicast over Fabric Connect is extremely scalable because you only apply the multicast bridging and routing functionality at the SPBM fabric edge, with the streams mapped to SPBM multicast trees in the fabric.

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

### **IP Multicast over Fabric Connect and Universal Plug and Play Filtering**

When multicast packets are received on IGMP-enabled interfaces and the multicast group matches the range of groups to be filtered, Universal Plug and Play (uPnP) Filtering drops them.

For more information, see [Universal Plug and Play Filtering](#) on page 1661.

### How IP Multicast over Fabric Connect works

The BEBs act as the boundary between the multicast domain (currently only IGMP dynamic or static) and the SPBM domain. Multicast senders (sources) and receivers connect directly or indirectly (using Layer 2 switches) to the BEBs. You can enable IP Multicast over Fabric Connect services at the Layer 2 VSN level or the Layer 3 VSN level (including the GRT).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

**Figure 155: IP Multicast over Fabric Connect streams**

The following list describes how multicast senders and receivers connect to the SPBM cloud using BEBs in the preceding diagram:

1. The sender transmits multicast traffic with group IP address 233.252.0.1.
2. After the BEB receives the IP multicast stream from the sender, the BEB allocates data I-SID 16000001 for the S,G multicast stream. The BEB sends an LSP with the TLV 185 (for Layer 2 VSN multicast and Layer 3 VSN multicast) or TLV 186 (for IP Shortcuts multicast) with the transmit bit set. The BEB also sends an IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the I-SID is the Data I-SID).
3. The receiver sends a join request to Group 233.252.0.1.
4. The BEB (acting as the IGMP Querier) queries the IS-IS database to find all senders for group 233.252.0.1. If the group exists, the BEB sends an LSP with the IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the nickname is the stream transmitter BEB and the I-SID is the data I-SID).
5. The multicast tree is calculated for the data I-SID and the data starts flowing from the sender.

### Scope level

IP Multicast over Fabric Connect constrains all multicast streams within the level in which they originate, which is called the scope level. In other words, if a sender transmits a multicast stream to a BEB on a C-VLAN (a VLAN that is mapped to an I-SID, for instance, a Layer 2 VSN) with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream. Similarly, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT or a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 instance (GRT or L3 VSN) can receive that stream.

#### Note

In the context of IP Multicast over Fabric Connect, scope is either the Global Routing Table or the I-SID value of the Layer 2 or Layer 3 VSN associated with the local VLAN on which the IP multicast data was received.

### Data I-SID

After the BEB receives the IP multicast stream from the sender, a BEB allocates a data Service Identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the S,G, V tuple, which is the source IP address, the group IP address, and the local VLAN the multicast stream is received on.

The BEB propagates this information through the SPBM cloud by using IS-IS TLV updates in LSPs, which results in the creation of a multicast tree for that stream. All BEBs now know what data I-SID to use for that stream and its scope. The data I-SID is a child of the scope or VSN I-SID. If no receiver requests the IP multicast stream, the ingress BEB does not forward the multicast stream.

### IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver, and this information is propagated through the SPBM cloud.

IS-IS acts dynamically using the TLV information it receives from BEBs that connect to the sender and the receivers to create a multicast tree between them. IS-IS creates very efficient multicast trees for the data I-SID allocated at the sender edge of the SPBM cloud to transport data between the sender and the receivers. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID. After IS-IS creates the multicast tree, the sender transports data to the receiver across the SPBM cloud using the data I-SID.

The trigger to send IS-IS updates to announce a multicast stream into the SPBM cloud is the multicast traffic arriving at the BEB. Because the BEB only interacts with IGMP and not PIM, all multicast traffic must be drawn towards the BEB for the stream to be announced, which SPBM accomplishes by making the BEB an IGMP Querier. In a VLAN, the IGMP Querier sends out periodic IGMP queries.

#### Note

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, it causes unexpected behavior, including traffic loss.

### *BEB as IGMP Querier*

The BEB acts as the IGMP Querier and creates tables for links that need IP multicast streams. IGMP and IGMP Snooping cannot work without an IGMP Querier that sends out periodic IGMP queries.

The BEB only interacts with IGMP messages and not PIM. All multicast traffic must enter the BEB for the data stream to be announced.

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, unexpected behavior results, including traffic loss.

The IGMP query message is an IP packet and requires a source IP address. However, Layer 2 IGMP Snooping with SPBM by default turns on the service without the configuration of an IP address on the VLAN. By default, the BEB sends an IGMP query message with an IP source address of 0.0.0.0. If there are interoperability issues with third party vendors as a result of the 0.0.0.0 IP address, then you can configure the querier address under IGMP, without having to configure an IP address for the Layer 2 VSN VLAN.

IGMP Snooping, operating on the Layer 2 VSN, listens to conversations between hosts and routers, and maintains a table for links that need IP multicast streams.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

For more conceptual and configuration information on IGMP, see [IP Multicast](#) on page 1431.

### *Switch Clustering at the Edge of the SPBM Network*

Typical customer deployments require redundancy all the way to the access side of the network. IP Multicast over Fabric Connect supports switch clustering, Split Multilink Trunking (SMLT) technology, at the edge of the SPBM fabric, providing redundancy to the access Layer 2 switch where you can attach multicast senders and receivers. Typical SPBM fabric deployments use two or more B-VLANs for Equal Cost Multipath (ECMP) and resiliency. For simplicity in understanding how the SPBM network works, assume that there are two B-VLANs (primary and secondary).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

**Figure 156: IP Multicast over Fabric Connect streams in an SMLT configuration**

The following list describes the preceding diagram:

1. The edge switch hashes the sender multicast data to a specific MLT link.
2. A multicast stream received at the edge of the SPBM fabric is mapped to a dedicated multicast data I-SID.
3. For the non-SMLT attached sender 2, the stream is hashed to the primary or secondary B-VLAN based on whether the data I-SID is even or odd numbered. For the SMLT attached to sender 1, IS-IS advertises the stream to the rest of the fabric on the primary B-VLAN and synchronizes information to the vIST peer.
4. The edge switch hashes the receiver IGMP join to a specific MLT link.
5. Both BEBs on both B-VIDs advertise the IGMP join.
6. The multicast tree is built for (S1,G1), which is rooted in the primary sender BEB. The multicast tree is built for (S1,G1), which is rooted in the secondary sender BEB.

IGMP Snooping is widely used on Layer 2 access switches to prune multicast traffic. In IP Multicast over Fabric Connect, BEBs are the IGMP Queriers, therefore access switches forward multicast data from the senders as well as IGMP control messages from receivers to the BEBs.

When a sender transmits multicast data to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB allocates a data I-SID and sends a TLV update on either the primary B-VLAN or the secondary B-VLAN, depending on whether the BEB is the primary or secondary switch. The primary switch uses the primary B-VLAN, whereas, the secondary switch uses the secondary B-VLAN. This information is propagated through the SPBM fabric so all BEBs are aware of this stream availability.

The sender information is also synchronized over the vIST to the peer switch. Then the peer switch allocates a data I-SID for the multicast stream and sends a TLV update on the appropriate B-VLAN to

announce the availability of the stream. The data I-SIDs allocated by the primary and secondary switch cluster peers may be the same or different, as they are allocated independently by each switch.

**Note**

If a sender attaches to only one BEB in a switch cluster, the sender information is not synchronized over the vIST because it is not SMLT attached. The sender information is advertised, and data is sent on either the primary or secondary B-VLAN. The odd-numbered data I-SIDs use the primary B-VLAN, and the even-numbered data I-SIDs use the secondary B-VLAN. The same hashing rules apply to the forwarding of multicast data.

When a receiver sends an IGMP join message to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB queries the IS-IS Link State Database (LSDB) to check if a sender exists for the requested stream within the scope of the receiver.

If the requested stream does not exist, the BEB keeps the IGMP information but no further action is taken. If the requested stream exists, the BEB sends an IS-IS Link State Packet (LSP), with TLV update information, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of a receiver. The BEB propagates this information through LSPs through the SPBM cloud. The receiver information is also synchronized over the vIST to the peer switch. The peer switch then queries its IS-IS Link State Database (LSDB) and, if the requested stream exists, it sends an IS-IS LSP, with a TLV update, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of the receiver.

IS-IS uses these TLV updates in LSPs to create multicast shortest path first trees in the SPBM fabric. IS-IS creates a shortest path first tree for the primary and secondary B-VLANs, but only one of the B-VLANs transports multicast data with the other in active standby in case of failures at the SPBM edge. After IS-IS creates the trees, multicast data flows between senders and receivers.

**IP Multicast over Fabric Connect and SMLT**

The following section summarizes the IP Multicast over Fabric Connect actions in an SMLT environment. The BEBs on the sender side behave as follows:

- Primary SMLT peer BEB always advertises the streams it receives, and sends data for them on the primary B-VLAN.
- Secondary SMLT peer BEB always advertises the streams it receives, and sends data for them on the secondary B-VLAN.
- Non-SMLT BEBs or SMLT BEBs with single attached senders advertise streams, and send data on the primary or secondary B-VLAN based on hash criteria (odd-numbered data I-SIDs use primary B-VLAN; even-numbered data I-SIDs use secondary B-VLAN).

The BEBs on the receiver side behave as follows:

- The primary SMLT peer BEB that receives multicast data on the primary B-VLAN sends it to both SMLT and non-SMLT SPBM access (UNI) links.
- The primary SMLT peer BEB that receives multicast data on the secondary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.
- The secondary SMLT peer BEB that receives multicast data on primary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.

- The secondary SMLT peer BEB that receives multicast data on secondary B-VLAN sends data to both SMLT and non-SMLT SPBM access (UNI) links.
- The non-SMLT BEB that receives multicast data on primary or secondary B-VLAN sends data to all SPBM access (UNI) links.

### Layer 2 Querier behavior for a switch cluster

For C-VLANs in an SMLT environment, the vIST ports are not part of the VLAN.

IGMP on a C-VLAN behaves as follows to account for the fact that vIST peers do not see the membership queries of each other:

- The vIST peer with the higher IP address sends the queries out all SMLT and non-SMLT ports on SPBM access links.
- The vIST peer with the lower IP address only sends out queries on its non-SMLT ports. This includes SMLT ports whose remote ports are down (SMLT state of 'norm').
- With the existence of an vIST peer with a higher IP address and an vIST peer with a lower IP address, it means two queriers exist within the C-VLAN. Having two queriers poses no problems in this SPB environment, as all SMLT access devices see the vIST peer with the higher IP address as the querier, and non-SMLT access devices see the directly connected vIST peer as the querier. Non-SMLT access devices that connect on either side of the vIST peers can talk to each other using the SPBM cloud.

### Considerations when you connect an IP Multicast over Fabric Connect network to a PIM network

IP Multicast over Fabric Connect does not integrate PIM functionality. Apply the following considerations when you connect to a PIM network:

- You must configure static IGMP receivers on the BEB access interface that faces the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network.

#### Note

The PIM router must have a configuration option to accept streams with non-local sources or the router drops the packets. The switch does not support a configuration option to accept streams with non-local sources.

You must configure static IGMP receivers on the PIM interface that face the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.

#### Note

For security reasons and to limit unnecessary multicast streams from being injected into the SPBM domain, you should configure ACLs on the BEB facing the PIM network.

### IP Multicast over Fabric Connect restrictions

Review the following restrictions for the IP Multicast over Fabric Connect feature.

#### IGMP

The BEB must be the only IGMP querier in the network. If the BEB receives an IGMP query from any other device, it causes unpredictable behavior, including traffic loss.

SPBM supports IGMP Snooping on a C-VLAN, but it does not support PIM on a C-VLAN. If you enable IGMP Snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IP Multicast over Fabric Connect.

SPBM supports Network Load Balancing (NLB) unicast and multicast modes. SPBM does not support NLB Multicast operation with IGMP.

**Note**

The NLB Multicast operation feature is not supported on all hardware platforms. For more information about feature support, see [VLAN Feature Support](#) on page 3736.

You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is either the same as the IGMP version configured on the IGMP Snooping VLAN, or that compatibility mode is enabled.

**SSM**

If you delete any **ssm-map** in a static range group, the switch deletes the entire static range group. For example, create an ssm-map for 232.122.122.122 to 232.122.122.128 and after that configure this same range in a static group. If you delete any ssm-map between 232.122.122.122. to 232.122.122.128, the switch deletes the entire static range group.

**PIM**

There can be no interaction with PIM and multicast routers on the access.

The BEB only interacts with IGMP messages and not PIM, so all multicast traffic must be drawn towards the BEB, which acts as the IGMP querier, for the stream to be announced.

IP Multicast over Fabric Connect does not integrate PIM functionality so the following considerations apply when connecting to a PIM network:

- You must configure static IGMP receivers on the BEB access interface facing the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network. Static IGMP receivers make the PIM router accept streams and avoid a Reverse Path Forwarding (RPF) check that can change the source of the stream.
- You must configure static IGMP receivers on the PIM interface facing the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.
- You must configure Access Control Lists (ACLs) on the BEB facing the PIM network for security.

**Data I-SID**

The BEB matches a single multicast stream to a particular data I-SID. As a result there is a one-to-one mapping between the S,G to data I-SID for each BEB.

**Supported services**

The switch does not support IP Multicast over Fabric Connect routing on inter-VSN routing interfaces.

The switch supports the following modes of IP Multicast over Fabric Connect:

- Layer 2 VSN multicast service — Multicast traffic remains within the same Layer 2 VSN across the SPBM cloud.
- Layer 3 VSN multicast service — Multicast traffic remains within the same Layer 3 VSN across the SPBM cloud.
- IP Shortcuts multicast service — Multicast traffic can cross VLAN boundaries but remains confined to the subset of VLANs with the Global Routing Table that have IP Multicast over Fabric Connect enabled.

### SPBM Multicast FIB

#### Multicast FIB

SPBM runs all pair Dijkstras to produce the multicast FIB. The computing node loops through each node to run Dijkstra using that node as the root, and then prunes paths to only keep the shortest paths. The computing node then computes the intersection of the set of I-SIDs for which the root node transmits, with the set of I-SIDs for which the path endpoints receive.

The multicast addresses are built out of two pieces: the SPBM Node Nickname and the I-SID ID converted to hexadecimal format to form the multicast MAC address.

|                                    |
|------------------------------------|
| ----- -----                        |
| nickname 0x30000 hexadecimal I-SID |

For example, if the nickname is 0.00.10 and the I-SID is 100 (0x64), the multicast address is 03:00:10:00:00:64.

The following text shows an example of the multicast FIB.

```
Switch:1(config)#show isis spbm multicast-fib

### Universal Plug and Play Filtering

The switch can filter multicast packets destined for the Universal Plug and Play (uPnP) multicast IP address with a Universal Plug and Play (uPnP) Filtering option. uPnP Filtering drops all incoming multicast packets received by a switch on an IGMP-enabled interface if the destination multicast IP address matches the configured range.

uPnP Filtering applies to both multicast receivers and multicast senders. If you want to use the uPnP Filtering address range for actual multicast streaming, you must disable uPnP Filtering on the IGMP interface.

uPnP Filtering is disabled by default. If you create a new IGMP interface, uPnP Filtering is enabled automatically on the interface for the destination multicast IP address range 239.255.255.250/32. If you enable uPnP Filtering on an existing IGMP-enabled interface with senders and receivers already present, the filter does not delete the existing senders or receivers; the filter begins to drop packets from that point forward. Existing senders and receivers eventually expire and senders are not relearned.

You can use CLI or EDM to configure a different destination multicast IP address range.

uPnP Filtering functions in the following scenarios:

- IGMP snooping is enabled on a VLAN and IP Multicast over Fabric Connect on Layer 2 VSN is configured.
- IP Multicast over Fabric Connect within the Global Routing Table (GRT) is configured.
- IP Multicast over Fabric Connect on a Layer 3 VSN is configured.

## IP Multicast over Fabric Connect Configuration using the CLI

### *Enabling IP Multicast over Fabric Connect globally*

Use this procedure to enable IP Multicast over Fabric Connect globally on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose.

#### Note

IP Multicast over Fabric Connect uses I-SIDs starting at 16,000,000 and above. If Layer 2 or Layer 3 I-SIDs are in this range, the system displays an error message and the switch does not enable IP Multicast over Fabric Connect.

#### Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

### **Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must add IST slot/ports to the C-VLAN for an SMLT topology.

### **Procedure**

1. To enter User EXEC mode, log on to the switch.

## 2. Verify no I-SIDs exist in the default reserved range:

- a. For Layer 2 use the following command:

```
show vlan i-sid
```

- b. For Layer 3 use the following command:

```
show ip ipvpn vrf WORD<1-16>
```

## 3. Enter IS-IS Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router isis
```

## 4. Enable IP Multicast over Fabric Connect globally:

```
spbm <1-100> multicast enable
```

**Note**

The switch only supports one SPBM instance.

## 5. (Optional) Disable IP Multicast over Fabric Connect globally:

```
no spbm <1-100> multicast enable
```

```
default spbm <1-100> multicast enable
```

**Example**

Enable IP Multicast over Fabric Connect globally:

```
Switch:1>show vlan i-sid
=====
                Vlan I-SID
=====
VLAN_ID      I-SID      I-SID NAME
-----
1
10           100        Hospital-Server-10
90           1000       ISID-1000

3 out of 3 Total Num of Vlans displayed
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast enable
```

**Variable definitions**

The following table defines parameters for the **spbm** command.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-100>  | Enables IP Multicast over Fabric Connect globally. The default is disabled. Specifies the SPBM instance. The switch only supports one instance. |

*Display IP Multicast over Fabric Connect information*

Use this procedure to display IP Multicast over Fabric Connect summary information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the status of the global IP Multicast over Fabric Connect configuration:
 

```
show isis spbm multicast
```
3. Display IP Multicast over Fabric Connect summary information for each S, G, V tuple:
 

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```
4. Display information about the multicast routes on the switch:
 

```
show ip mroute route [vrf WORD<1-32>] [vrffids WORD<0-255>]
```

**Example**

Display IP Multicast over Fabric Connect global configuration information:

```
Switch:1>enable
Switch:1#show isis spbm multicast

                multicast : enable
                fwd-cache-timeout(seconds) : 210

Switch:1#show isis spb-mcast-summary

=====
                        SPB multicast - Summary
=====
SCOPE   SOURCE          GROUP           DATA           LSP  HOST

**Variable Definitions**

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                               | Value                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i>                           | Displays the total number of SPB multicast entries.                                                                                             |
| <i>host-name WORD&lt;0-255&gt;</i>     | Displays the IP Multicast over Fabric Connect summary information for a specific host-name.                                                     |
| <i>lspid &lt;xxx.xxx.xxx.xx-xx&gt;</i> | Displays the IP Multicast over Fabric Connect summary information for the specified LSP ID that you enter in xxx.xxx.xxx.xx-xx — 8 byte format. |

The following table defines parameters for the **show ip mroute route** command.

| Variable                        | Value                |
|---------------------------------|----------------------|
| <i>vrf WORD&lt;1-32&gt;</i>     | Specifies a VRF.     |
| <i>vrfids WORD&lt;0-255&gt;</i> | Specifies the VRF ID |

### Display the Multicast FIB

#### About This Task

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the SPBM multicast FIB:  
show isis spbm multicast-fib [vlan <1-4059>] [i-sid <1-16777215>]  
[nick-name <x.xx.xx>] [summary]

#### Example

```
Switch#show isis spbm multicast-fib
```

```
=====
                               SPBM MULTICAST FIB ENTRY INFO
=====
```

## Variable Definitions

The following table defines parameters for the `show isis spbm multicast-fib` command.

| Variable                               | Value                                         |
|----------------------------------------|-----------------------------------------------|
| <code>vlan &lt;1-4059&gt;</code>       | Displays the FIB for the specified SPBM VLAN. |
| <code>i-sid &lt;1-16777215&gt;</code>  | Displays the FIB for the specified I-SID.     |
| <code>nick-name &lt;x.xx.xx&gt;</code> | Displays the FIB for the specified nickname.  |
| <code>summary</code>                   | Displays a summary of the FIB.                |

## Configure Universal Plug and Play (uPnP) Filtering

### Before You Begin

Create a port-based VLAN.

### About This Task

Use the following procedure to enable Universal Plug and Play (uPnP) Filtering on an IGMP-enabled interface. uPnP Filtering is disabled by default.

The default uPnP Filtering multicast group address range is 239.255.255.250/32. If you do not configure the multicast group range, uPnP Filtering filters multicast packets destined for the default multicast group range.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable uPnP Filtering:

```
ip igmp upnp-filter [ip {A.B.C.D/X}]
```

### Example

Enable uPnP Filtering on a VLAN using the default multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter
```

Enable uPnP Filtering on a VLAN with configured multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter ip 233.252.0.0/24
```

## Variable Definitions

The following table defines parameters for the **ip igmp upnp-filter** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>ip</i> {A.B.C.D/X}                                                        | Configures the multicast destination IP address range to filter for an IGMP interface. The default multicast group address is 239.255.255.250/32.                                                                                                                                                                                                             |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |

View uPnP Filtering information on an IGMP-enabled interface

Use the following command to display uPnP Filtering information on an IGMP-enabled interface.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]]
```

## Example

View the default uPnP Filtering information on an IGMP-enabled interface:

```
Switch:1#show ip igmp interface vlan 2
=====
Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST PROXY SNOOP SNOOP SSM UPnP FAST FAST
ID INTVL MAX RESP MEMB SNOOP ENABLE ORIGIN SNOOP FILTER LEAVE LEAVE
          RESP          QUERY ENABLE          ENABLE ENABLE ENABLE PORTS
-----
2 125 100 2 2 10 false false RADIUS false false
false

VLAN SNOOP SNOOP DYNAMIC COMPATIBILITY EXPLICIT UPnP
ID QUERIER QUERIER DOWNGRADE MODE HOSTS FILTER
  ENABLE ADDRESS VERSION TRACKING ADDRESS
-----
2 false 0.0.0.0 enable disable disable 239.255.255.250/32
```

View uPnP Filtering information on an IGMP-enabled interface when uPnP Filtering is enabled and a non-default multicast group address is configured:

```
Switch:1(config)#show ip igmp interface vlan 2
=====
Vlan Ip Igmp
=====
VLAN QUERY QUERY ROBUST VERSION LAST PROXY SNOOP SNOOP SSM UPnP FAST FAST

=====
2 false 0.0.0.0 enable disable disable 233.252.0.0/24
=====
```

**Variable Definitions**

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan &lt;1-4059&gt;</i>                                                   | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf WORD&lt;1-16&gt;</i>                                                  | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids WORD&lt;0-512&gt;</i>                                              | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

**IP Multicast over Fabric Connect configuration using the EDM**

*Configure IP Multicast over Fabric Connect Globally*

Use this procedure to globally enable IP Multicast over Fabric Connect on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose. IP Multicast over Fabric Connect uses I-SIDs that start at

16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

#### Important

IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

#### Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

### Procedure

- In the navigation pane, expand **Configuration > IS-IS > SPBM** to determine if any I-SIDs are within the default range reserved for multicast..
- Select the **I-SID** tab to determine if the I-SIDs are within the default range reserved for multicast.
- In the navigation pane, expand **Configuration > IS-IS > SPBM**.
- Select the **SPBM** tab.
- If you want to enable multicast on an SPBM instance that already exists, in the **Mcast** column in the table, select **enable**.
- If you want to enable multicast on an SPBM instance that does not yet exist, select **Insert**.
- In the **Mcast** box, select **enable** to enable IP Multicast over Fabric Connect globally.
- Select **Insert**.
- Select **Apply**.

### SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

| Name                | Description                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------|
| <b>Id</b>           | Specifies the SPBM instance ID. Only one SPBM instance is supported.                                   |
| <b>NodeNickName</b> | Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>. |
| <b>PrimaryVlan</b>  | Specifies the primary SPBM B-VLANs to add to the SPBM instance.                                        |
| <b>Vlans</b>        | Specifies the SPBM B-VLANs to add to the SPBM instance.                                                |

| Name                                                                                                     | Description                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LsdbTrap</b>                                                                                          | Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.                                                                                                |
| <b>IpShortcut</b>                                                                                        | Enables or disables SPBM IP shortcut state. The default is disable.                                                                                                                               |
| <b>SmltSplitBEB</b>                                                                                      | Specifies whether the switch is the primary or secondary vIST peer. The default is primary.                                                                                                       |
| <b>SmltVirtualBmac</b>                                                                                   | Specifies a virtual MAC address that can be used by both peers.                                                                                                                                   |
| <b>SmltPeerSysId</b>                                                                                     | Specifies the system ID of the SPBM SMLT for this SPBM instance.                                                                                                                                  |
| <b>Mcast</b>                                                                                             | Specifies if IP multicast over SPBM is enabled. The default is disabled.                                                                                                                          |
| <b>McastFwdCacheTimeout</b>                                                                              | Specifies the global forward cache timeout in seconds. The default is 210 seconds.                                                                                                                |
| <b>Ipv6Shortcut</b>                                                                                      | Enables or disables SPBM IPv6 shortcut state. The default is disable.                                                                                                                             |
| <b>McastSpbPimGwControllerEnable</b>                                                                     | Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.                                                                                                          |
| <b>McastSpbPimGwGatewayEnable</b>                                                                        | Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.                                                                                                                     |
| <b>StpMultiHoming</b>                                                                                    | Enables or disables MSTP-Fabric Connect Multi Homing.<br>The default is disabled (false).                                                                                                         |
| <b>BVlanOrigin</b><br><br><b>Note:</b><br>Exception: not supported on XA1400 Series and VSP 8600 Series. | Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic. |

### View IP Multicast over Fabric Connect Routes

Use this procedure to display the IP Multicast over Fabric Connect routes.

#### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Select **SPBM**.
3. Select the **IpMcastRoutes** tab.

#### IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vsnlsid</b>       | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.                                                                                                                                                                                                                                                                                                           |
| <b>Group</b>         | Specifies the group IP address for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                           |
| <b>Source</b>        | Specifies the IP address where the IP Multicast over Fabric Connect route originated.                                                                                                                                                                                                                                                                                                    |
| <b>NickName</b>      | Specifies the nick name used to filter criteria.                                                                                                                                                                                                                                                                                                                                         |
| <b>SourceBeb</b>     | Specifies the source BEB for the IP multicast route.                                                                                                                                                                                                                                                                                                                                     |
| <b>VlanId</b>        | Specifies the ID for the C-VLAN.                                                                                                                                                                                                                                                                                                                                                         |
| <b>VrfName</b>       | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Datalsid</b>      | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>Type</b>          | Specifies the type for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                       |
| <b>Bvlan</b>         | Specifies the B-VLAN for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                     |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                                   |

### *Displaying the UNI ports for IP multicast routes*

Use this procedure to display UNI ports associated with particular IP multicast routes.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **IpMcastRoutes** tab.
3. Select the desired row and click the **UNI Ports** tab to display the UNI ports associated with a particular stream.

#### **IpMcastRoutes Uni Ports field descriptions**

Use the data in the following table to use the **IpMcastRoutes Uni Ports** tab.

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>     | Specifies the group IP address for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                               |
| <b>Source</b>    | Specifies the IP address where the IP Multicast over Fabric Connect route originated.                                                                                                                                                                                                                                                                                        |
| <b>Vsnlsid</b>   | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.                                                                                                                                                                                                                                                                                               |
| <b>Datalsid</b>  | Specifies the data I-SID for the IP multicast route. After a BEB receives the IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>SourceBeb</b> | Specifies the source BEB for the IP multicast route.                                                                                                                                                                                                                                                                                                                         |
| <b>VlanId</b>    | Specifies the ID for the C-VLAN.                                                                                                                                                                                                                                                                                                                                             |
| <b>VrfName</b>   | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                      |
| <b>NniPorts</b>  | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports facing a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                          |
| <b>Type</b>      | Specifies the type for the IP multicast route.                                                                                                                                                                                                                                                                                                                               |
| <b>Bvlan</b>     | Specifies the B-VLANs for the IP multicast route.                                                                                                                                                                                                                                                                                                                            |

### Displaying the multicast FIB

Use the following procedure to display the multicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS**.
2. Click **SPBM**.
3. Click the **Multicast FIB** tab.

## Multicast FIB field descriptions

Use the data in the following table to use the **Multicast FIB** tab.

| Name                      | Description                                                                |
|---------------------------|----------------------------------------------------------------------------|
| <b>SysId</b>              | System ID of the node where the multicast FIB entry originated.            |
| <b>Vlan</b>               | VLAN of the multicast FIB entry.                                           |
| <b>McastDestMacAddr</b>   | Multicast destination MAC Address of the multicast FIB entry               |
| <b>Isid</b>               | I-SID of the multicast FIB entry.                                          |
| <b>Isid Name</b>          | Name assigned to the I-SID.                                                |
| <b>HostName</b>           | Host name of the node where the multicast FIB entry originated.            |
| <b>OutgoingInterfaces</b> | Specifies the switched UNI port outgoing interface of multicast FIB entry. |
| <b>IncomingInterface</b>  | Specifies the incoming interface (port or MLT) of the multicast FIB entry. |

## IP Multicast over Fabric Connect configuration examples

### *IP multicast over Fabric Connect global configuration*

The following sections show the steps required to configure IP multicast over Fabric Connect at a global level

#### SwitchC

```
enable
configure terminal
prompt SwitchC

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

#### SwitchG

```
enable
configure terminal
prompt SwitchG

ISIS SPBM CONFIGURATION
router isis
spbm 1 multicast enable
exit
```

#### SwitchD

```
enable
configure terminal
prompt SwitchD

ISIS SPBM CONFIGURATION
```

```
router isis
spbm 1 multicast enable
exit
```

## IP Multicast over Fabric Connect Services Configuration

### Layer 2 VSN Configuration Fundamentals

#### *Layer 2 VSN IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect supports Layer 2 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. An application for Layer 2 VSNs using IP Multicast over Fabric Connect is multicast traffic in data centers.

For more information on Layer 2 VSN configuration, see [Layer 2 VSN configuration](#) on page 1257.

After you configure **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN), that VLAN is automatically enabled for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

Multicast traffic remains in the same Layer 2 VSN across the SPBM cloud for Layer 2 VSN IP Multicast over Fabric Connect. IP Multicast over Fabric Connect constrains all multicast streams within the scope level in which they originate. If a sender transmits a multicast stream to a BEB on a Layer 2 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream.

#### **I-SIDs**

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 2 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 2 VSN associated with the local VLAN on which the IP multicast data was received.

#### **TLVs**

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 2 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

#### **IGMP**

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the request stream exists, the

BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

### *Layer 2 VSN Configuration using the CLI*

#### **Configuring Layer 2 VSN IP Multicast over Fabric Connect**

Use this procedure to configure IP Multicast over Fabric Connect for Layer 2 VSN functionality. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

#### **Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must assign the same I-SID to the C-VLANs on all the BEBs where you configure the C-VLAN.
- You must enable IP Multicast over Fabric Connect globally.

#### **About This Task**

Traffic is only delivered to UNIs on the Layer 2 VSN where the switch receives IGMP joins and reports. Traffic does not cross the Layer 2 VSN boundary.

Configuring **ip igmp snooping** on a VLAN that has an I-SID configured (a C-VLAN) automatically enables that VLAN for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

SPBM supports enabling IGMP Snooping on a C-VLAN, but it does not support enabling Protocol Independent Multicast (PIM) on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

The switch only supports IPv4 multicast traffic.

#### **Procedure**

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable proxy snoop:

```
ip igmp proxy
```

3. Enable IGMP snooping:

```
ip igmp snooping
```

- (Optional) If you want to configure an address for the IGMP queries, enter the following command:

```
ip igmp snoop-querier-addr <A.B.C.D>
```

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

- (Optional) Enable IGMPv3 at a VLAN level by enabling SSM-snooping and IGMPv3:

```
ip igmp ssm-snoop
```

```
ip igmp version 3
```

You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

### Example

Enable IGMPv2 at a VLAN level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#interface vlan 501
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
```

Enable IGMPv3 at a VLAN level:

```
Switch:>enable
Switch:#configure terminal
Switch:1(config)#interface vlan 2256
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1(config-if)#ip igmp version 3
Switch:1(config-if)#ip igmp ssm-snoop
```

### View Layer 2 VSN IP Multicast over Fabric Connect information

Use the following options to display Layer 2 VSN information to confirm proper configuration.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- Display all IP Multicast over Fabric Connect route information:
 

```
show isis spbm ip-multicast-route [all]
```
- Display detailed IP Multicast over Fabric Connect route information:
 

```
show isis spbm ip-multicast-route [detail]
```
- Display IP multicast route information by VLAN:
 

```
show isis spbm ip-multicast-route [vlan <1-4059>]
```

5. Display IP Multicast over Fabric Connect route information by VSN I-SID:  

```
show isis spbm ip-multicast-route [vsn-isid <1-16777215>]
```
6. Display IP Multicast over Fabric Connect route information by group address:  

```
show isis spbm ip-multicast-route [group {A.B.C.D}]
```
7. Display IP Multicast over Fabric Connect route information by source address:  

```
show isis spbm ip-multicast-route [source {A.B.C.D}]
```

### Important

When you use the command `show isis spbm ip-multicast-route` without parameters or use the `detail` or `group` optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

8. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

```
show isis spbm ip-multicast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]
```

### Example

```
Switch:1#show isis spbm ip-multicast-route all

#### Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable                                          | Value                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                                        | Displays all IP Multicast over Fabric Connect route information.                                                                                              |
| <i>detail</i>                                     | Displays detailed IP Multicast over Fabric Connect route information.                                                                                         |
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i> | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. |
| <i>vlan &lt;0-4084&gt;</i>                        | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                          |
| <i>vrf WORD&lt;1-16&gt;</i>                       | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                           |
| <i>vsn-isis &lt;1-16777215&gt;</i>                | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                         |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                                  | Value                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------|
| <i>count</i>                              | Displays the total number of SPB multicast entries.                          |
| <i>host-name WORD&lt;0-255&gt;</i>        | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID.    |

#### View IGMP Information for Layer 2 VSN Multicast

Use the following commands to display IGMP information.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display information about the interfaces where IGMP is enabled:  
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]]

Ensure that the output displays snoop-spb under MODE.

3. Display information about the IGMP cache:  
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
4. Display information about the IGMP group:  
show ip igmp group [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
5. Display information about the IGMP sender:  
show ip igmp sender [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
6. Display information about IGMP snoop-trace information:  
show ip igmp snoop-trace [group {A.B.C.D}][source {A.B.C.D}][vrf WORD<1-16>][vrfids WORD<0-512>]

**Example**

```

### Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                        | Value                        |
|---------------------------------|------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp snoop-trace** command.

| Variable                        | Value                                                                      |
|---------------------------------|----------------------------------------------------------------------------|
| <i>group {A.B.C.D}</i>          | Specifies the group address.                                               |
| <i>source {A.B.C.D}</i>         | Specifies the source address.                                              |
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays the multicast route configuration for a particular VRF by VRF ID. |

### View TLV Information for Layer 2 VSN IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For Layer 2 VSN with IP multicast over Fabric Connect, TLV 185 on the BEB where the source is located, displays the multicast source and group addresses and has the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge,

where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by Type-Length-Value (TLV):  

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:  

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```

### Example

```
Switch:1# show isis lsdb tlv 185 detail

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                                 | Value                                                                                                                                                                                       |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>                            | Displays detailed information about the IS-IS Link State database.                                                                                                                          |
| <i>home</i>                              | Displays the IS-IS LSDB information that the system configures in the home area.                                                                                                            |
| <i>level {11, 12, 112}</i>               | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 and combined Level 1 and 2 (112) function is disabled. |
| <i>local</i>                             | Displays information on the local LSDB.                                                                                                                                                     |
| <i>lspid&lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Specifies information about the IS-IS Link State database by LSP ID.                                                                                                                        |
| <i>remote</i>                            | Displays the IS-IS LSDB information that the system configures in the remote area.                                                                                                          |

| Variable                      | Value                                                                   |
|-------------------------------|-------------------------------------------------------------------------|
| <i>sub-tlv</i> <1-3>          | Specifies information about the IS-IS Link State database by sub-TLV.   |
| <i>sysid</i> <xxxx.xxxx.xxxx> | Specifies information about the IS-IS Link State database by System ID. |
| <i>tlv</i> <1-236>            | Specifies information about the IS-IS Link State database by TLV.       |

### Layer 2 VSN Configuration using EDM

#### Viewing the IGMP interface table

Use the Interface tab to view the IGMP interface table. When an interface does not use an IP address, the system does not display it in the IGMP table.

#### Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Interface** tab.

#### Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                  |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                         |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                   |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                         |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                            |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                    |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds).<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval. |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WrongVersionQueries</b>         | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Joins</b>                       | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Robustness</b>                  | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.<br>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                                                                                                                                    |
| <b>LastMembQueryIntvl</b>          | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FlushAction</b>                 | Configures the flush action to one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>RouterAlertEnable</b>           | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                          |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopQuerierAddr</b>           | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                          |
| <b>McastMode</b>                  | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>pim — Indicates PIM is enabled.</li> <li>routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul> |
| <b>ExtnUpnpFilterEnable</b>       | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                        |
| <b>ExtnUpnpFilterAddress</b>      | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                   |
| <b>ExtnUpnpFilterAddressMask</b>  | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopOrigin</b>                | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                          |

### Configure IP Multicast over Fabric Connect on a Layer 2 VSN

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 2 VSN. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

No explicit configuration exists for a Layer 2 VSN. After you configure IP IGMP snooping on a VLAN that has an I-SID configured, the device enables that VLAN for IP Multicast over Fabric Connect services.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

#### About This Task

SPBM supports enabling IGMP snooping on a C-VLAN, but it does not support enabling PIM on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

This switch only supports IPv4 multicast traffic.

## Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.
6. Select the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. (Optional) Select the **SsmSnoopEnable** check box, if you use IGMP version 3.
9. (Optional) Select the **ProxySnoopEnable** check box.
10. (Optional) If you want to enable IGMP version 3, select version3 in the **Version** check box.  
You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.
11. If you want to enable IGMP version 2, select version2 in the **Version** check box.  
For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.
12. (Optional) If you want to enable snoop querier, select **SnoopQuerierEnable**.
13. (Optional) If you want to configure an address for IGMP queries, enter the IP address in **SnoopQuerierAddr**.

### Note

This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

14. Select **Apply**.

### *Layer 2 VSN with IP Multicast over Fabric Connect configuration example*

The example below shows the configuration steps to enable IP Multicast over Fabric Connect support on C-VLAN 1001 that is part of a Layer 2 VSN, including the querier address.

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 9
ip igmp snooping
ip igmp snoop-querier-addr 192.0.2.201
exit
```

When using IGMPv3, the configuration is:

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 19
ip igmp snooping
ip igmp version 3
ip igmp ssm-snoop
ip igmp snoop-querier-addr 192.0.2.201
exit
```

#### Note

You must enable SSM snoop before you configure IGMP version to version 3, and you must enable both **ssm-snoop** and **snooping** for IGMPv3.

#### Note

You must configure basic SPBM and IS-IS infrastructure.

## IP Shortcuts Configuration

This section provides fundamentals concepts for IP Shortcuts configuration. For more information on IP Shortcuts basic configuration, see [IP Shortcuts Configuration](#) on page 1338.

### *IP Multicast over Fabric Connect within the GRT*

IP Multicast over Fabric Connect within the GRT enables you to exchange IP multicast traffic with all or a subset of VLANs that are in the Global Routing Table (GRT). This restriction is called the *scope level*, which IP Multicast over Fabric Connect uses to constrain the multicast streams within the level in which they originate. For example, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT with IP Multicast over Fabric Connect enabled, only receivers that are part of the same GRT can receive that stream.

Applications that can use IP Multicast over Fabric Connect within the GRT include: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.

Both **IP Shortcuts** and **IP Multicast over Fabric Connect within the GRT** use the GRT for the scope level to constrain multicast streams. However, they are separate features that work independently from each other.

#### Important

You do not have to enable IP Shortcuts to support IP Multicast over Fabric Connect within the GRT.

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP

Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable **ip spb-multicast** on each of the VLANs within the GRT that need to support IP multicast traffic. Enable IP Multicast over Fabric Connect on all VLANs to which IP multicast senders and receivers attach. IP Multicast over Fabric Connect is typically configured only on BEBs.

#### Note

If no IP interface exists on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

### I-SIDs

Unlike IP Shortcuts with unicast, a data I-SID (for mac-in-mac encapsulation of the multicast traffic) is required for IP Multicast over Fabric Connect within the GRT. When the multicast stream reaches the BEB, the BEB assigns a data I-SID to the stream. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

Unlike Layer 2 VSNs and Layer 3 VSNs, IP Multicast over Fabric Connect within the GRT does not have a scope I-SID to determine the scope of the multicast traffic. Instead the scope is the Global Routing Table.

### TLVs

The scope and data I-SID information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, and result in the multicast tree creation for that stream. For IP Multicast over Fabric Connect within the GRT, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 186.

### IGMP

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, the system displays an error message.

After you configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

### DvR

When you enable **ip spb-multicast** on the Controller nodes, the configuration is automatically pushed to all the Leaf nodes within the domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 680.

## IP Shortcuts Configuration using the CLI

### Configure IP Multicast over Fabric Connect within the GRT

Use this procedure to configure IP Multicast over Fabric Connect within the GRT. The default is disabled.

-  **Note**
  - You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
  - You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

### About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled. After you enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an IP interface on the VLAN:

```
ip address <A.B.C.D/X>
```

3. Enable IP Multicast over Fabric Connect:

```
ip spb-multicast enable
```

### Note

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, an error message displays.

### Note

When you configure **ip spb-multicast enable** on the Controller node of a DVR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

4. (Optional) Disable IP Multicast over Fabric Connect:

```
no ip spb-multicast enable
```

```
default ip spb-multicast enable
```

5. Ensure IP Multicast over Fabric Connect within the GRT is configured properly:

```
show ip igmp interface
```

If `routed-spb` displays under mode, IP Multicast over Fabric Connect within the GRT is properly enabled on the VLAN.

## Example

Enable IP Multicast over Fabric Connect within the GRT:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 500
Switch:1(config-if)#ip address 192.0.2.1 255.255.255.0
Switch:1(config-if)#ip spb-multicast enable
Switch:1#show ip igmp interface
=====
```

```

### Variable Definitions

The following table defines parameters for the **interface vlan** command.

| Variable | Value                  |
|----------|------------------------|
| <1-4059> | Specifies the VLAN ID. |

The following table defines parameters for the **interface GigabitEthernet** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip address** command.

| Variable    | Value                           |
|-------------|---------------------------------|
| <A.B.C.D/X> | Specifies the address and mask. |

### Configuring the VRF timeout value

Use this procedure to configure the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.

#### Note

You can use this procedure for Layer 3 VSN with IP Multicast over Fabric Connect services and IP Multicast over Fabric Connect for IP Shortcuts.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

router vrf WORD<1-16>
```
2. Configure the timeout value on the VRF:
 

```
mvpn fwd-cache-timeout (seconds) <10-86400>
```
3. (Optional) Configure the timeout value to the default value of 210 seconds:
 

```
no mvpn fwd-cache-timeout

default mvpn fwd-cache-timeout (seconds)
```

## Example

Configure the timeout value on the VRF to 500 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#mvpn fwd-cache-timeout (seconds) 500
```

Variable definitions

The following table defines parameters for the **router vrf** command.

| Variable   | Value                   |
|------------|-------------------------|
| WORD<1-16> | Specifies the VRF name. |

The following table defines parameters for the **mvpn fwd-cache-timeout (seconds)** command.

| Variable   | Value                                                    |
|------------|----------------------------------------------------------|
| <10-86400> | Specifies the timeout value. The default is 210 seconds. |

## Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time in seconds. The default timeout value is 210 seconds.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

## Procedure

1. Enter IS-IS Router Configuration mode:
 

```
enable

configure terminal

router isis
```
2. Configure the IP Multicast over Fabric Connect forward-cache timeout:
 

```
spbm <1-100> multicast fwd-cache-timeout (seconds) <10-86400>
```
3. (Optional) Configure the IP Multicast over Fabric Connect forward-cache timeout to the default value of 210 seconds:
 

```
default spbm <1-100> multicast fwd-cache-timeout (seconds)

no spbm <1-100> multicast fwd-cache-timeout (seconds)
```

## Example

Configure the IP Multicast over Fabric Connect forward-cache timeout to 300:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast 1 fwd-cache-timeout 300
```

Variable definitions

The following table defines parameters for the **spbm** command.

| Variable   | Value                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------|
| <1-100>    | Specifies the SPBM instance. The switch only supports one instance.                                          |
| <10-86400> | Specifies the IP Multicast over Fabric Connect forward-cache timeout in seconds. The default is 210 seconds. |

## Viewing IP Multicast over Fabric Connect within the GRT information

Use the following options to display IP Multicast over Fabric Connect within the GRT information to confirm proper configuration.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:
 

```
show isis spbm ip-multicast-route [all]
```
3. Display detailed IP Multicast over Fabric Connect route information:
 

```
show isis spbm ip-multicast-route [detail]
```
4. Display the IP Multicast over Fabric Connect multicast group and source address information:
 

```
show isis spbm ip-multicast-route [group {A.B.C.D}] [source {A.B.C.D}]
[source-beb WORD<0-255>]
```

5. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid
<xxxx.xxxx.xxxx.xx-xx>]
```

### Example

Display IP Multicast over Fabric Connect within the GRT information:

```
Switch:1#show isis spbm ip-multicast-route all
=====
                        SPBM IP-multicast ROUTE INFO ALL

| <i>detail</i>                                                                                | Displays detailed IP Multicast over Fabric Connect route information.                                                                                                                           |
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i><br>[ <i>source-beb WORD&lt;0-255&gt;</i> ] | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address.<br>Specifies the source BEB name. |
| <i>vlan</i>                                                                                  | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                                                            |
| <i>vrf</i>                                                                                   | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                                                             |
| <i>vsn-isis</i>                                                                              | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                                                           |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                                | Value                                                                        |
|-----------------------------------------|------------------------------------------------------------------------------|
| <i>count</i>                            | Displays the total number of SPB multicast entries.                          |
| <i>host-name</i>                        | Displays the IP Multicast over Fabric Connect summary for a given host-name. |
| <i>lspid</i><br><xxxxx.xxxx.xxxx.xx-xx> | Displays the IP Multicast over Fabric Connect summary for a given LSP ID.    |

### View IGMP Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to display IGMP information.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display information about the interfaces where IGMP is enabled:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfrids WORD<0-
512>]
```

Ensure that the output displays `routed-spb` under `MODE`.

3. Display information about the IGMP cache:

```
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
```

4. Display information about the IGMP group:

```
show ip igmp group [count][group {A.B.C.D}][member-subnet default|
{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
```

5. Display information about the IGMP sender:

```
show ip igmp sender [count][group {A.B.C.D}][member-subnet default|
{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
```

## Example

Display IGMP information for IP multicast over Fabric Connect within the GRT:

```
Switch:1#show ip igmp interface
```

```

### Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN.                                                                                                                                                                                                                                                                                                                                           |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                  |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                  | Value                        |
|---------------------------|------------------------------|
| <i>vrf</i> WORD<1-16>     | Specifies the VRF by name.   |
| <i>vrfids</i> WORD<0-512> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group</i> {A.B.C.D}           | Specifies the group address.                                               |
| <i>member-subnet</i> {A.B.C.D/X} | Specifies the IP address and network mask.                                 |
| <i>vrf</i> WORD<1-16>            | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids</i> WORD<0-512>        | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

### View TLV Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to check TLV information.

For IP Multicast over Fabric Connect within the GRT, TLV 186 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set while on all BEB bridges, where a receiver exists, has the Rx bit set.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:  

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:  

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```

#### Example

Display TLV information:

```
Switch:1# show isis lsdb tlv 186 detail

### Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                   | Value                                                                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>              | Displays detailed information about the IS-IS Link State database.                                                                                         |
| <i>home</i>                | Displays the IS-IS LSDB information that the system configures in the home area.                                                                           |
| <i>level {11, 12, 112}</i> | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i>               | Displays information on the local LSDB.                                                                                                                    |

| Variable                                        | Value                                                                              |
|-------------------------------------------------|------------------------------------------------------------------------------------|
| <code>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</code> | Specifies information about the IS-IS Link State database by LSP ID.               |
| <code>remote</code>                             | Displays the IS-IS LSDB information that the system configures in the remote area. |
| <code>sub-tlv &lt;1-3&gt;</code>                | Specifies information about the IS-IS Link State database by sub-TLV.              |
| <code>sysid &lt;xxxx.xxxx.xxxx&gt;</code>       | Specifies information about the IS-IS Link State database by System ID.            |
| <code>tlv &lt;1-236&gt;</code>                  | Specifies information about the IS-IS Link State database by TLV.                  |

### IP Shortcuts configuration using the EDM

This section provides procedures to configure IP Shortcuts using the EDM.

#### Configuring IP Multicast over Fabric Connect on a VLAN within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled.

To configure a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3](#) on page 1721.

#### Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

#### About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing within the GRT does not depend on unicast routing. This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Choose a VLAN, and then click the **IP** button.
4. Click the **SPB Multicast** tab.

#### Note

After you enable IP Multicast over Fabric Connect, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where SPBM multicast is enabled, the system displays an error message.

#### Note

When you enable IP Multicast over Fabric Connect on a Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

5. Click **Enable**.
6. Click **Apply**.

### Configuring IP Multicast over Fabric Connect on a brouter port within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port IP interface. The default is enabled.

To configure a brouter port for a VRF with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN](#) on page 1722.

#### Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

## About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

## Procedure

1. Select an enabled port on the Physical Device View.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB Multicast** tab.
5. Click **Enable**.

### Note

When you enable IP Multicast over Fabric Connect on a DvR Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

6. Click **Apply**.

SPB Multicast field description

Use the data in the following table to use the SPB Multicast tab.

| Name          | Description                                                |
|---------------|------------------------------------------------------------|
| <b>Enable</b> | Enables or disables SPB Multicast. The default is disable. |

## Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time. The default timeout value is 210 seconds.

### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.

- You must enable IP Multicast over Fabric Connect globally.

### Procedure

1. In the navigation pane, expand **Configuration > IS-IS > SPBM**.
2. Click the **SPBM** tab.
3. Modify the **McastFwdCacheTimeout** value.
4. Click **Apply**.

#### *IP multicast over SPBM within the GRT configuration example*

The following example shows the configuration steps to enable IP multicast over SPBM support on VLANs 10 and 11 that are part of the GRT:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION - PHASE I

interface vlan 500
ip address 192.0.2.1 255.255.255.0
ip spb-multicast enable
exit

interface vlan 501
ip address 192.0.2.2 255.255.255.0
ip spb-multicast enable
exit
```

## Layer 3 VSN Fundamentals

This section provides fundamentals concepts for Layer 3 VSN configuration. For more information on Layer 3 VSN basic configuration, see [Layer 3 VSN Configuration](#) on page 1408.

#### *Layer 3 VSN with IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect supports Layer 3 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. Layer 3 VSN using IP Multicast over Fabric Connect is helpful when you need complete security and total isolation of data. No one outside of the Layer 3 VSN can join or even see the Layer 3 VSN. Applications that can use Layer 3 VSN with IP Multicast over Fabric Connect include: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. This configuration automatically enables IGMP snooping and proxy on those VLANs. IGMPv2 at the VLAN level is the default setting, with no other configuration required. If you want to use IGMPv3, you must configure IGMPv3.

IP Multicast over Fabric Connect is only configured on BEBs.

#### Note

- You do not need to enable IP Shortcuts to support multicast routing in the Layer 3 VSN using SPBM. IPVPN creation and I-SID assignment for the IPVPN is required, but you do not need to enable IPVPN.
- If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing for Layer 3 VSNs using VRFs, which allows you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

With Layer 3 VSN with IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud. For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that has IP Multicast over Fabric Connect enabled. If a sender transmits a multicast stream to a BEB on a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 VSN can receive that stream.

#### I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 3 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 3 VSN associated with the local VLAN that the IP multicast data was received on.

#### TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 3 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

#### IGMP

After a BEB receives an IGMP join message from a receiver, the BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

## DvR

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

For more information on DvR, see [Distributed Virtual Routing](#) on page 680.

### *Layer 3 VSN Configuration using the CLI*

## Configuring Layer 3 VSN with IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for a Layer 3 VSN.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. After you enable IP Multicast over Fabric Connect on VRF VLANs, snooping and proxy on those VLANs is enabled. IGMPv2 at the VLAN level is the default setting. No configuration is required.

### Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

## Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- You must assign an I-SID for the IPVPN.

## About This Task

With Layer 3 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud.

For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that have `ip spbm-multicast` enabled. The default is disabled.

All or a subset of VLANs within a Layer 3 VSN can exchange multicast traffic. The BEB only sends out traffic for a multicast stream on which IGMP joins and reports are received.

The switch only supports IPv4 multicast traffic.

### Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
mvpn enable
```

The default is disabled.

3. (Optional) If you want to disable Layer 3 VSN IP Multicast over Fabric Connect, enter:

```
no mvpn enable

default mvpn enable
```

4. Exit to Global Configuration mode:

```
exit
```

5. Enter Interface Configuration mode:

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

6. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

```
ip spb-multicast enable
```

7. (Optional) Disable Layer 3 multicast on the VRF:

```
no ip spb-multicast enable
```

8. (Optional) Enable IGMP version 3:

```
ip igmp snooping

ip igmp ssm-snoop

ip igmp compatibility-mode

ip igmp version 3
```

#### Note

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to use these commands if you use IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

9. (Optional) Enable the IGMP Layer 2 Querier address:

```
ip igmp snoop-querier-addr {A.B.C.D}
```

#### Note

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

## Example

Configure IP Multicast over Fabric Connect for a Layer 3 VSN:

```
Switch:>enable
Switch:#configure terminal
Switch:(config)# router vrf green
Switch:(config-vrf)#mvpn enable
Switch:(config)#exit
Switch:(config)#interface vlan 500
Switch:(config-if)#ip spb-multicast enable
```

### Variable Definitions

The following table defines parameters for the **router vrf** command.

| Variable           | Value                          |
|--------------------|--------------------------------|
| <i>WORD</i> <1-16> | Specifies the name of the VRF. |

The following table defines parameters for the **interface vlan** command.

| Variable                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

The following table defines parameters for the **GigabitEthernet** command.

| Variable                                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>GigabitEthernet{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **ip igmp** command.

| Variable                                                                                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>access-list WORD&lt;1-64&gt; {A.B.C.D/X} &lt;deny-tx deny-rx deny-both allow-only-tx allow-only-rx allow-only-both&gt;</code> | Specifies the name of the access list from 1-64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic.                                                                         |
| <code>compatibility-mode</code>                                                                                                     | Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:<br><code>default ip igmp compatibility-mode</code><br>, or use the no option to disable compatibility mode:<br><code>no ip igmp compatibility-mode</code>                                                                                                                                                                                                                                    |
| <code>dynamic-downgrade-version</code>                                                                                              | Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:<br><code>default ip igmp dynamic-downgrade-version</code><br>or use the no option to disable downgrade:<br><code>no ip igmp dynamic-downgrade-version</code> |
| <code>igmpv3-explicit-host-tracking</code>                                                                                          | Enables explicit host tracking on IGMPv3. The default state is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>ssm-snoop</code>                                                                                                       | Activates support for SSM on the snoop interface.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>static-group {A.B.C.D} {A.B.C.D} [port] {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]} [static blocked]</code> | Configures IGMP static members to add members to a snoop group.<br><code>{A.B.C.D} {A.B.C.D}</code> indicates the IP address range of the selected multicast group.<br><code>[port] {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]}</code> adds ports to a static group entry.<br><code>[static blocked]</code> configures the route to static or blocked.                                                                                                                          |
| <code>stream-limit stream-limit-max-streams &lt;0-65535&gt;</code>                                                           | Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.                                                                                                                                                                                                                                                                                                                                                        |
| <code>stream-limit-group {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]} enable max-streams &lt;0-65535&gt;</code>    | Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default <code>max-streams</code> value is 4.                                                                                                                                                                                                                                                                                                  |
| <code>version &lt;1-3&gt;</code>                                                                                             | Configures the version of IGMP that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).                                                                                                                                                                                                                                                                                              |

### View Layer 3 VSN with IP Multicast over Fabric Connect Information

Use the following options to display Layer 3 VSN with IP Multicast over Fabric Connect information to confirm proper configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all the VRFs that have MVPN enabled and their corresponding forward cache timeout values:  
`show ip vrf mvpn`
3. Display IP Multicast over Fabric Connect route information:  
`show isis spbm ip-multicast-route [all][detail]`

4. Display IP Multicast over Fabric Connect by group and source address:  

```
show isis spbm ip-multicast-route [group {A.B.C.D}] [detail] [source {A.B.C.D}]
```
5. Display IP Multicast over Fabric Connect route information by VRF:  

```
show isis spbm ip-multicast-route [vrf WORD<1-16>] [group {A.B.C.D}]
```
6. Display IP Multicast over Fabric Connect route information by VLAN:  

```
show isis spbm ip-multicast-route [vlan <1-4059>] [detail] [group {A.B.C.D}]
```
7. Display IP Multicast over Fabric Connect information by VSN I-SID:  

```
show isis spbm ip-multicast-route [vsn-isid <1-16777215>] [detail] [group {A.B.C.D}]
```
8. Display summary information for each S, G, V tuple with the corresponding scope, Data I-SID, and the host name of the source:  

```
show isis spb-mcast-summary [count] [host-name WORD<0-255>] [lspid <xxxx.xxxx.xxxx.xx-xx>]
```

### Example

Display Layer 3 VSN with IP Multicast over Fabric Connect information:

```
Switch:1>enable
Switch:1#show ip vrf mvpn

                Vrf name : green
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

                Vrf name : 4
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

                Vrf name : blue
                mvpn : enable
                fwd-cache-timeout(seconds) : 210

Switch:1#show isis spbm ip-multicast-route all

### Variable Definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

| Variable                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>all</i>                        | Displays all IP Multicast over Fabric Connect route information.                                                                                                                                                                                                                                                                                                                                                           |
| <i>detail</i>                     | Displays detailed IP Multicast over Fabric Connect route information.                                                                                                                                                                                                                                                                                                                                                      |
| <i>group{A.B.C.D}</i>             | Displays information on the group IP address for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                               |
| <i>vlan&lt;1-4059&gt;</i>         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrfWORD&lt;1-16&gt;</i>        | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                                                                                                                                                                                                                                                                                        |
| <i>vsn-isis&lt;1-16777215&gt;</i> | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                                                                                                                                                                                                                                                                                      |

The following table defines parameters for the **show isis spb-mcast-summary** command.

| Variable                                 | Value                                                                           |
|------------------------------------------|---------------------------------------------------------------------------------|
| <i>count</i>                             | Displays the total number of SPB multicast entries.                             |
| <i>host-nameWORD&lt;0-255&gt;</i>        | Displays the IP Multicast over Fabric Connect summary information by host-name. |
| <i>lspid&lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Displays the IP Multicast over Fabric Connect summary information by LSP ID.    |

### View IGMP Information for Layer 3 VSN Multicast

Use the following commands to check IGMP information.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display information about the interfaces where IGMP is enabled:  
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]

Ensure that the output displays routed-spb under MODE.

3. Display information about the IGMP cache:  
show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
4. Display information about the IGMP group:  
show ip igmp group [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
5. Display information about the IGMP sender:  
show ip igmp sender [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]

**Example**

Display IGMP information for Layer 3 VSN with IP multicast over Fabric Connect:

```
Switch:#enable
Switch:1#show ip igmp interface vrf green

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF by name.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF by VRF ID.                                                                                                                                                                                                                                                                                                                                                                                               |

The following table defines parameters for the **show ip igmp cache** command.

| Variable                        | Value                        |
|---------------------------------|------------------------------|
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the VRF by VRF ID. |

The following table defines parameters for the **show ip igmp group** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

The following table defines parameters for the **show ip igmp sender** command.

| Variable                         | Value                                                                      |
|----------------------------------|----------------------------------------------------------------------------|
| <i>count</i>                     | Specifies the number of entries.                                           |
| <i>group {A.B.C.D}</i>           | Specifies the group address.                                               |
| <i>member-subnet {A.B.C.D/X}</i> | Specifies the IP address and network mask.                                 |
| <i>vrf WORD&lt;1-16&gt;</i>      | Displays the multicast route configuration for a particular VRF by name.   |
| <i>vrfids WORD&lt;0-512&gt;</i>  | Displays the multicast route configuration for a particular VRF by VRF ID. |

### View TLV Information for a Layer 3 VSN with IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For a Layer 3 VSN multicast, TLV 185 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group should have its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:
 

```
show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]
```
3. Display IS-IS Link State Database information by Link State Protocol ID:
 

```
show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> [tlv <1-236>] [sub-tlv <1-3>] [detail] [home|remote]
```

## Example

Display TLV information for a Layer 3 VSN with IP Multicast over Fabric Connect:

```
Switch:1# show isis lsdb tlv 185 detail
=====
                ISIS LSDB (DETAIL)
=====

### Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

| Variable                                  | Value                                                                                                                                                      |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>detail</i>                             | Displays detailed information about the IS-IS Link State database.                                                                                         |
| <i>home</i>                               | Displays the IS-IS LSDB information that the system configures in the home area.                                                                           |
| <i>level {11, 12, 112}</i>                | Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled. |
| <i>local</i>                              | Displays information on the local LSDB.                                                                                                                    |
| <i>lspid &lt;xxxx.xxxx.xxxx.xx-xx&gt;</i> | Specifies information about the IS-IS Link State database by LSP ID.                                                                                       |
| <i>remote</i>                             | Displays the IS-IS LSDB information that the system configures in the remote area.                                                                         |
| <i>sub-tlv &lt;1-3&gt;</i>                | Specifies information about the IS-IS Link State database by sub-TLV.                                                                                      |
| <i>sysid &lt;xxxx.xxxx.xxxx&gt;</i>       | Specifies information about the IS-IS Link State database by System ID.                                                                                    |
| <i>tlv &lt;1-236&gt;</i>                  | Specifies information about the IS-IS Link State database by TLV.                                                                                          |

### Layer 3 VSN Configuration using EDM

#### Enable MVPN for a VRF

Use this procedure to enable MVPN for a particular VRF. IP Multicast over Fabric Connect, constrains multicast streams of senders to all receivers in the same Layer 3 VSN. MVPN functionality is disabled by default.

#### Note

VLAN level configuration is also required to turn on the service on each VLAN within the VRF on which this services is required. You can turn it on under the VLAN context or the router context.

#### Before You Begin

- You must enable IP Multicast over Fabric Connect globally.

#### Procedure

- In the navigation pane, expand **Configuration > IP**.
- Select **IP-MVPN**.
- Select the **MVPN** tab.

4. Double-click in the **Enable** field in the table.
5. Select **Enable** from the drop down menu.
6. Double-click in the **FwdCacheTimeout** field in the table, and then type the VRF timeout value.
7. Select **Apply**.

#### MVPN Field Descriptions

Use the data in the following table to use the **MVPN** tab.

| Name                   | Description                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VrfId</b>           | Specifies the VRF ID.                                                                                                                             |
| <b>Enable</b>          | Enables Layer 3 VSN IP Multicast over Fabric Connect services for a particular VRF. The default is disabled.                                      |
| <b>FwdCacheTimeout</b> | Specifies the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.. |

#### Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 3 VSN. The default is disabled.

To configure a VLAN for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a VLAN within the GRT](#) on page 1702.

#### Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

#### Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

#### About This Task

You must configure VLANs to turn on the service on each VLAN within the VRF on which the service is required. You can turn it on under the VLAN context or the router context.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing (for Layer 3 VSN). This allows for you to more easily migrate from a PIM environment

to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

**Note**

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > VLAN**.
7. Click **VLANs**.
8. Choose a VLAN, and then click the **IP** from under the tab bar.
9. Click the **SPB Multicast** tab.
10. Check the **Enable** box.
11. Click **Apply**.

**Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN**

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port. The default is disabled.

To configure a brouter port for IP Shortcuts with IP Multicast over Fabric Connect, see [Configuring IP Multicast over Fabric Connect on a brouter port within the GRT](#) on page 1703.

**Before You Begin**

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 2 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

**About This Task**

You must enable IP Multicast over Fabric Connect on each of the VLANs that need to support IP multicast traffic.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

### Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration > Edit > Port**.
7. Click **IP**.
8. Click the **SPB Multicast** tab.
9. Click **Enable**.
10. Click **Apply**.

### Configuring IGMP on a VLAN interface for a Layer 3 VRF

Use this procedure to configure IGMP for each VLAN interface to enable the interface to perform multicast operations.

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to enable IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

#### Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance with an I-SID on the switch.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect for a Layer 3 VSN.

### About This Task

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

### Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.

5. In the navigation pane, expand **Configuration > VLAN**.
6. Click **VLANs**.
7. Select the desired VLAN from the listing.
8. Click the **IP** button.
9. Click the **IGMP** tab.
10. (Optional) If you want to enable SsmSnoopEnable, select the **SsmSnoopEnable** box.
11. (Optional) If you want to enable Snoop, select the **SnoopEnable** box.
12. (Optional) In the **Version** box, select the correct IGMP version.  
 You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.
13. (Optional) Select **SnoopQuerierEnable**, to enable Snoop Querier. Only select this option, if you want to configure an address for the IGMP queries.
14. (Optional) In the **SnoopQuerierAddr** box, type an IP address, if you want to configure a snoop querier address.

**Note**

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

**IGMP** field descriptions

Use the data in the following table to use the **IGMP** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1-65535 and the default is 125.                                                                                                                                                                                                                                                                                 |
| <b>QueryMaxResponseTime</b> | Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0-255 and the default is 100 tenths of a second (equal to 10 seconds.)<br><br><b>Important:</b><br>You must configure this value lower than the QueryInterval.                                 |
| <b>Robustness</b>           | Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2-255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out. |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LastMembQueryIntvl</b>         | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0-255 and the default is 10 tenths of a second.<br>Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.) |
| <b>SnoopEnable</b>                | Enables or disables snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SsmSnoopEnable</b>             | Enables or disables support for SSM on the snoop interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ProxySnoopEnable</b>           | Enables or disables proxy snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Version</b>                    | Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.<br>For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.                                                                                                                                                                                                    |
| <b>FastLeaveEnable</b>            | Enables or disables fast leave on the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>StreamLimitEnable</b>          | Enables or disables stream limitation on this VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Maximum Number Of Stream</b>   | Configures the maximum number of streams allowed on this VLAN. The range is from 0-65535 and the default is 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Current Number Of Stream</b>   | Displays the current number of streams. This value is a read-only value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FastLeavePortMembers</b>       | Selects the ports that are enabled for fast leave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SnoopMRouterPorts</b>          | Selects the ports in this interface that provide connectivity to an IP multicast router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DynamicDowngradeEnable</b>     | Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.                                                                                                                                                                                                                            |
| <b>CompatibilityModeEnable</b>    | Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ExplicitHostTrackingEnable</b> | Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SnoopQuerierEnable</b> | Enables Snoop Querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups. Enable Layer 2 Querier on only one node in the VLAN. |
| <b>SnoopQuerierAddr</b>   | Specifies the pseudo IP address of the IGMP Snoop Querier. The default IP address is 0.0.0.0. If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPBM bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.                                                                                 |

### Layer 3 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration to enable IP Multicast over Fabric Connect support on VLANs 500 and 501 that are part of VRF Green:

```

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1
ip spb-multicast enable
exit

vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn
i-sid 100
mvpn enable
exit

```

When using IGMPv3, the configuration is:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1
ip spb-multicast enable
ip igmp version 3
exit

vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
ip igmp version 3
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn

**Table 123: Internet Protocol Flow Information eXport (IPFIX) product support**

| Feature                                           | Product         | Release introduced |
|---------------------------------------------------|-----------------|--------------------|
| Internet Protocol Flow Information eXport (IPFIX) | 5420 Series     | VOSS 8.4           |
|                                                   | 5520 Series     | VOSS 8.2.5         |
|                                                   | VSP 4450 Series | Not Supported      |
|                                                   | VSP 4900 Series | Not Supported      |
|                                                   | VSP 7200 Series | Not Supported      |
|                                                   | VSP 7400 Series | VOSS 8.0           |
|                                                   | VSP 8200 Series | Not Supported      |
|                                                   | VSP 8400 Series | Not Supported      |
|                                                   | VSP 8600 Series | Not Supported      |
|                                                   | XA1400 Series   | Not Supported      |

## IPFIX Fundamentals

Internet Protocol Flow Information eXport (IPFIX) is an Internet Engineering Task Force (IETF) standard of export for Internet Protocol flow information.

IPFIX monitors flows that pass an observation point. The switch organizes flows into a flow group, which is contained in an observation domain.

An IPFIX flow is a set of packets that pass an observation point in the network during a certain time interval. Packets that belong to a particular flow have a common set of properties. The switch defines each property using values from the following:

- Source IP address
- Destination IP address
- IP protocol
- L4 source port
- L4 destination port

A packet belongs to a flow if it completely satisfies all defined properties of the flow.

The switch logically organizes flows into a flow group, which corresponds to a single observation point. A flow can belong to only 1 flow group. A flow group is a collection of packet flows that meet match criteria. Examples of flow groups are packets ingressing a specific physical port, or packets with a destination IP address belonging to a specific subnet.

A flow group is contained in an observation domain. The switch assigns the flow group to an observation domain. The observation domain has a unique observation domain ID that you can configure. You can configure only 1 observation domain.

The IPFIX solution consists of the following processes:

- Filtering Rules process: The Filtering Rules process gathers information about flows through different ports, or the observation point. Flow information includes the following:
  - The IPv4 source address.
  - The IPv4 destination address.
  - The L4 source port.
  - The L4 destination port.
  - The transport protocol.
  - The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The absolute timestamp of the first packet of this flow.
  - The absolute timestamp of the last packet of this flow.

The Filtering Rules process runs on the switch.

- Exporting process: The Filtering Rules process sends information to the Exporting process. The Exporting process uses the UDP transport protocol for network communication with the Collecting process.

The Exporting process runs on the switch.

- Collecting process: You can view flows and export flow information periodically to a collector. A collector can store a large number of flow records from several devices in the network. The IPFIX standard specifies the protocol for exporting the flows to a collector, including the formatting of flow records and the underlying UDP transport protocol.

Use the collected information for network planning, troubleshooting a live network, and monitoring security threats.

The best practice is to use the ExtremeAnalytics™ solution as the collector. The ExtremeAnalytics™ solution provides an enhanced method of collecting IPFIX flow information.

The external collector for the IPFIX solution must support our IPFIX template, which contains the following element IDs defined by Internet Assigned Numbers Authority (IANA) IPFIX assignments.

**Table 124: IPFIX element IDs**

| Element ID | Name                     | Description                                                                                                                                                      |
|------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | unknown                  | Reserved                                                                                                                                                         |
| 4          | protocolIdentifier       | The value of the protocol number in the IP packet header.                                                                                                        |
| 7          | sourceTransportPort      | The source port identifier in the transport header.                                                                                                              |
| 8          | sourceIPv4Address        | The IPv4 source address in the IP packet header.                                                                                                                 |
| 11         | destinationTransportPort | The destination port identifier in the transport header.                                                                                                         |
| 12         | destinationIPv4Address   | The IPv4 destination address in the IP packet header.                                                                                                            |
| 85         | octetTotalCount          | The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point. |
| 86         | packetTotalCount         | The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.           |
| 145        | templateId               | The local template unique to the observation domain.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only.                         |
| 152        | flowStartMilliseconds    | The absolute timestamp of the first packet of this flow.<br><br><b>Note:</b><br>This element ID applies to VSP 7400 Series only.                                 |
| 153        | flowEndMilliseconds      | The absolute timestamp of the last packet of this flow.<br><br><b>Note:</b><br>This element ID applies to VSP 7400 Series only.                                  |
| 156        | flowStartNanoseconds     | The absolute timestamp of the last packet of this flow.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only.                      |
| 157        | flowEndNanoseconds       | The absolute timestamp of the last packet of this flow.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only.                      |

**Table 124: IPFIX element IDs (continued)**

| Element ID | Name         | Description                                                                                                                                              |
|------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 192        | ipTTL        | The value of the time-to-live (TTL) field in the IPv4 packet header.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only. |
| 234        | ingressVRFID | The VRF name that receives packets for this flow.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only.                    |
| 243        | dot1qVlanId  | The VLAN ID in the Tag Control information of an Ethernet frame.<br><br><b>Note:</b><br>This element ID applies to 5420 Series and 5520 Series only.     |

IPFIX is a push protocol. The Filtering Rules and Exporting processes periodically send IPFIX messages to configured receivers without interaction from the Collecting process.

IPFIX collects IPv4 flow information on the switch and conforms with the following:

- IPFIX supports only 1 collector.
- IPFIX learns only IPv4 flows.
- IPFIX sends and receives only TCP/UDP flows.
- IPFIX uses only UDP to export packets.
- You can configure only the template exporting timer.
- The Out-of-Band (OOB) port does not support IPFIX.
- IPFIX exports TCP/UDP IPv4 flows on IS-IS interfaces that are members of a VLAN. IPFIX does not capture Mac-In-Mac encapsulated flows on IS-IS interfaces.

IPFIX processes IPv4 UDP or TCP Mac-in-Mac packet flows that are terminated by the switch. IPFIX does not process Mac-in-Mac packet flows that are only traversing the switch (Layer 2 switching).

- Layer 3 Virtual Services Network (L3 VSN) flow packets on NNI ports are not learned by IPFIX.
- The switch supports only ingress sampling. The switch does not support egress sampling.

**Note**

IPFIX is not supported on OOB, Circuitless IP (CLIP), or VLAN Segmented Management Instance interfaces.

## IPFIX Configuration Using CLI

This section provides procedures to configure IPFIX using Command Line Interface (CLI).

## Enabling IPFIX Globally

### About This Task

Use the following procedure to enable IPFIX globally. IPFIX provides the ability to monitor IPv4 traffic flows.

The default global state is disabled.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable IPFIX:  
`ip ipfix enable`
3. (Optional) Configure the flow aging interval:  
`ip ipfix aging-interval <1-60>`
4. (Optional) Configure a value for observation domain:  
`ip ipfix observation-domain <0-4294967295>`

### Example

Enable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix enable
Switch:1(config)#ip ipfix aging-interval 30
Switch:1(config)#ip ipfix observation-domain 1
```

Disable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no ip ipfix enable
```

```
By disabling IPFIX globally, all the processes and traffic
sent to collector(s) will be stopped.Do you agree (y/n) ? y
```

## Variable Definitions

Use the data in the following table to use the **ip ipfix** command.

| Variable                          | Value                                                                                                                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aging-interval <1-60>             | Specifies (in seconds) the flow record aging interval. The <b>aging-interval</b> determines how long a traffic flow that is no longer being received is retained as a flow. The default value is 40 seconds. |
| enable                            | Enables IPFIX globally.                                                                                                                                                                                      |
| observation-domain <0-4294967295> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain.      |

## Displaying IPFIX Global Status

### About This Task

Use the following procedure to display global status information for IPFIX.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IPFIX global status:

```
show ip ipfix
```

### Example

```
Switch:1#show ip ipfix
```

```

=====
                                IPFIX Global
=====
      Global-State : enable
  Observation-Domain ID : 1
        Flow Limit : 20000
        Flow Count : 0
      Aging Interval : 40

```

## Configure the IPFIX Aging Interval

### About This Task

Use the following procedure to configure an aging interval for IPFIX. The aging interval determines how long a traffic flow that is no longer being received, is retained as a flow.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure a value for the aging interval:
 

```
ip ipfix aging-interval <interval>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix aging-interval 30
```

*Variable Definitions*

The following table defines parameters for the **ip ipfix aging-interval** command.

**Table 125:**

| Variable                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>aging-interval</i><br><interval> | <p>Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch.</p> <p>The default varies depending on the platform:</p> <ul style="list-style-type: none"> <li>• 5420 Series - 10 seconds</li> <li>• 5520 Series - 10 seconds</li> <li>• VSP 7400 Series - 40 seconds</li> </ul> |

## Configuring the IPFIX Collector

**About This Task**

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

2. Configure values for the collector ID, the IP address of the collector, and the IP address of the exporter. Optionally, you can configure values for the source port sending flow information and the destination port receiving flow information:

```
ip ipfix collector <1-1> {A.B.C.D} exporter-ip {A.B.C.D} [dest-port
<1-65535>] [src-port <1-65535>]
```

#### Note

You cannot configure collector or exporter IP addresses in the following formats:

- 255.255.255.255
- 127. x.x.x
- 0.x.x.x
- 224.0.0.0 to 239.255.255.255

If you configure a collector or exporter IP address in any of these formats, the following error message is displayed:

```
Error: Invalid IP address
```

3. (Optional) Configure a value for the export interval:

```
ip ipfix collector 1 export-interval <1-120>
```

4. (Optional) Configure a value for the initial burst of template packets:

```
ip ipfix collector 1 initial-burst <1-10>
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix collector 1 192.0.2.15 exporter-ip 192.0.2.16
dest-port 2 src-port 4
Switch:1(config)#ip ipfix collector 1 export-interval 40
Switch:1(config)#ip ipfix collector 1 initial-burst 4
```

#### Variable Definitions

Use the data in the following table to use the **ip ipfix collector** command.

| Variable              | Value                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------------|
| <1-1>                 | Specifies the IPFIX collector ID.                                                                                  |
| {A.B.C.D}             | Specifies the IP address of the collector.                                                                         |
| exporter-ip {A.B.C.D} | Specifies the IP address of the exporter.                                                                          |
| dest-port <1-65535>   | Specifies the destination port receiving flow information.                                                         |
| src-port <1-65535>    | Specifies the source port sending flow information.                                                                |
| export-interval       | Specifies, in seconds, the frequency of template packet exports to the collector. The default value is 60 seconds. |
| initial-burst         | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.        |

## Displaying IPFIX Collector Information

### About This Task

Use the following procedure to display information about the IPFIX collector. The IPFIX collector can store flow information from multiple network devices.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the IPFIX collector:

```
show ip ipfix collector [<1-1>]
```

### Example

```

=====
                                IPFIX Collector-Info
=====
ID  Collector      Exporter      Source  Destination  Collector  Reachable  Exporting  Initial
   IP Address    IP Address   Port    Port         State      Via        Interval  Burst
-----
1   20.20.20.2     20.20.20.1   2055    2055         Enabled   -          60        5

```

### Variable Definitions

Use the data in the following table to use the **show ip ipfix collector** command.

| Variable | Value                             |
|----------|-----------------------------------|
| <1-1>    | Specifies the IPFIX collector ID. |

## Configuring an IPFIX Observation Domain

### About This Task

An observation domain consists of a collection of flow groups. Use this procedure to assign a unique ID to an observation domain. The default value is 0.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure the observation domain ID:
 

```
ip ipfix observation-domain <0-4294967295>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ipfix observation-domain 1
```

### Variable Definitions

Use the data in the following table to use the **ip ipfix observation-domain** command.

| Variable                             | Value                                                                                                                                                                                                   |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| observation-domain<br><0-4294967295> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain. |

## Display IPFIX Flows

### About This Task

Use the following procedure to display information about IPFIX flows. You can display information for all IPFIX flows, or you can specify a single IPFIX flow and display additional information about that flow.

### Procedure

- To enter User EXEC mode, log on to the switch.
- Display information about all IPFIX flows:
 

```
show ip ipfix flows
```
- Display information about an IPFIX flow learned on an ingress port:

#### Note

This step only applies to VSP 7400 Series.

```
show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-port <rx-nni
| {slot/port[/sub-port]}>
```

- Display information about an IPFIX flow learned on an ingress VRF:

#### Note

This step only applies to 5420 Series and 5520 Series.

```
show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-vrf <0-511>
{in-vlan <1-4095> | untagged} ip-ttl <0-255>
```

### Example

Display all IPFIX flows:

```
Switch:1>show ip ipfix flows
```

```
=====
IPFIX Flows
=====
Source      Destination  Source  Destination  Protocol  In
IP          IP           Port    Port         IP        Port
=====
```

|             |              |    |    |     |        |
|-------------|--------------|----|----|-----|--------|
| 192.0.2.1   | 198.51.100.1 | 63 | 63 | UDP | 1/17   |
| 203.0.113.2 | 203.0.113.1  | 63 | 63 | UDP | RX-NNI |

Display information about a specific IPFIX flow:

```
Switch:1>#show ip ipfix flows source-addr 203.0.113.2 dest-addr 203.0.113.1 s 63 d 63 p
udp in-port rx-nni
```

```
=====
                                IPFIX Flows
=====
```

| Source IP/<br>Destination IP | Src Port/<br>Dest Port | Protocol/<br>In Port | Start Time/<br>Observation Time | Byte Count/<br>Packet Count |
|------------------------------|------------------------|----------------------|---------------------------------|-----------------------------|
| 203.0.113.2                  | 63                     | UDP                  | Tue Apr 09 06:48:57 2019 UTC    | 352376                      |
| 203.0.113.1                  | 63                     | RX-NNI               | Tue Apr 09 06:49:49 2019 UTC    | 5182                        |

### Variable Definitions

The following table defines parameters for the **show ip ipfix flows** command.

| Variable                                                                                                              | Value                                             |
|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| <i>dest-addr</i> {A.B.C.D}                                                                                            | Specifies an IP address for the flow destination. |
| <i>dest-port</i> <1-65535>                                                                                            | Specifies a value for the destination port.       |
| <i>in-port</i> <rx-nni   {slot/port[/sub-port]}><br><br><b>Note:</b><br>Exception: only supported on VSP 7400 Series. | Specifies the port that learns the flow.          |
| <i>in-vlan</i> <1-4095><br><br><b>Note:</b><br>Exception: only supported on 5420 Series and 5520 Series.              | Specifies an ingress VLAN ID for the flow.        |
| <i>in-vrf</i> <0-511><br><br><b>Note:</b><br>Exception: only supported on 5420 Series and 5520 Series.                | Specifies an ingress VRF ID for the flow.         |
| <i>ip-ttl</i> <0-255><br><br><b>Note:</b><br>Exception: only supported on 5420 Series and 5520 Series.                | Specifies the IP time-to-live (TTL) for the flow. |
| <i>protocol</i> {udp tcp}                                                                                             | Specifies the transport protocol.                 |
| <i>source-addr</i> {A.B.C.D}                                                                                          | Specifies an IP address for the flow source.      |

| Variable                                                                  | Value                                  |
|---------------------------------------------------------------------------|----------------------------------------|
| <i>source-port</i> <1-65535>                                              | Specifies a value for the source port. |
| <i>untagged</i>                                                           | Specifies ingress untagged flows.      |
| <b>Note:</b><br>Exception: only supported on 5420 Series and 5520 Series. |                                        |

## IPFIX Configuration Using EDM

This section provides procedures to configure IPFIX in Enterprise Device Manager (EDM).

### Enabling IPFIX Globally

#### About This Task

IPFIX allows you to monitor IPv4 traffic flows. Use the following procedure to enable IPFIX globally.

The default global state is disabled.

#### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **IPFIX**.
3. Click the **Globals** tab.
4. To enable IPFIX, click **enable** in the **ConfState** option box.
5. (Optional) To configure an observation domain ID, type a value in the **ObservationDomainID** field.
6. (Optional) To configure the aging interval, type a value in the **AgingInterval** field.

*Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConfState</b>           | Specifies whether IPFIX is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ObservationDomainID</b> | Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain.                                                                                                                                                                                                                                                            |
| <b>AgingInterval</b>       | Specifies (in seconds) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. Depending on the hardware platform, the parameter range and default value can vary.<br>The default varies depending on the platform: <ul style="list-style-type: none"> <li>• 5420 Series - 10 seconds</li> <li>• 5520 Series - 10 seconds</li> <li>• VSP 7400 Series - 40 seconds</li> </ul> |

## Configuring the IPFIX Collector

### About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **IPFIX**.
3. Click the **Collector** tab.
4. Click **Insert**.
5. In the **Num** field, specify a value for the collector ID number.
6. In the **AddressType** field, specify a value for the IP address type of the collector.
7. In the **Address** field, specify a value for the IP address of the collector.
8. (Optional) In the **SrcPort** field, specify a value for the source port sending flow information. The default value is 2055.
9. (Optional) In the **DestPort** field, specify a value for the destination port receiving flow information. The default value is 2055.
10. In the **ExporterIpType** field, specify a value for the IP address type of the exporter for the collector.
11. In the **ExporterIp** field, specify the IP address of the exporter for the collector.
12. (Optional) In the **ExportInterval** field, specify the frequency of template packets exports to the collector.
13. (Optional) In the **InitialBurst** field, specify the number of template packets to send when the collector becomes reachable.

14. Click **Insert**.

#### *Collector field descriptions*

Use the data in the following table to use the **Collector** tab.

| Name                  | Description                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Num</b>            | Specifies the ID number of the collector                                                                            |
| <b>AddressType</b>    | Specifies the IP address type of the collector.                                                                     |
| <b>Address</b>        | Specifies the IP address of the collector.                                                                          |
| <b>Protocol</b>       | Specifies the protocol used to export data from the exporter to the collector.                                      |
| <b>SrcPort</b>        | Specifies the source port sending flow information.                                                                 |
| <b>DestPort</b>       | Specifies the destination port receiving flow information.                                                          |
| <b>ExporterIpType</b> | Specifies the IP address type of the exporter for the collector.                                                    |
| <b>ExporterIp</b>     | Specifies the IP address of the exporter for the collector.                                                         |
| <b>State</b>          | Specifies the state of the collector. The default value is enabled.                                                 |
| <b>IsReachable</b>    | Specifies whether the collector is reachable. The default value is false (not reachable)                            |
| <b>ViaNextHopName</b> | Specifies the next-hop through which the collector is reachable.                                                    |
| <b>ExportInterval</b> | Specifies, in seconds, the frequency of template packets exports to the collector. The default value is 60 seconds. |
| <b>InitialBurst</b>   | Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.         |

|                                               | VSP 7400 Series | VOSS 8.3 for Fabric Extend over IPsec | Not Applicable     |
|                                               | VSP 8200 Series | Not Supported                         | Not Applicable     |
|                                               | VSP 8400 Series | Not Supported                         | Not Applicable     |
|                                               | VSP 8600 Series | Not Supported                         | Not Applicable     |
|                                               | XA1400 Series   | VOSS 8.3 for Fabric Extend over IPsec | Not Applicable     |

## IPsec Fundamentals

Internet Protocol Security (IPsec) ensures the authenticity, integrity, and confidentiality of data at the network layer of the Open System Interconnection (OSI) stack.

The IPsec feature is a set of security protocols and cryptographic algorithms that protect communication in a network. Use IPsec in scenarios where you need to encrypt packets between two hosts, or two routers, or a router and a host.

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols.

IPsec adds support for OSPF virtual link for the security protection of the communication between the end points. You can also use IPsec with OSPFv3 on a brouter port or VLAN interface, for example, if you want to encrypt OSPFv3 control traffic on a broadcast network. You can also use IPsec with ICMPv6.

### Note

- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.
- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

### Note

- When an OSPFv3 virtual link between two end points is secured using IPsec, the IPsec status on the IPv6 interfaces is automatically updated. This is applicable only on those interfaces that have no IPSEC policies manually configured on them

The following figure displays the movement of traffic using IPsec.

**Figure 157: Internet Protocol Security (IPsec)**

The IPsec feature uses security ciphers and encryption algorithms like AES, DES, and 3DES to ensure confidentiality of data, and keyed MAC for authenticity of data. The encryption algorithms require shared keys to secure the communication. The device only supports manual keying and configuration for IPsec. The IPsec feature supports IPv4 and IPv6 interfaces.

To configure IPsec, you create an IPsec policy, and then link the IPsec policy to an interface. You also link each IPsec policy to an IPsec security association. The IPsec policies define the amount of security applied to specific traffic on a specific interface. The IPsec feature supports the following security protocols:

- Encapsulating security payload (ESP)
- Authentication header (AH)

The device restricts IPsec encryption to control traffic through the CPU. The IPsec feature processes either the ingress, the egress, or both the egress and ingress control packets to and from the CPU.

The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to the packet. The device consults the SPD for both ingress and egress traffic. For egress traffic, the device consults the SPD to determine if IPsec needs to apply security considerations. For ingress traffic, the device consults the SPD to determine whether the traffic received with IPsec encapsulation complies with the policies defined in the system.

For more information on IPsec, see [IPsec Support with OSPFv3](#) on page 2442, [View IPsec Statistics](#) on page 1773, and [Display IPsec Interface Statistics](#) on page 1786.

## Authentication header

The authentication header (AH) authenticates IP traffic and ensures you connect with who you want to connect. The authentication header can detect if data is altered in transit and protect against replay attacks. The authentication header does not encrypt traffic.

The authentication header provides a small header that precedes the payload with the use of the security parameters index (SPI) and sequence number. The authentication header provides:

- IP datagram sender authentication by HMAC or MAC
- IP datagram integrity assurance by HMAC or MAC
- Replay detection and protection by sequence number

The IPsec feature inserts the AH header after the IP header in transport mode. Transport mode with AH authenticates only the payload of the IP packet.

Tunnel mode authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

You can apply AH alone, or in combination with the Encapsulating Security Payload (ESP).

The following figures show an original IP packet and an IP packet with an AH header.

**Figure 158: Original IP packet**

**Figure 159: AH in transport mode**

## Encapsulating security payload

The encapsulating security payload (ESP) encrypts traffic with use of encryption algorithms, such as 3DES, AES-CBC, and AES-CTR. The security association specifies the algorithm and key used in ESP.

The encapsulating security payload can protect origin authenticity, integrity, and confidentiality of packets. ESP supports encryption-only and authentication-only configurations. The IPsec feature inserts the ESP header after the IP header and before the next layer protocol header in transport mode. Transport mode with ESP encrypts or authenticates only the payload of the IP packet.

Tunnel mode encrypts or authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

The following figures display the original IP packet and an IP packet with ESP.

**Figure 160: Original IP packet**

**Figure 161: ESP in transport mode**

## IPsec modes

The IPsec feature security protocols use two different modes to protect the entire IP payload or the upper layer protocols:

- Transport mode
- Tunnel mode

Transport mode IPsec protects the upper layer protocols. In transport mode, IPsec adds an IPsec header between the IP header and upper layer protocol header.

Tunnel mode IPsec protects the whole IP packet. In tunnel mode, IPsec inserts the IPsec header between another IP datagram IP header and inner IP header.

## Security association

A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet. IPsec identifies SAs by:

- Security Parameter Index (SPI)
- Protocol value (either AH or ESP)
- Destination address to which the SA applies

### *Creation of a security association*

Typically SAs exist in pairs; one in each direction, either inbound or outbound.

You can create SAs manually or dynamically. After you create an SA manually, the SA has no defined lifetime and the SA exists until you manually delete the SA.

After the device creates the SA dynamically, the SA can have a lifetime value that IPsec peers negotiate through use of a key management protocol. If the device uses the key excessively unauthorized access can occur. You must define the IPsec lifetime and other configurable parameters manually.

Security associations reside in the Security Association Database (SADB), which maintains a list of active SAs. The IPsec feature uses outbound SAs to secure the outgoing traffic and inbound SAs to process the incoming traffic. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature restricts SAs to the source and destination address of the connected router.

## Security policy

Use IPsec to create IPsec security policies that define the levels of security for different types of traffic. You can use IPsec security policies to create rules to filter traffic with IPsec. IPsec policies determine what IP traffic to secure. An IPsec security policy typically consists of:

- An IP filter
- Security algorithms for authentication and key exchange
- An action

### *Creation of a security policy*

You can configure IPsec on IPv4/IPv6 interfaces. First, create and configure an IPsec policy, and then add and enable the policy on an interface.

After you enable IPsec, the device encrypts all control traffic on the interface based on the policy. You have to specify individual policies to target a particular interface address or multiple addresses. By default, this implementation does not work on a subnet.

The Security Policy Database (SPD) maintains the IPsec security policies. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature only adds policies if the source address in the policy specified matches an interface IP address.

The IPsec feature restricts the policy match source address to the interface address of the router and destination IPv6 address.

## IPsec NAT-T

IP security (IPsec) Network Address Translation Traversal (NAT-T) allows IPsec tunnel traffic through Network Address Translation (NAT) or Port Address Translation (PAT) points in the network. To enable IPsec NAT-T connectivity, you must deploy and configure an IPsec NAT-T supported IPsec logical interface on each side of the IPsec tunnel.

The following terms are specific to the IPsec NAT-T feature:

- IPsec Initiator - The initiator mode of an IPsec tunnel initiates IKE negotiation and rekeying. A supported IPsec logical interface configured as an IPsec Initiator initiates IKE message exchange and IPsec security association (SA) establishment, rekeys IKE, and initiates IPsec SAs. Configure the IPsec Initiator device on the branch side of the tunnel.

### Note

IPsec Initiator is the default mode of the logical interface IPsec tunnel.

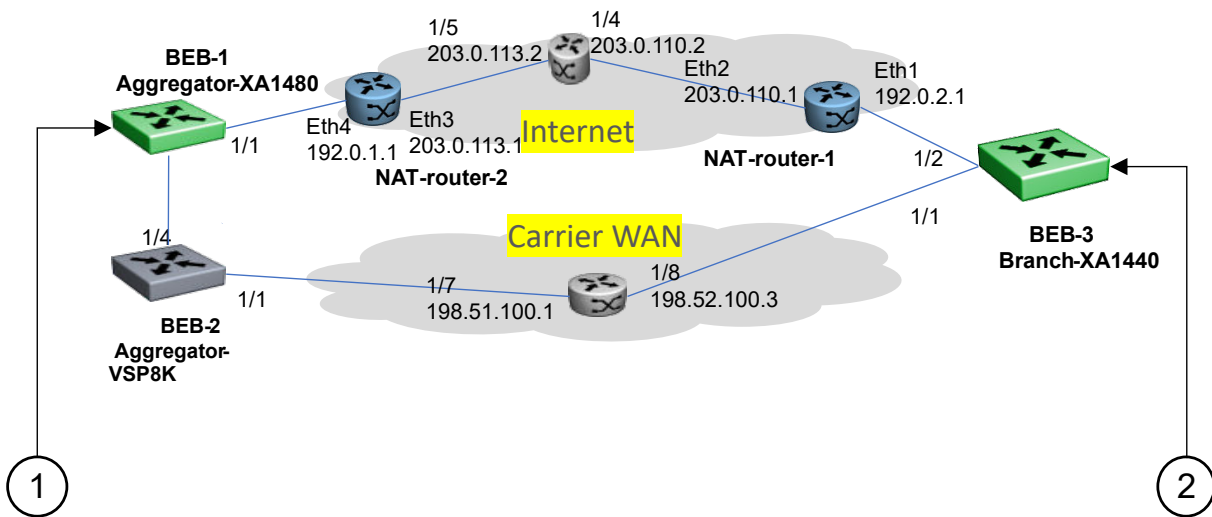

- IPsec Responder - The responder-only mode of an IPsec tunnel responds to IKE negotiation and rekeying and only responds to IPsec negotiations from an IPsec Initiator. A VOSS device with a logical interface configured as an IPsec Responder does not initiate IKE message exchange and IPsec SA establishment, and does not rekey IKE and IPsec SAs. Configure the IPsec Responder device on the aggregator side of the tunnel.
- IPsec Remote NAT IP - The remote-nat-ip is the public IP address of the NAT router connected to the IPsec Responder device. Only configure an IPsec Initiator with the IPsec Remote NAT IP address when NAT routers are present on both sides of the IPsec tunnel.

### Note

Only configure the logical interface of the IPsec Initiator device with the Remote NAT IP address of the responder.

The following diagram illustrates an example of an IPsec NAT-T configuration with both sides of the connection behind NAT:

**Figure 162: IPsec NAT-T with NAT router on both sides**

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.3
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec remote-nat-ip 203.0.113.1
ipsec
```

The following diagram illustrates an example of an IPsec NAT-T configuration with only 1 side of the connection behind NAT:

**Figure 163: IPsec NAT-T with NAT router on one side**

1. BEB-1 Aggregator side IPsec Responder device configuration example:

```
logical-intf isis 2 dest-ip 192.0.2.2
mtu 1300
name "Tunnel-to-BEB3"
auth-key <key value>
ipsec responder-only
ipsec
```

2. BEB-3 Branch side IPsec Initiator device configuration example:

```
logical-intf isis 2 dest-ip 192.0.1.2
mtu 1300
name "Tunnel-to-BEB1"
auth-key <key value>
ipsec
```

### *IPsec NAT-T Considerations*

The following considerations apply to IPsec NAT-T:

- You must configure one side of the IPsec NAT-T tunnel as an IPsec responder. If IPsec is configured on the IPsec Initiator device and subsequently configured on the IPsec Responder device, IPsec must be restarted on the Initiator device. If IPsec is not restarted, it can take approximately 3 minutes for the adjacency to open.
- You must configure the aggregator device as the IPsec Responder device, and configure the branch device as the IPsec Initiator device.
- Among all the IPsec responders, the system uses the lowest configured maximum transmission unit (MTU) value of any responder IPsec tunnel as the MTU value for all IPsec responder-only tunnels. The system uses the lowest configured IPsec tunnel MTU value regardless of manually configured MTU tunnel values, and higher MTU values might be visible in the IPsec information for the logical

interface. For non-responder IPsec tunnels or VXLAN tunnels, the configured and visible MTU value for the tunnel is used for fragmentation and reassembly.

- If both the IPsec Initiator device and the IPsec Responder device are behind NAT, you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.
- You must add route table entries on the IPsec Responder device with the public IP address and private IP address of the remote NAT for the IPsec Initiator device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.
- You must add a route table entry on the IPsec Initiator device with the public IPsec Remote NAT IP address for the IPsec Responder device. A configured route table is required for IPsec NAT-T Fabric Extend (FE) connectivity.

## Digital Certificates for IPsec Authentication

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. The default method for IPsec authentication is a pre-shared key, which is easy to configure, but does not scale well and is less secure than a certificate. You can use a digital certificate, instead of a pre-shared key, to authenticate IPsec for Fabric Extend.

Consider a hub and spoke topology with two branch locations. The network carries both private traffic and encrypted IPsec traffic. To use Public Key Infrastructure (PKI) with IPsec Fabric Extend technology, all devices must acquire the digital-signed certificates. The CA server can be accessed from the devices, a public network, or an internal network. Each device must configure a profile for the CA server. The switch uses Simple Certificate Enrollment Protocol (SCEP) to obtain the trusted, signed certificates.

### *XA1400 Series*

XA1400 Series supports digital certificate configuration through VOSS. VOSS supports both offline and online certificate management; they are mutually exclusive. Use offline certificate management if the switches cannot communicate with the certificate authority (CA).

Digital certificate support for IPsec authentication provides an alternate method to validate the CA certificate chain. You can configure the IPsec authentication type as RSA signature instead of pre-shared key.

VOSS supports only one CA server and one subject certificate.

To use IPsec with Digital Certificates for XA1400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1767.
- Configure certificate information in VOSS.

For information about certificate configuration, see [Security](#) on page 2987.

### *VSP 4900 Series and VSP 7400 Series*

VSP 4900 Series and VSP 7400 Series support digital certificate configuration through the Fabric IPsec Gateway virtual machine. Fabric IPsec Gateway supports both offline and online certificate management simultaneously. Use offline certificate management if the switches cannot communicate with the CA.

Fabric IPsec Gateway supports multiple CA trustpoints and multiple identity subject certificates. You can use different certificates for different IPsec tunnels. Fabric IPsec Gateway acts like a hub to isolate IPsec domains.

To use IPsec with Digital Certificates for VSP 4900 Series and VSP 7400 Series:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see [Configure Public Key Infrastructure for IPsec Tunnels](#) on page 1767.
- Configure certificate information in Fabric IPsec Gateway.

For information about certificate configuration, see [Extreme Integrated Application Hosting](#) on page 846 for Fabric IPsec Gateway virtual machine configuration.

## IPsec Limitations

- The IPsec feature implementation is available only in software. Hardware implementation is not available. Only control packets to and from the CPU are subject to IPsec. IPsec implements IPsec policies in the software on the control path.
- The device does not support address ranges facility for an IPsec policy.
- No fast-path support exists for IPsec.

## IPsec configuration using CLI

The following section provides procedures to configure Internet Protocol Security (IPsec).

### Creating an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

#### Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create an IPsec policy:  

```
ipsec policy WORD<1-32>
```
3. (Optional) Delete an IPsec policy:  

```
no ipsec policy WORD<1-32>
```

## Example

Create an IPsec policy named newpolicy:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy
```

### Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable                | Value                            |
|-------------------------|----------------------------------|
| <i>WORD&lt;1-32&gt;</i> | Specifies the IPsec policy name. |

## Enable an IPsec Policy

Use the following procedure to enable an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

### Before You Begin

- Create an IPsec policy.

### About This Task

The IPsec feature adds policies only if the admin status of the policy and the IPsec status on the interface are enabled.

If you disable the IPsec policy on an IPv4 or IPv6 interface, IPsec removes the policy-related information from the security policy database (SPD) and the security association database (SADB), but the information remains on the system. After you re-enable, the information reapplies on the interface.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable an IPsec policy:  

```
ipsec policy WORD<1-32> admin enable
```
3. (Optional) Disable an IPsec policy:  

```
no ipsec policy WORD<1-32> admin enable
```

## Example

Enable an IPsec policy named newpolicy:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy admin enable
```

### Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable                | Value                            |
|-------------------------|----------------------------------|
| <i>admin enable</i>     | Enables the policy.              |
| <i>WORD&lt;1-32&gt;</i> | Specifies the IPsec policy name. |

## Creating an IPsec security association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create an IPsec security association:  

```
ipsec security-association WORD<1-32>
```
3. (Optional) Delete an IPsec security association:  

```
no ipsec security-association WORD<1-32>
```

## Example

Create an IPsec security association named newsa:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa
```

### Variable Definitions

The following table defines parameters for the **ipsec security-association** command.

| Variable                | Value                                          |
|-------------------------|------------------------------------------------|
| <i>WORD&lt;1-32&gt;</i> | Specifies the security association identifier. |

## Configuring an IPsec security association

Use the following procedure to configure an IPsec security association (SA). An SA is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### Before You Begin

- Create an IPsec security association to configure.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from a policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the IPsec security association key-mode:
 

```
ipsec security-association WORD<1-32> key-mode <automatic|manual>
```

This device only supports manual mode.

3. Configure the IPsec security association mode:
 

```
ipsec security-association WORD<1-32> mode <transport|tunnel>
```

This device only supports transport mode.

4. Configure the IPsec security association encapsulation protocol:
 

```
ipsec security-association WORD<1-32> encap-proto <AH|ESP>
```

5. Configure the IPsec security association security parameters index:

```
ipsec security-association WORD<1-32> spi <1-4294967295>
```

For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.

6. Configure the IPsec security association encryption algorithm:

```
ipsec security-association WORD<1-32> Encrpt-algo <3DES|AES-CBC|AES-CTR|NULL> [EncrptKey WORD<1-256>][KeyLength <1-256>]
```

The encryption algorithm parameters are only accessible if you configure the encapsulation protocol to ESP.

7. Configure the IPsec security association authentication algorithm:

```
ipsec security-association WORD<1-32> auth-algo <AES-XCBC-MAC|MD5|SHA1|SHA2> [auth-key WORD<1-256>][KeyLength <1-256>]
```

8. Configure the IPsec security association lifetime value:

```
ipsec security-association WORD<1-32> lifetime <Bytes<1-4294967295>|seconds<1-4294967295>
```

9. (Optional) Delete the IPsec security association:

```
no ipsec security-association WORD<1-32>
```

## Example

Configure an IPsec security association named `new_sa` to have a key-mode of ASCII, an SA mode of transport, and an encapsulation protocol of ESP. Configure the encryption algorithm to 3DES, with an encryption key of 1111111111111111111111111111111111, and a keylength of 24. Configure the authorization algorithm to SHA1, the authorization key to 11111111111111111111111111111111, and key length to 20. Configure the SPI to 1 and the lifetime in seconds to 1000.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa mode transport
Switch:1(config)#ipsec security-association newsa encap-proto ESP
Switch:1(config)#ipsec security-association newsa Encrpt-algo 3DES Encrpt-key
11 KeyLength 48
Switch:1(config)#ipsec security-association newsa auth-algo SHA1 auth-key
11 KeyLength 20
Switch:1(config)#ipsec security-association newsa key-mode manual
Switch:1(config)#ipsec security-association newsa spi 1
Switch:1(config)#ipsec security-association newsa lifetime seconds 1000
```

## Variable Definitions

The following table defines parameters for the **ipsec security-association** command.

| Variable                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The default lifetime value in seconds is 28800. The default lifetime value in bytes is 4294966272.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Variable                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mode &lt;transport   tunnel&gt;</code> | <p>Specifies the mode value as one of the following:</p> <ul style="list-style-type: none"> <li>• <code>transport</code>—Transport mode encapsulates the IP payload and provides a secure connection between two end points.</li> <li>• <code>tunnel</code>—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel.</li> </ul> <p>The default is transport mode.</p>                                  |
| <code>spi&lt;1-4294967295&gt;</code>         | <p>Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet.</p> <p>For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.</p> <p>The default value is 0.</p> |

## Configuring an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

### Before You Begin

- Create an IPsec policy.

### About This Task

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the remote address:
 

```
ipsec policy WORD<1-32> raddr WORD<1-32>
```
3. (Optional) Configure the local address:
 

```
ipsec policy WORD<1-32> laddr WORD<1-32>
```

The `laddr` parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.

4. Configure the protocol:

```
ipsec policy WORD<1-32>[protocol <icmp|icmpv6|ospfv3|tcp|udp>]
[sport<1-65535|any>][dport<1-65535|any>]
```

5. Configure the policy action:

```
ipsec policy WORD<1-32> [action <drop|permit>]
```

### Example

Configure the remote address to 2001:db8:0:0:0:0:0:1 and local address to 2001:db8:0:0:0:0:0:15. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to permit.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv6policy raddr 2001:db8:0:0:0:0:0:1
Switch:1(config)#ipsec policy Ipv6policy laddr 2001:db8:0:0:0:0:0:15
Switch:1(config)#ipsec policy Ipv6policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv6policy action permit
```

Configure the remote address to 192.0.1.1 and local address to 192.0.1.2. configure the protocol to TCP source port 4 and destination port 5. Configure the policy to drop.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv4policy raddr 192.0.1.1
Switch:1(config)#ipsec policy Ipv4policy laddr 192.0.1.2
Switch:1(config)#ipsec policy Ipv4policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv4policy action drop
```

### Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable                                                                                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>action</i> <drop permit>                                                                                                   | Specifies the action the policy takes.<br>The default is permit.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>laddr</i> WORD<1-32>                                                                                                       | Specifies the local address. The <i>laddr</i> parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.<br>The default is 0::0.                                                                                                                                                                                                                                                                                                                              |
| <i>protocol</i> <icmp icmpv6 ospfv3 tcp udp>] [ <i>sport</i> <1-65535>  <i>any</i> >] [ <i>dport</i> <1-65535>  <i>any</i> >] | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> <li>• ICMP</li> <li>• ICMPv6</li> <li>• OSPFv3</li> <li>• TCP</li> <li>• UDP</li> </ul> <i>sport</i> — Specifies the source port for TCP and UDP. You can specify any to configure any port as the source port.<br><i>dport</i> — Specifies the destination port for TCP and UDP. You can specify any to configure any port as the destination port.<br>The default protocol is TCP any.<br>IPv4 only supports ICMP, UDP, and TCP. |

| Variable                      | Value                                                 |
|-------------------------------|-------------------------------------------------------|
| <i>raddr WORD&lt;1-32&gt;</i> | Specifies the remote address.<br>The default is 0::0. |

## Linking the IPsec security association to an IPsec policy

Use the following procedure to link the security association to an IPsec policy.

### Before You Begin

- The IPsec security association and IPsec policy must exist.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

- Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
- Link the IPsec security association to the IPsec policy:  
`ipsec policy WORD<1-32> security-association WORD<1-32>`
- (Optional) Unlink the IPsec security association to the IPsec policy:  
`no ipsec policy WORD<1-32> security-association WORD<1-32>`

### Example

Link the IPsec security association named `new_sa` to the IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy security-association newsa
```

### Variable Definitions

The following table defines parameters for the **ipsec policy** command.

| Variable                                     | Value                                  |
|----------------------------------------------|----------------------------------------|
| <i>WORD&lt;1-32&gt;</i>                      | Specifies the policy ID.               |
| <i>security-association WORD&lt;1-32&gt;</i> | Specifies the security association ID. |

## Enable IPsec on an Interface

Use the following procedure to enable IPsec on an interface. You can configure IPsec on a port, management port, VLAN, or loopback interface.

### Note

IPsec support on the management port applies to VSP 8600 Series only.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]}`
- `interface loopback <1-256>`
- `interface mgmtEthernet <mgmt | mgmt2>`
- `interface vlan <1-4059>`

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPsec on an IPv6 interface:

```
ipv6 ipsec enable
```

```
default ipv6 ipsec enable
```

3. Enable IPsec on an IPv4 interface:

```
ip ipsec enable
```

```
default ip ipsec enable
```

4. (Optional) Disable IPsec on an IPv6 interface:

```
no ipv6 ipsec enable
```

5. (Optional) Disable IPsec on an IPv4 interface:

```
no ip ipsec enable
```

### Example

Enable IPsec for IPv6 on VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec enable
```

### Variable Definition

The following table defines parameters for the **ip ipsec** and **ipv6 ipsec** commands.

| Variable      | Value                           |
|---------------|---------------------------------|
| <i>enable</i> | Enables IPsec on the interface. |

## Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

### Note

IPsec support on the management port applies to VSP 8600 Series only.

### Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

### About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

### Procedure

- Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

followed by one of the following:

- `interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]][,...]}`
- `interface loopback <1-256>`
- `interface mgmtEthernet <mgmt | mgmt2>`
- `interface vlan <1-4059>`

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Link the IPsec policy to an IPv4 interface:

```
ip ipsec policy WORD<1-32> dir <both|in|out>
```

- Link the IPsec policy to an IPv6 interface:

```
ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv4 interface:

```
no ip ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv6 interface:

```
no ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

## Example

Link the IPsec policy newpolicy to the IPv6 interface VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec policy newpolicy dir both
```

## Variable Definitions

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

| Variable                          | Value                                                                                                                                                                                                                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1–32>                | Specifies the policy ID.                                                                                                                                                                                                                                                                        |
| <i>dir</i> < <i>both in out</i> > | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>• <i>both</i>—Specifies both ingress and egress traffic.</li> <li>• <i>in</i>—Specifies ingress traffic.</li> <li>• <i>out</i>—Specifies egress traffic.</li> </ul> The default is <i>both</i> . |

## Enable IPsec on a Management Interface

Use the following procedure to enable IPsec on a management interface.

By default, IPsec is disabled on the management interface.

### Note

This procedure applies to VSP 8600 Series only.

## Procedure

1. Enter mgmtEthernet Interface Configuration mode:

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Enable IPsec on an IPv6 interface:

```
ipv6 ipsec enable
```
3. Enable IPsec on an IPv4 interface:

```
ip ipsec enable
```

## Example

Enable IPsec for IPv4 on the management interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtEthernet mgmt
Switch:1(config-if)#ip ipsec enable
```

## Link an IPsec Policy to a Management Interface

Use the following procedure to link an IPsec policy to a management interface, and configure a policy direction. By default, the direction is both.

### Note

This procedure applies to VSP 8600 Series only.

### Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

### Procedure

- Enter mgmtEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface mgmtEthernet <mgmt | mgmt2>
```

- Link the IPsec policy to an IPv4 interface:

```
ip ipsec policy WORD<1-32> dir <both|in|out>
```

- Link the IPsec policy to an IPv6 interface:

```
ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv4 interface:

```
no ip ipsec policy WORD<1-32> dir <both|in|out>
```

- (Optional) Unlink the IPsec policy from an IPv6 interface:

```
no ipv6 ipsec policy WORD<1-32> dir <both|in|out>
```

### Example

Link the IPsec policy for IPv4 to the management interface:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtEthernet mgmt
Switch:1(config-if)#ip ipsec policy newpolicy dir both
```

### Variable Definitions

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

| Variable                       | Value                                                                                                                                                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-32&gt;</i>        | Specifies the policy ID.                                                                                                                                                                                                                                            |
| <i>dir &lt;both in out&gt;</i> | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>both—Specifies both ingress and egress traffic.</li> <li>in—Specifies ingress traffic.</li> <li>out—Specifies egress traffic.</li> </ul> <p>The default is both.</p> |

## Configure the IPsec Initiator with the IPsec Responder Remote NAT IP Address

### About This Task

If both the Responder device and the Initiator device are behind Network Address Translation (NAT), you must configure the IPsec Initiator device with the public IP address of the NAT router connected to the IPsec Responder device.

#### Note

Only perform this procedure on the IPsec Initiator device.

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:  

```
enable  
  
configure terminal  
  
logical-intf isis <1-255>
```
2. Configure the public IP address of the NAT router connected to the IPsec Responder device:  

```
ipsec remote-nat-ip {A.B.C.D}
```

### Variable Definitions

The following table defines parameters for the **logical-intf isis** command.

| Variable                                                                       | Value                                                                                                                                                                                                                 |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| isis <1-255>                                                                   | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID.                                                                                                                                |
| dest-ip {A.B.C.D}                                                              | Specifies the destination IP address for the logical interface.                                                                                                                                                       |
| name WORD<1-64>                                                                | Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.                                                                                                             |
| mtu <mtu_value><br><b>Note:</b><br>Exception: only supported on XA1400 Series. | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch. The default value is 1950. |

The following table defines parameters for the **ipsec remote-nat-ip** command.

| Variable  | Value                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| {A.B.C.D} | Specifies the public IP address of the NAT router connected to the Responder device in an IPsec Network Address Translation Traversal (NAT-T) connection. |

## Configure an IPsec NAT-T Responder

### About This Task

One side of an IPsec Network Address Translation Traversal (NAT-T) connection must be a responder device and the other side must be the Initiator device. By default, both sides of an IPsec NAT-T connection are Initiators. Use the following procedure to configure one side of an IPsec NAT-T connection as a Responder device.

### Procedure

1. Enter Logical IS-IS Interface Configuration mode:

```
enable

configure terminal

logical-intf isis <1-255>
```

2. Configure an IPsec Responder:

```
ipsec responder-only
```

### Variable Definitions

The following table defines parameters for the **logical-intf isis** command.

| Variable                                                    | Value                                                                                                                                                                                                                    |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| isis <1-255>                                                | Specifies the Intermediate-System-to-Intermediate-System (IS-IS) logical interface ID.                                                                                                                                   |
| dest-ip {A.B.C.D}                                           | Specifies the destination IP address for the logical interface.                                                                                                                                                          |
| name WORD<1-64>                                             | Specifies the administratively assigned name of this logical interface, which can be up to 64 characters.                                                                                                                |
| mtu <mtu_value>                                             | Specifies the Maximum Transmission Unit (MTU) size for each packet. Different hardware platforms support different MTU ranges. Use the CLI Help to see the available range for the switch.<br>The default value is 1950. |
| <b>Note:</b><br>Exception: only supported on XA1400 Series. |                                                                                                                                                                                                                          |

## Configure Public Key Infrastructure for IPsec Tunnels

### Note

This procedure only applies to VSP 4900 Series, VSP 7400 Series, and XA1400 Series.

### Before You Begin

- Configure the Fabric Extend tunnels between the branch and hub switches.
- Configure digital certificates on the switch using either VOSS or the Fabric IPsec Gateway virtual machine, as appropriate.

## About This Task

XA1400 Series, VSP 4900 Series, and VSP 7400 Series switches support IPsec authentication and encryption of Fabric Extend tunnels; VSP 4900 Series and VSP 7400 Series provide that support using Fabric IPsec Gateway. You can use a digital certificate to authenticate IPsec for Fabric Extend.

The default IPsec authentication method for Fabric Extend tunnels is a pre-shared key. If you configure the authentication method to RSA signature, the tunnels use the installed digital certificate.

## Procedure

1. On XA1400 Series, configure IPsec authentication in the VOSS CLI:
  - a. Enter Layer 3 Logical IS-IS Interface Configuration mode:
 

```
enable

configure terminal

logical-intf isis <1-255>
```
  - b. Configure the authentication type as RSA signature:
 

```
ipsec auth-method rsa-sig
```
2. On VSP 4900 Series and VSP 7400 Series, configure IPsec authentication in the Fabric IPsec Gateway virtual machine:

- a. Enter Fabric IPsec Gateway Configuration mode:
 

```
enable

virtual-service WORD<1-128> console
```

### Note

Type CTRL+Y to exit the console.

- b. Configure the authentication type as RSA signature:
 

```
set ipsec <1-255> auth-method rsasig
```
- c. Configure the subject identity to use with the IPsec tunnel:
 

```
set ipsec <1-255> cert-subject <subject-label>
```

## Variable Definitions

The following table defines parameters for the **set ipsec** command.

| Variable        | Value                           |
|-----------------|---------------------------------|
| <1-255>         | Specifies the tunnel ID.        |
| <subject-label> | Specifies the subject identity. |

## Display IPsec Information on an Interface

Use the following procedure to display IPsec information on an interface.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IPsec status on an Ethernet interface:

```
show ipsec interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

3. Display the IPsec status on a VLAN interface:

```
show ipsec interface vlan <1-4059>
```

4. Display the IPsec status on a management interface:

```
show ipsec interface mgmtethernet mgmt
```

### Note

This step applies to VSP 8600 Series only.

5. Display the IPsec status on a loopback interface:

```
show ipsec interface loopback <1-256>
```

## Example

Display the IPsec status on a VLAN interface.

```
Switch:1>show ipsec interface vlan 22
=====
                        VLAN Interface Policy Table
=====
Vlan Interface      Policy Name      IPsec State      Direction
-----
22                  AAA              Enable            both
22                  tcp              Enable            both
22                  icmp             Enable            both
```

### Variable Definitions

The following table defines parameters for the **show ipsec interface** command.

| Variable                                                                               | Value                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i><br><i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>mgmtethernet mgmt</i>                                                               | Identifies the interface as the management interface.<br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series.                                                                                                                                                                                                                                    |

| Variable                | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>loopback</i> <1-256> | Specifies the loopback interface.                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>vlan</i> <1-4059>    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Displaying configured IPsec policies

Use the following procedure to display IPsec policies.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all of the IPsec policies on the switch:  
*show ipsec policy all*
3. Display a specific IPsec policy based on the policy name on the interface:  
*show ipsec policy interface WORD<1-32>*
4. Display the IPsec policy based on the policy name:  
*show ipsec policy name WORD<1-32>*

### Example

Display IPsec policy information:

```
Switch:1>show ipsec policy all
=====
IPSEC Policy Table
=====
PolicyName      : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable

Switch:1>show ipsec policy interface ospf1
=====
IPsec Policy Interface Table
=====
POLICY NAME      InterfaceIndex      Policy State      Direction
-----
ospf1             2/3                 Enable            both

Switch:1>show ipsec policy name ospf1
=====
IPSEC Policy Table
=====
PolicyName      : ospf1
LocalAddress: 0::0
```

```

RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable

```

### Variable Definitions

The following table defines parameters for the **show ipsec policy** command.

| Variable                          | Value                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------|
| <i>all</i>                        | Displays all of the IPsec policies on the switch.                           |
| <i>interface WORD&lt;1-32&gt;</i> | Displays a specific IPsec policy based on the policy name on the interface. |
| <i>name WORD&lt;1-32&gt;</i>      | Displays the IPsec policy based on the name of the policy.                  |

## Displaying IPsec security association information

Use the following procedure to display IPsec security association information.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display all IPsec security associations:  
`show ipsec sa all`
3. Display a specific IPsec security association:  
`show ipsec sa name WORD<1-32>`
4. Display all security associations linked to a specific policy:  
`show ipsec sa-policy`

### Example

Display information on IPsec security association policies:

```

Switch:1>enable
Switch:1#show ipsec sa all
=====
                        IPSEC Security Association Table
=====
sa-name: ospf1
key-Mode: manual
Encap protocol: ESP
SPI Value: 9
Encrypt Algorithm: 3dec-cbc
Encrypt-key: 52fb29f723b0800870dc83e3
Encrypt-key-Len: 24
Auth Algorithm: hmac-md5
Auth-key: 123456789abcdef0
Auth-key-Len: 16
Mode: transport
Lifetime-Sec: 1000
Lifetime-Byte: 20000

Switch:1#show ipsec sa name ospf1

```

```

=====
                        IPSEC Security Association Table
=====

=====

```

### Variable Definitions

The following table defines parameters for the **show ipsec sa** command.

| Variable                     | Value                                                   |
|------------------------------|---------------------------------------------------------|
| <i>all</i>                   | Displays all security associations.                     |
| <i>name WORD&lt;1-32&gt;</i> | Displays a specific security association based on name. |

Use the data in the following table to use the **show ipsec** command.

| Variable         | Value                                                           |
|------------------|-----------------------------------------------------------------|
| <i>sa-policy</i> | Displays all security associations linked to a specific policy. |

## Display Logical Interface IPsec and Authentication Key

Displays the IS-IS logical interface IPsec ID and authentication keys.

### About This Task

Use the following procedure to display the IS-IS logical interface IPsec ID and authentication keys.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IS-IS logical interface ID and related IPsec authentication key:

```
show isis logical-interface ipsec
```

### Example

```
Switch:1>show isis logical-interface ipsec
=====
ISIS Logical Interface IPsec
=====
ID   Status   Auth-Method   Auth-Key   ESP           Responder-Only   Remote NAT IP   Auth-Key-Len   Compression   Frag-before-encrypt
-----

-----
1 out of 1 Total Num of Logical ISIS interfaces
-----
```

## View IPsec Statistics

Use the following procedure to clear Internet Protocol Security (IPsec) system statistics counters and view IPsec statistics on an interface. The device only clears system statistics counters on system reboot.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPsec statistics for the system:  
`show ipsec statistics system`
3. View IPsec statistics for an Ethernet interface:  
`show ipsec statistics gigabitethernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]`
4. View IPsec statistics for a VLAN interface:  
`show ipsec statistics vlan <1-4059>`
5. View statistics for IPsec on the management interface:  
`show ipsec statistics mgmtethernet <mgmt | mgmt2>`

#### Note

This step applies to VSP 8600 Series only.

6. View statistics for IPsec on the loopback interface:  
`show ipsec statistics loopback <1-256>`
7. Clear IPsec system statistics counters:  
`clear ipsec stats all`

### Example

View IPsec statistics. Output is partial due to length.

```
Switch:1>show ipsec statistics system
```

```

### Variable Definitions

Use the data in the following table to use the **show ipsec statistics** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>loopback &lt;1-256&gt;</code>                               | Identifies the loopback interface.                                                                                                                                                                                                                                                                                                                            |

| Variable                                                                                                             | Value                                                 |
|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <code>mgmtethernet &lt; mgmt   mgmt2&gt;</code><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Identifies the interface as the management interface. |
| <code>system</code>                                                                                                  | Shows statistics for the entire system.               |

## IPsec configuration using EDM

The following section provides procedures to configure Internet Protocol security (IPsec).

### Create an IPsec Policy

Use the following procedure to configure an IPsec policy for an IPv4 or an IPv6 interface. An IPsec policy defines the level of security for different types of traffic.

#### Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

#### About This Task

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

#### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Select **IPSec**.
- Select the **Policy** tab.
- Select **Insert**.
- In the **Name** field, type a policy name.
- Complete the remaining optional configuration to customize the policy.
- Select **Insert**.

#### Policy field descriptions

Use the data in the following table to use the **Policy** tab.

| Name              | Description                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>       | Specifies the IPsec policy name.                                                                                                                                                                                                                      |
| <b>DstAddress</b> | Specifies the remote address. This field accepts IPv4 and IPv6 address, depending on the selected source address type.                                                                                                                                |
| <b>SrcAddress</b> | Specifies the local address. The local address is optional that you can configure to have multiple local addresses for each remote (destination) address.<br>This field accepts IPv4 and IPv6 address, depending on the selected source address type. |
| <b>SrcPort</b>    | Specifies the source port for TCP and UDP. Leave this field empty to configure any port as the source port. The default is value is 1.                                                                                                                |
| <b>DstPort</b>    | Specifies the destination port for TCP and UDP. Leave this field empty to configure any port as the destination port. The default value is 1.                                                                                                         |
| <b>AdminFlag</b>  | Enables or disables the policy. The default is disabled.                                                                                                                                                                                              |
| <b>L4Protocol</b> | Specifies the protocol, as one of the following: <ul style="list-style-type: none"> <li>• tcp</li> <li>• udp</li> <li>• icmp</li> <li>• icmpv6</li> <li>• ospfv3</li> </ul> IPv4 interfaces only support TCP, UDP, and ICMP. The default is TCP.      |
| <b>Action</b>     | Specifies the action the policy takes. The default is to permit the packet.                                                                                                                                                                           |

## Create an IPsec Security Association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **IPSec**.
3. Click the **Security Association** tab.
4. Click **Insert**.
5. In the **Name** field, type a name to identify the SA.
6. In the **SPI** field, type the security parameters index.

**Note**

For IPsec to function, each peer must have the same SPI value configured for a particular policy.

7. Complete the remaining optional configuration.
8. Click **Insert**.

*Security Association field descriptions*

Use the data in the following table to use the **Security Association** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>             | Specifies the name of the security association.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Spi</b>              | Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet.<br>For IPsec to function, each peer must have the same SPI value configured for a particular policy. The default value is 0.                                                  |
| <b>HashAlgorithm</b>    | Specifies the authorization algorithm, which includes one of the following values: <ul style="list-style-type: none"> <li>• AESXCBC</li> <li>• MD5</li> <li>• SHA1</li> <li>• SHA2</li> </ul> The default authentication algorithm name is MD5.                                                                                                                                                                                            |
| <b>EncryptAlgorithm</b> | Specifies the encryption algorithm value as one of the following: <ul style="list-style-type: none"> <li>• DES3CBC</li> <li>• AES128CBC</li> <li>• AESCTR</li> <li>• NULL—Only use the NULL parameter to debug. Do not use this parameter in any other circumstance.</li> </ul> The default encryption algorithm is AES128CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AuthMethod</b>       | Specifies the encapsulation protocol: <ul style="list-style-type: none"> <li>• ah—Specifies authentication header.</li> <li>• es—Specifies encapsulation security payload.</li> </ul> If you configure the encapsulation protocol as ah, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to es. The default value is es. |
| <b>Mode</b>             | Specifies the mode value as one of the following: <ul style="list-style-type: none"> <li>• transport—Transport mode encapsulates the IP payload and provides a secure connection between two end points. This device only supports transport mode.</li> <li>• tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. This device does not support tunnel mode.</li> </ul> The default is transport mode.                                 |
| <b>KeyMode</b>          | Specifies the key-mode as one of the following: <ul style="list-style-type: none"> <li>• manual</li> <li>• auto</li> </ul> The default is manual.                                                                                                                                                                                                                                                                                                                    |
| <b>EncryptKeyName</b>   | Specifies the encryption key.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EncryptKeyLength</b> | Specifies the numbers of bits used in the encryption key. The key length values are as follows: <ul style="list-style-type: none"> <li>• DES3CBC is 48</li> <li>• AES128CBC is 32, 48, 64</li> <li>• AESCTR is 32</li> </ul>                                                                                                                                                                                                                                         |
| <b>HashKeyName</b>      | Specifies the authentication key.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>HashKeyLength</b>    | Specifies the numbers of bits used in the hash key. The key length values are as follows: <ul style="list-style-type: none"> <li>• AESXCBC is 32</li> <li>• MD5 is 32</li> <li>• SHA1 is 40</li> </ul>                                                                                                                                                                                                                                                               |
| <b>LifetimeSeconds</b>  | Specifies the lifetime value in seconds. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in seconds is 28800.                                                                                                                                                                                                                                |
| <b>LifetimeKbytes</b>   | Specifies the lifetime value in kilobytes. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in bytes is 4294967295.                                                                                                                                                                                                                           |

## Link the IPsec Security Association to an IPsec Policy

Use the following procedure to link the security association to an IPsec policy.

### About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

### Before You Begin

- The IPsec security association and IPsec policy must exist.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Policy SA Link** tab.
4. Click **Insert**.
5. In the **PolicyName** field, type the IPsec policy name.
6. In the **SAName** field, type the security association name.
7. Click **Insert**.

#### *Policy SA Link field descriptions*

Use the data in the following table to use the **Policy SA Link** tab.

| Name              | Description                                     |
|-------------------|-------------------------------------------------|
| <b>PolicyName</b> | Specifies the name of the IPsec policy.         |
| <b>SAName</b>     | Specifies the name of the security association. |

## Enable IPsec on an IPv6 Interface

Use the following procedure to enable IPsec on an IPv6 interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **IPSec**.
3. Select the **IPv6 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Select **Apply**.

## Enable IPsec on an IPv4 Interface

Use the following procedure to enable IPsec on an IPv4 interface.

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **IPv4 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Click **Apply**.

### IPv4 Interfaces tab field descriptions

Use the data in the following table to use the **IPv4 Interfaces** tab.

| Name               | Description                                                 |
|--------------------|-------------------------------------------------------------|
| <b>Interface</b>   | Specifies the interface.                                    |
| <b>IpsecEnable</b> | Specifies if IPsec is enabled on that particular interface. |

## Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

### About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

### Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Interface Policy** tab.
4. Click **Insert**.
5. In the **Name** field, type the name of the IPsec policy.

- In the **IfIndex** field, click either **Port**, **Vlan**, or **Mgmt Port**, and then select an interface.

#### Note

The system displays the Mgmt Port button only for hardware with a dedicated, physical management interface. If you click this button, EDM automatically populates the IfIndex value.

- Click **Okay**.
- Complete the remaining optional configuration.
- Click **Insert**.

### **Interface Policy** field descriptions

Use the data in the following table to use the **Interface Policy** tab.

| Name               | Description                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>        | Specifies the IPsec policy name.                                                                                                                                                                                                                                                           |
| <b>IfIndex</b>     | Links a policy to either a port, VLAN, loopback, or management interface.                                                                                                                                                                                                                  |
| <b>IfEnabled</b>   | Shows if the IPsec is enabled on the interface and if the administrative state of the policy is enabled.                                                                                                                                                                                   |
| <b>IfDirection</b> | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>inbound—Specifies ingress traffic.</li> <li>outbound—Specifies egress traffic.</li> <li>bothDirections—Specifies both ingress and egress traffic.</li> </ul> The default is bothDirections. |

## Configure IPsec NAT-T

### About This Task

By default, both sides of an IPsec connection are Initiator devices. IPsec Network Address Translation Traversal (NAT-T) connections require that one side of the connection is a Responder device and the other side of the connection is an Initiator device.

If the Responder device and the Initiator device are both behind NAT, the IPsec NAT-T Initiator device requires the public IP address of the Responder device.

### Procedure

Perform the following steps to configure one side of an IPsec NAT-T connection as a Responder device:

- In the navigation pane, expand **Configuration > IS-IS**.
- Select **IS-IS**.
- Select **Logical Interfaces**.
- Select **Insert**.
- Select **IpsecNatConfigResponderOnly**.

If required, perform the following steps on the IPsec NAT-T Initiator device to configure the public IP address of the Responder device:

6. In the navigation pane, expand **Configuration > IS-IS**.
7. Select **IS-IS**.
8. Select **Logical Interfaces**.
9. Select **Insert**.
10. For **IpssecNatConfigRemoteNatIPAddr**, enter the public IP address of the Responder device.

### **Logical Interfaces** Field Descriptions

Use the data in the following table to use the **Logical Interfaces** tab and the **Insert Logical Interfaces** dialog. The available fields in the dialog differ depending on the type of core you select: **layer 2** or **ip**.

| Name                                                                                      | Description                                                                                                                                                                                                                                                                    |

## Display IPsec Interface Statistics

Use this procedure to view IPsec statistics and counter values for each IPsec-enabled interface.

### About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.

### Interface Stats Field Descriptions

Use the data in the following table to use the **Interface Stats** tab.

| Name                       | Description                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>             | Shows the interface index for which the statistic is captured.                                                 |
| <b>InSuccesses</b>         | Specifies the number of ingress packets IPsec successfully carries.                                            |
| <b>InSPViolations</b>      | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation. |
| <b>InNotEnoughMemories</b> | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available. |

| Name                         | Description                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>InAHESPReplays</b>        | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.                     |
| <b>InESPReplays</b>          | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.                    |
| <b>InAHFailures</b>          | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.             |
| <b>InESPFailures</b>         | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails.            |
| <b>OutSuccesses</b>          | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutSPViolations</b>       | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.             |
| <b>OutNotEnoughMemories</b>  | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| <b>generalError</b>          | Specifies a general error.                                                                                                    |
| <b>InAhSuccesses</b>         | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.                                 |
| <b>OutAHSuccesses</b>        | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>InESPSuccesses</b>        | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.                |
| <b>OutESPSuccesses</b>       | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutKBytes</b>             | Specifies the total number of kilobytes on egress.                                                                            |
| <b>OutBytes</b>              | Specifies the total number of bytes on egress.                                                                                |
| <b>InKBytes</b>              | Specifies the total number of bytes on ingress.                                                                               |
| <b>InBytes</b>               | Specifies the total number of bytes on ingress.                                                                               |
| <b>TotalPacketsProcessed</b> | Specifies the total number of packets processed.                                                                              |
| <b>TotalPacketsByPassed</b>  | Specifies the total number of packets bypassed.                                                                               |
| <b>OutAHFailures</b>         | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.              |
| <b>OutESPFailures</b>        | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails.             |
| <b>InMD5Hmacs</b>            | Specifies the number of inbound HMAC MD5 occurrences since boot time.                                                         |

| Name                       | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <b>InSHA1Hmacs</b>         | Specifies the number of inbound HMAC SHA1 occurrences since boot time.                          |
| <b>InAESXCBCs</b>          | Specifies the number of inbound AES XCBC MAC occurrences since boot time.                       |
| <b>InAnyNullAuth</b>       | Specifies the number of inbound null authentication occurrences since boot time.                |
| <b>In3DESCBCs</b>          | Specifies the number of inbound 3DES CBC occurrences since boot time.                           |
| <b>InAESCBCs</b>           | Specifies the number of inbound AES CBC occurrences since boot time.                            |
| <b>InAESCTRs</b>           | Specifies the number of inbound AES CTR occurrences since boot time.                            |
| <b>InAnyNullEncrypt</b>    | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.  |
| <b>OutMD5Hmacs</b>         | Specifies the number of outbound HMAC MD5 occurrences since boot time.                          |
| <b>OutSHA1Hmacs</b>        | Specifies the number of outbound HMAC SHA1 occurrences since boot time.                         |
| <b>OutAESXCBCs</b>         | Specifies the number of outbound AES XCBC MAC occurrences since boot time.                      |
| <b>OutInAnyNullAuth</b>    | Specifies the number of outbound null authentication occurrences since boot time.               |
| <b>Out3DESCBCs</b>         | Specifies the number of outbound 3DES CBC occurrences since boot time.                          |
| <b>OutAESCBCs</b>          | Specifies the number of outbound AES CBC occurrences since boot time.                           |
| <b>OutAESCTRs</b>          | Specifies the number of outbound AES CTR occurrences since boot time.                           |
| <b>OutInAnyNullEncrypt</b> | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

## Graphing IPsec Interface Statistics

Use this procedure to graphically view IPsec statistics and counter values for each IPsec-enabled interface.

### About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

### Procedure

1. In the navigation pane, expand the **Security > Control Path** folders.
2. Click **IPSec**.

3. Click the **Interface Stats** tab.
4. Select a row, and click **Graph**.
5. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart, or a pie chart.
6. To clear existing counters, and fix a reference point in time to restart the counters, click **Clear Contents**.
7. To export the statistical data to a file, click **Export**.
8. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

## Display Switch Level Statistics for IPsec-Enabled Interfaces

Use this procedure to view IPsec statistics and counter values at the switch level for all IPsec-enabled interfaces.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **IPSec**.
3. Click the **Global Stats** tab.

### *Global Stats Field Descriptions*

Use the data in the following table to use the **Global Stats** tab.

| Name                       | Description                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>InSuccesses</b>         | Specifies the number of ingress packets IPsec successfully carries.                                                |
| <b>InSPViolations</b>      | Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation.     |
| <b>InNotEnoughMemories</b> | Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available.     |
| <b>InAHESPReplays</b>      | Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.          |
| <b>InESPReplays</b>        | Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.         |
| <b>InAHFailures</b>        | Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.  |
| <b>InESPFailures</b>       | Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails. |
| <b>OutSuccesses</b>        | Specifies the number of egress packets IPsec successfully carries since boot time.                                 |

| Name                         | Description                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>OutSPViolations</b>       | Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.             |
| <b>OutNotEnoughMemories</b>  | Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time. |
| <b>generalError</b>          | Specifies a general error.                                                                                                    |
| <b>InAHSuccesses</b>         | Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.                                 |
| <b>OutAHSuccesses</b>        | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>InESPSuccesses</b>        | Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.                |
| <b>OutESPSuccesses</b>       | Specifies the number of egress packets IPsec successfully carries since boot time.                                            |
| <b>OutKBytes</b>             | Specifies the total number of kilobytes on egress.                                                                            |
| <b>OutBytes</b>              | Specifies the total number of bytes on egress.                                                                                |
| <b>InKBytes</b>              | Specifies the total number of bytes on ingress.                                                                               |
| <b>InBytes</b>               | Specifies the total number of bytes on ingress.                                                                               |
| <b>TotalPacketsProcessed</b> | Specifies the total number of packets processed.                                                                              |
| <b>TotalPacketsByPassed</b>  | Specifies the total number of packets bypassed.                                                                               |
| <b>OutAHFailures</b>         | Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.              |
| <b>OutESPFailures</b>        | Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails.             |
| <b>InMD5Hmacs</b>            | Specifies the number of inbound HMAC MD5 occurrences since boot time.                                                         |
| <b>InSHA1Hmacs</b>           | Specifies the number of inbound HMAC SHA1 occurrences since boot time.                                                        |
| <b>InAESXCBCs</b>            | Specifies the number of inbound AES XCBC MAC occurrences since boot time.                                                     |
| <b>InAnyNullAuth</b>         | Specifies the number of inbound null authentication occurrences since boot time.                                              |
| <b>In3DESCBCs</b>            | Specifies the number of inbound 3DES CBC occurrences since boot time.                                                         |
| <b>InAESCBCs</b>             | Specifies the number of inbound AES CBC occurrences since boot time.                                                          |
| <b>InAESCTRs</b>             | Specifies the number of inbound AES CTR occurrences since boot time.                                                          |

| Name                       | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <b>InAnyNulEncrypt</b>     | Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.  |
| <b>OutMD5Hmacs</b>         | Specifies the number of outbound HMAC MD5 occurrences since boot time.                          |
| <b>OutSHA1Hmacs</b>        | Specifies the number of outbound HMAC SHA1 occurrences since boot time.                         |
| <b>OutAESXCBCs</b>         | Specifies the number of outbound AES XCBC MAC occurrences since boot time.                      |
| <b>OutInAnyNullAuth</b>    | Specifies the number of outbound null authentication occurrences since boot time.               |
| <b>Out3DESCBCs</b>         | Specifies the number of outbound 3DES CBC occurrences since boot time.                          |
| <b>OutAESCBCs</b>          | Specifies the number of outbound AES CBC occurrences since boot time.                           |
| <b>OutAESCTRs</b>          | Specifies the number of outbound AES CTR occurrences since boot time.                           |
| <b>OutInAnyNullEncrypt</b> | Specifies the number of outbound null occurrences since boot time. Used for debugging purposes. |

## Configure IPsec for the OSPF Virtual Link

Use the following procedure to configure and enable IPsec for the OSPF virtual link.

IPsec is disabled by default.

### About This Task

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You must disable IPsec before you can perform virtual link policy configuration changes.

### Before You Begin

- Configure the OSPF virtual link.
- Create the IPsec security association.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Panel**.
2. Click **IPSec**.
3. Click the **OSPF Virtual Link** tab.
4. Click **Insert**.
5. Specify the area ID.
6. Specify the neighbor address.
7. Complete the remaining optional configuration.

8. Click **Insert**.

### OSPF Virtual Link field descriptions

Use the data in the following table to use the **OSPF Virtual Link** tab.

| Name               | Description                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AreaId</b>      | Identifies the OSPF virtual link area.                                                                                                                                                                                                                                                           |
| <b>Neighbor</b>    | Identifies the OSPF virtual link neighbor.                                                                                                                                                                                                                                                       |
| <b>SAName</b>      | Links the security association to the OSPF virtual link.                                                                                                                                                                                                                                         |
| <b>AdminStatus</b> | Enables the policy. The default is disabled.                                                                                                                                                                                                                                                     |
| <b>Action</b>      | Configures the action of the IPsec policy under the OSPF virtual tunnel to one of the following: <ul style="list-style-type: none"> <li>• permit—Permits the IP packets.</li> <li>• drop—Drops the IP packets.</li> </ul> The default is permit.                                                 |
| <b>Direction</b>   | Specifies the direction you want to protect with IPsec: <ul style="list-style-type: none"> <li>• inBound—Specifies ingress traffic.</li> <li>• outBound—Specifies egress traffic.</li> <li>• bothDirections—Specifies both ingress and egress traffic.</li> </ul> The default is bothDirections. |
| <b>SrcAddress</b>  | Shows the address of the source interface to which the policy applies.                                                                                                                                                                                                                           |
| <b>DstAddress</b>  | Shows the address of the destination interface to which the policy applies.                                                                                                                                                                                                                      |
| <b>LinkID</b>      | Shows a unique ID for the OSPF virtual link. The default is 0.                                                                                                                                                                                                                                   |
| <b>IfIndex</b>     | Shows the interface index to which OSPF virtual link the policy applies.                                                                                                                                                                                                                         |
| <b>OperStatus</b>  | Shows the operational status of the link, either up or down. The default is down.                                                                                                                                                                                                                |

## IPsec configuration examples

The following section provides examples to configure Internet Protocol Security (IPsec).

### Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

## IPsec configuration example

Review the following information to understand IPsec configuration.

Use the following steps to configure IPsec.

1. Create and configure an IPsec policy.
2. Enable the policy.
3. Create an IPsec security association to correspond with the IPsec policy.
4. Configure the key mode format.
5. Configure the security association.
6. Link the IPsec security association to the IPsec policy.
7. Enable the IPsec policy on the interface.
8. Link the IPsec policy with the interface.
9. Enable the IPsec on the interface that links to the IPsec policy.

For an example configuration and for more information on IPsec OSPFv3 and OSPFv3 virtual link, see [OSPF](#) on page 2422.

Create a policy named `newpolicy` with a security association named `new_sa` on VLAN 100.

The following displays the IPsec policy configuration:

```
ipsec policy newpolicy raddr 2001:db8:0:0:0:0:0:1
ipsec policy newpolicy laddr 2001:db8:0:0:0:0:0:15
ipsec policy newpolicy protocol tcp sport 4 dport 5
ipsec policy newpolicy action permit
```

The following example displays the IPsec security association:

```
ipsec security-association new_sa
ipsec security-association new_sa key-mode manual
ipsec security-association new_sa mode transport
ipsec security-association new_sa encap-proto ESP
ipsec security-association new_sa Encrpt-algo 3DES-CBC encrypt-key
11111111111111111111111111111111 KeyLength 24
ipsec security-association new_sa auth-algo SHA1 auth-key 11111111111111111111111111111111 KeyLength
20
ipsec security-association new_sa spi 1
ipsec security-association new_sa lifetime seconds 1000
```

## IPsec with ICMPv6 configuration example

The following displays configuration of IPsec with ICMPv6.

**Figure 164: IPsec configuration with ICMPv6**

*Switch 10 security association configuration*

The following example displays the configuration of the security association on Switch 10.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
1234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1
```

*Switch 10 policy configuration*

The following example displays the configuration of the security policy on Switch 10.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::2
ipsec policy ICMP_Policy laddr 2001::1
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy security-association icmp
```

*Switch 10 interface configuration*

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
interface vlan 3
interface address 2000::1
interface enable
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

*Switch 10 VLAN configuration*

The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
interface enable
interface address 2000::1
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

*Switch 30 security association configuration*

The following example displays the configuration of the security association on Switch 30.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
1234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Enrcpt-algo AES-CBC EnrcptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1
```

*Switch 30 policy configuration*

The following example displays the configuration of the security policy on Switch 30.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::1
ipsec policy ICMP_Policy laddr 2001::2
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy security-association icmp
```

*Switch 30 interface configuration*

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface enable
ipv6 interface vlan 3
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

*Switch 30 VLAN configuration*

The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/20
```

```

interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable

```

## OSPFv3 IPsec configuration example

The following example displays a network using IPsec used with OSPFv3.

The following example displays the configuration of IPsec with OSPFv3. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2422.

### Switch 10 security associations

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```

ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1

ipsec security-association ospf2
ipsec security-association ospf2 encap-proto ESP
ipsec security-association ospf2 mode transport
ipsec security-association ospf2 spi 2
ipsec security-association ospf2 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf2 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf2 key-mode manual
ipsec security-association ospf2 lifetime seconds 1
ipsec security-association ospf2 lifetime bytes 1

ipsec security-association ospf3
ipsec security-association ospf3 encap-proto ESP
ipsec security-association ospf3 mode transport
ipsec security-association ospf3 spi 3
ipsec security-association ospf3 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32

```

```

ipsec security-association ospf3 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf3 key-mode manual
ipsec security-association ospf3 lifetime seconds 1
ipsec security-association ospf3 lifetime bytes 1

ipsec security-association ospf4
ipsec security-association ospf4 encap-proto ESP
ipsec security-association ospf4 mode transport
ipsec security-association ospf4 spi 4
ipsec security-association ospf4 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf4 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf4 key-mode manual
ipsec security-association ospf4 lifetime seconds 1
ipsec security-association ospf4 lifetime bytes 1

ipsec security-association ospf5
ipsec security-association ospf5 encap-proto ESP
ipsec security-association ospf5 mode transport
ipsec security-association ospf5 spi 5
ipsec security-association ospf5 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf5 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf5 key-mode manual
ipsec security-association ospf5 lifetime seconds 1
ipsec security-association ospf5 lifetime bytes 1

ipsec security-association ospf6
ipsec security-association ospf6 encap-proto ESP
ipsec security-association ospf6 mode transport
ipsec security-association ospf6 spi 6
ipsec security-association ospf6 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf6 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf6 key-mode manual
ipsec security-association ospf6 lifetime seconds 1
ipsec security-association ospf6 lifetime bytes 1

```

### Switch 10 policy configuration

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as outbound.

```

ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 protocol ospfv3
ipsec policy ospf1 action permit

```

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as inbound.

For a policy direction of inbound, laddr and raddr are reversed before storing to the stack. Because of this, even though the policy requires you to configure the laddr as the remote link local address, you need to configure laddr as the link local address in the configuration.

```
ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit
```

Laddr is configured to the link local and raddr is configured to ff02::05 with the direction configured as outbound.

```
ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::05 with the direction configured as inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local and raddr is configured to ff02::06 with the direction as outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::06 with the direction configured as inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

### *Switch 10 link table configuration*

The following example displays the linking of the policy with the security association on Switch 10.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf3
ipsec policy ospf4 security-association ospf4
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

*Switch 10 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
```

*Switch 10 interface configuration*

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

*Switch 10 VLAN configuration*

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

*Switch 30 security associations*

The following example displays the configuration of security associations for OSPFv3 for Switch 30.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 2
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Enchrpt-algo AES-CTR EnchrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
```

```
ipsec security-association ospf1 lifetime bytes 1
ipsec security-association ospf2
ipsec security-association ospf2 encap-proto ESP
ipsec security-association ospf2 mode transport
ipsec security-association ospf2 spi 1
ipsec security-association ospf2 auth-algo MD5 auth-key 12345678901234567890123456789012

ipsec security-association ospf6 lifetime bytes 1
```

*Switch 30 policy configuration*

In the example, the local address is fe80:0:0:0:b2ad:aaff:fe43:4d00, and the remote address is fe80:0:0:0:b2ad:aaff:fe43:100. The policy has the laddr configured to the link local address and the raddr is configured to the remote link local address with the direction configured to outbound.

```
ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 protocol ospfv3
ipsec policy ospf1 action permit
```

Laddr is configured to the remote link local address and raddr is configured to the local link local address with the direction configured to inbound.

```
ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::05 with the direction configured to outbound.

```
ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit
```

Laddr is configured to the remote link local address and the raddr is configured to ff02::05 with the direction configured to inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::06 with the direction configured to outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local address and raddr is configured to ff02::06 with the direction configured to inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

### Switch 30 link table configuration

The following example displays the linking of the policy with the security association on Switch 30.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf4
ipsec policy ospf4 security-association ospf3
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

### Switch 30 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 30.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

### Switch 30 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

### Switch 30 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
minvlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

## OSPFv3 virtual link IPsec configuration example

The following example displays a network using IPsec with OSPFv3 virtual link.

**Figure 165: OSPFv3 virtual link with IPsec configuration**

The following example displays the configuration of IPsec with OSPFv3 virtual link. For OSPFv3 conceptual and procedural information, see [OSPF](#) on page 2422.

### *Switch 10 security association configuration*

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

### *Switch 10 OSPFv3 configuration*

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
ipv6 as-boundary-router
ipv6 area 0.0.0.0
```

### *Switch 10 virtual link and policy configuration*

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 3.3.3.3
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec action permit
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec direction both
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec enable
```

### Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

### Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 port-member
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

### Switch 20 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 20.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

### Switch 20 interface configuration

The following example displays the interface configuration on slot/port 1/10 and 1/20.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

### Switch 20 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3 and VLAN 4.

```
interface gigabitEthernet 1/10
no shut
```

```

exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20 portmember
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

```

### Switch 40 security association configuration

The following example displays the configuration of security associations for OSPFv3 for Switch 40.

```

ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1

```

### Switch 40 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 40.

```

router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 3.3.3.3
ipv6 area 0.0.0.1
ipv6 area 0.0.0.2
ipv6 as-boundary-router

```

### Switch 40 OSPFv3 virtual link and policy configuration

The following example displays the configuration of a OSPFv3 virtual link.

```

ipv6 area virtual-link 0.0.0.1 1.1.1.1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec security-association ospf1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec action permit
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec direction both
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec enable

```

*Switch 40 interface configuration*

The following example displays the interface configuration on slot/port 1/20.

```
interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

*Switch 40 VLAN interface configuration*

The following example displays the creation of VLAN 4 and the configuration of IPsec on VLAN 4.

```
interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

## IPsec configuration of TCP

The following example displays the configuration of IPsec for TCP.

*Switch 10 IPsec security association configuration*

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

*Switch 10 IPsec policy configuration*

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::2
ipsec policy tcp1 raddr 2000::2 laddr 2000::1
ipsec policy tcp1 raddr 2000::2 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::2 action permit
```

*Switch 10 linking the IPsec policy with the IPsec security association*

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

*Switch 10 interface configuration*

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

*Switch 10 VLAN configuration*

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

*Switch 30 IPsec security association configuration*

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-protol ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

### Switch 30 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::1
ipsec policy tcp1 raddr 2000::1 laddr 2000::2
ipsec policy tcp1 raddr 2000::1 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::1 action permit
```

### Switch 30 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

### Switch 30 interface configuration

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

### Switch 30 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

# IPv4 Routing Basics

---

[IP routing operations fundamentals](#) on page 1809

[IP routing configuration using the CLI](#) on page 1820

[IP routing configuration using Enterprise Device Manager](#) on page 1848

This section provides conceptual information and procedures to configure IP Routing using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

## IP routing operations fundamentals

---

Use the information in this section to understand IP routing.

For more information about Border Gateway Protocol (BGP), see [BGP](#) on page 383.

For more information about Open Shortest Path First (OSPF), see [OSPF](#) on page 2422. For more information about Routing Information Protocol (RIP), see [RIP](#) on page 2779.

## IP addressing

An IP version 4 address consists of 32 bits expressed in dotted-decimal format (x.x.x.x). The IP version 4 address space is divided into classes, with classes A, B, and C reserved for unicast addresses and accounting for 87.5 percent of the 32-bit IP address space. Class D is reserved for multicast addressing. The following table lists the breakdown of IP address space by address range and mask.

| Class | Address range          | Mask          | Number of addresses |
|-------|------------------------|---------------|---------------------|
| A     | 1.0.0.0 to 126.0.0.0   | 255.0.0.0     | 126                 |
| B     | 128.0.0.0 to 191.0.0.0 | 255.255.0.0   | 127 * 255           |
| C     | 192.0.0.0 to 223.0.0.0 | 255.255.255.0 | 31 * 255 * 255      |
| D     | 224.0.0.0 to 239.0.0.0 | —             | —                   |

To express an IP address in dotted-decimal notation, you convert each octet of the IP address to a decimal number and separate the numbers by decimal points. For example, you specify the 32-bit IP address 10000000 00100000 00001010 10100111 in dotted-decimal notation as 128.32.10.167.

Each IP address class, when expressed in binary, has a different boundary point between the network and host portions of the address as illustrated in the following figure. The network portion is a network number field from 8 through 24 bits. The remaining 8 through 24 bits identify a specific host on the network.

**Figure 166: Network and host boundaries in IP address classes**

### Subnet Addressing

Subnetworks (or subnets) extend the IP addressing scheme an organization uses to one with an IP address range for multiple networks. Subnets are two or more physical networks that share a common network-identification field (the network portion of the 32-bit IP address).

You create a subnet address by increasing the network portion to include a subnet address, thus decreasing the host portion of the IP address. For example, in the address 128.32.10.0, the network portion is 128.32, while the subnet is found in the first octet of the host portion (10). A subnet mask is applied to the IP address and identifies the network and host portions of the address.

The following table illustrates how subnet masks used with class B and class C addresses can create differing numbers of subnets and hosts. This example includes the zero subnet, which is permitted on the switch.

**Table 127: Subnet masks for class B and class C IP addresses**

| Number of bits | Subnet mask   | Number of subnets | Number of hosts for each subnet |
|----------------|---------------|-------------------|---------------------------------|
| Class B        |               |                   |                                 |
| 2              | 255.255.192.0 | 2                 | 16 382                          |
| 3              | 255.255.224.0 | 6                 | 8 190                           |
| 4              | 255.255.240.0 | 14                | 4 094                           |
| 5              | 255.255.248.0 | 30                | 2 046                           |
| 6              | 255.255.252.0 | 62                | 1 022                           |
| 7              | 255.255.254.0 | 126               | 510                             |
| 8              | 255.255.255.0 | 254               | 254                             |

**Table 127: Subnet masks for class B and class C IP addresses (continued)**

| Number of bits | Subnet mask     | Number of subnets | Number of hosts for each subnet |
|----------------|-----------------|-------------------|---------------------------------|
| 9              | 255.255.255.128 | 510               | 126                             |
| 10             | 255.255.255.192 | 1 022             | 62                              |
| 11             | 255.255.255.224 | 2 046             | 30                              |
| 12             | 255.255.255.240 | 4 094             | 14                              |
| 13             | 255.255.255.248 | 8 190             | 6                               |
| 14             | 255.255.255.252 | 16 382            | 2                               |
| Class C        |                 |                   |                                 |
| 1              | 255.255.255.128 | 0                 | 126                             |
| 2              | 255.255.255.192 | 2                 | 62                              |
| 3              | 255.255.255.224 | 6                 | 30                              |
| 4              | 255.255.255.240 | 14                | 14                              |
| 5              | 255.255.255.248 | 30                | 6                               |
| 6              | 255.255.255.252 | 62                | 2                               |

You use variable-length subnet masking (VLSM) to divide your intranet into pieces that match your requirements. Routing is based on the longest subnet mask or network that matches. Routing Information Protocol version 2 and Open Shortest Path First are routing protocols that support VLSM.

### *Supernet Addressing and CIDR*

A supernet, or classless interdomain routing (CIDR) address, is a group of networks identified by contiguous network addresses. IP service providers can assign customers blocks of contiguous addresses to define supernets as needed. You can use supernetting to address an entire block of class C addresses and avoid using large routing tables to track the addresses.

Each supernet has a unique supernet address that consists of the upper bits shared by all of the addresses in the contiguous block. For example, consider the class C addresses shown in the following figure. By adding the mask 255.255.128.0 to IP address 192.32.128.0, you aggregate the addresses 192.32.128.0 through 192.32.255.255 and 128 class C addresses use a single routing advertisement. In the bottom half of the following figure, you use 192.32.0.0/17 to aggregate the 128 addresses (192.32.0.0/24 to 192.32.127.0/24).

9577EA

### Figure 167: Class C address supernet

Another example is the block of addresses 192.32.0.0 to 192.32.7.0. The supernet address for this block is 11000000 00100000 000000, with the 21 upper bits shared by the 32-bit addresses.

A complete supernet address consists of an address and mask pair:

- The address is the first 32-bit IP address in the contiguous block. In this example, the address is 11000000 00100000 00000000 00000000 (192.32.0.0 in dotted-decimal notation).
- The mask is a 32-bit string containing a set bit for each bit position in the supernet part of the address. The mask for the supernet address in this example is 11111111 11111111 11111000 00000000 (255.255.248.0 in dotted-decimal notation).

The complete supernet address in this example is 192.32.0.0/21.

Although classes prohibit using an address mask with the IP address, you can use CIDR to create networks of various sizes using the address mask. With CIDR, the routers outside the network use the addresses.

## Loopback

Circuitless IP (CLIP) is a virtual (or loopback) interface that is not associated with a physical port. You can use the CLIP interface to provide uninterrupted connectivity to your device as long as a path exists to reach the device.

For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Use an interior Border Gateway

Protocol (iBGP) session between two additional addresses, 195.39.128.1/30 (CLIP 1) and 195.39.281.2/30 (CLIP 2).

CLIP 1 and CLIP 2 represent the virtual CLIP addresses that you configure between R1 and R2. These virtual interfaces are not associated with the physical link or hardware interface, which permits the BGP session to continue as long as a path exists between R1 and R2. An IGP (such as OSPF) routes addresses that correspond to the CLIP addresses. After the routers learn all the CLIP addresses in the AS, the system establishes iBGP and exchanges routes.

The system advertises loopback routes to other routers in the domain either as external routes using the route-redistribution process, or after you enable OSPF in passive mode to advertise an OSPF internal route.

You can also use CLIP for PIM-SM, typically, as a Rendezvous Point (RP), or as a source IP address for sending SNMP traps and Syslog messages.

**Figure 168: Routers with iBGP connections**

The system treats the CLIP interface as an IP interface. The network associated with the CLIP is treated as a local network attached to the device. This route always exists and the circuit is always up because there is no physical attachment.

## Static routes

**Table 128: Static routing product support**

| Feature        | Product         | Release introduced |
|----------------|-----------------|--------------------|
| Static routing | 5420 Series     | VOSS 8.4           |
|                | 5520 Series     | VOSS 8.2.5         |
|                | VSP 4450 Series | VSP 4000 4.0       |
|                | VSP 4900 Series | VOSS 8.1           |
|                | VSP 7200 Series | VOSS 4.2.1         |
|                | VSP 7400 Series | VOSS 8.0           |
|                | VSP 8200 Series | VSP 8200 4.0       |
|                | VSP 8400 Series | VOSS 4.2           |
|                | VSP 8600 Series | VSP 8600 4.5       |
|                | XA1400 Series   | VOSS 8.0.50        |

### Note

VSP 8600 Series uses the routing stack to create static routes for data traffic as well as management purposes. For all other platforms, static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management](#) on page 60. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

A static route is a route to a destination IP address that you manually create.

Create static routes to enhance network stability. Use the local next hop option to configure a static route with or without local next hop.

You can configure static routes with a next hop that is not directly connected, but that hop must be reachable. Otherwise, the static route is not enabled.

Layer 3 redundancy supports only address resolution protocol (ARP) and static route. Static ARP must configure the nonlocal next-hop of static routes. No other dynamic routing protocols provide nonlocal next-hop.

### Note

Static ARP entries are not supported for NLB Unicast or NLB Multicast operations.

You can use a default static route to specify a route to all networks for which no explicit routes exist in the forwarding information base or the routing table. This route has a prefix length of zero (RFC1812). You can configure the switch with a route through the IP static routing table.

To create a default static route, you must configure the destination address and subnet mask to 0.0.0.0.

#### Note

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

### Static Route Tables

A router uses the system routing table to make forwarding decisions. In the static route table, you can change static routes directly. Although the two tables are separate, the static route table manager entries are automatically reflected in the system routing table if the next-hop address in the static route is reachable, and if the static route is enabled.

The system routing table displays only active static routes with a best preference. A static route is active only if the route is enabled and the next-hop address is reachable (for example, if a valid ARP entry exists for the next hop).

You can enter multiple routes (for example, multiple default routes) that have different costs, and the routing table uses the lowest cost route that is available. However, if you enter multiple next hops for the same route with the same cost, the software does not replace the existing route. If you enter the same route with the same cost and a different next-hop, the first route is used. If the first route becomes unreachable, the second route (with a different next-hop) is activated with no connectivity loss.

## Routing Protocols

Routers and routing switches use routing protocols to exchange reachability information. Routers use a routing protocol to advertise available paths on which the router can forward data. The routers use the protocol to determine the most efficient path to use. Routers use dynamic routing protocols to avoid sending data to inoperable links, and to send data to links that generally result in the fastest transmission times.

The switch routes frames using one of the following dynamic unicast IP routing protocols for path selection:

- Routing Information Protocol version 1 (RIPv1) (RFC 1058)
- RIPv2 (RFC 2453)
- Open Shortest Path First version 2 (OSPFv2) (RFC 2328)
- OSPFv3 (RFC 2740)
- Border Gateway Protocol version 4 (BGPv4) (RFC 1771)

Unlike static IP routing, where you must create a manual entry in the routing table to specify a routing path, dynamic IP routing uses a learning approach to determine the paths and routes to other routers. Dynamic routing uses two basic types of routing: distance vector and link-state. Routing Information Protocol (RIP) is a distance vector protocol and Open Shortest Path First (OSPF) is a link-state protocol.

The switch uses routing protocols like OSPF and RIP to populate routing tables. Routers use a routing protocol to exchange network topology information. A router uses the IP address of an incoming data packet to send the packet according to the routing tables.

The most commonly used unicast routing protocols include OSPF, RIP, and BGP. For more information about BGP, see [BGP](#) on page 383. For information about multicast routing protocols, see [IP Multicast](#) on page 1431. For information about OSPFv3 routing protocols, see [OSPF](#) on page 2422.

## Black hole static routes

A black hole static route is a route with an invalid next hop, and the device drops data packets destined for this network.

While the router aggregates or injects routes to other routers, the router does not have a path to the aggregated destination. In such cases, the result is a black hole and a routing loop. To avoid routing loops, configure a black hole static route to the destination the router is advertising.

You can configure a preference value for a black hole route. However, you must configure that preference value appropriately so that when you want to use the black hole route, it is elected as the best route.

Before you add a black hole static route, perform a check to ensure that no other static route to that identical destination is enabled. If such a route exists, you cannot add the black hole route and the system displays an error message.

If you enable a black hole route, you cannot add another static route to that destination. You must first delete or disable the black hole route before you add a regular static route to that destination.

## VLANs and routing

When traffic is routed on a virtual local area network (VLAN), an IP address is assigned to the VLAN and is not associated with a particular physical port. Brouter ports are VLANs that route IP packets and bridge nonroutable traffic in a single-port VLAN.

### *Virtual Routing Between VLANs*

The switch supports wire-speed IP routing between VLANs. As shown in the following figure, VLAN 1 and VLAN 2 are on the same device, yet for traffic to flow from VLAN 1 to VLAN 2, the traffic must be routed.

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN (a virtual router interface is not associated with a particular port). You can reach the VLAN IP address through the VLAN ports, and frames are routed from the VLAN through the gateway IP address. Routed traffic is forwarded to another VLAN within the device.

**Figure 169: IP routing between VLANs**

When Spanning Tree Protocol is enabled in a VLAN, the spanning tree convergence must be stable before the routing protocol begins. This requirement can lead to an additional delay in the IP traffic forwarding.

Because a port can belong to multiple VLANs (some of which are configured for routing on the device and some of which are not), a one-to-one correspondence no longer exists between the physical port and the router interface.

As with an IP address, virtual router interface addresses using Virtual Router Redundancy Protocol (VRRP) are also used for device management. For Simple Network Management Protocol (SNMP) or Telnet management, you can use virtual router interface address to access the device as long as routing is enabled on the VLAN.

### Brouter Ports

The switch also supports brouter ports. A brouter port is a single-port VLAN that routes IP packets and bridges all nonroutable traffic. The difference between a brouter port and a standard IP protocol-based VLAN configured to route traffic is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

Because a brouter port is a single-port VLAN, each brouter port decreases the number of available VLANs by one and uses one VLAN ID.

The switch allows IP routing to be enabled on VLANs and brouter ports. For the maximum number of interfaces, see the Software scaling capabilities section of the [VOSS Release Notes](#).

## Equal Cost Multipath

**Table 129: Equal Cost Multiple Path for IPv4 product support**

| Feature                                  | Product         | Release introduced |
|------------------------------------------|-----------------|--------------------|
| Equal Cost Multiple Path (ECMP) for IPv4 | 5420 Series     | VOSS 8.4           |
|                                          | 5520 Series     | VOSS 8.2.5         |
|                                          | VSP 4450 Series | VSP 4000 4.0       |
|                                          | VSP 4900 Series | VOSS 8.1           |
|                                          | VSP 7200 Series | VOSS 4.2.1         |
|                                          | VSP 7400 Series | VOSS 8.0           |
|                                          | VSP 8200 Series | VSP 8200 4.0       |
|                                          | VSP 8400 Series | VOSS 4.2           |
|                                          | VSP 8600 Series | VSP 8600 4.5       |
|                                          | XA1400 Series   | VOSS 8.0.50        |

With Equal Cost Multipath (ECMP), the switch can determine up to eight equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of traffic. These multiple paths provide faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use links between routers more efficiently when sending IP traffic. Equal Cost Multipath is formed using routes from the same source or protocol.

All IP ECMP routes that share the same combination of ECMP next hops consume the same ECMP group resource. The following list illustrates how shared next hops affect resource consumption:

- Prefix 3.1.1.0/16 is learned as an ECMP route with next hops A and B, and consumes one entry in the ECMP GROUP table.
- Prefix 4.1.1.0/16 is learned as an ECMP route with the same next hops, A and B. No additional resource is taken in the ECMP GROUP table.
- Prefix 5.1.1.0/16 is learned as an ECMP route with next hops B and C, and consumes one additional entry in the ECMP GROUP table.

ECMP is supported on both the Global Routing Table (GRT) and Virtual Routing and Forwarding (VRF).

The ECMP feature supports and complements the following protocols and route types:

- Border Gateway Protocol (BGP)
- Default route
- Intermediate System-to-Intermediate System (IS-IS)
- Open Shortest Path First (OSPF)
- Routing Information Protocol (RIP)
- Static route
- VRF

#### *ECMP Pathlist*

Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

#### **Note**

Product Notice: Not all products support Equal Cost Multipath Pathlist with Fabric Connect. For more information, see [VOSS Feature Support Matrix](#).

## IP Source Routing

**Table 130: IP Source Routing product support**

| Feature                             | Product         | Release introduced |
|-------------------------------------|-----------------|--------------------|
| IP Source Routing enable or disable | 5420 Series     | VOSS 8.4           |
|                                     | 5520 Series     | VOSS 8.2.5         |
|                                     | VSP 4450 Series | VOSS 5.1           |
|                                     | VSP 4900 Series | VOSS 8.1           |
|                                     | VSP 7200 Series | VOSS 5.1           |
|                                     | VSP 7400 Series | VOSS 8.0           |
|                                     | VSP 8200 Series | VOSS 5.1           |
|                                     | VSP 8400 Series | VOSS 5.1           |
|                                     | VSP 8600 Series | VSP 8600 4.5       |
|                                     | XA1400 Series   | Not Supported      |

IP Source Routing allows the sender of a packet to specify the route that the packet must travel through the network. When the Source Route option is not enabled, the router chooses the primary routing path to send the packets. If IP Source Routing flag is on, the source host dictates the datapath for the packet to reach the destination using the information contained in the IP header.

The routing behavior in VSP 8600 Series is controlled by the datapath specified, and not by status of the IP Source Route. VSP 8600 Series inspects the packets only if the router itself is specified in the Source Routing. Otherwise, the switch forwards the packets to another router in the network using IP Routing, whether or not IP Source Route is enabled. You can use an ACL filter to block the datapath from forwarding any IP Source Routing packets.

IP Source Routing is considered as a security risk because it allows the users to specify their own path through the network outside of the primary forwarding path. This can cause packets to bypass the security devices. Therefore, the Source Routing is disabled by default.

## Multihoming

The switch uses the multihoming feature to support clients or servers that have multiple IP addresses associated with a single MAC address. Multihomed hosts can be connected to port-based and policy-based VLANs.

The IP addresses associated with a single MAC address on a host must be in the same IP subnet.

## Enabling or Disabling IPv4 ICMP Broadcast

**Table 131: Internet Control Message Protocol product support**

| Feature                                  | Product         | Release introduced |
|------------------------------------------|-----------------|--------------------|
| Internet Control Message Protocol (ICMP) | 5420 Series     | VOSS 8.4           |
|                                          | 5520 Series     | VOSS 8.2.5         |
|                                          | VSP 4450 Series | VSP 4000 4.0       |
|                                          | VSP 4900 Series | VOSS 8.1           |
|                                          | VSP 7200 Series | VOSS 4.2.1         |
|                                          | VSP 7400 Series | VOSS 8.0           |
|                                          | VSP 8200 Series | VSP 8200 4.0       |
|                                          | VSP 8400 Series | VOSS 4.2           |
|                                          | VSP 8600 Series | VSP 8600 4.5       |

**Table 131: Internet Control Message Protocol product support (continued)**

| Feature                                        | Product         | Release introduced |
|------------------------------------------------|-----------------|--------------------|
| ICMP broadcast and multicast enable or disable | 5420 Series     | VOSS 8.4           |
|                                                | 5520 Series     | VOSS 8.2.5         |
|                                                | VSP 4450 Series | VOSS 5.1           |
|                                                | VSP 4900 Series | VOSS 8.1           |
|                                                | VSP 7200 Series | VOSS 5.1           |
|                                                | VSP 7400 Series | VOSS 8.0           |
|                                                | VSP 8200 Series | VOSS 5.1           |
|                                                | VSP 8400 Series | VOSS 5.1           |
|                                                | VSP 8600 Series | VSP 8600 4.5       |
|                                                | XA1400 Series   | Not Supported      |

On IPv4 networks, a packet can be directed to an individual machine or broadcast to an entire network. When a packet is sent to an IP broadcast address from a machine on the local network, that packet is delivered to all machines on that network.

If a packet that is broadcast is an ICMP echo request packet, the machines on the network receive this ICMP echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMP echo request, the result can be severe network congestion or outages.

The switch always responds to IPv4 ICMP packets sent to a broadcast address. You can disable the processing of these IPv4 ICMP packets sent to the broadcast address. On disabling the ICMP broadcast processing, all the packets containing ICMP sent to the broadcast addresses will be dropped when the packets reach the control plane.

You can disable or enable the IPv4 ICMP broadcast processing at the VRF level.

## IP routing configuration using the CLI

Configure the IP router interface so that you can configure and use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

### Enabling routing globally or on a VRF instance

Use IP forwarding (routing) on a global level so that the device supports routing. You can use the IP address of an interface for IP-based network management.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Activate IP forwarding:  

```
ip routing
```
3. View the forwarding configuration:  

```
show ip routing [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

Activate IP forwarding and view the forwarding configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#ip routing
Switch:1(router-vrf)#show ip routing
```

```
=====
                               IP - GlobalRouter
=====
```

```

IP Forwarding is enabled
IP ECMP feature is disabled
Maximum ECMP paths number is 1
ECMP 1 pathlist :
ECMP 2 pathlist :
ECMP 3 pathlist :
ECMP 4 pathlist :
ECMP 5 pathlist :
ECMP 6 pathlist :
ECMP 7 pathlist :
ECMP 8 pathlist :
Gratuitous-Arp : enable
IP Alternative Route feature is enabled
IP More Specific Non Local Route feature is disabled
IP ICMP Unreachable Message is disabled
IP Supernetting is disabled
IP Icmp-echo-broadcast-request is enabled

IP Default TTL is 255 seconds
IP ARP life time is 360 minutes
IP Source Route Option is disabled
```

### Variable Definitions

Use the data in the following table to use the **show ip routing** command.

| Variable                              | Value                                   |
|---------------------------------------|-----------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies a VRF instance by VRF name.   |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies a VRF instance by VRF number. |

## Enabling routing on an IP interface

### About This Task

You can enable or disable routing capabilities on a VLAN or brouter port.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable routing:

```
routing enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#routing enable
```

## Deleting a dynamically learned route

### About This Task

Delete a dynamically learned route from the routing table if you do not want the switch to use the route. Exercise caution when you delete entries from the routing table.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- View IP route information:

```
show ip route [<A.B.C.D>] [-s default|-s <A.B.C.D/X>] [alternative]
[count-summary] [spbm-nh-as-mac][preference] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [static]
```

- Delete the dynamically learned route:

```
no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> dynamic
```

### Example

Delete a dynamically learned route:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip route 192.0.2.32 255.255.255.0 198.51.100.31 dynamic
```

### Variable Definitions

Use the data in the following table to use the **show ip route** commands.

| Variable                        | Value                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------|
| <A.B.C.D>                       | Specifies the IP address of the route to the network.                                       |
| <i>alternative</i>              | Displays the alternative routes.                                                            |
| <i>count-summary</i>            | Displays a summary of the number of routes learned from each routing protocol for each VRF. |
| <i>preference</i>               | Displays the route preference.                                                              |
| -s <A.B.C.D/X>                  | Indicates the IP address and subnet mask for which to display routes.                       |
| -s default                      | Indicates the default subnet.                                                               |
| <i>static</i>                   | Displays the static route information.                                                      |
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays the route for a particular VRF.                                                    |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays the route for a particular VRF number.                                             |
| <i>spbm-nh-as-mac</i>           | Displays the spbm route next hop as mac.                                                    |

Use the data in the following table to use the **no ip route** command.

| Variable                             | Value                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------|
| <A.B.C.D> <A.B.C.D><br><A.B.C.D>     | Specifies the IP address, the subnet mask, and the next-hop IP address, respectively. |
| <i>dynamic</i>                       | Specifies that a dynamic route is to be deleted.                                      |
| <i>enable</i>                        | Disables the route.                                                                   |
| <i>local-next-hop enable</i>         | Disables the local-next-hop option.                                                   |
| <i>preference</i>                    | Deletes the value of the route preference.                                            |
| <i>next-hop-vrf WORD&lt;1-16&gt;</i> | Specifies the name of the next-hop VRF router.                                        |

## Configuring IP route preferences

### Before You Begin

- Disable ECMP before you configure route preferences

#### Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. You must therefore change a prefix list or a routing protocol before you activate the protocols.

### About This Task

Configure IP route preferences to give preference to routes learned for a specific protocol. You must disable ECMP before you configure route preferences.

To configure route preferences for a VRF, access VRF Router Configuration mode, rather than Global Configuration mode.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the route preference:

```
ip route preference protocol <static|ospf-intra|ospf-inter|ebgp|ibgp|rip|ospf-extern1|ospf-extern2|spbm-level1> <0-255>
```

3. Confirm that the configuration is correct:

```
show ip route preference [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Configure the route preference to SPBM Level 1 and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route preference protocol spbm-level1 7
Switch:1(config)#show ip route preference
```

```
=====
                        IP Route Preference - GlobalRouter
=====
```

| PROTOCOL   | DEFAULT | CONFIG |
|------------|---------|--------|
| LOCAL      | 0       | 0      |
| STATIC     | 5       | 5      |
| SPBM_L1    | 7       | 7      |
| OSPF_INTRA | 20      | 20     |
| OSPF_INTER | 25      | 25     |
| EBGP       | 45      | 45     |
| RIP        | 100     | 100    |
| OSPF_E1    | 120     | 120    |
| OSPF_E2    | 125     | 125    |
| IBGP       | 175     | 175    |

View the route preference configuration for a specific VRF, for example 444.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf test
Switch:1(router-vrf)#show ip route preference vrf 444
```

```
=====
                        IP Route Preference - VRF 444
=====
PROTOCOL      DEFAULT    CONFIG
-----
LOCAL         0          0
STATIC        5          5
SPBM_L1       7          7
OSPF_INTRA    20         20
OSPF_INTER    25         25
EBGP          45         45
RIP           100        100
OSPF_E1       120        120
OSPF_E2       125        125
IBGP          175        175
```

### Variable definitions

Use the data in the following table to use the **ip route preference protocol** command.

| Variable            | Value                      |
|---------------------|----------------------------|
| <i>ebgp</i>         | Protocol type eBGP         |
| <i>ibgp</i>         | Protocol type iBGP         |
| <i>ospf-extern1</i> | Protocol type ospf-extern1 |
| <i>ospf-extern2</i> | Protocol type ospf-extern2 |
| <i>ospf-intra</i>   | Protocol type ospf-intra   |
| <i>ospf-inter</i>   | Protocol type ospf-inter   |
| <i>rip</i>          | Protocol type rip          |
| <i>spbm-level1</i>  | Protocol type spbm-level1  |
| <i>static</i>       | Protocol type static       |

## Flushing routing tables by VLAN or port

### About This Task

For administrative and troubleshooting purposes, flush the routing tables.

To flush tables on a VRF instance for a port or VLAN, ensure that the VRF is associated with the port or VLAN.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush the routing tables:

```
action flushIp
```

## Example

Flush the routing tables:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface gigabitethernet 3/6  
Switch:1(config-if)#action flushIp
```

## Assign an IP address to a Port

Assign an IP address to a port so that it supports routing operations.

### About This Task

Use a brouter port to route IP packets and to bridge all nonroutable traffic. The routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Use the `vrf` parameter to associate the port or VLAN with a VRF instance.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IP address to the port:

```
brouter port {slot/port[/sub-port]} vlan <2-4059> subnet <A.B.C.D/X>
[mac-offset <MAC-offset> | [name WORD <0-64>]
```

3. If required, associate the port with a VRF:

```
vrf WORD<1-16>
```

4. Confirm that the configuration is correct:

```
show brouter [<1-4059>]
```

## Example

Assign an IP address to a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/11
Switch:1(config-if)#brouter port 1/11 vlan 2202 subnet 47.17.10.31/255.255.255.0
```

### Variable Definitions

Use the data in the following table to use the **brouter port** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mac-offset</i> <MAC-offset>  | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help. |
| <i>name</i> WORD <0-64>         | Specifies the IP address name in the range of 0 to 64 characters.                                                                                                                                                                                                                                                                                                        |
| { <i>slot/port</i> [/sub-port]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                             |
| <i>subnet</i> <A.B.C.D/X>       | Specifies the IP address and subnet mask (0-32).                                                                                                                                                                                                                                                                                                                         |
| <2-4059>                        | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged.                                                                                                                                                                                                            |

Use the data in the following table to use the **show brouter** command.

| Variable | Value                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged. |

## Configure an IP Address for the Management Port

### Note

This procedure only applies to VSP 8600 Series. For information about how to configure an IP address for a Segmented Management Instance, see [Configure an IP Address for a Segmented Management Instance](#) on page 85.

### About This Task

Configure the IP address for the management port so that you can remotely access the device using the management port. The management port runs on a dedicated VRF. As a best practice, redirect all commands that are run on the management port to its VRF.

The configured IP subnet has to be globally unique because the management protocols can go through in-band or out-of-band ports.

### Procedure

1. Enter mgmtEthernet Interface Configuration mode:
 

```
enable

configure terminal

interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the IP address and mask for the management port:
 

```
ip address <A.B.C.D> <A.B.C.D>
```
3. Show the complete network management information:
 

```
show interface mgmtEthernet
```
4. Show the management IP interface information:
 

```
show ip interface vrf mgmtrouter
```

### Example

Configure the IP address for the management port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface mgmtethernet mgmt
Switch:1(config-if)#ip address 192.0.2.31 255.255.255.0
Switch:1(config-if)#show interface mgmtethernet
```

```
=====
Port Interface
=====
```

```

PORT          LINK  PORT          PHYSICAL  STATUS
NUM  INDEX  DESCRIPTION  TRAP  LOCK  MTU  ADDRESS  ADMIN  OP
ERATE
-----
mgmt    64    mgmtEthernet true  false 1522  192.0.2.31 up    up

```

### Variable Definitions

Use the data in the following table to use the **ip address** command.

| Variable            | Value                                                 |
|---------------------|-------------------------------------------------------|
| <A.B.C.D> <A.B.C.D> | Specifies the IP address followed by the subnet mask. |

## Viewing IP addresses for all router interfaces

### About This Task

Perform the following procedure to display information about all IP interfaces configured on the device.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Show the IP interfaces and addresses on the device:  
show ip interface

### Example

Show the IP interfaces and addresses on the device:

```

Switch:1>enable
Switch:1#show ip interface

=====
                        IP Interface - GlobalRouter
=====
INTERFACE      IP          NET          BCASTADDR  REASM      VLAN  BROUTER
                ADDRESS    MASK          FORMAT      MAXSIZE   ID    PORT
-----
Port1/6        192.0.2.6   255.255.255.0 ones        1500      200   true
Vlan100        192.0.2.5   255.255.255.0 ones        1500      100   false
Vlan4000       198.51.100.21 255.255.255.0 ones        1500      4000  false

```

### Variable Definitions

Use the data in the following table to **show ip interface** command.

| Variable               | Value                                                         |
|------------------------|---------------------------------------------------------------|
| <i>gigabitethernet</i> | Displays IP interface information for Gigabit Ethernet ports. |
| <i>vrf</i>             | Displays interface information for a particular VRF.          |
| <i>vrfids</i>          | Displays interface information for particular VRF IDs.        |

## Configure IP Routing Globally or for a VRF

Configure the IP routing protocol stack to specify which routing features the device can use. You can configure global parameters before or after you configure the routing protocols.

### About This Task

To configure IP routing globally for a VRF instance, use VRF Router Configuration mode rather than Global Configuration mode.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  
`enable`  
`configure terminal`  
Optional: `router vrf WORD<1-16>`
2. Configure the default TTL for all routing protocols to use:  
`ip ttl <1-255>`  
This value is placed into routed packets that have no TTL specified.
3. Activate the alternative route feature globally:  
`ip alternative-route`
4. Configure the remaining global parameters as required.

## Variable Definitions

The following table defines parameters for the **ip** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>alternative-route</i>             | Enables or disables the alternative route feature. The default value is enabled.<br>If the alternative-route parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readed.<br>The default form of this command is <code>default ip alternative-route</code> . The no form of this command is <code>no ip alternative-route</code> .                             |
| <i>max-routes-trap enable</i>        | Enables the device to send a trap after the maximum number of routes is exceeded.<br>The no form of this command is <code>no max-routes-trap enable</code> . The default form of this command is <code>default max-routes-trap enable</code> .                                                                                                                                                                                           |
| <i>more-specific-non-local-route</i> | Enables the more-specific-non-local-route feature. If enabled, the device can enter a more-specific nonlocal route into the routing table. The default is disabled.<br>The default form of this command is <code>default ip more-specific-non-local-route</code> . The no form of this command is <code>no ip more-specific-non-local-route</code> .                                                                                     |
| <i>routing</i>                       | Enables routing.<br>The no form of this command is <code>no ip routing</code> .                                                                                                                                                                                                                                                                                                                                                          |
| <i>supernet</i>                      | Enables or disables supernetting.<br>If you globally enable supernetting, the device can learn routes with a route mask of less than eight bits. Routes with a mask length less than eight bits cannot have ECMP paths, even if the ECMP feature is globally enabled. The default is disabled.<br>The default form of this command is <code>default ip supernet</code> .<br>The no form of this command is <code>no ip supernet</code> . |
| <i>ttl &lt;1-255&gt;</i>             | Configures the default time-to-live (TTL) value for a routed packet. The TTL is the maximum number of seconds before a packet is discarded. The default value of 255 is used whenever a time is not supplied in the datagram header.<br>The default form of this command is <code>default ip ttl</code> .                                                                                                                                |

The following table defines parameters for the **ip icmp** commands.

| Variable           | Value                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>unreachable</i> | Enables the device to send ICMP unreachable messages. When enabled, this variable generates Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this router. These messages help determine if the device is reachable over the network. The default is disabled.<br>The default form of this command is <code>default ip icmp unreachable</code> . |

## Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which provides fast convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

### About This Task

To configure ECMP for a VRF instance, after you enable ECMP globally, use VRF Router Configuration mode rather than Global Configuration mode.

Different hardware platforms can support a different number of ECMP paths. For more information, see [VOSS Release Notes](#).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable ECMP globally:  
`ip ecmp`
3. (Optional) Configure the maximum number of ECMP paths:  
`ip ecmp max-path <ECMP-Paths>`
4. (Optional) Configure a prefix-list for the target destination:  
`ip prefix-list WORD<1-64> <A.B.C.D/X> [ge <0-32>] [le <0-32>]`
5. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths:  
`ip ecmp pathlist-<1-8> WORD<1-64>`
6. (Optional) Return to Privileged EXEC mode:  
`end`
7. (Optional) Apply changes to all ECMP pathlist configurations:  
`ip ecmp pathlist-apply [vrf WORD<1-16>]`

### Example

Define which IP prefixes use ECMP and which do not.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip ecmp
Switch:1(config)#ip prefix-list ecmpAllowed 192.0.2.0/24 ge 24 le 24
Switch:1(config)#ip prefix-list ecmpDenied 0.0.0.0/0 ge 0 le 32
Switch:1(config)#ip ecmp pathlist-2 ecmpAllowed
Switch:1(config)#ip ecmp pathlist-1 ecmpDenied
Switch:1(config)#end
Switch:1#ip ecmp pathlist-apply
```

## Variable Definitions

The following table defines parameters for the **ip ecmp** command.

| Variable                                           | Value                                                                                                                                                                                                                                                                        |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max-path &lt;ECMP-Paths&gt;</code>           | Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in <a href="#">VOSS Release Notes</a> . |
| <code>pathlist-1 WORD&lt;0-64&gt;</code>           | Specifies one equal-cost path to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                                    |
| <code>pathlist-2 WORD&lt;0-64&gt;</code>           | Specifies up to two equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                             |
| <code>pathlist-3 WORD&lt;0-64&gt;</code>           | Specifies up to three equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-4 WORD&lt;0-64&gt;</code>           | Specifies up to four equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                            |
| <code>pathlist-5 WORD&lt;0-64&gt;</code>           | Specifies up to five equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                            |
| <code>pathlist-6 WORD&lt;0-64&gt;</code>           | Specifies up to six equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                             |
| <code>pathlist-7 WORD&lt;0-64&gt;</code>           | Specifies up to seven equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-8 WORD&lt;0-64&gt;</code>           | Specifies up to eight equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.                                                                                                                                                           |
| <code>pathlist-apply [vrf WORD&lt;1-16&gt;]</code> | Applies the pathlist configuration changes. You can optionally specify a VRF name.                                                                                                                                                                                           |

The following table defines parameters for the **ip prefix-list** command.

| Variable                       | Value                                                                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;0-64&gt;</code>  | Specifies the prefix list name.                                                                                                                                                  |
| <code>&lt;A.B.C.D/X&gt;</code> | Specifies the IP address and network mask in one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d/x</li> <li>a.b.c.d/x.x.x.x</li> <li>default</li> </ul> |
| <code>ge &lt;0-32&gt;</code>   | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                        |
| <code>le &lt;0-32&gt;</code>   | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.                                                        |

## Configure Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface. Specify the name of the VRF context in [Step 1](#).
- Create static routes for management purposes on VSP 8600 Series:
  - Specify the `mgmtRouter vrf` in [Step 1](#) to configure static routes for the OOB port.
  - Use Global Configuration mode in [Step 1](#) to configure static routes in the GRT for the inband VLAN or loopback interface.

VSP 8600 Series uses the routing stack to create static routes for data traffic as well as management purposes. For all other platforms, static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 77. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

### Before You Begin

- Ensure no black hole static route exists. If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

### About This Task

When you configure a static route with a `next-hop-vrf` context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept policies.

For route scaling information and for information on the maximum number of static routes supported on your hardware platform, see [VOSS Release Notes](#).

#### Note

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a Brouter port.

You cannot configure the preference of static routes on a Leaf node.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Create an IP static route:

```
ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> weight <1-65535>
```

3. Enable an IP static route:

```
ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> enable
```

4. Use the following variable definitions table to configure other static route parameters as required.
5. View existing IP static routes for the device, or for a specific network or subnet:

```
show ip route static
```

### Example

Create an IP static route, enable a static route, and view the existing IP static routes for the device, or for a specific network or subnet.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 weight 20 name ExtSer 10 preference 1
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 enable
Switch:1(config)#show ip route static
=====
                        IP Static Route - GlobalRouter
=====
DEST          MASK          NEXT          NH-VRF        COST  PREF  LCLNHOP  STATUS  ENABLE  NAME
-----
192.0.2.2    255.255.255.0 198.51.100.24 GlobalRouter  20    1    TRUE     ACTIVE  TRUE   ExtSer 10
```

### Variable Definitions

Use the data in the following table to use the **ip route** command.

| Variable                         | Value                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <A.B.C.D> <A.B.C.D><br><A.B.C.D> | The first and second <A.B.C.D> specify the IP address and mask for the route destination. The third <A.B.C.D> specifies the IP address of the next-hop router (the next router at which packets must arrive on this route). When you create a black hole static route, configure this parameter to 255.255.255.255 as the IP address of the router through which the specified route is accessible. |
| <i>disable</i>                   | Disables a route to the router or VRF.                                                                                                                                                                                                                                                                                                                                                              |
| <i>enable</i>                    | Adds a static route to the router or VRF.<br>The no form of this command is <code>no ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; enable</code> .<br>The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; enable</code> .                                                                                                         |
| <i>local-next-hop enable</i>     | Enables the local next hop for this static route. The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; local-next-hop enable</code> .<br>The no form of this command is <code>no ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; local-next-hop enable</code> .                                                                      |

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>next-hop-vrf &lt;WORD 1-16&gt;</code> | Specifies the next-hop VRF instance by name. After you configure the <code>next-hop-vrf</code> parameter, the static route is created in the local VRF, and the next-hop route is resolved in the next-hop VRF instance ( <code>next-hop-vrf</code> ). The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; next-hop-vrf &lt;WORD 1-16&gt;</code> . The no form of this command is <code>no ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; next-hop-vrf &lt;WORD 1-16&gt;</code> . |
| <code>weight &lt;1-65535&gt;</code>         | Specifies the static route cost. The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; weight</code> .<br><b>Note:</b><br>Do not configure a static interface subnet route with a weight of 1.                                                                                                                                                                                                                                                                                                |
| <code>name &lt;1-64&gt;</code>              | Specifies the name of the static route. You can name the route before or after it is created. Only 32 characters display. The tilde (~) symbol indicates that the name is truncated.                                                                                                                                                                                                                                                                                                                                                               |
| <code>preference &lt;1-255&gt;</code>       | Specifies the route preference. The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; preference</code> .                                                                                                                                                                                                                                                                                                                                                                                     |

Use the data in the following table to use the **show ip route static** command.

| Variable                                                      | Value                                                                                                                                                                                |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D&gt;</code>                                  | Specifies the route by IP address.                                                                                                                                                   |
| <code>-s { &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;   default }</code> | Specifies the route by IP address and subnet mask.                                                                                                                                   |
| <code>vrf WORD&lt;1-16&gt;</code>                             | Specifies a VRF by name.                                                                                                                                                             |
| <code>vrfids WORD&lt;0-512&gt;</code>                         | Specifies a range of VRF IDs.                                                                                                                                                        |
| <code>name &lt;1-64&gt;</code>                                | Specifies the name of the static route. You can name the route before or after it is created. Only 32 characters display. The tilde (~) symbol indicates that the name is truncated. |

## Configuring a black hole static route

### About This Task

Configure a black hole static route to the destination a router advertises to avoid routing loops after the router aggregates or injects routes to other routers.

If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Create a black hole static route:

```
ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 weight <1-65535>
```

3. Enable a black hole static route:

```
ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 enable [next-hop-vrf WORD<1-16>]
```

4. Configure other black hole static route parameters as required.

When you specify a route preference, appropriately configure the preference so that when the black-hole route is used, it is elected as the best route.

## Example

Create a black hole static route and enable the black hole static route.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 weight 200
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 enable
```

### Variable Definitions

Use the data in the following table to use the **ip route** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D&gt;</code>       | The first and second <code>&lt;A.B.C.D&gt;</code> specify the IP address and mask for the route destination. 255.255.255.255 is the destination of the black hole route.                                                                                                                                                          |
| <code>enable</code>                | Adds a static route to the router or VRF.<br>The no form of this command is <code>no ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; 255.255.255.255 enable</code> .                                                                                                                                                                     |
| <code>local-next-hop enable</code> | Enables the local next hop for this static route.<br>The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; local-next-hop enable</code> .<br>The no form of this command is <code>no ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; 255.255.255.255 local-next-hop enable</code> . |

| Variable                                   | Value                                                                                                                                                                                                                                                                                                                                          |

| <code>weight &lt;1-65535&gt;</code>        | Specifies the static route cost.<br>The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; 255.255.255.255 weight</code> .<br><b>Note:</b><br>Do not configure a static interface subnet route with a weight of 1.                                                                                         |
| <code>preference &lt;1-255&gt;</code>      | Specifies the route preference.<br>The default form of this command is <code>default ip route &lt;A.B.C.D&gt; &lt;A.B.C.D&gt; 255.255.255.255 preference</code> .                                                                                                                                                                              |

## Configuring a default static route

### About This Task

The default route specifies a route to all networks for which there are no explicit routes in the forwarding information base or the routing table. This route has a prefix length of zero (RFC 1812). You can configure the switch with a static default route, or they can learn it through a dynamic routing protocol.

To create a default static route, you configure the destination address and subnet mask to 0.0.0.0.

#### Note

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept polices.

#### Note

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a Brouter port.  
You cannot configure the preference of static routes on a Leaf node.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Create a default static route:

```
ip route 0.0.0.0 0.0.0.0 <A.B.C.D> weight <1-65535>
```

3. Enable a default static route:

```
ip route 0.0.0.0 0.0.0.0 <A.B.C.D> enable [next-hop-vrf WORD<1-16>]
```

4. Configure other default static route parameters as required.

### Example

Create a default static route and enable the default static route.

```
Switch:1>enable
Switch:1>configure terminal
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 weight 100
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 enable
```

### Variable Definitions

Use the data in the following table to use the **ip route** command.

| Variable                             | Value                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>&lt;A.B.C.D&gt;</i>               | <i>&lt;A.B.C.D&gt;</i> specifies the IP address of the next-hop router (the next router at which packets must arrive on this route).                                                                                                                                                                   |
| <i>enable</i>                        | Adds a static or default route to the router or VRF. The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; enable</code> .                                                                                                                                                  |
| <i>local-next-hop enable</i>         | Enables the local next hop for this static route. The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; local-next-hop enable</code> . The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; local-next-hop enable</code> .            |
| <i>next-hop-vrf WORD&lt;1-16&gt;</i> | Specifies the next-hop VRF instance by name. The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; next-hop-vrf WORD&lt;1-16&gt;</code> . The no form of this command is <code>no ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; next-hop-vrf WORD&lt;1-16&gt;</code> . |
| <i>weight &lt;1-65535&gt;</i>        | Specifies the static route cost. The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; weight</code> .<br><br><b>Note:</b><br>Do not configure a static interface subnet route with a weight of 1.                                                                |
| <i>preference &lt;1-255&gt;</i>      | Specifies the route preference. The default form of this command is <code>default ip route 0.0.0.0 0.0.0.0 &lt;A.B.C.D&gt; preference</code> .                                                                                                                                                         |

## Enabling ICMP Router Discovery globally

### About This Task

Enable Router Discovery globally so that the device supports Router Discovery. Use ICMP Router Discovery to enable hosts attached to the broadcast network to discover the IP addresses of their neighboring routers.

If you enable ICMP Router Discovery globally, you automatically enable it for all VLANs. If you do not require ICMP Router Discovery on a specific VLAN, you must manually disable the feature.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable ICMP Router Discovery on the device:

```
ip irdp
```

3. Confirm that Router Discovery is enabled:

```
show ip irdp [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Enable ICMP router discovery on the device and confirm that router discovery is enabled.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip irdp
Switch:1(config)#show ip irdp
      VRF "GlobalRouter" (Global Routing Table) : Router Discovery Enabled
```

### Variable Definitions

Use the data in the following table to **show ip irdp** command.

| Variable                        | Value                                            |
|---------------------------------|--------------------------------------------------|
| <i>interface</i>                | Displays route discovery interface information.  |
| <i>vrf WORD&lt;1-16&gt;</i>     | Displays route discovery for particular VRF.     |
| <i>vrfids WORD&lt;0-512&gt;</i> | Displays route discovery for particular VRF IDs. |

## Enabling or disabling IPv4 ICMP broadcast globally

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

### About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the global router.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable IPv4 ICMP broadcast feature, enter:  
`ip icmp echo-broadcast-request`
3. Disable IPv4 ICMP broadcast feature, enter:  
`no ip icmp echo-broadcast-request`
4. Set the IPv4 ICMP broadcast feature to default state, enter:  
`default ip icmp echo-broadcast-request`

#### Note

By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:  
`show ip routing`

## Enabling or disabling IPv4 ICMP broadcast per VRF

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

### About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the VRF router.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:  
`enable`  
`configure terminal`  
`router vrf WORD<1-16>`
2. Enable IPv4 ICMP broadcast feature, enter:  
`ip icmp echo-broadcast-request`
3. Disable IPv4 ICMP broadcast feature, enter:  
`no ip icmp echo-broadcast-request`
4. Set the IPv4 ICMP broadcast feature to default state, enter:  
`default ip icmp echo-broadcast-request`

#### Note

By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:  
`show ip routing`

## View IPv4 ICMP Statistics

View the collective IPv4 ICMP statistics for all VRF instances.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv4 ICMP statistics:

```
show ip icmp statistics
```

### Example

View IPv4 ICMP statistics:

```
Switch:1#show ip icmp statistics

Icmp Statistics:
-----
ICMP IN STATISTICS (includes GRT and all VRF instances) :
IcmpInMsgs          = 0
IcmpInErrors        = 0
IcmpInDestUnreachs  = 0
IcmpInTimeExcds    = 0
IcmpInParmProbs     = 0
IcmpInSrcQuenchs    = 0
IcmpInRedirects     = 0
IcmpInEchos         = 0
IcmpInEchoReps      = 0
IcmpInTimestamps    = 0
IcmpInTimestampReps = 0
IcmpInAddrMasks     = 0
IcmpInAddrMaskReps  = 0
ICMP OUT STATISTICS (includes GRT and all VRF instances) :
IcmpOutMsgs         = 0
IcmpOutErrors       = 0
IcmpOutDestUnreachs = 0
IcmpOutTimeExcds   = 0
IcmpOutParmProbs    = 0

IcmpOutSrcQuenchs   = 0

IcmpOutRedirects    = 0

IcmpOutEchos        = 0

IcmpOutEchoReps     = 0

IcmpOutTimestamps   = 0

IcmpOutTimestampReps = 0

IcmpOutAddrMasks    = 0

IcmpOutAddrMaskReps = 0

0 messages dropped due to rate limiting
```

## Configuring Router Discovery on a port or VLAN

Enable Router Discovery so that the device forwards Router Discovery Advertisement packets to the VLAN or port.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Specify the address placed in advertisement packets:

```
ip irdp address <A.B.C.D>
```

3. Enable the interface to send the advertisement packets:

```
ip irdp multicast
```

4. Configure other Router Discovery parameters for the interface as required.

## Example

Log on to the GigabitEthernet Interface mode:

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/16
```

Specify the address placed in advertisement packets to the all-systems multicast address:

```
Switch:1(config-if)# ip irdp address 244.0.0.1
```

Enable the interface to send the advertisement packets:

```
Switch:1(config-if)# ip irdp multicast
```

Configure the lifetime for advertisements:

```
Switch:1(config-if)# ip irdp holdtime 180
```

### Variable Definitions

Use the data in the following table to use the `ip irdp` command.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>address &lt;A.B.C.D&gt;</code>                   | Specifies the IP destination address use for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address, 224.0.0.1, or the limited-broadcast address, 255.255.255.255.<br>The default address is 255.255.255.255.<br>The default form of this command is <code>default ip irdp address</code> . |
| <code>holdtime &lt;4-9000&gt;</code>                   | Configures the lifetime for advertisements. The default form of this command is <code>default ip irdp holdtime</code> .                                                                                                                                                                                                                                     |
| <code>maxadvertinterval &lt;4-1800&gt;</code>          | Specifies the maximum time (in seconds) that elapses between unsolicited router advertisement transmissions from the router interface. The default is 600 seconds.<br>The default form of this command is <code>default ip irdp maxadvertinterval</code> .                                                                                                  |
| <code>minadvertinterval &lt;3-1800&gt;</code>          | Specifies the minimum time (in seconds) that elapses between unsolicited router advertisement transmissions from the interface. The range is 3 seconds to <code>maxadvertinterval</code> .<br>The default is 450 seconds.<br>The default form of this command is <code>default ip irdp minadvertinterval</code> .                                           |
| <code>multicast</code>                                 | Specifies if multicast advertisements are sent. The no form of this command is <code>no ip irdp multicast</code> .                                                                                                                                                                                                                                          |
| <code>preference &lt;-2147483648-2147483647&gt;</code> | Specifies the preference (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The default is 0.<br>The default form of this command is <code>default ip irdp preference</code> .                                                                                    |

## Configure a CLIP Interface

### About This Task

Configure a circuitless IP (CLIP) interface to provide a virtual interface that is not associated with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your device.

For scaling information and for information on the maximum number of CLIP interfaces you can configure on your device, see [VOSS Release Notes](#).

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

2. Create or access a CLIP interface:

```
interface loopback <1-256>
```

<1-256> indicates the identification number for the CLIP.

The command prompt changes to indicate you now access the Loopback Interface Configuration mode.

3. Configure an IP address and name for the interface:

```
ip address [<1-256>] <A.B.C.D/X> [vrf WORD<1-16>] [name WORD <0-64>]
```

4. Enable OSPF on the CLIP interface:

```
ip ospf [<1-256>] [vrf WORD<1-16>]
```

You can configure other protocols on the CLIP interface; OSPF is the most common. See the following variable definitions table for other options.

5. View the IP address on the CLIP interface:

```
show ip interface
```

## Example

Create a CLIP interface.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 3
Switch:1(config-if)#ip address 23.23.23.23 255.255.255.0 name ExtNet
Switch:1>show ip interface
```

```
=====
                        IP Interface - GlobalRouter
=====
```

## Display BFD Configurations on the Loopback Interface

### About This Task

Use the following procedure to display all BFD configurations on the loopback interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:  

```
show ip bfd interfaces loopback
```

### Example

The following example displays BFD configurations on the Loopback Interface:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
=====
                        Circuitless IP Interface Bfd
=====
INTF ID   STATUS    MIN_RX   INTERVAL  MULTIPLIER  VRF-ID
-----
1         enable   200      200       3           0
2         enable   200      200       3           2
```

## Viewing TCP and UDP information

Use this procedure to view TCP and UDP configuration information for IPv4.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. View the IPv4 TCP connection information:  

```
show ip tcp connections
```
3. View the IPv4 TCP connection information for a specific vrf or vrfids:  

```
show ip tcp connections vrf WORD<0-16>
```

```
show ip tcp connections vrfids WORD<0-512>
```
4. View IPv4 TCP properties:  

```
show ip tcp properties
```
5. View IPv4 TCP statistics  

```
show ip tcp statistics
```
6. View IPv4 udp endpoints  

```
show ip udp endpoints
```
7. View IPv4 udp statistics  

```
show ip udp statistics
```

### Example

```
Switch:1#show ip tcp connections
```

```

```

*Variable definitions*

Use the data in the following table to use the **show ip tcp** command.

| Variable    | Value                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| connections | <p>Specifies the TCP connection information. Use the following parameters:</p> <ul style="list-style-type: none"> <li>vrf WORD&lt;0-16&gt;</li> </ul> <p>Specifies a virtual routing and forwarding (VRF) by name.</p> <ul style="list-style-type: none"> <li>vrfids WORD&lt;0-512&gt;</li> </ul> <p>Specifies the IDs of a VRF path as an integer from 1 to 512.</p> <p>Example: <code>show ip tcp connections vrf 0</code></p> |
| properties  | Specifies the TCP global properties information.                                                                                                                                                                                                                                                                                                                                                                                 |
| statistics  | Specifies the TCP global statistics.                                                                                                                                                                                                                                                                                                                                                                                             |

Use the data in the following table to use the **show ip udp** command.

| Variable   | Value                                      |
|------------|--------------------------------------------|
| endpoints  | Specifies the IP UDP endpoint information. |
| statistics | Specifies IP UDP statistics information.   |

## IP routing configuration using Enterprise Device Manager

Configure the IP router interface so that you can use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

### Enabling routing for a router or a VRF instance

#### About This Task

Enable IP forwarding (routing) on a router or a Virtual Router Forwarding (VRF) instance so that they support routing. You can use the IP address of any physical or virtual router interface for an IP-based network management.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Globals** tab.
4. To enable routing, select **Forwarding**.
5. Click **Apply**.

## Deleting a dynamically-learned route

### About This Task

Use the Routes tab to view and manage the contents of the system routing table. You can also delete a dynamically learned route using this table. Exercise caution if you delete entries from the route table.

To delete a static route, use the **StaticRoute** tab.

To delete dynamic routes from the table for a VRF instance, first select the appropriate instance.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Routes** tab.
4. To delete a route, select the route and click **Delete**.

### *Routes* field descriptions

Use the data in the following table to use the **Routes** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Dest</b>        | Specifies the destination IP network of this route. An entry with a value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to multiple entries depends on the table access mechanisms defined by the network management protocol in use. |
| <b>Mask</b>        | Indicates the network mask to logically add with the destination address before comparison to the destination IP network.                                                                                                                                                                                      |
| <b>NextHop</b>     | Specifies the IP address of the next hop of this route.                                                                                                                                                                                                                                                        |
| <b>AltSequence</b> | Indicates the alternative route sequence. The value of 0 denotes the best route.                                                                                                                                                                                                                               |
| <b>NextHopId</b>   | Specifies the identifier of the next-hop, hostname or MAC address.                                                                                                                                                                                                                                             |
| <b>HopOrMetric</b> | Specifies the primary routing metric for this route. The semantics of this metric are specific to various routing protocols.                                                                                                                                                                                   |
| <b>Interface</b>   | Specifies the router interface for this route. <ul style="list-style-type: none"> <li>• Virtual router interfaces are identified by the VLAN number of the VLAN followed by the (VLAN) designation.</li> <li>• Brouter interfaces are identified by the slot and port number of the brouter port.</li> </ul>   |
| <b>Proto</b>       | Specifies the routing mechanism through which this route was learned: <ul style="list-style-type: none"> <li>• local—nonprotocol information, for example, manually configured entries</li> <li>• static</li> <li>• isis</li> <li>• inter-vrf redistributed route</li> </ul>                                   |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Age</b>           | Specifies the number of seconds since this route was last updated or otherwise determined correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>PathType</b>      | <p>Indicates the route type, which is a combination of direct, indirect, best, alternative, and ECMP paths.</p> <ul style="list-style-type: none"> <li>• iA indicates Indirect Alternative route without an ECMP path</li> <li>• iAE indicates Indirect Alternative ECMP path</li> <li>• iB indicates Indirect Best route without ECMP path</li> <li>• iBE indicates Indirect Best ECMP path</li> <li>• dB indicates Direct Best route</li> <li>• iAN indicates Indirect Alternative route not in hardware</li> <li>• iAEN indicates Indirect Alternative ECMP route not in hardware</li> <li>• iBN indicates Indirect Best route not in hardware</li> <li>• iBEN indicates Indirect Best ECMP route not in hardware</li> <li>• dBN indicates Direct Best route not in hardware</li> <li>• iAU indicates Indirect Alternative Route Unresolved</li> <li>• iAEU indicates Indirect Alternative ECMP Unresolved</li> <li>• iBU indicates Indirect Best Route Unresolved</li> <li>• iBEU indicates Indirect Best ECMP Unresolved</li> <li>• dBU indicates Direct Best Route Unresolved</li> <li>• iBF indicates Indirect Best route replaced by FTN</li> <li>• iBEF indicates Indirect Best ECMP route replaced by FTN</li> <li>• iBV indicates Indirect best IPVPN route</li> <li>• iBEV indicates Indirect best ECMP IP VPN route</li> <li>• iBVN indicates Indirect best IP VPN route not in hardware</li> <li>• iBEVN indicates Indirect best ECMP IP VPN route not in hardware</li> </ul> |
| <b>Pref</b>          | Specifies the preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>NextHopVrflid</b> | Specifies the VRF ID of the next-hop address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Configuring IP route preferences

### Before You Begin

- Disable ECMP before you configure route preferences.

### About This Task

Change IP route preferences to force the routing protocols to prefer a route over another. Configure IP route preferences to override default route preferences and give preference to routes learned for a specific protocol.

#### Important

Changing route preferences is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. Therefore, if you want to change default preferences for routing protocols, you do so before you enable the protocols.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **RoutePref** tab.
4. In the **ConfiguredValue** column, change the preference for the given protocol.
5. Click **Apply**.

### *RoutePref* field descriptions

Use the data in the following table to use the **RoutePref** tab.

| Name                   | Description                                                        |
|------------------------|--------------------------------------------------------------------|
| <b>DefaultValue</b>    | Specifies the default preference value for the specified protocol. |
| <b>Protocol</b>        | Specifies the protocol name.                                       |
| <b>ConfiguredValue</b> | Configures the preference value for the specified protocol.        |

## Flushing routing tables by VLAN

### About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use Enterprise Device Manager (EDM) to flush the routing tables by VLAN or by port. Use this procedure to flush the IP routing table for a VLAN.

To flush routing tables by VLAN for a VRF instance, first select the appropriate instance.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Advanced** tab.
4. In the **Vlan Operation Action** column, select a flush option.
 

In a VLAN context, all entries associated with the VLAN are flushed. You can flush the ARP entries and IP routes for the VLAN.
5. Click **Apply**.

## Flushing routing tables by port

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Use this procedure to flush the IP routing table for a port.

### About This Task

To flush routing tables by port for a VRF instance, first select the appropriate instance.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **Interface** tab.
5. In the **Action** section, select **flushAll**.

In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port.

After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.

6. Click **Apply**.

## Assigning an IP address to a port

Assign an IP address to a port so that it acts as a routable VLAN (a brouter port) and supports IP routing.

To configure a brouter port, assign an IP address to an IP policy-based single-port VLAN.

### Before You Begin

- Ensure routing (forwarding) is globally enabled.
- Ensure the VLAN is configured.
- If required, ensure the VRF instance exists.

### About This Task

#### Important

After you configure the IP address, you cannot edit the IP address, and you can assign only one IP address to any router interface (brouter or virtual).

You cannot assign an IP address to a brouter port that is a member of a routed VLAN. To assign an IP address to the brouter port, you must first remove the port from the routed VLAN.

If you want to assign a new IP address to a VLAN or brouter port that already has an IP address, first delete the existing IP address and then insert the new IP address.

### Procedure

1. In Device Physical View, select the port.
2. In the navigation tree, expand the **Configuration > Edit > Port** folders.
3. Click **IP**.
4. Click the **IP Address** tab.
5. Click **Insert**.
6. In the **Insert IP Address** dialog box, type the IP address, network mask, and VLAN ID.
7. Click **Insert**.

**IP Address** Field Descriptions

Use the data in the following table to help use the **IP Address** tab.

| Name                   | Description                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Specifies the router interface. <ul style="list-style-type: none"> <li>The name of the VLAN followed by the VLAN designation identifies virtual router interfaces.</li> <li>The slot and port number of the brouter port identifies brouter interfaces.</li> </ul> |
| <b>Ip Address</b>      | Specifies the IP address of the brouter interface on this port. You can define only one IP address on a given port interface.                                                                                                                                      |
| <b>Net Mask</b>        | Specifies the subnet mask of the brouter interface on this port. The mask is an IP address with all the network bits set to 1 and all the hosts bits set to 0.                                                                                                     |
| <b>Name</b>            | Specifies the name of the brouter interface. The value ranges from 0 to 64 characters.                                                                                                                                                                             |
| <b>BcastAddrFormat</b> | Specifies the IP broadcast address format used on this interface.                                                                                                                                                                                                  |
| <b>ReasmMaxSize</b>    | Specifies the size of the largest IP packet which the interface can reassemble from fragmented incoming IP packets.                                                                                                                                                |
| <b>VlanId</b>          | Specifies the ID of the VLAN associated with the brouter port. This parameter is used to tag ports.                                                                                                                                                                |
| <b>BrouterPort</b>     | Indicates whether this is a brouter port.                                                                                                                                                                                                                          |
| <b>MacOffset</b>       | Specifies a number by which to offset the MAC address of the VLAN from the chassis MAC address. This ensures that each IP address has a different MAC address.                                                                                                     |
| <b>VrfId</b>           | Specifies the associated VRF interface. The VrfId associates VLANs or brouter ports to a VRF after the creation of VLANs or brouter ports. VRF ID 0 is reserved for the Global Router.                                                                             |

## Assigning an IP Address to a VLAN

**Before You Begin**

- Ensure routing (forwarding) is globally enabled.
- Ensure VLAN is configured.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

**About This Task**

Specify an IP address for a VLAN so that the VLAN can perform IP routing.

**Important**

You can assign only one IP address to any router interface (brouter or VLAN). You cannot assign an IP address to a VLAN if a brouter port is a member of the VLAN. To assign an IP address to the VLAN, you must first remove the brouter port member.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click **Insert**.
6. In the **Insert IP Address** dialog box, type the IP address and network mask.
7. Click **Insert**.

## Viewing IP addresses for all router interfaces

**About This Task**

Use the Addresses tab to view IP addresses (and their associated router interfaces) from one central location.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Addresses** tab.

**Addresses** field descriptions

Use the data in the following table to use the **Addresses** tab.

| Name                   | Description                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Specifies the router interface. <ul style="list-style-type: none"> <li>• The name of the VLAN followed by the VLAN designation identifies virtual router interfaces.</li> <li>• The slot and port number of the brouter port identifies brouter interfaces.</li> </ul> |
| <b>Ip Address</b>      | Specifies the IP address of the router interface.                                                                                                                                                                                                                      |
| <b>Net Mask</b>        | Specifies the subnet mask of the router interface.                                                                                                                                                                                                                     |
| <b>BcastAddrFormat</b> | Specifies the IP broadcast address format used on this interface; that is, whether 0 (zero) or one is used for the broadcast address. The switch uses 1.                                                                                                               |
| <b>ReasmMaxSize</b>    | Specifies the size of the largest IP packet that this interface can reassemble from incoming fragmented IP packets.                                                                                                                                                    |
| <b>VlanId</b>          | Identifies the VLAN associated with this entry. This value corresponds to the lower 12 bits in the IEEE 802.1Q VLAN tag.                                                                                                                                               |
| <b>BrouterPort</b>     | Indicates whether this is a brouter port (as opposed to a routable VLAN).                                                                                                                                                                                              |
| <b>MacOffset</b>       | Specifies a number by which to offset the MAC address of the VLAN from the chassis MAC address. This ensures that each IP address has a different MAC address.                                                                                                         |

## Configuring IP routing features globally

### About This Task

Configure the IP routing protocol stack to determine which routing features the switch can use.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Globals** tab.
4. To globally enable routing, select **Forwarding**.
5. To globally configure the default TTL parameter type a value in the **DefaultTTL** field.  
This value is placed into routed packets that have no TTL specified.
6. To globally enable IPv4 ICMP broadcast, select **IcmpEchoBroadcastRequestEnable**.
7. To globally enable the Alternative Route feature, select **AlternativeEnable**.
8. To globally enable ICMP Router Discovery, select **RouteDiscoveryEnable**.
9. To globally enable IP Source Routing, select **SourceRouteEnable**.
10. To globally enable ECMP, select **EcmpEnable**.
11. Configure the remaining parameters as required.
12. Click **Apply**.

### *Globals* Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                | Description                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Forwarding</b>   | Configures the system for forwarding (routing) or nonforwarding. The default value is forwarding.                                                                                                                                                                          |
| <b>DefaultTTL</b>   | Configures the default time-to-live (TTL) value for a routed packet. TTL indicates the maximum number of seconds elapsed before a packet is discarded. Enter an integer from 1 to 255. The default value of 255 is used if a value is not supplied in the datagram header. |
| <b>ReasmTimeout</b> | Specifies the maximum number of seconds that received fragments are held while they wait for reassembly. The default value is 30 seconds.                                                                                                                                  |

| Name                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ICMPUnreachableMsgEnable</b>             | <p>Enables the generation of Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this system. These messages help determine if the system is reachable over the network. The default is disabled.</p> <p><b>Important:</b><br/>As a best practice, enable icmp-unreach-msg only if it is absolutely required. If icmp-unreach-msg is enabled and a packet is received for which there is no route in the routing table, CPU utilization can dramatically increase.</p> |
| <b>ICMPRedirectMsgEnable</b>                | Enables or disables the system sending ICMP destination redirect messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>IcmpEchoBroadcastRequestEnable</b>       | Enables or disables IP ICMP echo broadcast request feature. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AlternativeEnable</b>                    | <p>Globally enables or disables the Alternative Route feature.</p> <p>If the alternative-route parameter is disabled, all existing alternative routes are removed. After the parameter is enabled, all alternative routes are re-added. The default is enabled.</p>                                                                                                                                                                                                                                                                       |
| <b>RouteDiscoveryEnable</b>                 | Enables the ICMP Router Discovery feature. The default is disabled (not selected). Use ICMP Router Discovery to enable hosts attached to multicast or broadcast networks to discover the IP addresses of neighboring routers.                                                                                                                                                                                                                                                                                                             |
| <b>AllowMoreSpecificNonLocalRouteEnable</b> | Enables or disables a more-specific nonlocal route. If enabled, the system can enter a more-specific nonlocal route into the routing table. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SuperNetEnable</b>                       | Enables or disables supernetting. If supernetting is globally enabled, the system can learn routes with a route mask less than 8 bits. Routes with a mask length less than 8 bits cannot have ECMP paths, even if you globally enable the ECMP feature. The default is disabled.                                                                                                                                                                                                                                                          |
| <b>UdpChecksumEnable</b>                    | Enables or disables the UDP checksum calculation. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SourceRouteEnable</b>                    | Enables or disables IP Source Routing globally. It is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ARPLifeTime</b>                          | Specifies the lifetime of an ARP entry within the system, global to the switch. The default value is 360 minutes.                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which allows fast convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

### Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.
- To configure an ECMP pathlist, you must first configure a prefix list that you reference in the pathlist configuration.

### About This Task

Different hardware platforms can support a different number of ECMP paths. For more information, see [VOSS Release Notes](#).

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **EcmpEnable**.
5. (Optional) In **EcmpMaxPath**, type the preferred maximum number of equal-cost paths.
6. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths.
7. (Optional) If you modified the ECMP pathlist configuration, select **EcmpPathListApply**.
8. Select **Apply**.

## Configure Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.

- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface.
- Create static routes for management purposes on VSP 8600 Series:
  - Use the mgmtRouter VRF context to configure static routes for the OOB port.
  - Use the default VRF context to configure static routes in the GRT for the inband VLAN or loopback interface.

VSP 8600 Series uses the routing stack to create static routes for data traffic as well as management purposes. For all other platforms, static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 100. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

### Before You Begin

- Ensure no black hole static route exists. If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

### About This Task

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept policies.

For route scaling information, see [VOSS Release Notes](#).

#### Note

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

### Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Static Routes** tab.
4. Select **Insert**.
5. If required, in the **OwnerVrflid** check box, select the appropriate VRF ID. By default, the VRF is the GlobalRouter VRF 0.
6. In the **Dest** field, type the IP address.
7. In the **Mask** field, type the subnet mask.
8. In the **NextHop** field, type the IP address of the router through which the specified route is accessible.
9. (Optional) In the **NextHopVrflid** field, select the appropriate value.
10. (Optional) To enable the static route, select the **Enable** check box.
11. (Optional) In the **Metric** field, type the metric.
12. (Optional) In the **Preference** field, type the route preference.

13. (Optional) If required, select the **LocalNextHop** check box.

Use this option to create Layer 3 static routes.

14. Select **Insert**.

The system displays the new route in the **IP** dialog box, **Static Routes** tab.

### **Static Routes** Field Descriptions

Use the data in the following table to use the **Static Routes** tab.

| Name                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerVrflid</b>                                                                  | Specifies the VRF ID for the static route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Dest</b>                                                                         | Specifies the destination IP address of this route. A value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to such multiple entries is dependent on the table-access mechanisms defined by the network management protocol in use.                                                                                                                                                                                                  |
| <b>Mask</b>                                                                         | Indicates the mask that the system operates a logically AND function on, with the destination address, to compare the result to the Route Destination. For systems that do not support arbitrary subnet masks, an agent constructs the Route Mask by determining whether it belongs to a class A, B, or C network, and then uses one of:<br>255.0.0.0—Class A<br>255.255.0.0—Class B<br>255.255.255.0—Class C<br>If the Route Destination is 0.0.0.0 (a default route) then the mask value is also 0.0.0.0. |
| <b>NextHop</b>                                                                      | Specifies the IP address of the next hop of this route. In the case of a route bound to an interface which is realized through a broadcast media, the Next Hop is the IP address of the agent on that interface.<br>When you create a black hole static route, configure this parameter to 255.255.255.255.                                                                                                                                                                                                 |
| <b>NextHopVrflid</b>                                                                | Specifies the next-hop VRF ID in interVRF static route configurations. Identifies the VRF in which the ARP entry resides.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name for the static route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Enable</b>                                                                       | Determines whether the static route is available on the port. The default is enable.<br>If a static route is disabled, it must be enabled before it can be added to the system routing table.                                                                                                                                                                                                                                                                                                               |
| <b>Status</b>                                                                       | Specifies the status of the route. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Name                | Description                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b>       | Specifies the primary routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route RouteProto value. If this metric is not used, configure the value to 1. The default is 1.<br><br><b>Note:</b><br>Do not configure a static interface subnet route with a metric of 1. |
| <b>IfIndex</b>      | Specifies the route index of the Next Hop. The interface index identifies the local interface through which the next hop of this route is reached.                                                                                                                                                                                    |
| <b>Preference</b>   | Specifies the routing preference of the destination IP address. If more than one route can be used to forward IP traffic, the route that has the highest preference is used. The higher the number, the higher the preference.                                                                                                        |
| <b>LocalNextHop</b> | Enables and disables LocalNextHop. If enabled, the static route becomes active only if the system has a local route to the network. If disabled, the static route becomes active if the system has a local route or a dynamic route.                                                                                                  |

## Deleting a static route

### About This Task

Delete static routes that are no longer needed to prevent routing errors.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Static Routes** tab.
4. Select the static route you want to delete.
5. Click **Delete**.

## Configure a Default Static Route

### Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

### About This Task

The default route specifies a route to all networks for which there no explicit routes exist in the Forwarding Information Base or in the routing table. This route has a prefix length of zero (RFC 1812). You can configure the switch with a static default route, or they can learn it through a dynamic routing protocol.

To create a default static route, you configure the destination address and subnet mask to 0.0.0.0.

**Tip**

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Static Routes** tab.
4. Select **Insert**.
5. In the **OwnerVrflid** check box, select the appropriate VRF ID.
6. In **Dest**, type 0.0.0.0.
7. In **Mask**, type 0.0.0.0.
8. In **NextHop**, type the IP address of the router through which the specified route is accessible.
9. In **Metric**, type the HopOrMetric value.
10. Select **Insert**.

## Configure a Black Hole Static Route

**Before You Begin**

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

**About This Task**

Create a black hole static route to the destination that a router advertises to avoid routing loops when aggregating or injecting routes to other routers.

If an existing black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Static Routes** tab.
4. Click **Insert**.
5. In the **OwnerVrflid** check box, select the appropriate VRF ID.
6. In the **Dest** field, enter the IP address.
7. In the **Mask** field, enter the network mask.
8. In the **NextHop** field, type 255.255.255.255.

To create a black hole static route, you must configure the NextHop address to 255.255.255.255.

9. Select the **enable** option.
10. In the **Metric** box, type the HopOrMetric value.

11. In the **Preference** check box, select the route preference.

When you specify a route preference, be sure to appropriately configure the preference so that when the black hole route is used, it is elected as the best route.

12. Click **Insert**.

## Viewing IP routes

View IP routes learned on the device.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Routes** tab to view IP routes learned on the device.
4. If you want to limit the routes displayed, click **Filter** to show a smaller subset of the learned routes.
5. In the Filter dialog box, select an option, or options, and enter information to limit the routes to display in the Routes table.
6. Click **Filter** and the Routes table displays only the routes that match the options and information that you enter.

### *Routes Field Descriptions*

Use the data in the following table to use the **Routes** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Dest</b>        | Specifies the destination IP network of this route. An entry with a value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to multiple entries depends on the table access mechanisms defined by the network management protocol in use. |
| <b>Mask</b>        | Indicates the network mask to logically add with the destination address before comparison to the destination IP network.                                                                                                                                                                                      |
| <b>NextHop</b>     | Specifies the IP address of the next hop of this route.                                                                                                                                                                                                                                                        |
| <b>AltSequence</b> | Indicates the alternative route sequence. The value of 0 denotes the best route.                                                                                                                                                                                                                               |
| <b>NextHopId</b>   | Displays the MAC address or hostname of the next hop.                                                                                                                                                                                                                                                          |
| <b>HopOrMetric</b> | Displays the primary routing metric for this route. The semantics of this metric are specific to different routing protocols.                                                                                                                                                                                  |
| <b>Interface</b>   | Specifies the router interface for this route. <ul style="list-style-type: none"> <li>• Virtual router interfaces are identified by the VLAN number of the VLAN followed by the (VLAN) designation.</li> <li>• Brouter interfaces are identified by the slot and port number of the brouter port.</li> </ul>   |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Proto</b>         | Specifies the routing mechanism through which this route was learned: <ul style="list-style-type: none"> <li>• other—none of the following</li> <li>• local—nonprotocol information, for example, manually configured entries</li> <li>• static</li> <li>• ICMP</li> <li>• EGP</li> <li>• GGP</li> <li>• Hello</li> <li>• RIP</li> <li>• IS-IS</li> <li>• ES-IS</li> <li>• Cisco IGRP</li> <li>• bbnSpfIgp</li> <li>• OSPF</li> <li>• BGP</li> <li>• Inter-VRF Redistributed Route</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Age</b>           | Displays the number of seconds since this route was last updated or otherwise determined to be correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PathType</b>      | Indicates the route type, which is a combination of direct, indirect, best, alternative, and ECMP paths. <ul style="list-style-type: none"> <li>• iA indicates Indirect Alternative route without an ECMP path</li> <li>• iAE indicates Indirect Alternative ECMP path</li> <li>• iB indicates Indirect Best route without ECMP path</li> <li>• iBE indicates Indirect Best ECMP path</li> <li>• dB indicates Direct Best route</li> <li>• iAN indicates Indirect Alternative route not in hardware</li> <li>• iAEN indicates Indirect Alternative ECMP route not in hardware</li> <li>• iBN indicates Indirect Best route not in hardware</li> <li>• iBEN indicates Indirect Best ECMP route not in hardware</li> <li>• dBN indicates Direct Best route not in hardware</li> <li>• iAU indicates Indirect Alternative Route Unresolved</li> <li>• iAEU indicates Indirect Alternative ECMP Unresolved</li> <li>• iBU indicates Indirect Best Route Unresolved</li> <li>• iBEU indicates Indirect Best ECMP Unresolved</li> <li>• dBU indicates Direct Best Route Unresolved</li> <li>• iBF indicates Indirect Best route replaced by FTN</li> <li>• iBEF indicates Indirect Best ECMP route replaced by FTN</li> <li>• iBV indicates Indirect best IPVPN route</li> <li>• iBEV indicates Indirect best ECMP IP VPN route</li> <li>• iBVN indicates Indirect best IP VPN route not in hardware</li> <li>• iBEVN indicates Indirect best ECMP IP VPN route not in hardware</li> </ul> |
| <b>Pref</b>          | Displays the preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>NextHopVrflid</b> | Specifies the VRF ID of the next-hop address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Configuring ICMP Router Discovery globally

### About This Task

Enable ICMP Router Discovery so that it can operate on the system.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Globals** tab.
4. Select **RouteDiscoveryEnable**.
5. To select a preconfigured ECMP path, click the **EcmpPathList** ellipsis button.
6. Click **OK**.
7. Click **Apply**.

## Configure the ICMP Router Discovery Table

### Before You Begin

- ICMP Router Discovery must be globally enabled.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

### About This Task

Configure the ICMP Router Discovery table to ensure correct ICMP operation for all interfaces that use Router Discovery.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Router Discovery** tab.
4. Configure the Router Discovery parameters to suit your network.
5. Click **Apply**.

### **Router Discovery** field descriptions

Use the data in the following table to use the **Router Discovery** tab.

| Name              | Description                                                                                                                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>  | Indicates the VLAN ID or the port.                                                                                                                                                                                                                                      |
| <b>AdvAddress</b> | Specifies the IP destination address used for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address 224.0.0.1, or the limited-broadcast address 255.255.255.255. The default value is 255.255.255.255. |
| <b>AdvFlag</b>    | Indicates whether (true) or not (false) the address is advertised on the interface. The default value is true (advertise address).                                                                                                                                      |

| Name                   | Description                                                                                                                                                                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvLifetime</b>     | Specifies the time to-live-value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds.<br>The default value is 1800 seconds.                                                       |
| <b>MaxAdvInterval</b>  | Specifies the maximum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 4 to 1800 seconds.<br>The default value is 600 seconds.                    |
| <b>MinAdvInterval</b>  | Specifies the minimum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 3 seconds to MaxAdvInterval.<br>The default value is 450 seconds.          |
| <b>PreferenceLevel</b> | Specifies the preference value (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The range is -2147483648 to 2147483647.<br>The default value is 0. |

## Configuring ICMP Router Discovery for a Port

### Before You Begin

- You must globally enable ICMP Router Discovery.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

### About This Task

Use this procedure to configure Router Discovery on a port. When enabled, the port sends Router Discovery advertisement packets.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **Router Discovery** tab.
5. To enable Router Discovery, select **AdvFlag**.
6. Configure other parameters as required for proper operation.
7. Click **Apply**.

**Router Discovery** field descriptions

Use the data in the following table to use the **Router Discovery** tab.

| Name                   | Description                                                                                                                                                                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvAddress</b>      | Specifies the destination IP address used for broadcast or multicast router advertisements sent from the interface. The accepted values are the all-systems multicast address 224.0.0.1, or the limited-broadcast address 255.255.255.255. The default value is 255.255.255.255. |
| <b>AdvFlag</b>         | Indicates whether (true) or not (false) the address is advertised on the interface. The default value is True (advertise address).                                                                                                                                               |
| <b>AdvLifetime</b>     | Specifies the time to live value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds. The default value is 1800 seconds.                                                                                            |
| <b>MaxAdvInterval</b>  | Specifies the maximum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 4 seconds to 1800 seconds. The default value is 600 seconds.                                                 |
| <b>MinAdvInterval</b>  | Specifies the minimum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 3 seconds to MaxAdvInterval. The default value is 450 seconds.                                               |
| <b>PreferenceLevel</b> | Specifies the preference value (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The accepted values are -2147483648 to 2147483647. The default value is 0.                           |

## Configure ICMP Router Discovery on a VLAN

### Before You Begin

- You must globally enable ICMP Router Discovery.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832.

### About This Task

Configure Router Discovery on a VLAN so that the ICMP Router Discovery feature can run over the VLAN. When enabled, the system sends Router Discovery advertisement packets to the VLAN.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the VLAN ID that you want to configure to participate in Router Discovery.
4. Click **IP**.

5. Click the **Router Discovery** tab.
6. To enable Router Discovery for the VLAN, select **AdvFlag**.
7. Configure other parameters as required for proper operation.
8. Click **Apply**.

### **Router Discovery** field descriptions

Use the data in the following table to use the **Router Discovery** tab.

| Name                   | Description                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvAddress</b>      | Specifies the destination IP address used for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address, 224.0.0.1, or the limited-broadcast address, 255.255.255.255. The default value is 255.255.255.255. |
| <b>AdvFlag</b>         | Indicates whether (true) or not (false) the address is advertised on the interface. The default value is true (advertise address).                                                                                                                                        |
| <b>AdvLifetime</b>     | Specifies the time to-live-value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds. The default value is 1800 seconds.                                                                                     |
| <b>MaxAdvInterval</b>  | Specifies the maximum time (in seconds) allowed between sending unsolicited broadcast or multicast router advertisements from the interface. The range is 4 seconds to 1800 seconds. The default value is 600 seconds.                                                    |
| <b>MinAdvInterval</b>  | The minimum time (in seconds) allowed between unsolicited broadcast or multicast router advertisements sent from the interface. The range is 3 seconds to MaxAdvInterval. The default value is 450 seconds.                                                               |
| <b>PreferenceLevel</b> | Specifies the preference value (a higher number indicates more preferred) of the address as a default router address, relative to other router addresses on the same subnet. The range is -2147483648 to 2147483647. The default value is 0.                              |

## Configure a Circuitless IPv4 Interface

### About This Task

You can use a circuitless IPv4 (CLIPv4) interface to provide uninterrupted connectivity to your system.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP**.
3. Select the **Circuitless IP** tab.
4. Select **Insert**.
5. In the **Interface** field, assign a CLIP interface number.
6. Enter the IP address.

7. Enter the network mask.
8. Select **Insert**.
9. To delete a CLIP interface, select the interface and select **Delete**.

### **Circuitless IP** Field Descriptions

Use the data in the following table to use the **Circuitless IP** tab.

| Name              | Description                                           |
|-------------------|-------------------------------------------------------|
| <b>Interface</b>  | Specifies the number assigned to the interface.       |
| <b>Ip Address</b> | Specifies the IP address of the CLIP.                 |
| <b>Net Mask</b>   | Specifies the network mask.                           |
| <b>Name</b>       | Specifies the name assigned to the IPv4 CLIP address. |

## Enabling OSPF on a CLIP interface

### Before You Begin

- You must globally enable OSPF.
- The OSPF area must already exist.

### About This Task

Enable Open Shortest Path First (OSPF) on a CLIP interface so that it can participate in OSPF routing.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IP**.
2. Click **IP**.
3. Click the **Circuitless IP** tab.
4. Select the required CLIP interface.
5. Click **OSPF**.
6. Select the **Enable** check box.  
You must enable OSPF on the CLIP interface for CLIP to function.
7. In the current **AreaID** field, enter the IP address of the OSPF backbone area.
8. Click **Apply**.

### **Circuitless OSPF** field descriptions

Use the data in the following table to use the **Circuitless OSPF** tab.

| Name          | Description                         |
|---------------|-------------------------------------|
| <b>Enable</b> | Enables OSPF on the CLIP interface. |
| <b>AreaID</b> | Specifies the OSPF area ID.         |

## Enabling PIM on a CLIP interface

Enable Protocol Independent Multicasting (PIM) on a CLIP interface so that it can participate in PIM routing.

### Before You Begin

- You must globally enable PIM.

### About This Task

#### Note

The PIM button does not apply for all hardware platforms.

### Procedure

- In the navigation tree, expand the following folders: **Configuration** > **IP**.
- Click **IP**.
- Click the **Circuitless IP** tab.
- Select the required CLIP interface.
- Click **PIM**.
- Select the **Enable** check box.  
You must enable PIM on the CLIP interface for PIM to function. The mode is indicated on this tab.
- Click **Apply**.

### **Circuitless PIM** field descriptions

Use the data in the following table to use the **Circuitless PIM** tab.

| Name          | Description                        |
|---------------|------------------------------------|
| <b>Enable</b> | Enables PIM on the CLIP interface. |
| <b>Mode</b>   | Specifies the PIM mode.            |

## Enable BFD on a CLIP interface

### Before You Begin

- The CLIP Interface must already exist.

### About This Task

Enable Bidirectional Forwarding Detection (BFD) over Fabric Extend tunnels on a CLIP interface.

#### Note

The BFD button does not apply for all hardware platforms.

### Procedure

- In the navigation pane, expand the **Configuration** > **IP** folders.
- Click **IP**.
- Click the **Circuitless IP** tab.

4. Select the required CLIP interface.
5. Click **BFD**.
6. Select the **Enable** check box.
7. (Optional) In the **MinRxInterval** field, specify the minimum receive interval.
8. (Optional) In the **TxInterval** field, specify the transmit interval.
9. (Optional) In the **Multiplier** field, specify the multiplier used to calculate a receive timeout.

### BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>        | Enable BFD on the CLIP interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>MinRxInterval</b> | <p>Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms.</p> <p><b>Note:</b> For XA1400 Series, the default is 1000 ms.</p> <p><b>Note:</b><br/>The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.</p> |
| <b>TxInterval</b>    | <p>Specifies the transmit interval in milliseconds. The default is 200 ms.</p> <p><b>Note:</b> For XA1400 Series, the default is 1000 ms.</p> <p><b>Note:</b><br/>The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.</p>                                                                                   |
| <b>Multiplier</b>    | <p>Specifies a value for the multiplier used to calculate a receive timeout. The default is 3.</p> <p><b>Note:</b><br/>If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.</p>                                                                                                                                                                                                                                                                                               |

## Viewing TCP global information

View TCP and UDP information to view the current configuration.

### About This Task

The fields on the TCP global tab provide information about the handshake (SYN) configuration and the maximum number of TCP connections you can create on your system.

When you initiate a TCP connection, both end points send handshake information to create the channel.

The retransmission algorithm and fields display the configured timeout value and minimum and maximum retransmission times that your system uses to terminate a connection attempt that falls outside your specified parameters.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Globals** tab.

### *TCP Global field descriptions*

Use the data in the following table to use the **TCP Globals** tab.

| Name                | Description                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------|
| <b>RtoAlgorithm</b> | Determines the timeout value used for retransmitting unacknowledged octets.                                   |
| <b>RtoMin</b>       | Displays the minimum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout. |
| <b>RtoMax</b>       | Displays the maximum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout. |
| <b>MaxConn</b>      | Displays the maximum connections for the device.                                                              |

## Viewing TCP connections information

View information about TCP connections.

### About This Task

Among other things, the fields on the TCP connections tab provide important information about the health of connections that traverse your switch.

In particular, the state column lets you know the state of each TCP connection. Of these, synSent, synReceived, and established indicate whether or not a channel is established and listen indicates when an end system is waiting for a returning handshake (SYN).

### Procedure

1. In the navigation pane, expand the : **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Connections** tab.

**TCP Connections** field descriptions

Use the data in the following table to use the **TCP Connections** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalAddressType</b> | Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.                                                                                                                                                                                                                                                                                    |
| <b>LocalAddress</b>     | Displays the IPv6 address for the TCP connection.                                                                                                                                                                                                                                                                                                              |
| <b>LocalPort</b>        | Displays the local port number for the TCP connection.                                                                                                                                                                                                                                                                                                         |
| <b>RemAddressType</b>   | Displays the type (IPv6 or IPv4) for the remote address of the TCP connection.                                                                                                                                                                                                                                                                                 |
| <b>RemAddress</b>       | Displays the IPv6 address for the remote TCP connection.                                                                                                                                                                                                                                                                                                       |
| <b>RemPort</b>          | Displays the remote port number for the TCP connection.                                                                                                                                                                                                                                                                                                        |
| <b>State</b>            | Displays an integer that represents the state for the connection: <ul style="list-style-type: none"> <li>• closed</li> <li>• listen</li> <li>• synSent</li> <li>• synReceived</li> <li>• established</li> <li>• finWait1</li> <li>• finWait2</li> <li>• closeWait</li> <li>• lastAck(9)</li> <li>• closing</li> <li>• timeWait</li> <li>• deleteTCB</li> </ul> |
| <b>Process</b>          | Displays the process ID for the system process associated with the TCP connection.                                                                                                                                                                                                                                                                             |

## Viewing TCP listeners information

View TCP listener information.

**About This Task**

The TCP listeners table provides a detailed list of systems that are in the listening state.

When a connection is in the listen state an end point system is waiting for a returning handshake (SYN).The normal listening state should be very transient, changing all of the time.

Two or more systems going to a common system in an extended listening state indicates the need for further investigation.

End systems in an extended listening state can indicate a broken TCP connection or a DOS attack on a resource.

This type of DOS attack, known as a SYN attack, results from the transmission of SYNs with no response to return replies.

While many systems can detect a SYN attack, the TCP listener statistics can provide additional forensic information.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Listeners** tab.

### **TCP Listeners** field descriptions

Use the data in the following table to use the **TCP Listeners** tab.

| Name                    | Description                                                                        |
|-------------------------|------------------------------------------------------------------------------------|
| <b>LocalAddressType</b> | Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.        |
| <b>LocalAddress</b>     | Displays the IPv6 address for the TCP connection.                                  |
| <b>LocalPort</b>        | Displays the local port number for the TCP connection.                             |
| <b>Process</b>          | Displays the process ID for the system process associated with the TCP connection. |

# IPv6 Routing Basics

The following sections provide concepts and procedures to complete basic IPv6 configuration, for example, IPv6 forwarding and static routes.

## Origins of IPv6

---

The growth of IP address use is exponential.

Predictions indicated that the IPv4 address pool could be exhausted as early as 1994.

So, in July 1991, the Internet Engineering Task Force (IETF) began researching a replacement for IPv4.

That replacement is IPv6.

The Internet Assigned Numbers Authority (IANA) free pool of IPv4 addresses reached 0% in February 2011, according to the American Registry for Internet Numbers (ARIN).

While IPv4 addresses may remain available for some time within reserved pools, no further IPv4 addresses are available for reservation.

Although IPv6 is designed to replace IPv4, IPv6 is not backward-compatible and IPv4 and IPv6 need to coexist within your network during and after the transition to IPv6.

## Advantages of IPv6

IPv6 can provide more addresses and support more networks than IPv4. For example, IPv6 offers enough addresses for every person on Earth to have 1 million addresses.

Because IPv6 offers a larger address space it offers improved scalability.

Following are additional advantages of IPv6 over IPv4:

- With 128 bit addresses, the larger IPv6 address space offers global access and scalability and solves the pending exhaustion of IP addresses.
- Network Address Translation (NAT) is no longer required.

Flat address space and transparency are restored by IPv6 because NAT is eliminated.

- Routing efficiency is improved due to the hierarchical network architecture.

IPv6 allows for hierarchical routing and effective route summarization.

- IPv6 supports Auto-configuration.
- IPv6 supports plug-and-play.
- Enhanced support is included for mobile IP and mobile computing devices.

Addresses can be permanently assigned to end devices such as DSL, PDAs, mobile terminals and PCs.

- Neighbor discovery (ND) replaces ARP in IPv6.

ND combines the IPv4 services for IPv4 Address Resolution Protocol (ARP) and router discovery.

## Comparison of IPv4 and IPv6

The following table compares the key differences between IPv4 and IPv6.

### Note

This information may not reflect IPv6 support in the current release.

**Table 132: IPv4 and IPv6 key differences compared**

| Feature        | IPv4     | IPv6     |
|----------------|----------|----------|
| Address length | 32 bits  | 128 bits |
| IPsec support  | Optional | Required |

**Table 132: IPv4 and IPv6 key differences compared (continued)**

| Feature                       | IPv4              | IPv6                                  |
|-------------------------------|-------------------|---------------------------------------|
| QoS support                   | Limited           | Improved                              |
| Fragmentation                 | Hosts and routers | Hosts only                            |
| Minimum MTU packet size       | 576 bytes         | 1280 bytes                            |
| Checksum in header            | Yes               | No                                    |
| Options in header             | Yes               | Yes                                   |
| Link-layer address resolution | ARP (broadcast)   | Multicast neighbor discovery messages |
| Multicast membership          | IGMP              | Multicast Listener Discovery          |
| Router discovery              | Optional          | Optional                              |
| Uses broadcasts               | Yes               | No                                    |
| Address configuration         | Manual, DHCP      | Automatic, DHCP                       |

## IPv6 packet

Each IPv6 packet can include mandatory and non-mandatory components.

An IPv6 packet includes:

- The basic header, which has a fixed length and is mandatory
- Extension header(s) , which has a variable length and is not mandatory
- Payload, which has a variable length and is not mandatory

The following figure illustrates the components of an IPv6 packet.

**Figure 170: IPv6 packet components**

### Note

Nodes must be able to handle packets up to 1,280 octets in length.

## IPv6 header

The IPv6 header basic length is fixed at 40 octets (bytes) and it contains the following fields:

**Table 133: Fields in the IPv6 header**

| Field                                                                      | Size in bits |
|----------------------------------------------------------------------------|--------------|
| Ver—Internet Protocol version number, with a value of 6                    | 4            |
| DS byte—Traffic class field, similar to Type of Service in IPv4            | 8            |
| Flow label—identifies traffic flow for additional Quality of Service (QoS) | 20           |

**Table 133: Fields in the IPv6 header (continued)**

| Field                                                                                                                              | Size in bits |
|------------------------------------------------------------------------------------------------------------------------------------|--------------|
| Payload Length—Unsigned integer, the length of the IPv6 payload                                                                    | 16           |
| Next header selector—identifies the next header                                                                                    | 8            |
| Hop limit unsigned integer—decrements by 1 each time a node forwards the packet (nodes discard packets with hop limit values of 0) | 8            |
| Source address                                                                                                                     | 128          |
| Destination address                                                                                                                | 128          |

The following figure illustrates the basic IPv6 header, without extension headers.

**Figure 171: IPv6 header**

## IPv6 extension headers

IPv6 extension headers describe processing options.

Each extension header contains a separate category of options and is identified by a number, similar to protocol identification numbers.

An IPv6 packet can include extension headers, but they are not mandatory.

The following figure illustrates the IPv6 header with extension headers.

**Figure 172: IPv6 header with extension headers**

IPv6 examines the destination address in the main header of each packet it receives.

This examination determines whether the router is

- the packet destination - if the router is the packet destination, IPv6 examines the header extensions that contain options for destination processing.
- an intermediate node in the packet data path - if the router is an intermediate node, IPv6 examines the header extensions that contain forwarding options.

By examining only the extension headers that apply to the operations it performs, IPv6 reduces the amount of time and resources required to process a packet.

IPv6 defines the following extension headers as described in the following table:

**Table 134: IPv6 extension headers**

| Extension header name                                                                                                                                            | Description                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hop-by-hop                                                                                                                                                       | Contains optional information, and sub-options for Router Alert and Jumbo Payload, that all intermediate IPv6 routers examine between the source and the destination.                                                                                 |
| destinations-options                                                                                                                                             | Contains optional information for the destination node. The system can display this option twice, once for way points and once for final destination.                                                                                                 |
| source-routing                                                                                                                                                   | Contains a list of one or more intermediate nodes that define a path for the packet to follow through the network to the destination. The packet source creates this list. The source-routing function is similar to the IPv6 source routing options. |
| fragmentation                                                                                                                                                    | Uses an IPv6 source to send packets larger than the size specified for the path maximum transmission unit (MTU).                                                                                                                                      |
| authentication                                                                                                                                                   | provides security for IPv6 datagrams                                                                                                                                                                                                                  |
| encapsulated security payload (ESP)                                                                                                                              | provides security for IPv6 datagrams                                                                                                                                                                                                                  |
| The authentication extension header and the encapsulated security payload extension header can be used together to provide security services for IPv6 datagrams. |                                                                                                                                                                                                                                                       |

The following extension header order is:

- Hop-by-hop
- Destination option 1
- Routing
- Fragmentation

- Authentication/ESP
- Destination Option 2

The presence of particular extension headers within a packet can cause slower packet processing if the IPv6 implementation handles only certain headers and diverts others to a slow path. For example, many IPv6 implementations usually process Hop-by-Hop extension headers on the control plane.

---

## IPv6 address component summary

---

The IPv6 Internet is divided into addressing zones and IPv6 addresses can be categorized by type and scope.

IPv6 addressing is represented in RFC 4291.

### Address types

IPv6 addresses are divided into the following types:

- Unicast

Unicast addresses provide one-to-one communication.

- Multicast

Multicast addresses are similar in operation to IPv4 and provide one-to-many communication.

- Anycast

An Anycast address is a Unicast address used for several devices to allow them to communicate with the device closest to the source; one-to-nearest communication.

- Broadcast

In IPv6, broadcast addresses have been superseded by multicast addresses per RFC 4291.

For more information about address types and scopes, see [IPv6 Address Types](#).

### Address scopes

Following are IPv6 address scopes:

- node-local
- link-local
- global

The switch does not support site-local addresses and, according to RFC 4193, site-local addresses will be replaced by unique-local addresses.

For more information about address types and scopes, see [IPv6 address formats](#).

### Address zones

The IPv6 Internet is divided into zones.

For example:

- Each node is a separate zone of the node-local scope.
- Each link is a separate zone of the link-local scope.
- The entire Internet is a single zone of global scope.

Zones of the same scope do not overlap.

## IPv6 address formats

IPv6 addresses are 128 bits long. In comparison, IPv4 addresses are 32 bits in length.

The IPv6 address contains an

- address type
- address prefix
- interface ID

The following figure illustrates the IPv6 address format.

|      |                |              |
|------|----------------|--------------|
| Type | Address prefix | Interface ID |
|------|----------------|--------------|

**Figure 173: IPv6 address format**

## Address types

IPv6 uses three main address types to help route packets.

Address types are:

- Unicast: global, link—local, special unspecified, special loopback
- Multicast
- Anycast

## Difference between multicast and anycast

Anycast address delivery is from one to one-of-many, whereas multicast address delivery is from one to many.

## Unicast addresses

Unicast addresses provide one-to-one communication

Unicast addresses provide one-to-one communication.

*Global*

A Unicast global address identifies a single interface and is similar to an IPv4 public address.

Unicast global addresses are globally routable in the same manner as IPv4 addresses.

The following figure illustrates the Unicast global address parts.

**Figure 174: Unicast global address parts**

An IPv6 Unicast global address is composed of the following 3 levels:

- public topology (48 bit Global Routing Prefix)
  - 001, specifies an IPv6 Unicast global address
  - Top Level Aggregation Identifier (TLA ID), the highest level in routing hierarchy
  - Res, reserved for future use
  - Next Level Aggregation Identifier (NLA ID), specifies a customer site
- site topology (16 bit Subnet ID)
  - Site Level Aggregation Identifier (SLA ID); assigned within the site, an ISP cannot affect the SLA ID, enables up to 65,536 subnets within a site
- interface ID (64 bits)
  - specifies the interface for a node on a subnet

The system uses the 48 bit global routing prefix for the route prefix exchange.

The IPv6 Prefix for Unicast global is 2000::/3 (RFC3513).

*Link-local*

Hosts on the same link/subnet use automatically configured IPv6 Unicast link-local addresses to communicate with each other.

Link-local addresses are automatically configured on all interfaces.

Routers do not forward packets containing a destination or source address with a link-local address.

IPv6 uses neighbor discovery (ND) for address resolution.

The IPv6 prefix for link-local Unicast addresses is FE80::/10 (RFC3513).

The following figure illustrates the parts of a Unicast Link-local address.

**Figure 175: Unicast Link-local address**

*Special addresses*

The Unicast/special/unspecified address indicates the absence of an address and is the only valid SRC address for IPv6 Duplicate Address Detection (DAD).

Equivalent to the IPv4 unspecified address 0.0.0.0, represented as 0:0:0:0:0:0:0:0 or ::1; an IPv6 host that does not have a valid address uses the unspecified address as its source address when it sends a packet to discover whether an address is used by another node (during the boot process when the host requests address configuration information).

**Note**

Do not assign an unspecified address, either statically or dynamically, to an interface.

The Unicast/special/loopback address is a special case Unicast address only found inside a single node.

The switch does not support the loopback address.

Equivalent to the IPv4 loopback address 127.0.0.1, represented as 0:0:0:0:0:0:0:1 or ::1; a node uses a loopback address to send a packet to itself.

The loopback address is beneficial in troubleshooting and testing the IP stack because you can use it to send a packet to the protocol stack without sending it onto the subnet.

**Note**

Do not assign a loopback address, either statically or dynamically, to an interface.

Both Loopback and Unspecified addresses are not valid destination addresses.

An example of a unicast IPv6 address is 1080:0:0:0:8:8000:200C:417A

An example of a link-local Unicast IPv6 address is FE80::4445:4eff:fe54:1212

## Multicast addresses

Multicast addresses provide one-to-many communication

Multicast addresses provide one-to-many communication.

An IPv6 multicast address identifies a group of nodes.

The scope is built into the multicast address structure.

The system uses a multicast address to send traffic to multiple destinations. In this situation traffic experiences less delay with a multicast address than it would with Unicast address.

The following figure shows the format of an IPv6 multicast address.

| 8 bits   | 4 bits | 4 bits | 112 bits |
|----------|--------|--------|----------|
| 11111111 | flags  | scope  | group ID |

**Figure 176: IPv6 multicast address format**

A value of FF (1111111) in the 8 high-order bits of an IPv6 address indicates that the address is an IP multicast address.

The Multicast IPv6 Prefix is FF00::/8 (RFC3513).

### *Flags*

The 4-bit flags field indicates whether the group is permanent or transient. The first 3 bits are reserved and the 4th bit represents the Transient flag. Currently only the Transient (T) flag is defined. A T flag set to 0 specifies a permanently assigned multicast address. A T flag set to 1 specifies a transient address.

### *Group ID*

The 112 bit group ID identifies the multicast group.

An example of a multicast address is FF01:0:0:0:0:0:101

### *Scope field*

The 4-bit scope field within the group ID specifies the multicast traffic scope.

Following is a list of the scope options that limit the scope of the multicast address:

- 1 - node-local
- 2 - link-local
- 3 - subnet local
- 4 - admin local
- 5 - site-local – not supported
- 8 - organization-local
- B - community-local
- E - global

### *Examples of multicast addresses*

All-nodes addresses look like this:

FF01::1 (Node Local), FF02::1 (Link Local)

All-routers addresses look like this:

FF01::2 (Node Local), FF02::2 (Link Local)

A solicited node or host address looks like this:

FF02::1:FF1E:8329.

In this case the MAC is 00-02-B3-1E-83-29 and the IPv6 address is fe80::202:B3FF:FE1E:8329.

The following table lists some well-known multicast IPv6 addresses

**Table 135: Well-known multicast IPv6 addresses**

| Name                      | Address               |
|---------------------------|-----------------------|
| All Nodes                 | FF02:0:0:0:0:0:0:1    |
| All Routers               | FF02:0:0:0:0:0:0:2    |
| OSPFv2                    | FF02:0:0:0:0:0:0:5    |
| OSPFv2 Designated Routers | FF02:0:0:0:0:0:0:6    |
| All PIM Routers           | FF02:0:0:0:0:0:0:D    |

## Anycast

Anycast addresses provide one-to-nearest (one to one-of-many) communication.

Anycast addresses provide one-to-nearest (one to one-of-many) communication.

An anycast address designates a set of interfaces that share an address.

A packet sent to an anycast address goes only to the nearest member of the group. Considering routing distance, the system delivers packets with anycast addresses only to the nearest member of a group of multiple interfaces.

### *Restrictions*

An anycast address must not be:

- used as the source address in an IPv6 packet
- assigned to an IPv6 host (you can assign an anycast address to an IPv6 router)

### *Anycast address scopes*

Anycast addresses have the following scopes:

- Link-local—the local link; nodes on the same subnet
- Global—IPv6 Internet addresses

Similar to anycast IPv4 addresses, IPv6 anycast addresses are more efficient. They use the unicast address space but identify multiple interfaces.

IPv6 delivers a packet bearing an anycast address to the nearest interface identified by the address.

Currently anycast addresses are assigned to routers and are used as destination addresses. Because packets bearing anycast addresses are delivered to the closest router, you can also access the closest name server or time server with an anycast address.

Visually there is no distinction between an anycast address and a unicast address.

**Note**

The switch supports only the subnet-router anycast address.

You cannot configure any specific anycast addresses beyond the automatic, generic subnet-router anycast address.

## IP address prefix

---

Address prefixes represent one of the following:

- network identifier
- fixed address part

### Examples of IP address prefixes

2001:10F2::/48 represents a summarized route prefix

2001:10F2:0:102F::/64 represents a subnet or link prefix

FF00::/8 represents Multicast IPv6

## Interface ID

---

Interface identifiers identify interfaces on a link.

As long as the interfaces are attached to different subnets, you can use the same identifier on more than one interface on a single node.

The IPv6 interface ID is as unique as the MAC address.

The interface ID is derived by a formula that uses the link layer 48-bit MAC address. In most cases, the interface ID is a 64-bit interface ID that contains the 48-bit MAC address. If you enter less than 64 bits, the system adds leading zeroes to extend the interface ID length to 64 bits.

You can configure the interface ID in the following ways:

- Manual configuration
- DHCPv6 (can configure the whole address)
- Automatic derivation from EUI-64 (MAC address or other HW serial)—enables serverless or stateless auto-configuration when combined with high order part of address learned from router advertisements
- Pseudo-random generation (client privacy)—enables serverless or stateless auto-configuration when combined with high order part of address learned from router advertisements

The switch supports manual interface ID configuration or automatic derivation from EUI-64.

**Note**

You must manually specify the network prefix, regardless of the interface ID formation method.

For stateless autoconfiguration, the ID is 64 bits in length.

For more information about stateless autoconfiguration, see [Host autoconfiguration](#) on page 1964.

## How to write an IPv6 address

---

The appearance of IPv6 addresses differs from IPv4 addresses and you express them differently.

### Hexadecimal IPv6 address representations

The 128 bits in an IPv6 address are divided into 8 blocks of 16 bits each.

Following is the preferred IPv6 address format:

```
XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX
```

Each 16 bit block in an IPv6 address is converted into a 1 to 4 digit hexadecimal number separated by colons (:).

The format to represent an IPv6 address is n:n:n:n:n:n:n:n, where n is the hexadecimal representation of 16 bits in the address; for example, 2001:0:0:0:0:0:0:43.

Each nonzero field must contain at least one numeral.

Within a hexadecimal field, you do not need leading zeros.

Certain classes of IPv6 addresses commonly include multiple adjacent fields that contain hexadecimal 0.

The sample address—2001::43—includes six adjacent fields that contain zeroes represented by a double colon (::).

You can use a double colon to compress the leading zero fields in a hexadecimal address.

The system can display a double colon only once in an address.

### Four more ways to write an IPv6 address

```
2001:DB8:0000:0000:25AB:0000:0000:0001  
2001:DB8:0:0:25AB:0:0:1  
2001:DB8:0:0:25AB::1  
2001:DB8::25AB:0:0:1
```

## ICMPv6

---

Internet Control Message Protocol version 6 (ICMPv6) maintains and improves on features from ICMP for IPv4.

ICMPv6 reports the delivery of forwarding errors.

For example:

- Destination unreachable
- Packet too big (path MTU)
- Time exceeded (fragmentation)
- Parameter problem

ICMPv6 also delivers information messages such as ping, otherwise known as

- Echo request
- Echo reply

#### Important

By providing a framework for informational messages, ICMPv6 plays an important role in IPv6 features such as

- Neighbor discovery (ND)
- Path MTU discovery
- Multicast Listener Discovery (MLD)

You can identify an IPv6 ICMP packet because the Next Header field in the IPv6 packet header is 58.

## Internet Protocol Security (IPsec) with ICMPv6

You can configure IPsec with ICMPv6. For a configuration example of IPsec with ICMPv6, see [IPsec with ICMPv6 configuration example](#) on page 1793.

## Path MTU discovery

IPv6 routers do not fragment packets.

The source node may send packets less than or equal to the maximum transmission unit (MTU) of the link layer.

As the packet travels through the network to the source it may encounter a link with a smaller MTU. If so, the router sends the source node an ICMP error message that contains the MTU size of the next link. The source IPv6 node then resends a packet equal to the size of the MTU included in the ICMP message.

The default Layer 3 IPv6 MTU value is 1500 where the system MTU default value is 1950.

The default IPv6 MTU value is always less than the default System MTU value.

You can configure the MTU for each IPv6 interface.

#### Note

The MTU value for an IPv6 interface is not configurable on 5420 Series.

**Note**

To configure separate Layer 3 MTU values for IPv4 and IPv6 packets on the same VLAN interface, you must disable Unicast Reverse Path Forwarding (uRPF) mode. If you enable the uRPF mode using the command **boot config flags urpf-mode**, the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

## Routing

---

A routing table is present on all nodes.

The routing table stores information about IPv6 network prefixes and how to reach them.

**Note**

The switch requires routing protocols, such as OSPFv3 to exchange IPv6 routing prefixes.

For each incoming packet, the switch checks the destination neighbor cache first. If the destination is not in the destination neighbor cache, the routing table determines:

- the next-hop interface (the interface used for forwarding)
- the next-hop address

**Note**

The system uses the IPv6 Neighbor Cache for on-link, directly-connected destinations only. Off-link destinations go through a next-hop router, as determined by the next-hop address lookup.

IPv6 routes in a routing table can be:

- directly attached network routes using a 64-bit prefix
- remote network routes using a 64-bit or lower prefix
- host routes using a 128-bit prefix length
- the default route using a prefix of `::/0`

The switch supports the following IPv6 routing protocols:

- RIPng
- OSPFv3
- BGP+ (over 6in4 tunnels)
- IPv6 Shortcuts (over Fabric Connect)

You can redistribute IPv6 routes between any of these routing protocols.

To configure IPv6 routing on a VLAN, an IP address is assigned to the VLAN. This IP address is not associated with any particular physical port, but is used on all ports where this VLAN is a member.

On a brouter port, a single port VLAN is used to route the traffic. IPv4 and IPv6 traffic is routed in the single-port brouter VLAN.

Other VLANs (which are multiple port VLANs) can bridge and route the traffic.

## Virtual routing between IPv6 subnets

The switch supports IPv6 routing between subnets.

When you add an IP address to the VLAN, the system maps an IP subnet to the VLAN.

As shown in the following figure, although VLAN 1 and VLAN 2 reside on the same switch, for traffic to flow from VLAN 1 to VLAN 2, you must route the traffic.

You must enable IPv6 forwarding to route IPv6 traffic between VLANs. And you must enable IPv6 both globally and on a specific VLAN basis in order for forwarding to function. You can enable or disable IPv6, either globally or on a specific VLAN basis.

IPv6 forwarding is enabled by default.

**Figure 177: IPv6 routing between VLANs**

When you configure routing on a VLAN, an IPv6 address assigned to the VLAN is the VLAN IP interface.

The VLAN IPv6 address can be reached through any VLAN port, and frames route from the VLAN through the gateway IPv6 address.

You can forward traffic to any IPv6 subnet in the switch. A VLAN can be reached only if it has an IPv6 interface configured on it.

Because a port can belong to multiple VLANs, a one-to-one correspondence no longer exists between the physical port and the router interface when VLAN tagging is enabled.

If you do not enable VLAN tagging a single port can belong only to one port-based VLAN, but that same single port can belong to multiple policy-based VLANs.

As with any IPv6 address, you can use any VLAN IP interface for device management.

For the Simple Network Management Protocol (SNMP) or Telnet management, you can use any VLAN IP interface to access the switch while routing is enabled on the VLAN.

## Router ports

A router port is a single-port VLAN that can route IP packets and bridge all nonroutable traffic.

The difference between a brouter port and a standard protocol-based VLAN configured for routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic while it routes IP traffic.

**Note**

Because a brouter port is a one-port VLAN, each brouter port decreases the number of available VLANs by one and uses one VLAN ID.

## Static routes

Static routes provide an alternative method for establishing route reachability.

Static routes, with dynamic routes, provide routing information from the forwarding database.

Only enabled static routes whose nexthop address is reachable are submitted to the Route Table Manager (RTM), which determines the best route based on reachability, route preference, and cost.

The RTM communicates all updates to best routes.

If the nexthop is not reachable you can use the **show ipv6 route static** command to display the status. If the nexthop is not reachable, the status is `TryToResolve` and the system does not display the route in the RTM until the nexthop address is resolved.

For directly-connected IPv6 Subnets you do not need to specify a nexthop address; you can specify outgoing Tunnel-ID, VLAN, or port. If you use outgoing Tunnel-ID, VLAN, or port, the implied nexthop value is `0::0`.

When you configure IPv6 static routes only by interface (VLAN or brouter), it lets the traffic to reach IPv6 prefixes configured on the link that is directly connected to the interface provided in the static route configuration. For example: `ipv6 route 180:0:0:0:0:0:0/64 cost 1 vlan 631`.

When you configure static routes with a link-local nexthop, you must also specify the outgoing Tunnel-ID, VLAN, or port because link-local addresses are ambiguous unless the proper interface binding is attached. For example: `ipv6 route 1234::/64 cost 1 next-hop fe80::1 vlan 1900`.

You must provide the following options to configure a static route:

- local or nonlocal hop option

Configure a static route either with a next hop that exists on a locally attached network or a next hop that is reachable through a dynamic route. The static route is available as long as the next hop is reachable.

- route preference

You can specify the route preference for the static routes as follows:

- Global value for all static routes: the preference is either static or dynamic routes.
  - Preference for each static route entry: if specified, this value overrides the global value for the entry which provides flexibility to change the general behavior of a specific static route.
- Administrative status

Controls when the static route is considered for forwarding. Administrative status differs from the operational status. An admin-enabled static route can still be unreachable and not used for forwarding. An admin-disabled static route is operationally a nonexistent route.

- Multiple static routes

Specify alternative paths to the same destination. Multiple static routes provide stability and load balancing.

To configure a default static route, supply a value of 0 for the prefix and the prefix length.

The following table describes events that affect static route operation.

**Table 136: Events and their affects on static route operation**

| Action                                               | Result                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change the administrative status of the static route | Makes the static route unavailable for forwarding<br>You can use one CLI command to administratively enable or disable all static routes as follows <code>ipv6 route static enable</code> .<br>You can administratively disable all routes but preserve the static route configuration when you use the CLI command: <code>no ipv6 static route enable</code> . |
| Delete the IPv6 addresses of a VLAN or brouter port  | Permanently deletes the static routes with the corresponding local neighbors from the RTM, the forwarding database, and the configuration database                                                                                                                                                                                                              |
| Delete a VLAN                                        | Removes static routes with a local next-hop option from the configuration database. Static routes with a nonlocal next-hop option become inactive (they are removed from the forwarding database).                                                                                                                                                              |
| Disable forwarding on a VLAN or brouter port         | Static routes reachable through the locally attached network become inactive                                                                                                                                                                                                                                                                                    |
| Disable a VLAN or brouter port                       | Makes the static route inactive                                                                                                                                                                                                                                                                                                                                 |
| Disable IPv6 forwarding globally                     | Stops forwarding all IPv6 traffic                                                                                                                                                                                                                                                                                                                               |
| Learn changes about a dynamically learned neighbor   | After a neighbor becomes unreachable or is deleted, the static route with the neighbor becomes inactive, and the configuration is not affected. The static route with the neighbor becomes active in the configuration and is added to the RTM and forwarding database when the neighbor becomes reachable.                                                     |
| Enable a static route                                | Adds the route to the RTM to change certain static routes to active.                                                                                                                                                                                                                                                                                            |
| Delete a static route                                | Permanently deletes a static route from the configuration.                                                                                                                                                                                                                                                                                                      |
| Disable a static route                               | Stops traffic on the static route but does not remove the route from the configuration.                                                                                                                                                                                                                                                                         |
| Change a route preference                            | After the static route preference changes, the best routes for the entries use both static and dynamic paths.                                                                                                                                                                                                                                                   |
| Delete or disable a tunnel                           | Removes the tunnel entry from the forwarding table                                                                                                                                                                                                                                                                                                              |
| Enable a tunnel                                      | Activates the tunnel static routes and adds an entry to the forwarding table.                                                                                                                                                                                                                                                                                   |

The local-nexthop flag is not required for IPv6.

An IPv4 device cannot learn a neighbor ARP entry unless the device uses a local route entry.

In IPv6, a host can learn a neighbor entry if the device is physically connected to the neighbor (one hop).

The static route becomes active when the next hop is reachable by a dynamic route neighbor resolution. The static route takes the forwarding information from the dynamic route. If the next hop is reachable using a local route, the neighbor resolution is required.

## Static route table

The static route table is separate from the system routing table that the router uses to make forwarding decisions.

You can use the static route table to directly change static routes.

Although the tables are separate, the system routing table automatically reflects the static routing table manager entries if the next-hop address in the static route is reachable and if the static route is enabled.

The static route table is indexed by four attributes:

- destination network
- destination mask
- next hop
- interface

You can insert static routes by using the static route table, and you can delete static routes by using either the static route table or the system routing table. For information on route scaling, see [VOSS Release Notes](#).

### Important

The system routing table stores only active static routes with the best route preference. A static route is active only if the route is enabled and if the next-hop address is reachable; for example, if a valid IPv6 neighbor cache entry exists for the next hop.

You can enter multiple routes (for example, multiple default routes) that use different costs and the lowest cost route that is reachable, the system displays the lowest cost route in the routing table.

If you enter multiple next hops for the same route with the same cost, the switch does not replace the existing route.

If you enter the same route with the same cost and a different next hop, the switch uses the first route. If that first route becomes unreachable, the system activates the second route, with a different next-hop, with no connectivity loss.

## Route scaling

IPv4 and IPv6 route scaling depends on the combination of the `ipv6-mode` and `urpf-mode` boot config flags. For more information, see [VOSS Release Notes](#).

## IPv6 Circuitless IP

---

IPv6 Circuitless IP (CLIP) is a virtual interface that is not associated with any physical port. You can use an IPv6 CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. The system treats the IPv6 CLIP interface like an IPv6 interface and treats the network associated with the IPv6 CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

You can use an IPv6 CLIP address as a logical IPv6 address for network management, as well as for other purposes. The IPv6 CLIP is typically a host address with any prefix length. You can redistribute this address as part of any other routing protocol update, so that the CLIP address is known to neighbors and available for use in routing or other types of connectivity. You can use IPv6 CLIP for many kinds of management connectivity such as telnet or SSH. You can also use IPv6 CLIP as a source IP address for sending Syslog messages.

For scaling information on IPv6 CLIP, see [VOSS Release Notes](#).

### IPv6 CLIP restrictions and limitations

This section describes the restrictions and limitations associated with IPv6 CLIP.

- Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
- IPv6 CLIP does not support link-local address configuration.
- To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.

#### Note

This flag does not apply to all hardware platforms. For more information, see [VOSS Feature Support Matrix](#).

- Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect duplicate IPv6 address assignment to this interface.
- Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
- IPv6 CLIP interface is enabled by default and it cannot be disabled.
- You cannot configure an IPv6 CLIP interface as the source or destination endpoint of an IPv6-in-IPv4 tunnel.

## Equal Cost Multipath

**Table 137: Equal Cost Multiple Path for IPv6 product support**

| Feature       | Product         | Release introduced |
|---------------|-----------------|--------------------|
| ECMP for IPv6 | 5420 Series     | VOSS 8.4           |
|               | 5520 Series     | VOSS 8.2.5         |
|               | VSP 4450 Series | VOSS 5.1           |
|               | VSP 4900 Series | VOSS 8.1           |
|               | VSP 7200 Series | VOSS 5.1           |
|               | VSP 7400 Series | VOSS 8.0           |
|               | VSP 8200 Series | VOSS 5.1           |
|               | VSP 8400 Series | VOSS 5.1           |
|               | VSP 8600 Series | VSP 8600 6.2       |
|               | XA1400 Series   | Not Supported      |

With Equal Cost Multipath (ECMP), the switch can determine equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP traffic. ECMP is formed using routes from the same source or protocol, and the ECMP routes are evaluated within each routing protocol.

The ECMP feature supports and complements the following protocols and route types:

- OSPFv3
- Static routes
- BGP+
- RIPng
- IPv6 Shortcuts

### ECMP with static routes

ECMP supports and complements static routes.

The following points need to be considered while configuring ECMP with static routes:

- When ECMP is globally enabled, the equal cost static routes are added in the Routing Table Manager (RTM).
- Static routes that are configured only using an interface, such as VLAN or port, do not support ECMP as these routes have a preference value of 0 and are treated like local routes.
- If your switch supports a management interface, then static routes configured on the management interface do not support ECMP.
- Static routes configured by next-hop are not considered equal cost with routes that are configured by tunnel even if the routes have the same cost and preference.

- A static route configured by tunnel is the least preferred and is programmed only when a next-hop or an interface does not configure a static route.
- Static routes configured by next-hop that resolves their next-hop using another static route will be in the `notReachable` state even if the next-hop can be pinged.
- If there are two static routes configured by next-hop, and both next-hops are resolved via a dynamic protocol to the same value, then only one route will be in the `reachableInRtm` state. The state of the other route will be `reachableNotInRtm`.

## Disable IPv6 ICMP multicast

---

On IPv6 networks, a packet can be directed to an individual machine or multicasted to a set of hosts. When a packet is sent to an IPv6 multicast address from a machine on the local network, that packet is delivered to a subset or all machines on that network.

If the packet that is sent to the multicast address is an ICMP Echo Request packet, the machines on the network will receive this ICMPv6 echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMPv6 echo request, the result can be severe network congestion or outages.

Network devices always respond to the IPv6 ICMP packets sent to a multicast address. However, you can disable the processing of IPv6 ICMP packets sent to a multicast address on the device. On disabling the ICMP multicast processing, all the packets containing ICMP sent to multicast addresses are dropped when the packets reach the control plane.

## Viewing IPv6 Connections

---

You can establish network connectivity with the following protocols:

- Transmission Control Protocol (TCP), for connection-oriented sessions
- User Datagram Protocol (UDP), for connectionless sessions

When you view TCP information you can:

- check the health of the connections, from the switch perspective, as they traverse the network
- detect intermittent connectivity
- detect attacks on resources
- determine which applications are active by checking the port numbers

UDP endpoint information tells you about local and remote UDP activity.

When you view UDP information you can:

- determine which applications are active by checking the local and remote port numbers
- identify processes within a UDP session to enable multiplexing of a port mapping for UDP

## IPv6 Basic Configuration using CLI

---

Use the procedures in this section to configure IPv6 basics using CLI.

## Enable the IPv6-Mode Boot Config Flag

Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits.

This flag is disabled by default. Use this procedure to enable (set to true) the IPv6-mode boot config flag.

When the IPv6-mode boot config flag is enabled, the maximum number of IPv4 routing table entries decreases. For scaling information, see [VOSS Release Notes](#).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the IPv6-mode boot config flag:  
`boot config flags ipv6-mode`
3. Save the configuration, and then reboot the switch for the change to the IPv6-mode boot config flag to take effect.
4. After you reboot the switch, verify that the IPv6-mode boot config flag is set to true:  
`show boot config flags`

## Configure an IPv6 Static Neighbor Address

You can use static IPv6 neighbors to manually specify the link-layer address for a given IPv6 endpoint.

### About This Task

Under normal operation you do not need to configure static IPv6 neighbors.

However, IPv6 static neighbors can be used to:

- avoid the overhead associated with dynamic neighbor discovery protocol traffic
- help troubleshoot specific network scenarios

#### Note

- IPv6 static neighbors are not supported on SMLT.
- When you add or remove IPv6 static neighbors that point to a nexthop router, make sure that you have disabled the IPv6 interface.

Not all parameters are available in non-default VRFs.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  
`enable`  
  
`configure terminal`  
  
Optional: `router vrf WORD<1-16>`

2. Configure an IPv6 neighbor address:

```
ipv6 neighbor WORD<0-128> port {slot/port[sub-port]} mac
<0x00:0x00:0x00:0x00:0x00:0x00> [vlan <1-4059>
```

3. Configure optional parameters if the default values do not meet your requirements:

- a. Configure the hop limit:

```
ipv6 hop-limit <0-255>
```

The default is 64.

- b. Configure ICMP network address unreachable messages:

```
ipv6 icmp addr-unreach
```

- c. Configure the ICMP error interval:

```
ipv6 icmp error-interval <1-2147483647>
```

The interval is in milliseconds. An interval of 0 results in no error messages. The default is 1000.

- d. Configure the ICMP error quota:

```
ipv6 icmp error-quota <0-2000000>
```

The default is 50.

- e. Configure ICMP port unreachable messages:

```
ipv6 icmp port-unreach
```

- f. Enable response to icmp echo multicast packets:

```
ipv6 icmp echo-multicast-request
```

The default is disabled.

- g. Enable ICMP network unreachable messages:

```
ipv6 icmp unreach-msg
```

The default is disabled.

### Examples

Add an IPv6 neighbor for a brouter port:

```
Switch:1(config)#ipv6 neighbor 3000:0:0:0:0:0:0:2 port 1/11 mac 00:0c:42:07:35:90
```

Add an IPv6 neighbor for a VLAN:

```
Switch:1(config)#ipv6 neighbor 3000::3 port 1/12 mac 01:02:03:04:05:06 vlan 20
```

### Variable Definitions

Use the data in the following table to use the **ipv6** commands in this procedure.

| Variable                 | Value                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>forwarding</i>        | Configures whether this entity is an IPv6 router with respect to the forwarding of datagrams received by, but not addressed to, this entity. Enable forwarding to act as a router. The default is enabled. |
| <i>hop-limit</i> <0-255> | Configures the hop limit. The default is 64.                                                                                                                                                               |

| Variable                                                                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>icmp addr-unreach</code>                                                                                                       | Enables ICMP address unreachable messages. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>icmp echo-multicast-request</code>                                                                                             | Enable response to icmp echo multicast packets. The default is enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>icmp error interval &lt;1-2147483647&gt;</code>                                                                                | Configures the interval (in milliseconds) for sending ICMPv6 error messages. The default is 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>icmp error-quota &lt;0-2000000&gt;</code>                                                                                      | Configures the number of ICMP error messages that can be sent during the ICMP error interval. A value of zero instructs the system not to send an ICMP error messages. The default value is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>icmp port-unreach</code>                                                                                                       | Enables ICMP port unreachable messages. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>icmp unreachable-msg</code>                                                                                                    | Enables ICMP network unreachable messages. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>neighbor WORD&lt;0-128&gt; port {slot/port [sub-port]} mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt; [vlan &lt;1-4059&gt; ]</code> | <p>Creates a static IPv6 neighbor with the following variables:</p> <ul style="list-style-type: none"> <li><code>WORD&lt;0-128&gt;</code> specifies the IPv6 address of the neighbor in hexadecimal colon format.</li> <li><code>{slot/port [/sub-port]}</code> specifies the router port to use for the neighbor.</li> </ul> <p>Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> <ul style="list-style-type: none"> <li><code>mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code> specifies the MAC address of the neighbor.</li> <li><code>vlan &lt;1-4059&gt;</code> specifies the VLAN ID to use for the neighbor.</li> </ul> <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>Static IPv6 neighbors do not maintain any state machine and the system assumes that they are always reachable.</p> |

## Configure an IPv6 Interface

The information in this section can help you configure an IPv6 interface to make IPv6 active on the interface and fine-tune IPv6 neighbor discovery to control the frequency of protocol traffic.

By default, IPv6 forwarding is enabled on an interface.

Compared to IPv4/ARP, the IPv6 neighbor discovery mechanism maintains more protocol state, timers, and protocol traffic overhead.

There are two important tunable parameters for IPv6 ND that can control the frequency of protocol traffic:

- `ipv6 interface reachable-time`
- `ipv6 interface retransmit-timer`

### Before You Begin

- Before you can assign an IPv6 address to the interface, you must configure an IPv6 interface for a VLAN or brouter port.

You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address.

The switch supports port-based and IPv6 protocol-based VLANs.

For information about how to configure VLANs, see the followings:

- [VLAN Configuration Using CLI](#) on page 3748
- [MultiLink Trunking and Split MultiLink Trunking](#) on page 2334

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Create IPv6 interface:

```
ipv6 interface
```

3. Configure optional parameters to meet your requirements:

- a. Enable IPv6 router advertisement on the interface:

```
ipv6 nd send-ra
```

- b. Configure the maximum number of hops before packets drop:

```
ipv6 interface hop-limit <1-255>
```

- c. Configure the link-local address:

```
ipv6 interface link-local WORD<0-19>
```

- d. Configure the mac offset:

```
ipv6 interface mac-offset <MAC-offset>
```

- e. Configure the maximum transmission unit (MTU):
 

```
ipv6 interface mtu <1280-9500>
```
- f. Configure an interface description:
 

```
ipv6 interface name WORD<0-255>
```
- g. Configure the time a neighbor is considered reachable after receiving a reachability confirmation:
 

```
ipv6 interface reachable-time <1-3600000>
```
- h. Configure the time between retransmissions of neighbor solicitation messages to a neighbor when resolving the address or when probing the reachability of a neighbor:
 

```
ipv6 interface retransmit-timer <1-4294967295>
```
- i. Configure a brouter port as part of an IPv6 VLAN:
 

```
ipv6 interface vlan <1-4059>
```
- j. Configure the interface to perform IPv6 unicast reverse path forwarding:
  - To enable urpf-mode boot flag, enter:
 

```
boot config flags urpf-mode
```
  - To configure unicast reverse path forwarding, enter:
 

```
ipv6 rvs-path-chk mode {strict|exist-only}
```

### Example

Create and administratively enable the interface:

```
Switch:1(config-if)#ipv6 interface enable
```

#### Note

In contrast to IPv6 interface creation and address assignment in EDM, you use the **ipv6 interface** CLI command to create an interface and specify a single global address in one step.

### Variable Definitions

Use the data in the following table to use the **ipv6 interface** command.

| Variable                     | Value                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>hop-limit</i> <1-255>     | Configures the maximum hops. The default is 64.                                                                       |
| <i>link-local</i> WORD<0-19> | Specifies the 64-bit interface ID used to calculate the actual link-local address as a name up to 19 characters long. |

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mac-offset</code><br><code>&lt;MAC-offset&gt;</code>         | <p>Use <code>mac-offset</code> to request a particular MAC for an IPv6 VLAN.</p> <p><b>Note:</b><br/>This parameter applies only to VLANs.</p> <p>You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.</p>                                                                                                                                                                               |
| <code>mtu &lt;1280-9500&gt;</code>                                 | <p>Configures the maximum transmission unit for the interface: 1280-1500, 1850, or 9500. This value must be the same for all addresses defined on this interface. The default is 1500.</p> <p>Different hardware platforms support different MTU values. To see what values your switch supports, use the CLI command completion help.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>name WORD&lt;0-255&gt;</code>                                | <p>Assigns a descriptive name. | <code>reachable-time</code><br><code>&lt;0-3600000&gt;</code>      | <p>Controls how long IPv6 neighbor entries learned on an interface remain in the REACHABLE state (as described in RFC 4861). The system randomizes the value you configure, per RFC specifications, to be 50%-150% of the configured value.</p> <p>By default the reachable-time base value is 30 seconds, with an actual 15-45 second range when you consider the randomization factor.</p> <p>The default is 3000 milliseconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>retransmit-timer</code><br><code>&lt;0-4294967295&gt;</code> | <p>Controls the time, in milliseconds, between retransmission of Neighbor Solicitation messages when the system attempts to resolve or reconfirm the reachability of an IPv6 neighbor.</p> <p>By default, the system sends three Neighbor Solicitation messages with a one second interval between each message. If the system does not receive a corresponding Neighbor Advertisement within an interval equal to 3 X retransmit-timer milliseconds, the system declares the IPv6 neighbor unreachable.</p> <p><b>Tip:</b><br/>You can increase the retransmit-timer to extend the interval that the switch waits until it declares the neighbor unreachable. For example: a retransmit-timer value of 5000 means the switch waits 3 X 5000 milliseconds which equals 15000 milliseconds or 15 seconds.</p> <p>The default is 1000 milliseconds</p> |
| <code>vlan &lt;1-4059&gt;</code>                                   | <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.</p>                                                                                                                                                                                                                                                                                                                        |

Use the data in the following table to use the **ipv6 rvs-path-chk** command.

| Variable                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mode</i><br>{ <i>strict</i>   <i>exist-only</i> } | Specifies the mode for Unicast Reverse Path Forwarding (uRPF).<br>In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet.<br>In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router. |

Use the data in the following table to use the **interface** command.

| Variable                                                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/ <i>sub-port</i> ]<br>[- <i>slot/port</i> [/ <i>sub-port</i> ]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Assigning IPv6 addresses to a brouter port or VLAN

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IPv6 address:

```
ipv6 interface address WORD<0-255>
```

### Example

Assign an IPv6 address specifying the full 128 bits of the address:

```
Switch:1(config-if)#ipv6 interface address 30:0:0:0:0:0:0:ffff/64
```

Assign an IPv6 address specifying only the upper 64 bits of the address:

```
Switch:1(config-if)#ipv6 nd prefix-interface <prefix> eui <1-3>
```

In this example you specify only the upper 64 bits of the address and allow the system to auto-generate the lower 64 bits from the MAC address.

### Variable Definitions

The following table defines parameters for the **ipv6 interface address** command.

| Variable            | Value                                            |
|---------------------|--------------------------------------------------|
| <i>WORD</i> <0-255> | Specifies the IPv6 address for the port or VLAN. |

The following table defines parameters for the **interface** command.

| Variable                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                                                                    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| { <i>slot/port</i> [/ <i>sub-port</i> ][/ <i>slot/port</i> [/ <i>sub-port</i> ]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Configure IPv6 Route Preferences

Configure IPv6 route preferences to give preference to routes learned for a specific protocol.

### Before You Begin

#### Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. Change a prefix list or a routing protocol before you activate the protocols.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

- Configure the route preference:

```
ipv6 route preference protocol <static|ebgp|ibgp|ospfv3-intra|ospfv3-
inter|ospfv3-extern1|ospfv3-extern2|ripng|spbm-level1> <0-255>
```

- Confirm that the configuration is correct:

```
show ipv6 route preference [vrf WORD<1-16> | vrfids WORD<0-512>]
```

### Example

Configure the route preference to RIPng and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ipv6 route preference protocol ripng 10
Switch:1(config)#show ipv6 route preference
=====
IPv6 Route Preference - GlobalRouter
=====
PROTOCOL          DEFAULT    CONFIG
-----
LOCAL              0          0

OSPFv3_E2         125        125
IBGP               175        175
```

### Variable definitions

Use the data in the following table to use the **ipv6 route preference** and the **show ipv6 route preference** commands.

| Variable              | Value                                                               |
|-----------------------|---------------------------------------------------------------------|
| <0-255>               | Assigns a route preference value.                                   |
| <i>ebgp</i>           | Configures the preference for protocol type EBGp.                   |
| <i>ibgp</i>           | Configures the preference for protocol type IBGP.                   |
| <i>ospfv3-extern1</i> | Configures the preference for protocol type OSPFv3 external type 1. |
| <i>ospfv3-extern2</i> | Configures the preference for protocol type OSPFv3 external type 2. |
| <i>ospfv3-intra</i>   | Configures the preference for protocol type OSPFv3 intra-area.      |
| <i>ospfv3-inter</i>   | Configures the preference for protocol type OSPFv3 inter-area.      |
| <i>ripng</i>          | Configures the preference for protocol type RIPng.                  |
| <i>spbm-level1</i>    | Configures the preference for protocol type spbm-level1.            |
| <i>static</i>         | Configures the preference for protocol type static.                 |

## View Global IPv6 Information

View and manage general IPv6 information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IPv6 information for an interface:

```
show ipv6 interface [gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}] [loopback <1-256>] [mgmtEthernet {slot/port[/
sub-port] [-slot/port[/sub-port]] [,...]}] [tunnel <1-2000>] [vlan
<1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

#### Note

The *mgmtEthernet* parameter is only supported on VSP 8600 Series.

3. Display IPv6 tunnel information:

```
show ipv6 interface tunnel <1-2000>
```

4. Display IPv6 address information for the specified slot and port:

```
show ipv6 address interface gigabitethernet {slot/port[/sub-port] [-
slot/port[/sub-port]] [,...]} [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

5. Display IPv6 address information for the specified IPv6 address:

```
show ipv6 address interface ip WORD<0-46> [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

6. Display IPv6 address information for the specified tunnel:

```
show ipv6 address interface tunnel <1-2000>
```

7. Display IPv6 address information for the specified VLAN:

```
show ipv6 address interface vlan <1-4059>
```

8. Display the current state of IPv6 forwarding:

```
show ipv6 forwarding [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

9. Display information on the current state of IPv6 functionality:

```
show ipv6 global [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

10. Display IPv6 Gigabit Ethernet (GbE) router advertisement information:

```
show ipv6 nd interface gigabitethernet [{slot/port[-slot/port]} [,...]]
```

11. Display IPv6 Gigabit Ethernet (GbE) router advertisement information:

```
show ipv6 nd interface gigabitethernet [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

12. Display IPv6 router advertisement information for the management port:

```
show ipv6 nd interface mgmtEthernet mgmt
```

#### Note

This step applies to VSP 8600 Series only.

13. Display IPv6 VLAN router advertisement information:

```
show ipv6 nd interface vlan [<1-4059>]
```

14. Display detailed information in IPv6 router advertisements:  

```
show ipv6 nd-prefix detail [vrf WORD<1-16> | vrfids WORD<0-512>]
```
15. Display GbE interface information in IPv6 router advertisements:  

```
show ipv6 nd-prefix interface gigabitethernet [{slot/port[-slot/port]} [,...]]
```
16. Display GbE interface information in IPv6 router advertisements:  

```
show ipv6 nd-prefix interface gigabitethernet [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```
17. Display VLAN interface information in IPv6 router advertisements:  

```
show ipv6 nd-prefix interface vlan [<1-4059>]
```
18. Display VLAN information in IPv6 router advertisements:  

```
show ipv6 nd-prefix vlan <1-4059>
```
19. Display IPv6 neighbor entries with specific router port numbers:  

```
show ipv6 neighbor interface gigabitethernet {slot/port[/sub-port]}
```
20. Display IPv6 neighbor information for neighbors of the specified type:  

```
show ipv6 neighbor type <1-4>
```
21. Display IPv6 neighbor information:  

```
show ipv6 neighbor [WORD<0-46>]
```

### Examples

```
Switch:1(config)#show ipv6 interface vlan
```

```

| <i>loopback</i> < <i>1-256</i> >                                                            | Specifies the loopback interface ID value. If you do not specify a value, the output includes all IPv6 loopback interfaces.                                                                                                                                                                                                                                   |
| { <i>slot/port</i> [/ <i>sub-port</i> ]<br>[- <i>slot/port</i> [/ <i>sub-port</i> ]][,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

| Variable                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type &lt;1-4&gt;</code>        | Specifies the neighbor type as one of the following: <ul style="list-style-type: none"> <li>• 1 - other</li> <li>• 2 - dynamic</li> <li>• 3 - static</li> <li>• 4 - local</li> </ul>                                                                                                                                                                                                                                                   |
| <code>tunnel &lt;1-2000&gt;</code>   | Specifies the tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>vlan &lt;1-4059&gt;</code>     | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrfWORD&lt;1-16&gt;</code>     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>vrfidsWORD&lt;1-256&gt;</code> | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Create IPv6 Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface. Specify the name of the VRF context in [Step 1](#).
- Create static routes for management purposes on VSP 8600 Series:
  - Specify the `mgmtRouter vrf` in [Step 1](#) to configure static routes for the OOB port.
  - Use Global Configuration mode in [Step 1](#) to configure static routes in the GRT for the inband VLAN or loopback interface.

VSP 8600 Series uses the routing stack to create static routes for data traffic as well as management purposes. For all other platforms, static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management Instance Configuration using the CLI](#) on page 77. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

### About This Task

Not all parameters are available in non-default VRFs.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
Optional: router vrf WORD<1-16>
```

2. Enable IPv6 static routes globally:

```
ipv6 route static enable
```

If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM.

3. Configure a static route:

```
ipv6 route WORD<0-46> [enable] [cost <1-65535>] [next-hop WORD<0-46>]
[preference <1-255>] [tunnel <1-2000>] [port {slot/port[sub-port]}]
[vlan <1-4059>]
```

4. (Optional) Disable all IPv6 static routes:

```
no ipv6 route static enable
```

5. (Optional) Permanently delete the IPv6 static route configuration:

```
clear ipv6 route static [vrf WORD<1-16> | vrfids WORD<0-512>]
```

### Examples

Enable IPv6 static routes globally:

```
Switch:1(config)#ipv6 route static enable
```

Create and enable a static route through a global nexthop:

```
Switch:1(config)#ipv6 route 4000::/64 cost 1 next-hop 3000::2 enable
```

Create and enable a static route through an outgoing interface (VLAN or router port):

```
Switch:1(config)# ipv6 route 4000::/64 cost 1 vlan 1900 enable
```

Create and enable a static route through a link local nexthop and an outgoing interface:

```
Switch:1(config)# ipv6 route 4000::/64 cost 1 next-hop fe80::1 vlan 1900
enable
```

In the preceding example, you must specify the outgoing interface so that the system can apply the correct context to the link-local address.

### Variable Definitions

Use the data in the following table to use the **ipv6 route** command.

| Variable                    | Value                                                                                                                                                                                                                                                       |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-46>          | Specifies the IPv6 destination address and prefix.                                                                                                                                                                                                          |
| <i>enable</i>               | Enables the static route. The default is enabled.                                                                                                                                                                                                           |
| <i>cost</i> <1-65535>       | Specifies the cost or distance ratio to reach the destination for this static route. The default is 1.                                                                                                                                                      |
| <i>next-hop Word</i> <0-46> | Specifies the IPv6 address of the next hop on this route. You do not need to specify the next hop if the devices directly connect to one another. Configure the next hop if the two nodes do not share the same network prefix but reside on the same link. |

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference &lt;1-255&gt;</code> | Specifies the routing preference of the destination IPv6 address. The default is 5.                                                                                                                                                                                                                                                                                                                                                    |
| <code>{slot/port[/sub-port]}</code>   | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                           |
| <code>tunnel &lt;1-2000&gt;</code>    | Specifies the tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>vlan &lt;1-4059&gt;</code>      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## View Routes Information

View routes information to view the current configuration.

### About This Task

Not all parameters are available in non-default VRFs.

IPv6 host routes created for the IPv6 local interfaces do not display in the routing table.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show route information for alternative routes:  

```
show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<1-256>]
```
3. Show the number of OSPF, RIP, static, and local routes:  

```
show ipv6 route count-summary [vrf WORD<1-16> | vrfids WORD<1-256>]
```
4. Show route information for a destination:  

```
show ipv6 route dest WORD<0-46> [vrf WORD<1-16> | vrfids WORD<1-256>]
```
5. Show route information for a port:  

```
show ipv6 route gigabitethernet {slot/port[sub-port]}
```
6. Show route information for a next-hop address:  

```
show ipv6 route next-hop WORD<0-46> [vrf WORD<1-16> | vrfids WORD<1-256>]
```
7. Show route information for an SPBM IPv6 route:  

```
show ipv6 route spbm-nh-as-mac
```
8. Show route information for a static route:  

```
show ipv6 route static [vrf WORD<1-16> | vrfids WORD<1-256>]
```
9. Show route information for a tunnel:  

```
show ipv6 route tunnel <1-2000>
```
10. Show route information for a VLAN:  

```
show ipv6 route vlan <1-4059>
```

**Example**

```
Switch:1(config-if)#show ipv6 route
```

```

## Variable Definitions

Use the data in the following table to use the **show ipv6 route** command.

| Variable                         | Value                                                                                                                                                                        |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count-summary</i>             | Shows the total number of OSPF, static, and local routes.                                                                                                                    |
| <i>dest WORD&lt;0-46&gt;</i>     | Specifies the IPv6 destination network address. The prefix value must match the prefix length.                                                                               |
| <i>next-hop WORD&lt;0-46&gt;</i> | Specifies the IPv6 address of the next hop on this route.                                                                                                                    |
| <i>spbm-nh-as-mac</i>            | Shows the B-MAC address as the next hop rather than the host name.                                                                                                           |
| <i>{slot/port[/sub-port]}</i>    | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>static</i>                    | Shows static IPv6 routes.                                                                                                                                                    |
| <i>tunnel &lt;1-2000&gt;</i>     | Shows route entries for a specific tunnel ID.                                                                                                                                |
| <i>vlan&lt;1-4059&gt;</i>        | Shows route entries for a specific VLAN ID.                                                                                                                                  |
| <i>vrfWORD&lt;1-16&gt;</i>       | Shows the VRF name.                                                                                                                                                          |
| <i>vrfidsWORD&lt;1-256&gt;</i>   | Shows the VRF ID.                                                                                                                                                            |

## Creating an IPv6 CLIP interface

### About This Task

Perform this procedure to create an IPv6 CLIP interface and associate it with a specific VRF.

### Procedure

1. Enter Loopback Interface Configuration mode  

```
enable
```

```
configure terminal
```

```
interface Loopback <1-256>
```
2. Create an IPv6 loopback interface address:  

```
ipv6 interface address WORD <0-255> vrf WORD <1-16>
```
3. (Optional) Enter a name for the IPv6 address:  

```
ipv6 interface name WORD <0-64>
```
4. Ensure the configuration is correct:  

```
show ipv6 interface loopback <1-256>
```

### Example

```
Switch:1#show ipv6 interface loopback
```

```
=====
```

```
Loopback Ipv6 Interfaces
```

```

### Variable definitions

Use the data in the following table to use the **ipv6** commands.

| Variable               | Value                                                      |
|------------------------|------------------------------------------------------------|
| <i>WORD</i> <1-256>    | Specifies the CLIP interface ID.                           |
| <i>WORD</i> <0-255>    | Specifies the IPv6 address.                                |
| <i>vrf WORD</i> <1-16> | Specifies the VRF name.                                    |
| <i>WORD</i> <0-64>     | Specifies the I-SID name associated with the IPv6 address. |

## Enabling IPv6 ECMP

### About This Task

Use the following procedure to enable IPv6 ECMP globally or on a specific VRF. IPv6 ECMP is disabled by default.

### Procedure

- Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
 

```
enable

configure terminal

Optional: router vrf WORD<1-16>
```
- Enter the following command to enable IPv6 ECMP:
 

```
ipv6 ecmp enable
```
- Set the default value, IPv6 ECMP is disabled by default.
 

```
default ipv6 ecmp enable
```
- Disable IPv6 ECMP globally:
 

```
no ipv6 ecmp enable
```

*Variable definitions*

Use the data in the following table to use the **ipv6 ecmp** command.

| Variable            | Value                                                                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code> | Enables IPv6 ECMP globally.<br><br><b>Note:</b> <ul style="list-style-type: none"> <li>Enabling IPv6 ECMP sets the maximum number of paths configured to its default value. This value is either 4 or 8 depending on your hardware platform.</li> <li>Disabling IPv6 ECMP sets the maximum number of paths configured to 1.</li> </ul> |

## Configuring maximum number of ECMP paths

### Before You Begin

Enable ECMP on the switch before configuring the max-path value. For more information, see [Enabling IPv6 ECMP](#) on page 1916.

### About This Task

Use the following procedure to configure the maximum number of ECMP paths.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the maximum number of ECMP paths.

```
ipv6 ecmp max-path <ECMP-Paths>
```

3. Set the configured maximum number of ECMP paths to its default value:

```
default ipv6 ecmp max-path
```

#### Note

The default value for max-path is the maximum value, which varies depending on your hardware platform.

### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable ECMP on the switch:

```
Switch:1(config)#ipv6 ecmp enable
```

Configure the maximum number of ECMP paths to 4:

```
Switch:1(config)#ipv6 ecmp max-path 4
```

### Variable definitions

Use the data in the following table to use the **ipv6 ecmp max-path** command.

| Variable     | Value                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ECMP-Paths> | Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in <a href="#">VOSS Release Notes</a> .<br>When ECMP is enabled, the default value is either 4 or 8 depending on your hardware platform. |

## Enabling or disabling IPv6 ICMP multicast

On disabling the ICMP multicast processing, ICMPv6 Echo Request packets sent to IPv6 multicast addresses are dropped when they reach the control plane.

### About This Task

Use this procedure to enable or disable the IPv6 ICMP multicast on the global router.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable IPv6 ICMP multicast, enter:

```
ipv6 icmp echo-multicast-request
```

3. Disable IPv6 ICMP multicast, enter:

```
no ipv6 icmp echo-multicast-request
```

4. Set IPv6 ICMP multicast to default state, enter:

```
default ipv6 icmp echo-multicast-request
```

#### Note

By default, the IPv6 ICMP multicast feature is enabled.

5. View the IPv6 ICMP multicast state:

```
show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]
```

## View IPv6 ICMP Statistics

View IPv6 ICMP statistics on an interface for ICMP messages sent over a particular interface.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv6 ICMP statistics:

```
show ipv6 interface icmpstatistics [gigabitethernet <slot/port[/sub-
port]> | loopback <1-256> | mgmtethernet mgmt|tunnel <1-2000> | vlan
<1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

View ICMP statistics:

```
Switch:1>show ipv6 interface icmpstatistics
=====
                                 Icmp Stats
=====

Icmp stats for IfIndex = 192

IcmpInMsgs: 0
IcmpInErrors: 0
IcmpInDestUnreachs : 0
IcmpInAdminProhibs : 0
IcmpInTimeExcds : 0
IcmpInParmProblems : 0
IcmpInPktTooBigs : 0
IcmpInEchos : 0
IcmpInEchoReplies : 0
IcmpInRouterSolicits : 0
IcmpInRouterAdverts : 0
InNeighborSolicits : 0
InNbrAdverts : 0
IcmpInRedirects : 0
IcmpInGroupMembQueries : 0
IcmpInGroupMembResponses : 0
```

### Variable Definitions

Use the data in the following table to use the **show ipv6 interface icmpstatistics** command

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                               | Shows ICMP statistics for the specific interface index. If you do not specify an interface index, the command output includes all IPv6 ICMP interfaces.<br>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>gigabitethernet</i> { <i>slot/port[/sub-port]</i> } | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>loopback</i> <1-256>>                               | Identifies a loopback interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Variable                                                                                  | Value                                                                                                                         |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <i>mgmtethernet mgmt</i><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Identifies the management interface. This parameter only applies to hardware with a dedicated, physical management interface. |
| <i>tunnel &lt;1-2000&gt;</i>                                                              | Identifies a 6in4 tunnel ID.                                                                                                  |
| <i>vrf WORD&lt;1-16&gt;</i>                                                               | Specifies the VRF name.                                                                                                       |
| <i>vrfids WORD&lt;0-512&gt;</i>                                                           | Specifies the VRF ID.                                                                                                         |

## Enabling Stateless Address Autoconfiguration

Enable IPv6 Stateless Address Autoconfiguration to generate addresses using a combination of locally available information and information advertised by routers.

The default is disabled.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable IPv6 autoconfiguration:

```
ipv6 autoconfig
```

### Example

```
Switch:1(config)#ipv6 autoconfig
```

The following example shows a sample output for the **show ipv6 global** command.

```
Switch:1#show ipv6 global
  forwarding                : disable
  default-hop-cnt           : 64
  number-of-interfaces      : 2
  icmp-error-interval       : 1000
  icmp-error-quota          : 50
  icmp-unreach-msg          : disable
  icmp-addr-unreach-msg     : enable
  icmp-port-unreach-msg     : enable
  icmp-echo-multicast-request : enable
  static-route-admin-status : enable
  alternative-route         : enable
  ecmp                      : disable
  ecmp-max-path             : 1
  source-route              : disable
  host-autoconfig           : enable
```

## Configure Route Advertisement on the Management Port

Configure route advertisement in IPv6 on the management port for neighbor discovery (ND).

**Note**

This procedure supports Layer 2 or Layer 3 route advertisement on VSP 8600 Series only.

**Procedure**

1. Enter mgmtEthernet Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface mgmtEthernet <mgmt | mgmt2>
```
2. Configure the number of neighbor solicitation messages from duplicate address detection:  

```
ipv6 nd dad-ns <0-600>
```
3. Configure the hop limit sent in router advertisements:  

```
ipv6 nd hop-limit <0-255>
```

**Example**

```
Switch:1(config-if)#ipv6 nd dad-ns 2
Switch:1(config-if)#ipv6 nd hop-limit 2
Switch:1(config-if)#show ipv6 nd interface mgmtethernet mgmt
```

```
=====
                                     Mgmt Ipv6 Nd
=====
```

| IFID | MGMT-IF | RTR-ADV | MAX-INT | MIN-INT | LIFETIME | MANAG | OTHER | DAD-NS | MTU   | HOP   | REACHABLE | RETRANSMIT |
|------|---------|---------|---------|---------|----------|-------|-------|--------|-------|-------|-----------|------------|
|      |         |         |         |         |          | FLAG  | CONF  |        |       | LIMIT | TIME      | TIME       |
| 64   | mgmt    | False   | 600     | 200     | 0        | False | False | 2      | 0 (d) | 2 (s) | 0 (d)     | 0 (d)      |

Note: (s) = Set, (d) = Default, (i) = inherit.

1 out of 5 Total Num of Ipv6 ND Entries displayed.

*Variable definitions*

Use the data in the following table to use the **ipv6 nd** command.

| Variable                 | Value                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dad-ns</i> <0-600>    | Specifies the number of neighbor solicitation messages for duplicate address detection (DAD).<br>A value of 0 disables the DAD process on this interface.<br>A value of 1 sends one advertisement without retransmissions.<br>The default is 1.                   |
| <i>hop-limit</i> <0-255> | Specifies the current hop limit field sent in router advertisements from this interface.<br>The value must be the current diameter of the Internet.<br>A value of zero indicates that the advertisement does not specify a hop-limit value.<br>The default is 64. |

## Configure Process-redirect for the Management Port

Configure process-redirect messages to honor or ignore redirect messages for the management port. Redirect messages are visible only when Stateless Address Autoconfiguration is configured on switches capable of routing IPv6 traffic.

The default is disabled.

### Note

This procedure supports Layer 2 or Layer 3 process-redirect on VSP 8600 Series only.

### Before You Begin

- Disable IPv6 forwarding.
- Enable Stateless Address Autoconfiguration
- Create an IPv6 interface.
- Configure an IPv6 address.

### Procedure

1. Enter mgmtEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface mgmtEthernet <mgmt | mgmt2>
```

2. Configure process-redirect messages:

```
ipv6 interface process-redirect
```

3. Verify that process-redirect messages are configured on the management port.

```
Switch:1(config-if)#ipv6 interface process-redirect
```

### Example

The following examples shows a sample output of the **show ipv6 interface process-redirect** command.

```
Switch:1#show ipv6 interface process-redirect
=====
                        Process ICMP redirect status
=====
IFINDX      DESCR          VLAN      STATUS
-----
64          PORT-mgmt        4092      Enabled
192         VLAN-5           5         Disabled
2050        VLAN-2           2         Disabled
```

## Viewing IPv6 default routers

View the table of default routers learned from router advertisement messages.

A maximum of four routers are visible in the default routers list.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Show IPv6 default routers:

```
show ipv6 default-routers
```

**Example**

```
Switch:1#show ipv6 default-routers
=====
                Default Routers
NET ADDRESS                VLAN  LIFETIME  IS ACTIVE
-----
fe80::211:58ff:fe2b:fc00    mgmt   1778      YES
fe80::215:e8ff:fe6e:2800    mgmt   1657      NO
```

## Configuring an IPv6 prefix list

Use IPv6 prefix lists to allow or deny specific IPv6 route updates. A prefix list policy specifies route prefixes to match. When there is a match, the route is used.

**About This Task**

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPv6 prefix list:

```
ipv6 prefix-list <WORD 1-64> <WORD 1-256> [ge <0-128>] [le <0-128>]
[id <1-2147483647>]
```

Use the same command to add additional prefixes to the list.

3. To rename the list:

```
ipv6 prefix-list <WORD 1-64> name <WORD 1-64>
```

4. Display the prefix list:

```
show ipv6 prefix-list <WORD 1-256> [vrf WORD<1-16>] [vrfids
WORD<1-512>] [WORD <1-64>]
```

**Example**

Create an IPv6 prefix list:

```
Switch:1<config>#ipv6 prefix-list list4 2001:DB8::/32 ge 32 le 32
```

To rename the list:

```
Switch:1<config>#ipv6 prefix-list list4 name list5
```

### Variable Definitions

Use the data in the following table to use the **ipv6 prefix-list** command.

| Variable          | Value                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------|
| <WORD 1-64>       | Specifies the IPv6 prefix-list name.                                                                                      |
| <WORD 1-256>      | Specifies the IPv6 prefix and length.                                                                                     |
| ge <0-128>        | Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |
| id <1-2147483647> | Specifies the Prefix list ID.                                                                                             |
| le <0-128>        | Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks. |
| name <WORD 1-64>  | Names the prefix list. The default value is none.                                                                         |

Use the data in the following table to use the **show ipv6 prefix-list** command.

| Variable           | Value                                                                |
|--------------------|----------------------------------------------------------------------|
| <WORD 1-256>       | Specifies the IPv6 prefix and length.                                |
| vrf WORD<1-16>     | Specifies the name of the VRF.                                       |
| vrfids WORD<0-512> | Specifies the ID of the VRF and is an integer in the range of 0-512. |
| WORD<1-64>         | Specifies a prefix list, by name, to use for the command output.     |

## Clear IPv6 Statistics

Clear all IPv6 statistics if you do not require previous statistics.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Clear all the IPv6 statistics:
 

```
clear ipv6 statistics all [vrf WORD<1-16> | vrfids WORD<0-512>]
```
3. Clear interface statistics:
 

```
clear ipv6 statistics interface [general|icmp] [gigabitethernet {slot/port[/sub-port]} | loopback <1-256> | mgmtethernet mgmt | tunnel <1-2000> | vlan <1-4059>] [vrf WORD<1-16> | vrfids WORD<0-512>]
```
4. Clear TCP statistics:
 

```
clear ipv6 statistics tcp [vrf WORD<1-16> | vrfids WORD<0-512>]
```
5. Enter the following command to clear UDP statistics:
 

```
clear ipv6 statistics udp [vrf WORD<1-16> | vrfids WORD<0-512>]
```

## Variable Definitions

Use the information in the following table to use the **clear ipv6 statistics** commands.

| Variable                                                                                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet {slot/port[/sub-port]}</i>                                             | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                               |
| <i>loopback &lt;1-256&gt;&gt;</i>                                                         | Identifies a loopback interface.                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>mgmtethernet mgmt</i><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series. | Identifies the management interface. This parameter only applies to hardware with a dedicated, physical management interface.                                                                                                                                                                                                                                                                                              |
| <i>tunnel &lt;1-2000&gt;</i>                                                              | Identifies a 6in4 tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>vlan&lt;1-4059&gt;</i>                                                                 | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf WORD&lt;1-16&gt;</i>                                                               | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>vrfids WORD&lt;0-512&gt;</i>                                                           | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

## View IPv6 Statistics on an Interface

View IPv6 statistics to view information about the IPv6 datagrams on an interface.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:  

```
show ipv6 interface statistics [gigabitethernet <slot/port[/sub-port]>
| loopback <1-256> | mgmtethernet mgmt | tunnel <1-2000> | vlan
<1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

View IPv6 statistics on an interface:

```
Switch:1>enable
Switch:1#show ipv6 interface statistics
```

```
=====
                        Interface Stats
=====
```

```
If Stats for mgmt, IfIndex = 64
```

```

InReceives: 404
InHdrErrors: 0
InTooBigErrors : 0
InNoRoutes : 0
InAddrErrors : 0
InUnknownProtos : 0
InTruncatedPkts : 0
InDiscards : 0
InDelivers : 404
OutForwDatagrams : 0
OutRequests : 417
OutDiscards : 0
OutFragOKs : 0
OutFragFails : 0
OutFragCreates : 0

--More-- (q = quit)

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 interface statistics** command

| Variable                                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/<br>port[/sub-port]}                                                    | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                                                                |

## Viewing IPv6 Connections using CLI

Use the procedures in this section to view IPv6 connections using CLI.

## View TCP and UDP Information

Perform this procedure to view the TCP and UDP configuration information for IPv6.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display IPv6 TCP connection information:  
show ipv6 tcp connections [vrf WORD<1-16> | vrfids WORD<0-512>]
3. Display IPv6 TCP listener information for the specified IPv6 address:  
show ipv6 tcp listener [vrf WORD<1-16> | vrfids WORD<0-512>]
4. Display IPv6 TCP properties  
show ipv6 tcp properties [vrf WORD<1-16> | vrfids WORD<0-512>]
5. Display IPv6 TCP statistics  
show ipv6 tcp statistics [vrf WORD<1-16> | vrfids WORD<0-512>]
6. Display IPv6 UDP information:  
show ipv6 udp endpoints [vrf WORD<1-16> | vrfids WORD<0-512>]

### Example

```
Switch:1>show ipv6 tcp connections
=====
TCP connection table info - GlobalRouter
=====
LOCALPORT   LOCALADDR           REMOTEPORT   REMOTEADDR         STATE
-----
21           0:0:0:0:0:0:0:0    0            0:0:0:0:0:0:0:0    listen
23           0:0:0:0:0:0:0:0    0            0:0:0:0:0:0:0:0    listen
Switch:1>show ipv6 tcp listener
=====
TCP listener table info - GlobalRouter
=====
LOCALPORT   LOCALADDR
-----
21           0:0:0:0:0:0:0:0
23           0:0:0:0:0:0:0:0
80           0:0:0:0:0:0:0:0
443         0:0:0:0:0:0:0:0
513         0:0:0:0:0:0:0:0

Switch:1#show ipv6 tcp properties
=====
TCP Global Properties - GlobalRouter
=====
RtoAlgorithm    constant
RtoMin          5002 milliseconds
RtoMax          60128 milliseconds
MaxConn         127

Switch:1#show ipv6 tcp statistics
=====
TCP Global Statistics - GlobalRouter
=====
ActiveOpens:    0
PassiveOpens:   5
AttemptFails:   0
```

```

EstabResets:      0
CurrEstab:        0
InSegs:           0
OutSegs:          0
RetransSegs:     0
InErrs:          0
OutRsts:          0
HCInSegs:        0
HCOutSegs:       0

Switch:1>show ipv6 udp endpoints

```

```

=====
                        UDP endpoint table info - GlobalRouter

0           0:0:0:0:0:0:0:0                               1220867644 0

```

## IPv6 Basic Configuration using EDM

Use the procedures in this section to configure IPv6 basics using EDM.

### Enable the IPv6-Mode Boot Config Flag

Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits.

This flag is disabled by default. Use this procedure to enable (set to true) the IPv6-mode boot config flag.

When the IPv6-mode boot config flag is enabled, the maximum number of IPv4 routing table entries decreases. For scaling information, see [VOSS Release Notes](#).

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**,
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Select the **EnableIpv6Mode** check box.
5. Select **Apply**.
6. Save the configuration, and then reboot the switch for the change to the IPv6-mode boot config flag to take effect.

### Configuring IPv6 globally

Global configuration includes the following:

- IPv6 alternative routes: To avoid traffic interruption, enable alternative routes globally on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

## Before You Begin

Change the VRF instance as required to configure IPv6 globally on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

## Procedure

1. In the navigation tree, expand the **Configuration > IPv6** folders.
2. Click **IPv6**.
3. Click the **Globals** tab.
4. In the **DefaultHopLimit** box, enter the preferred number of hops before packets drop.
5. To enable ICMP network unreachable messages, click **IcmpNetUnreach**.
6. In the **IcmpErrorInterval** box, enter the preferred interval for sending ICMPv6 error messages.
7. In the **IcmpErrorQuota** box, enter the preferred number of ICMP error messages that the system can send during the ICMP error interval.
8. To enable IPv6 multicast, click **IcmpMulticastRequestEnable**.
9. To enable IPv6 ICMP address unreachable messages, click **IcmpAddrUnreach**.
10. To enable IPv6 ICMP port unreachable messages, click **IcmpPortUnreach**.
11. To enable IPv6 autoconfiguration, click **Autoconfig**.
12. To enable IPv6 static routes globally, click **StaticRouteGlobalAdminEnabled**.
13. To enable IPv6 Source Routing, click **SourceRouteEnable**.
14. To clear all IPv6 static routes, click **RouteStaticClear**.
15. To enable IPv6 alternative routes, click **AlternativeRouteEnable**.
16. To configure IPv6 ECMP globally, select **enable** or **disable**, in the **EcmpEnable** option box.
17. In the **EcmpMaxPath** box, enter the preferred number of equal-cost paths.
18. Click **Apply**.

## Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Forwarding</b>        | Configures whether this switch is an IPv6 router with respect to the forwarding of datagrams received by, but not addressed to, the switch. Select <b>forwarding</b> for the switch to act as a router for IPv6 traffic. Select <b>notForwarding</b> to not act as a router for IPv6 traffic. The default is <b>forwarding</b> . You must enable forwarding to use Telnet or Ping with IPv6. |
| <b>DefaultHopLimit</b>   | Configures the hop limit. The default is 64.                                                                                                                                                                                                                                                                                                                                                 |
| <b>Interfaces</b>        | Shows the number of interfaces.                                                                                                                                                                                                                                                                                                                                                              |
| <b>IfTableLastChange</b> | Shows the date of the last interface table change.                                                                                                                                                                                                                                                                                                                                           |
| <b>IcmpNetUnreach</b>    | Enables ICMP network unreachable messages. The default is disabled.                                                                                                                                                                                                                                                                                                                          |

| Name                                 | Description                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IcmpErrorInterval</b>             | Configures the interval (in milliseconds) for sending ICMPv6 error messages. The default is 1000. An entry of 1 seconds results in no sent ICMPv6 error messages.                                                                                                                                                              |
| <b>IcmpErrorQuota</b>                | Configures the number of ICMP error messages that the system can send during the ICMP error interval. A value of zero specifies not to send any. The default value is 50.                                                                                                                                                      |
| <b>IcmpMulticastRequestEnable</b>    | Globally enables or disables the IPv6 ICMP echo multicast request feature. This is enabled by default.                                                                                                                                                                                                                         |
| <b>IcmpAddrUnreach</b>               | Enables or disabled ICMP address unreachable messages.<br>This is enabled by default.                                                                                                                                                                                                                                          |
| <b>IcmpPortUnreach</b>               | Enables or disables ICMP port unreachable messages.<br>This is enabled by default.                                                                                                                                                                                                                                             |
| <b>Autoconfig</b>                    | Enables or disables stateless address autoconfiguration.<br>This is disabled by default.                                                                                                                                                                                                                                       |
| <b>StaticRouteGlobalAdminEnabled</b> | Enables IPv6 static routes globally. If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM.<br>The default is enabled.                                                                                                                |
| <b>RouteStaticClear</b>              | Clears all IPv6 static routes.                                                                                                                                                                                                                                                                                                 |
| <b>SourceRouteEnable</b>             | Globally enables or disables the IPv6 Source Routing feature. It is disabled by default.                                                                                                                                                                                                                                       |
| <b>PrefixListTableSize</b>           | Displays the prefix list table size.                                                                                                                                                                                                                                                                                           |
| <b>RoutePrefTableSize</b>            | Displays the route preference table size.                                                                                                                                                                                                                                                                                      |
| <b>AlternativeRouteEnable</b>        | Globally enables or disables the IPv6 alternative route feature. By default, this feature is enabled.                                                                                                                                                                                                                          |
| <b>EcmpEnable</b>                    | Enables or disables the IPv6 ECMP globally. By default, it is disabled.                                                                                                                                                                                                                                                        |
| <b>EcmpMaxPath</b>                   | Globally configures the maximum number of ECMP paths.<br>The number of paths supported is either 1 to 4 or 1 to 8, depending on your hardware platform.<br>When ECMP is enabled, the default value is either 4 or 8 depending on your hardware platform.<br>You cannot configure this feature unless ECMP is enabled globally. |

## Viewing ICMP Statistics

View ICMP statistics for ICMP configuration information.

## Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **IPv6**.
3. Click **Interfaces** tab.
4. Select the interface on which you want to view the ICMP statistics.
5. Click **ICMPstats** option from the menu.

### **ICMP stats** Field Descriptions

Use the data in the following table to use the ICMP **Statistics** tab.

| Name                            | Description                                                                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InMsgs</b>                   | Specifies the total number of ICMP messages which the entity received.<br><br><b>Note:</b><br>This counter includes all those counted by icmpInErrors. |
| <b>InErrors</b>                 | Specifies the number of ICMP messages which the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, etc.).  |
| <b>InDestUnreachs</b>           | Specifies the number of ICMP Destination Unreachable messages received by the interface.                                                               |
| <b>InAdminProhibs</b>           | Specifies the number of ICMP destination unreachable/communication administratively prohibited messages received by the interface.                     |
| <b>InTimeExcds</b>              | Specifies the number of ICMP Time Exceeded messages by the interface.                                                                                  |
| <b>InParmProblems</b>           | Specifies the number of ICMP Parameter Problem messages received by the interface.                                                                     |
| <b>InPktTooBigs</b>             | Specifies the number of ICMP Packet Too Big messages received by the interface.                                                                        |
| <b>InEchos</b>                  | Specifies the number of ICMP Echo (request) messages received by the interface.                                                                        |
| <b>InEchoReplies</b>            | Specifies the number of ICMP Echo Reply messages received by the interface.                                                                            |
| <b>InRouterSolicits</b>         | Specifies the number of ICMP Router Solicit messages received by the interface.                                                                        |
| <b>InRouterAdvertisements</b>   | Specifies the number of ICMP Router Advertisement messages received by the interface.                                                                  |
| <b>InNeighborSolicits</b>       | Specifies the number of ICMP Neighbor Solicit messages received by the interface.                                                                      |
| <b>InNeighborAdvertisements</b> | Specifies the number of ICMP Neighbor Advertisement messages received by the interface.                                                                |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InRedirects</b>               | Specifies the number of ICMP Redirect messages received by the interface.                                                                                                                                                                                                                                                                                                        |
| <b>InGroupMembQueries</b>        | Specifies the number of ICMPv6 Group Membership Query messages received by the interface.                                                                                                                                                                                                                                                                                        |
| <b>InGroupMembResponses</b>      | Specifies the number of ICMPv6 Group Membership Response messages received by the interface.                                                                                                                                                                                                                                                                                     |
| <b>InGroupMembReductions</b>     | Specifies the number of ICMPv6 Group Membership Reduction messages received by the interface.                                                                                                                                                                                                                                                                                    |
| <b>OutMsgs</b>                   | Specifies the total number of ICMP messages which this interface attempted to send. Note that this counter includes all those counted by icmpOutErrors.                                                                                                                                                                                                                          |
| <b>OutErrors</b>                 | Specifies the number of ICMP messages which this interface did not send due to problems discovered within ICMP such as a lack of buffers. This value should not include errors discovered outside the ICMP layer such as the inability of IPv6 to route the resultant datagram. In some implementations there may be no types of error which contribute to this counter's value. |
| <b>OutDestUnreachs</b>           | Specifies the number of ICMP Destination Unreachable messages sent by the interface.                                                                                                                                                                                                                                                                                             |
| <b>OutAdminProhibs</b>           | Specifies the number of ICMP destination unreachable/communication administratively prohibited messages sent.                                                                                                                                                                                                                                                                    |
| <b>OutTimeExcds</b>              | Specifies the number of ICMP Time Exceeded messages sent by the interface.                                                                                                                                                                                                                                                                                                       |
| <b>OutParmProblems</b>           | Specifies the number of ICMP Parameter Problem messages sent by the interface.                                                                                                                                                                                                                                                                                                   |
| <b>OutPktTooBigs</b>             | Specifies the number of ICMP Packet Too Big messages sent by the interface.                                                                                                                                                                                                                                                                                                      |
| <b>OutEchos</b>                  | Specifies the number of ICMP Echo (request) messages sent by the interface.                                                                                                                                                                                                                                                                                                      |
| <b>OutEchoReplies</b>            | Specifies the number of ICMP Echo Reply messages sent by the interface.                                                                                                                                                                                                                                                                                                          |
| <b>OutRouterSolicits</b>         | Specifies the number of ICMP Router Solicitation messages sent by the interface.                                                                                                                                                                                                                                                                                                 |
| <b>OutRouterAdvertisements</b>   | Specifies the number of ICMP Router Advertisement messages sent by the interface.                                                                                                                                                                                                                                                                                                |
| <b>OutNeighborSolicits</b>       | Specifies the number of ICMP Neighbor Solicitation messages sent by the interface.                                                                                                                                                                                                                                                                                               |
| <b>OutNeighborAdvertisements</b> | Specifies the number of ICMP Neighbor Advertisement messages sent by the interface.                                                                                                                                                                                                                                                                                              |

| Name                          | Description                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>OutRedirects</b>           | Specifies the number of Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. |
| <b>OutGroupMembQueries</b>    | Specifies the number of ICMPv6 Group Membership Query messages sent.                                                            |
| <b>OutGroupMembResponses</b>  | Specifies the number of ICMPv6 Group Membership Response messages sent.                                                         |
| <b>OutGroupMembReductions</b> | Specifies the number of ICMPv6 Group Membership Reduction messages sent.                                                        |

## Configure an IPv6 Interface

You must configure an IPv6 interface for a VLAN or brouter port before you can assign an IPv6 address to the interface.

### Before You Begin

- You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address. The switch supports port-based, protocol-based, and MAC-source-based VLANs.

For information about how to configure VLANs, see [VLAN Configuration using EDM](#) on page 3780.

- Change the VRF instance as required to configure an IPv6 interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

You can also configure an IPv6 interface for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can create both types of interfaces.

### Procedure

- In the navigation pane, expand the **Configuration > IPv6** folders.
- Select **IPv6**.
- Select the **Interfaces** tab.
- Select **Insert**.
- In the **Interface** field, select **Port** or **VLAN**.
- Select a port or VLAN.
- Select **OK**.
- Select the **AdminStatus** field to activate the interface.
- Configure the remaining parameters as required.
- Select **Insert**.
- Select **Apply**.

**Interfaces** Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>            | Specifies the port or VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Identifier</b>           | Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>IdentifierLength</b>     | Shows the length of the identifier, in bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Descr</b>                | Specifies a description of the interface. The network management system also configures this string.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>VlanId</b>               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag. |
| <b>Type</b>                 | Shows the interface type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ReasmMaxSize(MTU)</b>    | Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500. Different hardware platforms support different MTU values.                                                                                                                                                                                                                                                                 |
| <b>PhysAddress</b>          | Specifies the media-dependent physical address. For Ethernet, this is a MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>AdminStatus</b>          | Specifies if IPv6 is active on this interface. The default is false (disabled).                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OperStatus</b>           | Specifies the current operational status of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ReachableTime</b>        | Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.                                                                                                                                                                                                                                                                                                                                                     |
| <b>RetransmitTimer</b>      | Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.                                                                                                                                                                                                                                                                                       |
| <b>CurHopLimit</b>          | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.                                                                                                                                                                                                                                      |
| <b>MulticastAdminStatus</b> | The option to select <b>MulticastAdminStatus</b> is disabled. You cannot configure the administrative status for multicast in this context.                                                                                                                                                                                                                                                                                                                                                         |
| <b>MacOffset</b>            | Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.                                                                                                                                                                                                                                               |
| <b>RSMLTEnable</b>          | Shows whether RSMLT is enabled on the interface. The default value is disabled (false).                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ProcessRedirect</b>      | Shows whether ND Redirect messages processing is enabled or disabled on this interface. The default value is disabled (false).                                                                                                                                                                                                                                                                                                                                                                      |

## Viewing IPv6 Statistics for an Interface

View IPv6 statistics to view information about the IPv6 datagrams on an interface.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **IPv6**.
3. Click the **Interfaces** tab.
4. Select an interface.
5. Click **IfStats**.
6. (Optional) Select one or more values, and then click on the type of graph to graph the data.

### **Statistics** Field Descriptions

Use the data in the following table to use the **Statistics** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InReceives</b>      | Shows the total number of input datagrams received by the interface, including those received in error.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>InHdrErrors</b>     | Shows the number of input datagrams discarded due to errors in their IPv6 headers, including version number mismatch, other format errors, hop count exceeded, and errors discovered in processing the IPv6 options.                                                                                                                                                                                                                                                              |
| <b>InTooBigErrors</b>  | Shows the number of input datagrams that could not be forwarded because their size exceeded the link MTU of the outgoing interface.                                                                                                                                                                                                                                                                                                                                               |
| <b>InNoRoutes</b>      | Shows the number of input datagrams discarded because no route could be found to transmit them to their destination.                                                                                                                                                                                                                                                                                                                                                              |
| <b>InAddrErrors</b>    | Shows the number of input datagrams discarded because the IPv6 address in the IPv6 header destination field was not a valid address to be received at this entity. This count includes invalid addresses, for example, ::0, and unsupported addresses, for example, addresses with unallocated prefixes. For entities which are not IPv6 routers and do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. |
| <b>InUnknownProtos</b> | Shows the number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. This counter is incremented at the interface to which these datagrams were addressed, which is not always the input interface for some of the datagrams.                                                                                                                                                                                       |
| <b>InTruncatedPkts</b> | Shows the number of input datagrams discarded because the datagram frame did not carry enough data.                                                                                                                                                                                                                                                                                                                                                                               |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InDiscards</b>       | Shows the number of input IPv6 datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. This counter does not include datagrams discarded while awaiting re-assembly.                                                                                                                     |
| <b>InDelivers</b>       | Shows the total number of datagrams successfully delivered to IPv6 user-protocols (including ICMP). This counter is incremented at the interface to which these datagrams were addressed which is not always the input interface for some of the datagrams.                                                                                                                               |
| <b>OutForwDatagrams</b> | Shows the number of output datagrams which this entity received and forwarded to their final destinations. In entities which do not act as IPv6 routers, this counter includes only those packets which were Source-Routed using this entity, and the Source-Route processing was successful. For a successfully forwarded datagram the counter of the outgoing interface is incremented. |
| <b>OutRequests</b>      | Shows the total number of IPv6 datagrams which local IPv6 user-protocols (including ICMP) supplied to IPv6 in requests for transmission. This counter does not include datagrams counted in <b>OutForwDatagrams</b> .                                                                                                                                                                     |
| <b>OutDiscards</b>      | Shows the number of output IPv6 datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded, for example , for lack of buffer space. This counter includes datagrams counted in <b>OutForwDatagrams</b> if such packets met this (discretionary) discard criterion.                                                       |
| <b>OutFragOKs</b>       | Shows the number of IPv6 datagrams that have been successfully fragmented at this output interface.                                                                                                                                                                                                                                                                                       |
| <b>OutFragFails</b>     | Shows the number of IPv6 datagrams that have been discarded because they needed to be fragmented at this output interface but could not be.                                                                                                                                                                                                                                               |
| <b>OutFragCreates</b>   | Shows the number of output datagram fragments that have been generated as a result of fragmentation at this output interface.                                                                                                                                                                                                                                                             |
| <b>ReasmReqds</b>       | Shows the number of IPv6 fragments received which needed to be reassembled at this interface. This counter is incremented at the interface to which these fragments were addressed, which is not always the input interface for some of the fragments.                                                                                                                                    |

| Name                | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReasmOKs</b>     | Shows the number of IPv6 datagrams successfully reassembled. This counter is incremented at the interface to which these datagrams were addressed, which is not always the input interface for some of the fragments.                                                                                                                                                                                          |
| <b>ReasmFails</b>   | Shows the number of failures detected by the IPv6 re-assembly algorithm). This value is not necessarily a count of discarded IPv6 fragments because some algorithms can lose track of the number of fragments by combining them as they are received. This counter is incremented at the interface to which these fragments were addressed, which is not always the input interface for some of the fragments. |
| <b>InMcastPkts</b>  | Shows the number of multicast packets received by the interface.                                                                                                                                                                                                                                                                                                                                               |
| <b>OutMcastPkts</b> | Shows the number of multicast packets transmitted by the interface.                                                                                                                                                                                                                                                                                                                                            |

## Configuring an IPv6 router port interface

You must configure an IPv6 interface for a router port before you can assign an IPv6 address to the interface.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **IPv6**.
4. Click the **IPv6 Interface** tab.
5. Click **Insert**.
6. Enter the interface identifier.
7. Select the **AdminStatus** field to activate the interface.
8. Configure the remaining parameters as required.
9. Click **Insert**.
10. Click **Apply**.

### *Interfaces* Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

| Name                    | Description                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>        | Specifies the port or VLAN.                                                                                          |
| <b>Identifier</b>       | Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order. |
| <b>IdentifierLength</b> | Shows the length of the identifier, in bits.                                                                         |

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Descr</b>                | Specifies a description of the interface. The network management system also configures this string.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>VlanId</b>               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br>This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag. |
| <b>Type</b>                 | Shows the interface type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ReasmMaxSize(MTU)</b>    | Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.<br>Different hardware platforms support different MTU values.                                                                                                                                                                                                                                                                 |
| <b>PhysAddress</b>          | Specifies the media-dependent physical address. For Ethernet, this is a MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>AdminStatus</b>          | Specifies if IPv6 is active on this interface. The default is false (disabled).                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OperStatus</b>           | Specifies the current operational status of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ReachableTime</b>        | Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.                                                                                                                                                                                                                                                                                                                                                        |
| <b>RetransmitTimer</b>      | Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.                                                                                                                                                                                                                                                                                          |
| <b>CurHopLimit</b>          | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.                                                                                                                                                                                                                                         |
| <b>MulticastAdminStatus</b> | The option to select <b>MulticastAdminStatus</b> is disabled. You cannot configure the administrative status for multicast in this context.                                                                                                                                                                                                                                                                                                                                                            |
| <b>MacOffset</b>            | Requests a particular MAC for an IPv6 VLAN.<br>You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range.<br>Different hardware platforms support different MAC offset ranges.                                                                                                                                                                                                                                            |
| <b>RSMLTEnable</b>          | Shows whether RSMLT is enabled on the interface.<br>The default value is disabled (false).                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ProcessRedirect</b>      | Shows whether ND Redirect messages processing is enabled or disabled on this interface.<br>The default value is disabled (false).                                                                                                                                                                                                                                                                                                                                                                      |

## Configure an IPv6 VLAN Interface

You must configure an IPv6 interface for a VLAN before you can assign an IPv6 address to the interface.

### Before You Begin

- You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address. The switch supports port-based, protocol-based, and MAC-source-based VLANs.

For information about how to configure VLANs, see [VLAN Configuration using EDM](#) on page 3780.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IPv6**.
6. Select the **IPv6 Interface** tab.
7. Select **Insert**.
8. Enter the interface identifier.
9. Select the **AdminStatus** field to activate the interface.
10. Configure the remaining parameters as required.
11. Select **Insert**.
12. Select **Apply**.

### IPv6 Interfaces Field Descriptions

Use the data in the following table to use the **IPv6 Interfaces** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>         | Specifies the port or VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Identifier</b>        | Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>IdentifierLength</b>  | Shows the length of the identifier, in bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Descr</b>             | Specifies a description of the interface. The network management system also configures this string.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>VlanId</b>            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag. |
| <b>Type</b>              | Shows the interface type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ReasmMaxSize(MTU)</b> | Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.                                                                                                                                                                                                                                                                                                                            |
| <b>PhysAddress</b>       | Specifies the media-dependent physical address. For Ethernet, this is a MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>AdminStatus</b>       | Specifies if IPv6 is active on this interface. The default is false (disabled).                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OperStatus</b>        | Specifies the current operational status of the interface.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ReachableTime</b>     | Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.                                                                                                                                                                                                                                                                                                                                                     |

| Name                        | Description                                                                                                                                                                                                                                                    |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RetransmitTimer</b>      | Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.                                                  |
| <b>CurHopLimit</b>          | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64. |
| <b>MulticastAdminStatus</b> | The option to select <b>MulticastAdminStatus</b> is disabled. You cannot configure the administrative status for multicast in this context.                                                                                                                    |
| <b>MacOffset</b>            | Requests a particular MAC for an IPv6 VLAN.<br>You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range.<br>Different hardware platforms support different MAC offset ranges.    |
| <b>RSMLTEnable</b>          | Shows whether RSMLT is enabled on the interface.<br>The default value is disabled (false).                                                                                                                                                                     |
| <b>ProcessRedirect</b>      | Shows whether ND Redirect messages processing is enabled or disabled on this interface.<br>The default value is disabled (false).                                                                                                                              |

## Assigning IPv6 addresses to interfaces

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

You can assign an IPv6 address to a VLAN or brouter port.

### Before You Begin

Change the VRF instance as required to assign IPv6 addresses to interfaces on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Addresses** tab.
4. Click **Insert**.
5. In the **Interface** field, click **Port** or **VLAN**.
6. Select the interface.
7. Click **OK**.
8. Type the IPv6 address and prefix length.
9. Click **Insert**.
10. Click **Apply**.

**Addresses** field descriptions

Use the data in the following table to use the **Addresses** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>   | Specifies the interface to which this entry applies.                                                                                                                                                                                                                                                                                                 |
| <b>Addr</b>        | Specifies the IPv6 address to which this entry applies.<br><br><b>Important:</b><br>If the IPv6 address exceeds 116 octets, the object identifiers (OIDs) of instances of columns in this row are more than 128 subidentifiers and you cannot use SNMP-v1, SNMPv2c, or SNMPv3 to access them.                                                        |
| <b>AddrLen</b>     | Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table.                                                                                                                                                                          |
| <b>Type</b>        | Specifies the type of address. The default is unicast.                                                                                                                                                                                                                                                                                               |
| <b>Origin</b>      | Specifies the origin of the address. The following list shows the possible origins: <ul style="list-style-type: none"> <li>• other</li> <li>• manual</li> <li>• dhcp</li> <li>• linklayer</li> <li>• random</li> </ul>                                                                                                                               |
| <b>Status</b>      | Specifies the status of the address, describing whether the address is used for communication. The following list shows the possible statuses: <ul style="list-style-type: none"> <li>• preferred (default)</li> <li>• deprecated</li> <li>• invalid</li> <li>• inaccessible</li> <li>• unknown</li> <li>• tentative</li> <li>• duplicate</li> </ul> |
| <b>Created</b>     | Specifies the sysUpTime of the creation of this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.                                                                                                                                                              |
| <b>LastChanged</b> | Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.                                                                                                                                            |

| Name                 | Description                                        |
|----------------------|----------------------------------------------------|
| <b>ValidLifetime</b> | Shows how long, in seconds, the address is valid.  |
| <b>PrefLifetime</b>  | Shows how long, in seconds, the address is in use. |

## Assigning IPv6 addresses to a brouter port interface

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

You can assign an IPv6 address to a VLAN or brouter port.

### Before You Begin

Change the VRF instance as required to assign IPv6 addresses to a brouter port interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
2. Click **IPv6**.
3. Click the **IPv6 Addresses** tab.
4. Click **Insert**.
5. Click **Insert**.
6. Click **Apply**.

### IPv6 Addresses field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

| Name             | Description                                                                                                                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b> | Specifies the port.                                                                                                                                                                                                                                                                      |
| <b>Addr</b>      | Specifies the IPv6 address to which this entry applies.<br><br><b>Note:</b><br>If the IPv6 address exceeds 116 octets, the object identifiers (OIDs) of instances of columns in this row are more than 128 subidentifiers and you cannot use SNMP-v1, SNMPv2c, or SNMPv3 to access them. |
| <b>AddrLen</b>   | Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table.                                                                                                              |

| Name               | Description                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>        | Specifies the type of address. The default is unicast.                                                                                                                                                    |
| <b>Origin</b>      | Specifies the origin of the address.                                                                                                                                                                      |
| <b>Status</b>      | Specifies the status of the address, describing whether the address is used for communication.                                                                                                            |
| <b>Created</b>     | Specifies the sysUpTime of the creation of this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.                   |
| <b>LastChanged</b> | Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value. |

## Assigning an IPv6 address to a VLAN

Assign an IPv6 address to a VLAN.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN interface.
5. Click **IPv6**.
6. Click the **IPv6 Addresses** tab.
7. Click **Insert**.
8. Type the IPv6 address and length in the fields.
9. Click **Insert**.
10. Click **Apply**.

### *IPv6 Addresses* field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

| Name             | Description                                                 |
|------------------|-------------------------------------------------------------|
| <b>Interface</b> | Identifies the address to which the address is assigned.    |
| <b>Addr</b>      | Specifies an IP address that is associated with a VLAN.     |
| <b>AddrLen</b>   | Specifies the prefix address length value for this address. |
| <b>Type</b>      | Specifies the type of address: either unicast or anycast.   |

| Name               | Description                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Origin</b>      | Specifies the origin of the address as one of the following: <ul style="list-style-type: none"> <li>• other</li> <li>• manual</li> <li>• dhcp</li> <li>• linklayer</li> <li>• random</li> </ul> |
| <b>Status</b>      | Shows the status of the address and if it can be used for communication.                                                                                                                        |
| <b>Created</b>     | Shows the time this address entry was created.                                                                                                                                                  |
| <b>LastChanged</b> | Shows the time this address entry was last updated.                                                                                                                                             |

## Create IPv6 Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface.
- Create static routes for management purposes on VSP 8600 Series:
  - Use the mgmtRouter VRF context to configure static routes for the OOB port.
  - Use the default VRF context to configure static routes in the GRT for the inband VLAN or loopback interface.

VSP 8600 Series uses the routing stack to create static routes for data traffic as well as management purposes. For all other platforms, static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see [Segmented Management Instance Configuration for VOSS using EDM](#) on page 100. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

### Before You Begin

- Enable IPv6 forwarding.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 3832. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. Select the **StaticRouteGlobalAdminEnabled** check box.

If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM. The default is enabled.

5. Select **Apply**.

6. Select the **Static Routes** tab.
7. Select **Insert**.
8. In the **Dest** field, type the IPv6 address.
9. In the **PrefixLength** field, type the length of the prefix for the IPv6 address.
10. In the **NextHop** field, type the IPv6 address of the router through which the specified route is accessible.
11. Beside the **Interface** field, select **Port** or **Vlan** or **Tunnel**.
12. Select the interface, and then select **OK**.
13. In the **Cost** field, type a number for the distance.
14. Select the **Enable** check box.
15. Select **Insert**.

### **Static Routes** Field Descriptions

Use the data in the following table to use the **Static Routes** tab.

| Name                                                                                      | Description                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Dest</b>                                                                               | Specifies the IPv6 destination network address. The prefix value must match the PrefixLength.                                                                                                                                                               |
| <b>PrefixLength</b>                                                                       | Specifies the number bits you want to advertise from the prefix. The prefix value must match the value in the Dest field. The range is 0 to 128.                                                                                                            |
| <b>NextHop</b>                                                                            | Specifies the IPv6 address of the next hop on this route. You do not need to specify the next hop if the devices directly connect to one another. Configure the next hop if the two nodes do not share the same network prefix but reside on the same link. |
| <b>Interface</b>                                                                          | Specifies the interface to which this entry applies. You must specify the port or VLAN if the next hop is a link-local address.                                                                                                                             |
| <b>Cost</b>                                                                               | Specifies the cost or distance ratio to reach the destination for this node. The range is 1-65535. The default value is 1.                                                                                                                                  |
| <b>Name</b><br><br><b>Note:</b><br>This field is not supported on all hardware platforms. | Specifies the name for the static route.                                                                                                                                                                                                                    |
| <b>Enable</b>                                                                             | Enables the static route on the port. The default value is enable.                                                                                                                                                                                          |

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b>     | Shows the status of the static route as one of the following: <ul style="list-style-type: none"> <li>• <b>notReachable</b>: The route is not reachable and no neighbor request entry is built to resolved the next-hop. The system displays this status if no route or neighbor exists to reach the next-hop of the static route.</li> <li>• <b>tryToResolve</b>: The route is not reachable but a neighbor request entry is built to resolve the next-hop. The system displays this status if a local equivalent route exists in the system to reach the next-hop but the neighbor is not learned.</li> <li>• <b>reachableNotInRtm</b>: The static route is reachable but it is not in RTM. The system displays this status if the static route is reachable, but it is not the best among alternative static routes.</li> <li>• <b>reachableInRtm</b>: The static route is reachable and it is in RTM. The system displays this status if the static route is reachable, and it is the best among alternative static routes to be added into RTM.</li> </ul> |
| <b>Preference</b> | Specifies the routing preference of the destination IPv6 address. The range is 1-255. The default value is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configuring IPv6 route preferences

Change IPv6 route preferences to force the routing protocols to prefer one route over another. Configure route preferences to override default route preferences and give preference to routes learned for a specific protocol.

### Before You Begin

Change the VRF instance as required to configure IPv6 route preferences on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

#### Important

Changing route preferences is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. If you want to change default preferences for routing protocols, do so before you enable the protocols.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **RoutePref** tab.

4. In the **ConfiguredValue** column, double-click a parameter to change the preference for the given protocol.
5. Click **Apply**.

### **RoutePref** field descriptions

Use the data in the following table to use the **RoutePref** tab.

| Name                   | Description                                                        |
|------------------------|--------------------------------------------------------------------|
| <b>DefaultValue</b>    | Specifies the default preference value for the specified protocol. |
| <b>Protocol</b>        | Specifies the protocol name.                                       |
| <b>ConfiguredValue</b> | Configures the preference value for the specified protocol.        |

## View Route Information

View routes information to view the current configuration.

### About This Task

IPv6 host routes created for the IPv6 local interfaces do not display in the routing table.

### Before You Begin

Change the VRF instance as required to view route information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Select **IPv6**.
3. Select the **Routes** tab.

### **Routes** Field Descriptions

Use the data in the following table to use the **Routes** tab.

| Name             | Description                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Dest</b>      | Specifies the IPv6 destination network address. The prefix value must match the PrefixLength.                             |
| <b>PfxLength</b> | Specifies the number bits you want to advertise from the prefix. The prefix value must match the value in the Dest field. |
| <b>Index</b>     | Specifies the unique value that identifies the route among the routes to the same network layer destination.              |
| <b>Interface</b> | Specifies the interface to which this entry applies.                                                                      |
| <b>NextHop</b>   | Specifies the IPv6 address of the next hop on this route.                                                                 |
| <b>Protocol</b>  | Specifies the routing protocol, such as OSPF.                                                                             |

| Name             | Description                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Metric</b>    | Specifies the metric assigned to this interface. The default value of the metric is the reference bandwidth or ifSpeed. The value of the reference bandwidth is configured by the rcOspfV3ReferenceBandwidth object. For more information about reference bandwidth, see <a href="#">Globals field descriptions</a> on page 2551. |
| <b>NextHopId</b> | Identifier of the next-hop, hostname, or mac address.                                                                                                                                                                                                                                                                             |
| <b>Age</b>       | Specifies the number of seconds since the route was last updated or is last active.                                                                                                                                                                                                                                               |
| <b>Type</b>      | Specifies the type of route.                                                                                                                                                                                                                                                                                                      |
| <b>PathType</b>  | Specifies the type of path.                                                                                                                                                                                                                                                                                                       |
| <b>SrcVrfId</b>  | Specifies the source VRF instance.                                                                                                                                                                                                                                                                                                |
| <b>Pref</b>      | Specifies the preference.                                                                                                                                                                                                                                                                                                         |

## Viewing IPv6 Default Routers

View the table of default routers learned from router advertisement messages.

A maximum of four routers are visible in the default routers list.

### Note

Not all hardware platforms include a dedicated, physical management interface. For more information about supported interfaces, see your hardware documentation.

### Procedure

1. In the navigation tree, expand the **Configuration > IPv6** folders.
2. Click **IPv6**.
3. Click the **Default Routers** tab.

### *Default Routers field descriptions*

Use the data in the following table to use the **Default Routers** tab.

| Name            | Description                                                                  |
|-----------------|------------------------------------------------------------------------------|
| <b>Address</b>  | Specifies the learned router address for an IPv6 default routers entry.      |
| <b>IfIndex</b>  | Specifies the interface number for an IPv6 default routers entry.            |
| <b>Lifetime</b> | Specifies the remaining router lifetime.                                     |
| <b>Active</b>   | Specifies if the default router is active for an IPv6 default routers entry. |

## Configure a Circuitless IPv6 Interface

### Before You Begin

Change the VRF instance as required to configure a Circuitless IPv6 interface on a specific VRF instance.

### About This Task

You can use a circuitless IPv6 (CLIPv6) interface to provide uninterrupted connectivity to your system.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Circuitless IP** tab.
4. Click **Insert**.
5. In the **Interface** field, assign a CLIP interface number.
6. Type the IPv6 address and prefix length.

### **Circuitless IPv6** Field Descriptions

Use the data in the following table to use the **Circuitless IPv6** tab.

| Name                                                                                | Description                                                                                                                                                                 |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>                                                                    | Specifies the interface to which this entry applies.                                                                                                                        |
| <b>Addr</b>                                                                         | Specifies the IPv6 address to which this entry applies.                                                                                                                     |
| <b>AddrLen</b>                                                                      | Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table. |
| <b>Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name assigned to the IPv6 CLIP address.                                                                                                                       |

## Configuring IPv6 Prefix List

Use IPv6 prefix lists to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. When there is a match, the route is used.

### Before You Begin

- Change the VRF instance as required to configure a prefix list on a specific VRF instance.

### Procedure

1. In the navigation pane, open the following folders: **Configuration > IPv6**.
2. Click **Policy**.
3. In the **Ipv6-Prefix List** tab, click **Insert**.
4. Edit the parameters as required.

- Click **Insert**.

### **IPv6-Prefix list** field descriptions

Use the data in the following table to use the **IPv6-Prefix List** tab.

| Name                 | Description                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>            | Specifies the list identifier. The range is 1 to 2147483647.                                                                                                                                |
| <b>Prefix</b>        | Specifies the prefix IPv6 address.                                                                                                                                                          |
| <b>PrefixMaskLen</b> | Specifies the length of the prefix mask. You must enter the full 128-bit mask to exact a full match of a specific IPv6 address (for example, when creating a policy to match the next-hop). |
| <b>Name</b>          | Names a specified prefix list during the creation process or renames the specified prefix list. The name can be from 1 to 64 characters in length.                                          |
| <b>MaskLenFrom</b>   | Specifies the lower bound on the mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.                            |
| <b>MaskLenUpto</b>   | Specifies the higher bound mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.                                  |

## Configuring an IPv6 Route Policy

### Procedure

- In the navigation pane, expand the following folders: **Configuration > IPv6**.
- Click **Policy**.
- Click the **Route Policy** tab.
- Click **Insert**.
- Enter the appropriate information for your configuration in the Insert Route Policy dialog box.
- Click **Insert**.

### **Route Policy** Field Descriptions

Use the data in the following table to use the **Route Policy** tab.

| Name                  | Description                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>             | Specifies the ID of an entry in the Prefix list table.                                                                 |
| <b>SequenceNumber</b> | Specifies a policy within a route policy group.                                                                        |
| <b>Name</b>           | Specifies the name of the policy. This command changes the name field for all sequence numbers under the given policy. |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>              | Indicates whether this policy sequence number is enabled or disabled. If disabled, the policy sequence number is ignored. The default is disabled.                                                                                                                                                                                                                                                                                                                      |
| <b>Mode</b>                | Specifies the action to take when a policy is selected for a specific route. Select permit (allow the route) or deny (ignore the route). The default is permit.                                                                                                                                                                                                                                                                                                         |
| <b>MatchProtocol</b>       | Selects the appropriate protocol. If configured, matches the protocol through which the route is learned. This field is used only for RIP Announce purposes. The default is to enable all match protocols.                                                                                                                                                                                                                                                              |
| <b>MatchNetwork</b>        | Specifies if the system matches the destination network against the contents of the specified prefix list.                                                                                                                                                                                                                                                                                                                                                              |
| <b>MatchIpRouteSource</b>  | Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.<br>Select the ellipsis and choose from the list in the Match Route Source dialog box. You can select up to four entries. To clear an entry, use the ALT key.<br>You can also change this field in the Route Policy tab of the Policy dialog box. |
| <b>MatchIpRouteDest</b>    | Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.                                                                                                                                                                                                                                                  |
| <b>MatchNextHop</b>        | Specifies if the system matches the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes.<br>Select the ellipsis and choose from the list in the Match Next Hop dialog box. You can select up to four entries. To clear an entry, use the ALT key.                                                                                                                                            |
| <b>MatchInterface</b>      | Specifies if the system matches the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other type of route.<br>Select the ellipsis and choose from the list in the Match Interface dialog box. You can select up to four entries. To clear an entry, use the ALT key.                                                                         |
| <b>MatchRouteType</b>      | Configures a specific route type to match (applies only to OSPF routes).<br>Externaltype1 and Externaltype2 specify the OSPF routes of the specified type only. OSPF internal refers to intra- and inter-area routes. The default is any.                                                                                                                                                                                                                               |
| <b>MatchMetric</b>         | Specifies if the system matches the metric of the incoming advertisement or existing route against the specified value (1 to 65535). If 0, this field is ignored. The default is 0.                                                                                                                                                                                                                                                                                     |
| <b>MatchMetricTypelsis</b> | Specifies the match metric type field in the incoming ISIS routes in accept policy.                                                                                                                                                                                                                                                                                                                                                                                     |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MatchAsPath</b>           | Configures if the system matches the BGP autonomus system path. Applicable to BGP only. This overrides the BGP neighbor filter list information.                                                                                                                                                                                                                                                                                                           |
| <b>MatchCommunity</b>        | Filters incoming and outgoing updates based on a Community List. Applicable to BGP only. The default is disable.                                                                                                                                                                                                                                                                                                                                           |
| <b>MatchCommunityExact</b>   | Indicates if the match must be exact (that is, all of the communities specified in the path must match). Applicable to BGP only. The default is disabled.                                                                                                                                                                                                                                                                                                  |
| <b>MatchTag</b>              | Specifies a list of tags used during the match criteria process. Applicable to BGP only. It contains one or more tag values.                                                                                                                                                                                                                                                                                                                               |
| <b>MatchVrf</b>              | Identifies the source VRFs that leaks routes to the local VRF (applies only to RIP routes).                                                                                                                                                                                                                                                                                                                                                                |
| <b>MatchLocalPref</b>        | Specifies the local preference value to be matched.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>NssaPbit</b>              | Configures or resets the P bit in specified type 7 link state advertisements (LSA). By default, the Pbit is always configured in case the user configures the Pbit to a disable state for a particular route policy other than all type 7. LSAs associated with that route policy have the Pbit cleared. With this intact, not so stubby area (NSSA) area border router (ABR) does not perform translation of these LSAs to type 5. The default is enable. |
| <b>SetRoutePreference</b>    | Configures a value from 0 to 255. The default value is 0. If the default is configured, the global preference value is used. When configured to a value greater than zero, specifies the route preference value assigned to the routes that matches the policy. This feature applies to accept policies only.                                                                                                                                              |
| <b>SetMetricTypeInternal</b> | Identifies the MED value for routes advertised to BGP numbers to the Interior Gateway Protocol (IGP) metric value. The value must be 0 or 1. The default is 0.                                                                                                                                                                                                                                                                                             |
| <b>SetMetricTypeIisis</b>    | Sets the metric type IS-IS.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SetMetric</b>             | Configures the system to use the metric value for the route while announcing or redistributing. The default-import-metric is 0. If the default is configured, the original cost of the route is advertised into OSPF; for RIP, the original cost of the route or the default value is used (applies to IS-IS routes also). The default is 0.                                                                                                               |
| <b>SetMetricType</b>         | Configures the metric type for the routes to announce into the OSPF routing protocol that matches this policy. Applicable to OSPF protocol only. The default is type 2. This field is applicable only for OSPF announce policies. The default is type2.                                                                                                                                                                                                    |
| <b>SetNextHop</b>            | Configures the IP address of the next-hop router. Applicable to BGP only. The default is 0.0.0.0.                                                                                                                                                                                                                                                                                                                                                          |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SetInjectNetList</b>    | Configures the destination network of the route that matches this policy with the contents of the specified prefix list. Select the ellipsis and choose from the list in the Set Inject NetList dialog box.                                                                                                                                                                                                                               |
| <b>SetMask</b>             | Configures the mask of the route that matches this policy. This applies only to RIP accept policies.                                                                                                                                                                                                                                                                                                                                      |
| <b>SetAsPath</b>           | Indicates the AS path value to use whether the SetAsPathMode field is Tag or Prepend. Applicable to BGP only.<br><br><b>Note:</b><br>Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy.                                                                                                                                                                                                                 |
| <b>SetAsPathMode</b>       | Configures if the system converts the tag of a route into an AS path. Applicable to BGP protocol only. The mode is either Tag or Prepend tag. The value is applicable only while redistributing routes to BGP. The default is prepend.<br><br><b>Note:</b><br>Prepend is not applicable to an iBGP peer with outbound route policy.                                                                                                       |
| <b>SetAutomaticTag</b>     | Enables the automatic tag feature. Applicable to BGP protocol only. The default is disable.                                                                                                                                                                                                                                                                                                                                               |
| <b>SetCommunityNumber</b>  | Configures the community number for BGP advertisements. This value can be a number (1 to 42949672000) or no-export or no-advertise.                                                                                                                                                                                                                                                                                                       |
| <b>SetCommunityMode</b>    | Configures the community mode for the BGP protocol. This value can be either append, none, or unchanged. The default is unchanged. <ul style="list-style-type: none"> <li>• Unchanged—keeps the community attribute in the route path as it is.</li> <li>• None—removes the community in the route path additive.</li> <li>• Append—adds the community number specified in SetCommunityNumber to the community list attribute.</li> </ul> |
| <b>SetExtCommunity</b>     | Configures a BGP community. The values are 0 to 256.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SetExtCommunityMode</b> | Configures the extended-community mode. The value can be append, unchanged, or overwrite. The default value is unchanged. <ul style="list-style-type: none"> <li>• append — creates another community string.</li> <li>• unchanged — keeps the community attribute as it is.</li> <li>• overwrite — changes the current value.</li> </ul>                                                                                                 |
| <b>SetOrigin</b>           | Configures the origin for the BGP protocol to IGP, EGP, incomplete, or unchanged. If not configured, the system uses the route origin from the IP routing table (protocol). The default is unchanged.                                                                                                                                                                                                                                     |

| Name                  | Description                                                                                                                                                                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SetLocalPref</b>   | Configures the local preference for the BGP protocol only. The system uses this value during the route decision process for the BGP protocol. The default is 0.                                                                                                             |
| <b>SetOriginEgpAs</b> | Indicates the remote autonomous system number for the BGP protocol. The default is 0.                                                                                                                                                                                       |
| <b>SetWeight</b>      | Configures the weight value for the routing table for the BGP protocol. This field must be used with the match as-path condition. For BGP, this value overrides the weight configured through the NetworkTableEntry, FilterListWeight, or NeighborWeight. The default is 0. |
| <b>SetTag</b>         | Configures the list of tags used during the match criteria process for the BGP protocol. The default is 0.                                                                                                                                                                  |
| <b>Ipv6SetNextHop</b> | Specifies the address of the IPv6 next hop router.                                                                                                                                                                                                                          |

## Configuring IPv6 Route Redistribution Policies

### About This Task

Configure route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF or BGP. Use a route policy to control the redistribution of routes. You can redistribute routes for the Global router (VRF 0) and within a user-defined VRF but not between different VRFs.

### Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **Policy**.
3. Click the **Route Redistribution** tab.
4. Click **Insert**.
5. Choose the protocol and route source.
6. Select **Enable**.
7. Choose the route policy to apply to the redistributed routes.
8. Configure other parameters as required.
9. Click **Insert**.

**Route Redistribution** Field Descriptions

Use the data in the following table to use the **Route Redistribution** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrfId</b>    | Specifies the destination VRF ID.                                                                                                                                                                                                                                                                                                  |
| <b>Protocol</b>    | Specifies the protocols for which you want to receive external routing information.                                                                                                                                                                                                                                                |
| <b>SrcVrfId</b>    | Specifies the source VRF ID.                                                                                                                                                                                                                                                                                                       |
| <b>RouteSource</b> | Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.                                                                                                                                                                             |
| <b>Enable</b>      | Enables or disables route redistribution. The default is disabled.                                                                                                                                                                                                                                                                 |
| <b>RoutePolicy</b> | Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.                                                                                                                                 |
| <b>Metric</b>      | Specifies the metric announced in advertisements. The default is 0.                                                                                                                                                                                                                                                                |
| <b>MetricType</b>  | Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2. |

## Viewing IPv6 Connections using EDM

Use the procedures in this section to view IPv6 connections using EDM.

### Viewing TCP global information

View TCP and UDP information to view the current configuration.

#### Before You Begin

Change the VRF instance as required to view TCP global information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### About This Task

The fields on the TCP global tab provide information about the handshake (SYN) configuration and the maximum number of TCP connections you can create on your system.

When you initiate a TCP connection, both end points send handshake information to create the channel.

The retransmission algorithm and fields display the configured timeout value and minimum and maximum retransmission times that your system uses to terminate a connection attempt that falls outside your specified parameters.

#### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders

2. Click **TCP/UDP**.
3. Click the **TCP Globals** tab.

### **TCP Global** field descriptions

Use the data in the following table to use the **TCP Globals** tab.

| Name                | Description                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------|
| <b>RtoAlgorithm</b> | Determines the timeout value used for retransmitting unacknowledged octets.                                   |
| <b>RtoMin</b>       | Displays the minimum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout. |
| <b>RtoMax</b>       | Displays the maximum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout. |
| <b>MaxConn</b>      | Displays the maximum connections for the device.                                                              |

## Viewing TCP connections information

View information about TCP connections.

### **Before You Begin**

Change the VRF instance as required to view TCP connections information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### **About This Task**

Among other things, the fields on the TCP connections tab provide important information about the health of connections that traverse your switch.

In particular, the state column lets you know the state of each TCP connection. Of these, synSent, synReceived, and established indicate whether or not a channel is established and listen indicates when an end system is waiting for a returning handshake (SYN).

### **Procedure**

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Connections** tab.

### **TCP Connections** field descriptions

Use the data in the following table to use the **TCP Connections** tab.

| Name                    | Description                                                                 |
|-------------------------|-----------------------------------------------------------------------------|
| <b>LocalAddressType</b> | Displays the type (IPv6 or IPv4) for the address in the LocalAddress field. |
| <b>LocalAddress</b>     | Displays the IPv6 address for the TCP connection.                           |

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LocalPort</b>      | Displays the local port number for the TCP connection.                                                                                                                                                                                                                                                                                                         |
| <b>RemAddressType</b> | Displays the type (IPv6 or IPv4) for the remote address of the TCP connection.                                                                                                                                                                                                                                                                                 |
| <b>RemAddress</b>     | Displays the IPv6 address for the remote TCP connection.                                                                                                                                                                                                                                                                                                       |
| <b>RemPort</b>        | Displays the remote port number for the TCP connection.                                                                                                                                                                                                                                                                                                        |
| <b>State</b>          | Displays an integer that represents the state for the connection: <ul style="list-style-type: none"> <li>• closed</li> <li>• listen</li> <li>• synSent</li> <li>• synReceived</li> <li>• established</li> <li>• finWait1</li> <li>• finWait2</li> <li>• closeWait</li> <li>• lastAck(9)</li> <li>• closing</li> <li>• timeWait</li> <li>• deleteTCB</li> </ul> |
| <b>Process</b>        | Displays the process ID for the system process associated with the TCP connection.                                                                                                                                                                                                                                                                             |

## Viewing TCP listeners information

View TCP listener information.

### Before You Begin

Change the VRF instance as required to view TCP listeners information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

The TCP listeners table provides a detailed list of systems that are in the listening state.

When a connection is in the listen state an end point system is waiting for a returning handshake (SYN).The normal listening state should be very transient, changing all of the time.

Two or more systems going to a common system in an extended listening state indicates the need for further investigation.

End systems in an extended listening state can indicate a broken TCP connection or a DOS attack on a resource.

This type of DOS attack, known as a SYN attack, results from the transmission of SYNs with no response to return replies.

While many systems can detect a SYN attack, the TCP listener statistics can provide additional forensic information.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Listeners** tab.

### **TCP Listeners** field descriptions

Use the data in the following table to use the **TCP Listeners** tab.

| Name                    | Description                                                                        |
|-------------------------|------------------------------------------------------------------------------------|
| <b>LocalAddressType</b> | Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.        |
| <b>LocalAddress</b>     | Displays the IPv6 address for the TCP connection.                                  |
| <b>LocalPort</b>        | Displays the local port number for the TCP connection.                             |
| <b>Process</b>          | Displays the process ID for the system process associated with the TCP connection. |

## Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

### Before You Begin

Change the VRF instance as required to view UDP endpoint information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### About This Task

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

**UDP Endpoints** field descriptions

Use the data in the following table to use the **UDP Endpoints** tab.

| Name                     | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <b>LocalAddressType</b>  | Displays the local address type (IPv6 or IPv4).                         |
| <b>LocalAddress</b>      | Displays the local IPv6 address.                                        |
| <b>LocalPort</b>         | Displays the local port number.                                         |
| <b>RemoteAddressType</b> | Displays the remote address type (IPv6 or IPv4).                        |
| <b>RemoteAddress</b>     | Displays the remote IPv6 address.                                       |
| <b>RemotePort</b>        | Displays the remote port number.                                        |
| <b>Instance</b>          | Distinguishes between multiple processes connected to the UDP endpoint. |
| <b>Process</b>           | Displays the ID for the UDP process.                                    |

# IPv6 Neighbor Discovery

---

[Neighbor Discovery on page 1960](#)

[Host autoconfiguration on page 1964](#)

[Neighbor Discovery Configuration using CLI on page 1966](#)

[Neighbor Discovery Configuration using EDM on page 1976](#)

The following sections provide concepts and procedures to complete IPv6 neighbor discovery configuration.

## Neighbor Discovery

---

IPv6 nodes (routers and hosts) on the same link use neighbor discovery (ND) to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services for IPv4 with the Address Resolution Protocol (ARP) and router discovery. In IPv6 ND performs a function similar to ARP (Address Resolution Protocol) in IPv4.

Hosts use ND to discover the routers in the network that you can use as the default routers, and to determine the link-layer address of neighbors attached to local links. Routers also use ND to discover neighbors and link-layer information. ND updates the neighbor database with valid entries, invalid entries, and entries migrated to various locations.

The ND protocol provides the following services:

- address and prefix discovery

Hosts determine the set of addresses that are on-link for the given link. Nodes determine which addresses or prefixes are locally reachable or remote with address and prefix discovery.

- router discovery

Hosts discover neighboring routers with router discovery. Hosts establish neighbors as default packet-forwarding routers.

- parameter discovery

Hosts and routers discover link parameters such as the link MTU or the hop-limit value placed in outgoing packets.

- address autoconfiguration

Hosts configure an address for an interface with address autoconfiguration.

- duplicate address detection

Hosts and nodes determine if an address is assigned to another router or a host.

- address resolution

Hosts determine link-layer addresses (MAC for Ethernet) of the local neighbors (attached on the local network), provided the IP address is known.

- next-hop determination

Hosts determine how to forward local or remote traffic with next-hop determination. The next hop can be a local or remote router.

- neighbor unreachability detection

Hosts determine if the neighbor is unreachable, and if address resolution must be performed again to update the database. For neighbors you use as routers, hosts attempt to forward traffic through alternative default routers.

- redirect

Routers inform the host of more efficient routes with redirect messages.

Neighbor discovery uses three components:

- host-router discovery

Host-router discovery performs the following functions:

- router discovery
- prefix discovery
- parameter discovery
- address autoconfiguration

- host-host communication

Host-host communication performs the following functions:

- address resolution
- next-hop determination
- neighbor unreachability detection
- duplicate address detection

- route redirect

#### Note

When a neighbor transitions to the STALE state, to initiate Neighbor Unreachability detection (NUD), a duplicate copy of the traffic destined to this neighbor is sent to the switch Control Processor (CP) on a low priority queue (queue 0). The original packet is forwarded to this neighbor. After NUD is initiated, the hardware records are updated and the traffic is no longer sent to the CP. When a high rate of such traffic is sent to the CP, the switch can drop some of these packets due to the built-in CP rate limiting feature, which protects the CP from DOS attacks.

Use the command **show qos cosq-stats cpu-port** to view drop statistics on the CPU queue. This design does not result in loss of traffic.

Use the command **ipv6 nd reachable-time <0-3600000>** to increase the default value of 3000 milliseconds, which in turn delays the scenario of data path sending STALE neighbor destined packets to the CP.

As a best practice, configure a reachable time value of 180000 and retransmit interval of 5000.

## ND messages

The following table compares the ICMP message types.

**Table 138: IPv4 and IPv6 neighbor comparison**

| IPv4 Function       | IPv6 Function                                                         | Description                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARP request message | Neighbor solicitation message                                         | A node sends this message to determine the link-layer address of a neighbor or to verify that a neighbor is still reachable through a cached link-layer address. You can also use neighbor solicitations for duplicate address detection.                                                                                                                                 |
| ARP reply message   | Neighbor advertisement                                                | A node sends this message either in response to a received neighbor solicitation message or to communicate a link-layer address change.                                                                                                                                                                                                                                   |
| ARP cache           | Neighbor cache                                                        | The neighbor cache contains information about neighbor types on the network.                                                                                                                                                                                                                                                                                              |
| Gratuitous ARP      | Duplicate address detection<br>New VRRP master interface announcement | A host or node sends a request with its own IP address to determine if another router or host uses the address. If the sender receives a reply, then there is a device with a duplicate address.<br>Both hosts and routers use this function. Gratuitous ARP can also be used to announce the new VRRP master interface so that all switches can adjust their MAC tables. |

**Table 138: IPv4 and IPv6 neighbor comparison (continued)**

| IPv4 Function                           | IPv6 Function                           | Description                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router solicitation message (optional)  | Router solicitation message (required)  | The host sends this message after it detects a change in a network interface operational state. The message includes a request for routers to generate router advertisement immediately rather than at the scheduled time.                                                                                     |
| Router advertisement message (optional) | Router advertisement message (required) | Routers send this message to advertise their presence with various links and Internet parameters either periodically or in response to a router solicitation message. Router advertisements contain prefixes that you use for on-link determination or address configuration, and a suggested hop limit value. |
| Redirect message                        | Redirect message                        | Routers send this message to inform hosts of a better first hop for a destination.                                                                                                                                                                                                                             |

## Neighbor discovery cache

The neighbor discovery cache lists information about neighbors in the network and can contain the following types of neighbors:

- static: a configured neighbor
- local: a device on the local system
- dynamic: a discovered neighbor

The following table describes the states in the neighbor cache.

**Table 139: Neighbor cache states**

| State      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Incomplete | Address resolution is in progress and the system has not yet determined the link-layer address of the neighbor.<br>The neighbor cache may also enter the Incomplete state when the switch cannot confirm subsequent reachability during the ND process for router neighbors. By contrast, the system deletes host neighbors, rather than enter the Incomplete state, if ND fails to confirm reachability.<br><br><b>Tip:</b><br>Router neighbors: when the R bit is set in the received neighbor advertisement<br>Host neighbors: when the R bit is not set in the received neighbor advertisement |
| Reachable  | A node receives positive confirmation within the last reachable time period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Stale      | Reachability of the neighbor is unknown.<br>Until the system sends traffic to the neighbor, make no attempt to verify its reachability.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 139: Neighbor cache states (continued)**

| State | Description                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Delay | A time period longer than the reachable time period passes since the node received the last positive confirmation, and a packet was sent within the last DELAY_FIRST_PROBE_TIME period.<br>If no reachability confirmation is received within the DELAY_FIRST_PROBE_TIME period after entering the DELAY state, neighbor solicitation is sent and the state changes to probe. |
| Probe | Reachability confirmation is sought from the device every retransmit timer period.                                                                                                                                                                                                                                                                                            |

The following events involve Layer 2 and Layer 3 interaction during processing and affect the neighbor cache:

- flushing the virtual LAN (VLAN) MAC
- removing a VLAN or brouter port
- performing an action on all VLANs
- removing a port from a VLAN
- removing a port from a spanning tree group (STG)
- removing a multilink trunk (MLT) group from a VLAN
- removing an MLT port from a VLAN
- removing an MLT port from an STG
- performing an action that disables a VLAN, such as removing all ports from a VLAN
- disabling a tagged port that is a member of multiple routable VLANs

## Router discovery

IPv6 nodes discover routers on the local link with router discovery.

IPv6 nodes discover routers on the local link with router discovery.

### *Router advertisement*

Configured interfaces on an IPv6 router send router-advertisement messages. Interfaces also send router advertisements in response to router-solicitation messages from IPv6 nodes on the link.

### *Router solicitation*

An IPv6 host without a configured unicast address sends router solicitation messages.

## Host autoconfiguration

The switch can automatically configure a host (node), and assign IPv6 addresses automatically. This process is called stateless address autoconfiguration (SLAAC). The neighbor discovery (ND) protocol performs autoconfiguration.

Stateless autoconfiguration enables serverless basic configuration of IPv6 nodes and renumbering from a mathematical perspective.

Stateless autoconfiguration uses the following equation:

$$\text{Stateless autoconfiguration} = \text{network prefix (router advertisement)} + \text{IPv6 interface identifiers}$$

Stateless autoconfiguration uses the network prefix information in the router advertisement and integrates this with the interface ID to form the node global address(es).

#### Note

The switch cannot autoconfigure an IPv6 address local to itself because IPv6 routers do not process router advertisements in the same manner as hosts. That is, routers check only for consistency in information advertised in IPv6 Router Advertisements on the same link.

#### Tip

You must manually assign all addresses/prefixes local to the switch.

Assuming an EUI-64 based interface ID is used, the IPv6 interface address is created from the 48-bit (6-byte) MAC address as follows:

1. EUI-64 hexadecimal digits 0xff-fe are inserted between the third and fourth bytes of the MAC address to obtain the EUI-64.
2. The universal or local bit, the second lower-order bit of the first byte of the MAC address, is complemented.

For example, the IPv6 identifier for host A uses the MAC address 00-AA-00-3F-2A-1C.

To automatically assign an address, the following occurs:

1. Convert to EUI-64 format  
00-AA-00-FF-FE-3F-2A-1C
2. Complement the Universal/Local (U/L) bit.

The first byte in binary form is 00000000. When the seventh bit is complemented, it becomes 00000010 (0x02).

The result is 02-AA-00-FF-FE-3F-2A-1C or 2AA:FF:FE3F:2A1C.

Host A with MAC address 00-AA-00-3F-2A-1C, combined with network prefix 2001::/64 provided by router advertisement, uses an IPv6 address 2001::2AA:FF:FE3F:2A1C.

A host generates a link-local address with the prefix FE80 regardless of whether an IPv6 router is present or not.

The link-local address for a node with the MAC address 00-AA-00-3F-2A-1C is FE80::2AA:FF:FE3F:2A1C.

The following list explains the states of an autoconfiguration address:

- Tentative: the address is being verified as unique (link-local address)
- Valid: an address from which unicast traffic can be sent and received; can be in one of two states—either preferred or deprecated

- Preferred: an address for which uniqueness was verified for unrestricted use; can be in one of three states—either tentative, preferred, or deprecated
- Deprecated: an address that remains valid but is withheld for new communication
- Invalid: an address for which a node can no longer send or receive unicast traffic

## Neighbor Discovery Configuration using CLI

---

Use the procedures in this section for neighbor discovery configuration using CLI.

### Configuring an IPv6 discovery prefix

Configure the discovery prefixes to send in router advertisement.

#### About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration.

The discovery prefix controls which IPv6 addresses will be automatically configured, and for how long they are valid.

#### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create neighbor discovery prefixes for an interface:

```
ipv6 nd prefix-interface WORD<0-255> [eui <1-3>] [no-advertise] [no-
autoconfig] [no-onlink]
```

3. Modify an existing neighbor discovery prefix:

```
ipv6 nd prefix WORD<0-255> infinite [no-advertise] [preferred-life
<0-4294967295>] [valid-life <0-4294967295>]
```

#### Example

Create a new neighbor discovery prefix:

```
Switch:1(config-if)#ipv6 nd prefix-interface fd48:bfb6:4c09:9499::1/64
```

## Variable Definitions

Use the data in the following table to use the **ipv6 nd prefix** and **ipv6 nd prefix-interface** commands.

| Variable                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>eui &lt;1-3&gt;</i>                     | <p>Configures the EUI address. The values are:</p> <ul style="list-style-type: none"> <li>• (1) EUI not used</li> <li>• (2) EUI with Universal/Local bit (U/L) complement enabled</li> <li>• (3) EUI used without U/L</li> </ul> <p>Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both global- and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the prefix length is 64 or less. The default is EUI not used.</p> <p>If you select EUI not used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. If you select either EUI used with UL complement or EUI used without UL complement, an associated IPv6 address is created by concatenating the specified prefix with the EUI-64 interface ID.</p> |
| <i>infinite</i>                            | Configures the prefix valid lifetime so it never expires. The default is disabled, which means the prefix expires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>no-advertise</i>                        | Removes the prefix from the neighbor advertisement. The default is disabled, which means the prefix is advertised.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>no-autoconfig</i>                       | Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. The value is a 1-bit flag. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>no-onlink</i>                           | Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. The value is a 1-bit flag. The default is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>preferred-life &lt;0-4294967295&gt;</i> | <p>Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800.</p> <p>The preferred lifetime is the length of time for the tentative, preferred, and deprecated state of an autoconfiguration address.</p> <p>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |

| Variable                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>valid-life &lt;0-0-4294967295&gt;</code> | Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000.<br>A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first. |
| <code>WORD &lt;0-255&gt;</code>                | Specifies the IPv6 address and prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Use the data in the following table to use the **interface** command.

| Variable                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>                                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |

## Configuring route advertisement

Configure route advertisement in IPv6 for neighbor discovery (ND).

### About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the number of neighbor solicitation messages from duplicate address detection:

```
ipv6 nd dad-ns <0-600>
```

3. Configure the hop limit sent in router advertisements:

```
ipv6 nd hop-limit <0-255>
```

4. Enable managed address configuration (M-bit) on the router:

```
ipv6 nd managed-config-flag
```

5. Configure the MTU for router advertisements:

```
ipv6 nd mtu <0-9500>
```

6. Enable other stateful configuration (O-bit) on the router:

```
ipv6 nd other-config-flag
```

7. Configure the router lifetime included in router advertisement:

```
ipv6 nd ra-lifetime <0-9000>
```

8. Configure the neighbor reachable time:

```
ipv6 nd reachable-time <0-3600000>
```

9. Configure the time between neighbor solicitation messages:

```
ipv6 nd retransmit-timer <0-4294967295>
```

10. Configure the maximum time allowed between sending unsolicited multicast router advertisements:

```
ipv6 nd rtr-advert-max-interval <4-1800>
```

11. Configure the minimum time allowed between sending unsolicited multicast router advertisements:

```
ipv6 nd rtr-advert-min-interval <3-1350>
```

12. Enable periodic router advertisement messages:

```
ipv6 nd send-ra
```

## Example

Configure the maximum time between sending unsolicited router advertisements:

```
Switch:1(config-if)#ipv6 nd rtr-advert-max-interval 700
```

Configure the minimum time between sending unsolicited router advertisements:

```
Switch:1(config-if)#ipv6 nd rtr-advert-min-interval 500
```

Enable periodic router advertisement messages:

```
Switch:1(config-if)#ipv6 nd send-ra
```

### Variable Definitions

Use the data in the following table to use the **ipv6 nd** commands.

| Variable                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dad-ns &lt;0-600&gt;</i>    | Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface.<br>A value of 1 sends one advertisement without retransmissions.                                                                                                                                                                                                                                                                           |
| <i>hop-limit &lt;0-255&gt;</i> | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet.<br>A value of zero indicates that the advertisement does not specify a hop-limit value. The default is 64.                                                                                                                                                                                                                                       |
| <i>managed-config-flag</i>     | Enables the system to configure the M-bit, or managed address configuration flag, in the router advertisements<br>When set, the M-bit flag indicates that addresses are available through DHCPv6.<br>If the M flag is set, the O flag is redundant because DHCPv6 returns all available configuration information.<br>If neither the M nor O flags are set, no information is available through DHCPv6.<br>The default is disabled.                                                               |
| <i>mtu &lt;0-9500&gt;</i>      | Shows the MTU value sent in router advertisements on this interface.<br>A value of zero indicates that the system sends no MTU options.<br>The default is 0.                                                                                                                                                                                                                                                                                                                                      |
| <i>other-config-flag</i>       | Enables the O-bit, or other stateful configuration, flag in the router advertisement.<br>Other stateful configuration autoconfigures received information without addresses.<br>When set, the O-bit flag indicates that other configuration information is available through DHCPv6; for example, DNS-related information or information about other servers within the network.<br>If neither the M nor O flags are set, no information is available through DHCPv6.<br>The default is disabled. |

| Variable                                            | Value                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ra-lifetime &lt;0-9000&gt;</code>             | Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0, or 4 to 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.                                                 |
| <code>reachable-time &lt;0-3600000&gt;</code>       | Specifies a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. The default is 0.       |
| <code>retransmit-timer &lt;0-4294967295&gt;</code>  | Specifies a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. The default is 0. |
| <code>rtr-advert-max-interval &lt;4-1800&gt;</code> | Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The default is 600.                                                                                                                                                         |
| <code>rtr-advert-min-interval &lt;3-1350&gt;</code> | Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The default is 200.                                                                                                                                                         |
| <code>send-ra</code>                                | Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is enabled.                                                                                                                                                   |

Use the data in the following table to use the **interface** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                          |

*System Interface Values Versus Advertised Values*

There are differences in the relationship between the system interface values and advertised values related to Neighbor Discovery (ND). The information in this section describes differences and similarities and provides examples for important IPv6 interface and IPv6 ND commands.

**Comparison of Default Values per Interface and as Advertised**

The following table compares the default behavior of values per interface and advertised values.

| Default values per interface | Default advertised values        |
|------------------------------|----------------------------------|
| hop-limit 64                 | hop-limit 64                     |
| mtu 1500                     | mtu 0 (unspecified)              |
| reachable-time 30000 ms      | reachable-time 0 (unspecified)   |
| retransmit-timer 1000 ms     | retransmit-timer 0 (unspecified) |

**What Happens When You Change the per Interface Value and the Advertised Value?**

When you change per-interface values from default to non-default values, the system changes the advertised values to match the interface values.

For example, when you enter the `ipv6 interface mtu 1300` command the values become

- interface mtu 1300
- advertised mtu 1300

Then, when you enter the `show ipv6 nd interface` command, the system marks the mtu value with an (i) which signifies that the ND advertised value is inherited from the interface configuration.

**Example: Changing both values**

Switch:1(config-if)#`ipv6 interface mtu 1300`

```
Switch:1(config-if)#
show ipv6 nd interface GigabitEthernet 1/1
```

```
=====
                                Port Ipv6 Nd
=====
IFID BTR  RTR-  MAX-  MIN-  LIFE-  MANAG  OTHER  DAD-NS  MTU    HOP  REACH-  RETRANS-
      ADV  INT  INT  FLAG  TIME  CONF   LIMIT  TIME   TIME   HOP  ABLE    MIT
-----
320  1/1  True  600  200   0     False  False  1     1300(i)  64(d)  0(d)  0(d)
Note: (s) = Set, (d) = Default, (i) = inherit
=====
```

**What Happens When You Change the per Interface Value but do not Change the Advertised Value?**

To change the per-interface value from the default value to a non-default value but retain the advertised value of 0 (unspecified), you must enter two commands.

For example, to set the reachable-time to 60000 but retain the advertised value of the reachable-time parameter at 0, enter the following commands:

```
ipv6 interface reachable-time 6000
```

```
ipv6 nd reachable-time 0
```

When you enter the `show ipv6 nd interface` command, the system marks the reachable-time value with an (s) to signify that this value is explicitly set by the ND configuration.

### Example: Changing only the per interface value

```
Switch:1(config-if)#ipv6 interface reachable-time 60000
```

```
Switch:1(config-if)#ipv6 nd reachable-time 0
```

```
Switch:1(config-if)#
show ipv6 nd interface GigabitEthernet 1/1
```

```

```

## Configure the Neighbor Cache

Configure the address translation table used to map IPv6 addresses to physical addresses. You can manually add static neighbors to the cache.

### Note

IPv6 static neighbors are not supported on SMLT.

### About This Task

Neighbor cache in IPv6 is similar to the IPv4 Address Resolution Protocol (ARP) table.

The neighbor cache is a set of entries for individual neighbors to which traffic was recently sent.

You make entries on the neighbor on-link unicast IP address, including information such as the link-layer address.

A neighbor cache entry contains information used by the Neighbor Unreachability Detection algorithm, including the reachability state, the number of unanswered probes, and the time the next Neighbor Unreachability Detection event is scheduled.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a static neighbor:

```
ipv6 neighbor WORD<0-128> port {slot/port[sub-port]} mac
<0x00:0x00:0x00:0x00:0x00:0x00> [vlan <1-4059> ]
```

When you create a static neighbor, it always remains in the reachable state. This differs from the general neighbor cache behavior where, among other things, timers and neighbor unreachability detection events can be generated.

### Example

Create a static neighbor:

```
Switch:1(config)#ipv6 neighbor 3000::3 port 1/11 mac 00-1A-4B-8A-FB-6B
```

### Variable Definitions

Use the data in the following table to use the **ipv6 neighbor** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>mac</i><br><0x00:0x00:0x00:0x00:0x00:0x00> | Specifies the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                 |
| { <i>slot/port[/sub-port]</i> }               | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                               |
| <i>vlan</i> <1-4059>                          | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>WORD</i> <0-128>                           | Specifies the IPv6 address in hexadecimal colon format.                                                                                                                                                                                                                                                                                                                                                                    |

## View Cached Destination Information

View the destination cache to see next-hop addresses for destinations.

The destination cache is only populated or updated when IPv6 packets originate locally on the central processor of the switch.

The main purpose of the destination cache is to store, on a per-destination basis, the dynamic Path MTU value currently used when transmitting packets from the local system to the remote destination.

The system uses the PMTU value to calculate how many bytes can fit into an individual packet before fragmentation should be applied.

## About This Task

The command output shows the following information:

- the IPv6 destination address
- the IPv6 address for the next hop to the destination
- the path maximum transmission unit (MTU) for the destination
- the time, in seconds, since an ICMPv6 packet-too-big message was received

Not all parameters are available in non-default VRFs.

## Procedure

1. To enter User EXEC mode, log on to the switch.

2. View the destination cache for all interfaces:

```
show ipv6 dcache [vrf WORD<1-16> | vrfids WORD<0-512>]
```

3. View the destination cache for a brouter port:

```
show ipv6 dcache gigabitethernet {slot/port[/sub-port]}
```

4. View the destination cache for a management port:

```
show ipv6 dcache mgmtethernet mgmt
```

### Note

This step applies to VSP 8600 Series only.

5. View the destination cache for a specific tunnel ID:

```
show ipv6 dcache tunnel <1-2000>
```

6. View the destination cache for a VLAN:

```
show ipv6 dcache vlan <1-4059>
```

7. Clear the destination cache:

```
clear ipv6 dcache [gigabitethernet {slot/port[/sub-port]}]
[mgmtethernet {slot/port[/sub-port]}] [tunnel <1-2000>] [vlan <1-4059>]
[vrf WORD<1-16> | vrfids WORD<0-512>]
```

### Note

mgmtEthernet is supported on VSP 8600 Series only.

## Example

```
Switch:1(config-if)#show ipv6 dcache
```

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 dcache** and **clear ipv6 dcache** commands.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                               |
| vrf WORD<1-16>         | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| vrfids WORD<0-512>     | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

## Neighbor Discovery Configuration using EDM

Use the procedures in this section for neighbor discovery configuration using EDM.

### Configuring an IPv6 discovery prefix

Configure the discovery prefixes to send in router advertisement.

#### Before You Begin

Change the VRF instance as required to configure an IPv6 discovery prefix on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

You can also configure an IPv6 interface for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Discovery Prefix** tab.
4. Click **Insert**.
5. Beside the **Interface** field, click **Port** or **VLAN**.

6. Select a port or VLAN.
7. Click **OK**.
8. Specify the prefix and prefix length.
9. Click **Insert**.
10. Click **Apply**.

### **Discovery Prefix** Field Descriptions

Use the data in the following table to use the **Discovery Prefix** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.                                                                                                                                                                                                                                                                                                          |
| <b>Prefix</b>        | Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>PrefixLen</b>     | Configures the mask to create an IPv6 address in the IPv6 interface table.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>VlanId</b>        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.                                                          |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                                                                                                                                                                                                                                                                                             |
| <b>ValidLifetime</b> | Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000.<br>A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PreferredLifetime</b> | Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800.<br>The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.                                                                                                                                                                                                      |
| <b>Infinite</b>          | Configures the prefix valid lifetime so it never expires. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OnLinkFlag</b>        | Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AutoFlag</b>          | Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AddressEui</b>        | Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both global and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used.<br>If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. If you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 address is created by concatenating the specified prefix with the EUI-64 interface ID. |
| <b>NoAdvertise</b>       | Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring an IPv6 discovery prefix port

Configure the discovery prefixes to send in router advertisement.

### About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
2. Click **IPv6**.
3. Click **Discovery Prefix**.
4. Click **Insert**.
5. Click **OK**.
6. Specify the prefix and prefix length.
7. Click **Insert**.
8. Click **Apply**.

### **IPv6 Discovery Prefix** field descriptions

Use the data in the following table to use the **IPv6 Discovery Prefix** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.                                                                                                                                                                                                                                                                                                          |
| <b>Prefix</b>        | Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>PrefixLen</b>     | Configures the mask to create an IPv6 address in the IPv6 interface table.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>VlanId</b>        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.                                                          |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                                                                                                                                                                                                                                                                                             |
| <b>ValidLifetime</b> | Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000.<br>A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PreferredLifetime</b> | Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800.<br>The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.                                                                                                                                                                                                      |
| <b>Infinite</b>          | Configures the prefix valid lifetime so it never expires. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OnLinkFlag</b>        | Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AutoFlag</b>          | Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AddressEui</b>        | Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both global and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used.<br>If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. If you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 address is created by concatenating the specified prefix with the EUI-64 interface ID. |
| <b>NoAdvertise</b>       | Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring an IPv6 discovery prefix on a VLAN

Configure the discovery prefixes to send in router advertisement.

### About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

## Procedure

1. In the navigation pane, expand the following folders: **VLAN > VLANs**.
2. Click the **Basic** tab.
3. Select an interface row.
4. Click **IPv6**.
5. Click the **IPv6 Discovery Prefix** tab.
6. Click **Insert**.
7. Specify the prefix and prefix length.
8. Configure the remaining parameters, as required.
9. Click **Insert**.
10. Click **Apply**.

### **IPv6 Discovery Prefix** Field Descriptions

Use the data in the following table to use the **IPv6 Discovery Prefix** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.                                                                                                                                                                                                                                                                                                         |
| <b>Prefix</b>        | Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PrefixLen</b>     | Configures the mask to create an IPv6 address in the IPv6 interface table.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>VlanId</b>        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.                                                         |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                                                                                                                                                                                                                                                                                            |
| <b>ValidLifetime</b> | Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000.<br>A valid lifetime is the length of time of the preferred and deprecated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PreferredLifetime</b> | Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800.<br>The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address.<br>The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.                                                                                                                                                                                                      |
| <b>Infinite</b>          | Configures the prefix valid lifetime so it never expires. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OnLinkFlag</b>        | Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AutoFlag</b>          | Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>AddressEui</b>        | Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both global and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used.<br>If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. If you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 address is created by concatenating the specified prefix with the EUI-64 interface ID. |
| <b>NoAdvertise</b>       | Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring route advertisement

Configure route advertisement in IPv6 for neighbor discovery (ND).

### Before You Begin

Change the VRF instance as required to configure route advertisement on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

## About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

### Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

You can also configure an IPv6 interface for a brouter port through the **Edit > Port > IPv6** navigation path, and for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

## Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Route Advertisement** tab.
4. Double-click a parameter to change the current value.  
You cannot modify the parameters in gray shading.
5. Click **Apply**.

### **Route Advertisement** field descriptions

Use the data in the following table to use the **Route Advertisement** tab.

| Name                 | Description                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the interface to which this entry applies.                                                                                                                                                                    |
| <b>SendAdverts</b>   | Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.                                                                          |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                                 |
| <b>MaxInterval</b>   | Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.                       |
| <b>MinInterval</b>   | Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and $0.75 \times \text{max-interval}$ . The default is 200. |

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReachableTime</b>   | Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface.       |
| <b>RetransmitTime</b>  | Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface. |
| <b>DefaultLifeTime</b> | Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.                                                                                                                          |
| <b>CurHopLimit</b>     | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.                                                                                                                       |
| <b>ManagedFlag</b>     | Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.                                                                                                                                                                                                                                                       |
| <b>DadNsNum</b>        | Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.                                                                                                                                                                 |
| <b>LinkMTU</b>         | Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.                                                                                                                                                                                                                                                 |
| <b>OtherConfigFlag</b> | Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.                                                                                                                                                                                           |

## Configuring route advertisement on an IPv6 interface for a brouter port

Configure route advertisement in IPv6 for neighbor discovery (ND).

## About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

### Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

You can also configure an IPv6 interface for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path.

## Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
2. Click **IPv6**.
3. Click the **Route Advertisement** tab.
4. Double-click a parameter to change the current value.  
You cannot modify the parameters in gray shading.
5. Click **Apply**.

### **Route Advertisement** field descriptions

Use the data in the following table to use the **Route Advertisement** tab.

| Name                 | Description                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the interface to which this entry applies.                                                                                                                                                     |
| <b>SendAdverts</b>   | Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.                                                           |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                  |
| <b>MaxInterval</b>   | Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.        |
| <b>MinInterval</b>   | Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and 0.75 x max-interval. The default is 200. |

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReachableTime</b>   | Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface.       |
| <b>RetransmitTime</b>  | Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface. |
| <b>DefaultLifeTime</b> | Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.                                                                                                                          |
| <b>CurHopLimit</b>     | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.                                                                                                                       |
| <b>ManagedFlag</b>     | Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.                                                                                                                                                                                                                                                       |
| <b>DadNsNum</b>        | Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.                                                                                                                                                                 |
| <b>LinkMTU</b>         | Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.                                                                                                                                                                                                                                                 |
| <b>OtherConfigFlag</b> | Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.                                                                                                                                                                                           |

## Configuring route advertisement on an IPv6 interface for a VLAN

Configure route advertisement in IPv6 for neighbor discovery (ND).

## About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

### Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

## Procedure

1. In the navigation pane, expand the following folders: **VLAN > VLANs**.
2. Click the **Basic** tab.
3. Select an interface row, and click **IPv6**.
4. Click **Route Advertisement**.
5. Double-click a parameter to change the current value.  
You cannot modify the parameters in gray shading.
6. Click **Apply**.

### **Route Advertisement** field descriptions

Use the data in the following table to use the **Route Advertisement** tab.

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>     | Specifies the interface to which this entry applies.                                                                                                                                                                                                                                                                                                                           |
| <b>SendAdverts</b>   | Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.                                                                                                                                                                                                                                 |
| <b>UseDefaultVal</b> | Specifies one included value to use the default value, or use all bits to configure all options to their default value.                                                                                                                                                                                                                                                        |
| <b>MaxInterval</b>   | Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.                                                                                                                                                                              |
| <b>MinInterval</b>   | Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and 0.75 x max-interval. The default is 200.                                                                                                                                                                       |
| <b>ReachableTime</b> | Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface. |

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RetransmitTime</b>  | Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the <b>Interfaces</b> tab to change the value for the interface. |
| <b>DefaultLifeTime</b> | Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.                                                                                                                          |
| <b>CurHopLimit</b>     | Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.                                                                                                                       |
| <b>ManagedFlag</b>     | Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.                                                                                                                                                                                                                                                       |
| <b>DadNsNum</b>        | Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.                                                                                                                                                                 |
| <b>LinkMTU</b>         | Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.                                                                                                                                                                                                                                                 |
| <b>OtherConfigFlag</b> | Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.                                                                                                                                                                                           |

## Configuring the neighbor cache

Configure the address translation table used to map IPv6 addresses to physical addresses. You can manually add static neighbors to the cache.

### Note

IPv6 static neighbors are not supported on SMLT.

### Before You Begin

Change the VRF instance as required to configure neighbor cache on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

## About This Task

Neighbor cache in IPv6 is similar to the IPv4 Address Resolution Protocol (ARP) table. The neighbor cache is a set of entries for individual neighbors to which traffic was sent recently. You make entries on the neighbor on-link unicast IP address, including information such as the link-layer address. A neighbor cache entry contains information used by the Neighbor Unreachability Detection algorithm, including the reachability state, the number of unanswered probes, and the time the next Neighbor Unreachability Detection event is scheduled.

## Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Neighbors** tab.
4. Click **Insert**.
5. Beside the **Interface** field, click **Port** or **Port in Vlan**.
6. Select a port or VLAN.
7. Configure the remaining parameters as required.
8. Click **Insert**.
9. Click **Apply**.

### *Neighbors* Field Descriptions

Use the data in the following table to use the **Neighbors** tab.

| Name               | Description                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>   | Specifies the interface to which this entry applies.                                                                                                                                                      |
| <b>NetAddress</b>  | Specifies the IP address of the media-dependent physical address.                                                                                                                                         |
| <b>PhyAddress</b>  | Specifies the MAC address.                                                                                                                                                                                |
| <b>Interface</b>   | Specifies a physical port ID or an MLT port ID.                                                                                                                                                           |
| <b>LastUpdated</b> | Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value. |
| <b>Type</b>        | Specifies the mapping type from manually configured entries. While the selection of either dynamic, static, or local is allowed; static is currently the only valid selection.                            |

| Name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>State</b> | Specifies the Neighbor Unreachability Detection state for the interface after the address mapping in this entry is used. If Neighbor Unreachability Detection is not in use (for example, for IPv4), this object is always unknown. The options include the following: <ul style="list-style-type: none"> <li>• reachable: confirmed reachability</li> <li>• stale: unconfirmed reachability</li> <li>• delay: waiting for reachability confirmation before entering the probe state</li> <li>• probe: actively probing</li> <li>• invalid: an invalidated mapping</li> <li>• unknown: state cannot be determined.</li> <li>• incomplete: address resolution is being performed</li> </ul> |
| <b>BMac</b>  | Specifies the backbone MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Cvid</b>  | Specifies the customer VID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Viewing cached destination information

View the destination cache to see next-hop addresses for destinations.

The destination cache is only populated or updated when IPv6 packets are locally originated on the central processor of the switch.

The main purpose of the destination cache is to store, on a per-destination basis, the dynamic Path MTU value currently used when transmitting packets from the local system to the remote destination. The PMTU value itself is used to calculate how many bytes can fit into an individual packet before fragmentation should be applied.

### Before You Begin

Change the VRF instance as required to view cached destination information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Destination Cache** tab.

### *Destination Cache* Field Descriptions

Use the data in the following table to use the **Destination Cache** tab.

| Name             | Description                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DestAddr</b>  | Shows the IPv6 destination address.                                                                                                                                                                              |
| <b>Interface</b> | Shows the interface number that is used to reach the destination.                                                                                                                                                |
| <b>NextHop</b>   | Shows the IPv6 address for the next hop to the destination.                                                                                                                                                      |
| <b>IfType</b>    | Specifies the interface type (tunnel, VLAN, or brouter) or virtual circuit (VRRP, RSMLT).                                                                                                                        |
| <b>IfData</b>    | Displays additional information about virtual circuits. For instance, for a VRRP or RSMLT the virtual router ID displays. If the interface type is tunnel, VLAN, or brouter, no additional information displays. |
| <b>Pmtu</b>      | Shows the path maximum transmission unit (MTU) for the destination.                                                                                                                                              |
| <b>PmtuAge</b>   | Shows the time, in seconds, since an ICMPv6 packet too big message was received.                                                                                                                                 |

# IPv6-in-IPv4 Tunneling

|                      | VSP 8600 Series | VSP 8600 6.2       |
|                      | XA1400 Series   | Not Supported      |

## Tunneling

---

Tunneling provides a mechanism to transfer IPv6 traffic through an IPv4-only network.

### How tunneling works

IPv6 tunneling encapsulates IPv6 packets in IPv4 packets for delivery across an IPv4 infrastructure.

At the tunnel source, or head end, the system encapsulates an IPv6 packet into an IPv4 packet and sends it to the remote tunnel destination.

The tunnel destination strips the IPv4 packet header and forwards the original IPv6 packet further into an IPv6 cloud.

These types of tunnels are called dual-stack tunnels because they support both IPv4 and IPv6.

## Manually configured tunnels

Manually configured tunnels can provide communication between two isolated IPv6 domains over an IPv4 network.

Manually configured tunnels are point-to-point.

You can configure tunnel endpoints to create a point-to-point connection between two isolated IPv6 domains by configuring IPv6 and IPv4 addresses at each end of the tunnel.

### Note

The router or host at the source and destination ends of the tunnel must support both IPv4 and IPv6 protocol stacks.

### Caution

Ensure that all single-homed point-to-point traffic ingresses and egresses a configured tunnel. Otherwise the traffic is dropped.

IPv6 reachability enables tunnel forwarding but tunnel operational status depends on the IPv4 reachability of the tunnel endpoint.

The IPv4 tunnel endpoint configuration must be symmetrical; that is, if you configure a tunnel with a source of 10.10.10.1 and a destination of 11.11.11.1 from switch A, then Switch B must have a source of 11.11.11.1 and a destination of 10.10.10.1.

Tunnel interfaces are logical point-to-point interfaces.

You can enable dynamic routing when you enable a routing protocol, for example OSPFv3, on the tunnel interfaces.

### *Unicast routing protocols can detect link loss and redirect IPv6 route information*

There is no explicit signaling protocol applied to IPv6-in-IPv4 configured tunnels (refer to RFC 4213).

Therefore, if the remote endpoint of a tunnel that terminates several Layer 3 hops away in the network fails, the local state of the tunnel remains active even though the endpoint has failed.

However, you can enable unicast routing protocols over tunnels, for example OSPFv3. These unicast routing protocols introduce their own protocol-specific signaling and, when a unicast routing protocol is present over the tunnel link, the routing protocol can detect link loss and re-direct the IPv6 route information to use an alternate, reachable nexthop.

### *Operational events that trigger tunnel state transition*

The switch must be able to locally detect operational events that can trigger a tunnel state transition.

These events include:

- deletion of local IPv4 interface
- change or loss of the IPv4 route to the remote tunnel endpoint
- change in the nexthop of the IPv4 route to the remote tunnel endpoint
- loss of the ARP entry for the nexthop router that is used to reach the IPv4 tunnel endpoint

### *Tunnels and MTU*

You cannot configure the MTU for tunnels.

The default MTU value for tunnels is 1280.

Packets are forwarded through the tunnel using the line card network processing units (NPUs) only. Since the packets are not forwarded through the central processing unit (CPU) they do not impact the CPU load.

### *Tunnels and BGP+*

You must configure an IPv6 tunnel and static routes on BGP+ peers when you use BGP+. For more information on IPv6 tunnel configuration for BGP+, see [IPv6 Tunnel Configurations for BGP+](#) on page 488.

## Limitations

The following list identifies tunnel configuration limitations.

- You cannot configure IPv6 CLIP addresses for IPv6-in-IPv4 tunnels. Also, you cannot configure an IPv6 CLIP interface as the source or destination endpoint of a tunnel.
- You cannot configure SMLT on the switch terminating a tunnel.
- Termination of tunnels on vIST peers is not supported.

## Tunneling Configuration using CLI

---

Use the procedures in this section to configure Tunnel using CLI.

### Configuring a tunnel

Configure a tunnel for IPv6 VLANs or brouter ports to communicate through an IPv4-only network. Create a point-to-point connection between the two isolated IPv6 devices by configuring the tunnel endpoints.

Do not create tunnels in a native IPv6 network.

#### **Before You Begin**

- The router or host at the source and destination of the tunnel must support both IPv4 and IPv6 protocol stacks.

#### **About This Task**

Manual tunnels are point-to-point, so you configure both source and destination addresses. You must configure both IPv6 and IPv4 addresses for both source and destination devices. The IPv6 addresses must represent the same network, for example 6666::1/96 and 6666::2/96.

Tunnel interfaces are automatically configured with a link-local address in the format fe80::<local\_ipv4\_source\_address>.

You cannot configure the maximum transmission unit (MTU) for tunnels. The default MTU value for tunnels is 1280.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Create a tunnel:  
ipv6 tunnel <1-2000> source {A.B.C.D} address WORD<0-46> destination {A.B.C.D}

**Example**

Create tunnel 2:

```
Switch:1(config)#ipv6 tunnel 2 source 11.11.11.1 address
3000:0:0:0:0:0:1/64 destination 12.12.12.2
```

*Variable definitions*

Use the data in the following table to use the **ipv6 tunnel** command.

| Variable              | Value                                                        |
|-----------------------|--------------------------------------------------------------|
| <1-2000>              | Configures the ID for the tunnel.                            |
| address WORD<0-46>    | Assigns an IPv6 address and prefix to the tunnel.            |
| destination {A.B.C.D} | Configures the address of the remote endpoint of the tunnel. |
| source {A.B.C.D}      | Configures the address of the local endpoint of the tunnel.  |

**View Tunnel Interfaces**

View tunnel interfaces to verify the current configuration and operational status of IPv6 tunnels.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Show IPv6 tunnel information:  
show ipv6 tunnel [<1-2000>] [detail] [local {A.B.C.D}] [remote {A.B.C.D}]

**Example**

```
Switch:1#show ipv6 tunnel detail
```

```
=====
                        Tunnel Interface Information
=====
ID          LOCAL ADDRESS  REMOTE ADDRESS  OPER STATUS  TYPE
-----
2           211.1.55.2      44.1.55.1      active       manual
1           211.1.55.2      44.1.55.43     active       manual
210         211.1.60.2      47.1.60.1      active       manual

3 out of 3 Total number of entries displayed.
```

```

-----
=====
                                Address Information
=====

fe80:0:0:0:0:0:d301:3702/64                            UNICAST LINKLAYER PREFERRED
44:211:0:0:0:0:0:2/64                                    UNICAST MANUAL    PREFERRED
fe80:0:0:0:0:0:d301:3702/64                            UNICAST LINKLAYER PREFERRED
    
```

*Variable definitions*

Use the data in the following table to use the **show ipv6 tunnel** command.

| Variable                | Value                                                                                |
|-------------------------|--------------------------------------------------------------------------------------|
| <1-2000>                | Shows information for a specific tunnel ID.                                          |
| <i>detail</i>           | Shows detailed address information for the tunnel.                                   |
| <i>local {A.B.C.D}</i>  | Shows information for a specific local address (the local endpoint of the tunnel).   |
| <i>remote {A.B.C.D}</i> | Shows information for a specific remote address (the remote endpoint of the tunnel). |

## Modifying tunnel hop limits

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

### About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Modify the hop limit:
 

```
ipv6 tunnel <1-2000> hop-limit <0-255>
```

### Example

Modify the hop limit for tunnel ID 5:

```
Switch:1(config)#ipv6 tunnel 5 hop-limit 200
```

### Variable definitions

Use the data in the following table to use the **ipv6 tunnel** command.

| Variable | Value                                                                          |
|----------|--------------------------------------------------------------------------------|
| <0–255>  | Configures the maximum number of hops in the tunnel. The default value is 255. |
| <1–2000> | Specifies the tunnel ID.                                                       |

## Tunneling Configuration using EDM

Use the procedures in this section to configure Tunnel using EDM.

### Configuring a tunnel

Configure a tunnel for IPv6 VLANs or brouter ports to communicate through an IPv4-only network. Create a point-to-point connection between the two isolated IPv6 devices by configuring the tunnel endpoints.

Do not create tunnels in a native IPv6 network.

#### Before You Begin

- The router or host at the source and destination of the tunnel must support both IPv4 and IPv6 protocol stacks.

#### About This Task

Manual tunnels are point-to-point, so you configure both source and destination addresses. You must configure both IPv6 and IPv4 addresses for both source and destination devices. The IPv6 addresses must represent the same network, for example 6666::1/96 and 6666::2/96.

Tunnel interfaces are automatically configured with a link-local address in the format fe80::<local\_ipv4\_source\_address>.

You cannot configure the maximum transmission unit (MTU) for tunnels. The default MTU value for tunnels is 1280.

#### Procedure

- In the navigation tree, expand the following folders: **Configuration > IPv6**.
- Click **Tunnel**.
- Click the **Tunnel Config** tab.
- Click **Insert**.
- Beside the **LocalAddress** field, click the button, and then select the IPv4 address for the local VLAN or brouter port.
- In the **RemoteAddress** field, type the IPv4 address for the destination VLAN or brouter port.
- In the **ID** field, type a number to represent the tunnel.
- In the **IPv6AddressAddr** field, type the IPv6 address for the tunnel VLAN or brouter port.
- In the **IPv6AddressPrefixLength** field, type the number of bits to advertise in the IPv6 address.
- Click **Insert**.

**Tunnel Config** field descriptions

Use the data in the following table to use the **Tunnel Config** tab.

| Name                           | Description                                                                                                                                                                                                          |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddressType</b>             | Shows the address type over which the tunnel encapsulates packets.                                                                                                                                                   |
| <b>LocalAddress</b>            | Configures the address of the local endpoint of the tunnel.                                                                                                                                                          |
| <b>RemoteAddress</b>           | Configures the address of the remote endpoint of the tunnel.                                                                                                                                                         |
| <b>EncapsMethod</b>            | Configures the tunnel mode, which is manual for manually configured tunnels.                                                                                                                                         |
| <b>ID</b>                      | Configures the ID for the tunnel.                                                                                                                                                                                    |
| <b>IfIndex</b>                 | Shows the value of ifIndex that corresponds to the tunnel interface. A value of 0 indicates that the interface index has not yet been assigned. The system displays this field only on the <b>Tunnel Config</b> tab. |
| <b>Ipv6AddressAddr</b>         | Specifies the IPv6 address for the local VLAN or brouter port. The system displays this field only on the <b>Insert Tunnel Config</b> dialog box.                                                                    |
| <b>Ipv6AddressPrefixLength</b> | Specifies the number of bits to advertise in the IPv6 address. The system displays this field only on the <b>Insert Tunnel Config</b> dialog box.                                                                    |

## Modifying tunnel hop limits

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

Use this procedure to modify the hop limits for multiple tunnels simultaneously.

### About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **Tunnel**.
3. Click the **Tunnel Interface** tab.
4. Double-click the **HopLimit** value to modify the information as required.
5. Click **Apply**.

**Tunnel Interface** field descriptions

Use the data in the following table to use the **Tunnel Interface** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>            | Identifies the tunnel interface internally. The value is derived from the tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EncapsMethod</b>     | Displays the encapsulation method for the tunnel: manual for manually configured tunnels and 6to4 for automatically configured tunnels.                                                                                                                                                                                                                                                                                                                                                     |
| <b>HopLimit</b>         | Configures the maximum number of hops in the tunnel. The default value is 255.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security</b>         | Indicates the type of security on the tunnel interface.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>TOS</b>              | Displays the method used to configure the high 6 bits (the differentiated services codepoint) of the IPv4 type of service (TOS) or IPv6 traffic class in the outer IP header.<br>A value of -1 indicates that the bits are copied from the payload header. A value of -2 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB module. A value from 0 to 63 indicates that the bit field is configured to the indicated value. |
| <b>FlowLabel</b>        | Displays the method used to configure the IPv6 flow label value. This object is not required where AddressType indicates the tunnel is not over IPv6. A value of -1 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB. Any other value indicates that the flow label field is configured to the indicated value.                                                                                                           |
| <b>AddressType</b>      | Displays manual for a manually configured tunnel, or sixToFour for autoconfigured tunnels.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>LocalNetAddress</b>  | Identifies the local endpoint address of the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>RemoteNetAddress</b> | Identifies the remote endpoint of the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EncapsLimit</b>      | Displays the maximum number of additional encapsulations permitted for packets undergoing encapsulation at this node. A value of -1 indicates that no limit exists, except as a result of the packet size.                                                                                                                                                                                                                                                                                  |

## Modifying tunnel hop limits for a specific tunnel

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

Use this procedure to modify the hop limits for a specific tunnel interface.

### About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

## Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **Tunnel**.
3. Click the **Tunnel Config** tab.
4. Select the tunnel row.
5. Click **Tunnel Interface**.
6. Double-click the **HopLimit** value to modify the information as required.
7. Click **Apply**.

### **Tunnel Interface** field descriptions

Use the data in the following table to use the **Tunnel Interface** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>           | Identifies the tunnel interface internally. The value is derived from the tunnel ID.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>EncapsMethod</b>    | Displays the encapsulation method for the tunnel: manual for manually configured tunnels and 6to4 for automatically configured tunnels.                                                                                                                                                                                                                                                                                                                                                     |
| <b>HopLimit</b>        | Configures the maximum number of hops in the tunnel. The default value is 255.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Security</b>        | Indicates the type of security on the tunnel interface.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>TOS</b>             | Displays the method used to configure the high 6 bits (the differentiated services codepoint) of the IPv4 type of service (TOS) or IPv6 traffic class in the outer IP header.<br>A value of -1 indicates that the bits are copied from the payload header. A value of -2 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB module. A value from 0 to 63 indicates that the bit field is configured to the indicated value. |
| <b>FlowLabel</b>       | Displays the method used to configure the IPv6 flow label value. This object is not required where AddressType indicates the tunnel is not over IPv6. A value of -1 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB. Any other value indicates that the flow label field is configured to the indicated value.                                                                                                           |
| <b>AddressType</b>     | Displays manual for a manually configured tunnel, or sixToFour for autoconfigured tunnels.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>LocalNetAddress</b> | Identifies the local endpoint address of the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Name                     | Description                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RemoteInetAddress</b> | Identifies the remote endpoint of the tunnel.                                                                                                                                                              |
| <b>EncapsLimit</b>       | Displays the maximum number of additional encapsulations permitted for packets undergoing encapsulation at this node. A value of -1 indicates that no limit exists, except as a result of the packet size. |

## Viewing IPv6 addresses on a tunnel

View a tunnel for IPv6 addresses.

You can assign an IPv6 address to a VLAN or brouter port.

### About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

You can also assign an IPv6 address through the **Edit > Port > IPv6** navigation path, and through the **VLAN > VLANs > Basic > IPv6** navigation path.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Click **Tunnel**.
3. Click the **Tunnel Config** tab.
4. Click **IPv6 Address**.

### **Tunnel Config** field descriptions

Use the data in the following table to use the **Tunnel Config** tab.

| Name                 | Description                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddressType</b>   | Shows the address type over which the tunnel encapsulates packets.                                                                                                                                                   |
| <b>LocalAddress</b>  | Configures the address of the local endpoint of the tunnel.                                                                                                                                                          |
| <b>RemoteAddress</b> | Configures the address of the remote endpoint of the tunnel.                                                                                                                                                         |
| <b>EncapsMethod</b>  | Configures the tunnel mode, which is manual for manually configured tunnels.                                                                                                                                         |
| <b>ID</b>            | Configures the ID for the tunnel.                                                                                                                                                                                    |
| <b>IfIndex</b>       | Shows the value of ifIndex that corresponds to the tunnel interface. A value of 0 indicates that the interface index has not yet been assigned. The system displays this field only on the <b>Tunnel Config</b> tab. |

## IPv6 Tunnel Configuration Example

This section shows examples of manually configured tunnels between router ports and VLANs.

### Between router ports

The following figure shows the tunnel configuration between router ports.

**Figure 178: Tunnel configuration between router ports**

You must configure static routes, RIP, or OSPF on both the source (Switch 1) and destination (Switch 2) IPv4 interfaces to communicate on the IPv4 network. You must configure IPv4 addresses on the source and destination.

#### Configuring Switch 1

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 10 type port-mstprstp 0
vlan mlt 10 4
vlan members 10 1/1 portmember
interface vlan 10
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:0:1/64
exit
```

Create an IPv4 router port and enable OSPF on the port.

```
interface GigabitEthernet 1/30
brouter port 1/30 vlan 1000 subnet 172.21.80.1/255.255.255.0 mac-offset
6
```

Create the tunnel from the source to the destination.

```
ipv6 tunnel 1 source 172.21.80.1 address 2500:0000:0000:0000:0000:0000:0000:0001/64
destination 192.168.20.1
```

Configure a static route on the source.

```
ipv6 route 4000:0:0:0:0:0:0:2/64 cost 1 tunnel 1
```

Optionally, you can create an OSPFv3 interface through the tunnel.

```
router ospf ipv6-enable
router ospf
ipv6 tunnel 1 area 0.0.0.0
ipv6 tunnel 1 enable
exit
```

## Configuring Switch 2

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 40 type port-mstprstp 0
vlan mlt 40 4
vlan members 40 1/2 portmember
interface vlan 40
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:2/64
exit
```

Create an IPv4 brouter port and enable OSPF on the port.

```
interface GigabitEthernet 1/30
brouter port 1/30 vlan 2000 subnet 192.168.20.1/255.255.255.0 mac-offset 6
```

Create the tunnel from the destination to the source.

```
ipv6 tunnel 1 source 192.168.20.1 address 2500:0000:0000:0000:0000:0000:0002/64
destination 172.21.80.1
```

Configure a static route on the destination.

```
ipv6 route 4000:0:0:0:0:0:1/64 cost 1 tunnel 1
```

Optionally, you can create an OSPFv3 interface through the tunnel.

```
router ospf ipv6-enable
router ospf
ipv6 tunnel 1 area 0.0.0.0
ipv6 tunnel 1 enable
exit
```

## Between VLANs

The following figure shows the tunnel configuration between VLANs.

**Figure 179: Tunnel configuration between VLANs**

You must configure static routes, and either RIP or OSPF on both the source (Switch 1) and destination (Switch 2) IPv4 interfaces to communicate on the IPv4 network. You must configure IPv4 addresses on the VLANs.

### Configuring Switch 1

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 10 type port-mstprstp 0
vlan mlt 10 4
vlan members 10 1/1 portmember
interface vlan 10
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:1/64
exit
```

Create an IPv4 VLAN, add ports to the VLAN, and enable OSPF on the VLAN.

```
vlan create 20 type port-mstprstp 0
vlan mlt 20 4
vlan members 20 1/30 portmember
interface vlan 20
ip address 172.21.80.1 255.0.0.0
ip ospf enable
exit
```

Create the tunnel from the source to the destination.

```
ipv6 tunnel
1 source 172.21.80.1 address 2500:0000:0000:0000:0000:0000:0001/64
destination 192.168.20.1
```

### Configuring Switch 2

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 40 type port-mstprstp 0
vlan mlt 40 4
vlan members 40 1/2 portmember
interface vlan 40
ipv6 interface
```

```

ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:2/64
exit

```

Create an IPv4 VLAN , add ports to the VLAN, and enable OSPF on the VLAN.

```

vlan create 30 type port-mstprstp 0
vlan mlt 30 4
vlan members 30 1/30 portmember
interface vlan 30
ip address 192.168.20.1 255.0.0.0
ip ospf enable
exit

```

Create the tunnel from the destination to the source.

```

ipv6 tunnel 1 source 192.168.20.1 address 2500:0000:0000:0000:0000:0000:0002/64
destination 172.21.80.1

```

## Verification

Use the following show command to verify tunnel creation on the source device:

```

Switch:1(config)#show ipv6 tunnel 1 detail
=====
                        Tunnel Interface Information
=====
ID          LOCAL ADDRESS  REMOTE ADDRESS  OPER STATUS  TYPE
-----
1           172.21.80.1    192.168.20.1   active       manual

1 out of 1 Total number of entries displayed.

-----

=====
                        Address Information

# Key Health Indicators (KHI)

[Key Health Indicators Using the CLI on page 2007](#)  
[Key Health Indicators Using EDM on page 2021](#)

**Table 141: Key Health Indicator product support**

| Feature                    | Product         | Release introduced |
|----------------------------|-----------------|--------------------|
| Key Health Indicator (KHI) | 5420 Series     | VOSS 8.4           |
|                            | 5520 Series     | VOSS 8.2.5         |
|                            | VSP 4450 Series | VSP 4000 4.0       |
|                            | VSP 4900 Series | VOSS 8.1           |
|                            | VSP 7200 Series | VOSS 4.2.1         |
|                            | VSP 7400 Series | VOSS 8.0           |
|                            | VSP 8200 Series | VSP 8200 4.0       |
|                            | VSP 8400 Series | VOSS 4.2           |
|                            | VSP 8600 Series | VSP 8600 4.5       |
|                            | XA1400 Series   | VOSS 8.0.50        |

The Key Health Indicators (KHI) feature provides a subset of health information that allows for quick assessment of the overall operational state of the device.

#### Note

KHI was not designed to provide a comprehensive debugging solution. Instead, KHI identifies key information that could lead support personnel towards discovery of a specific failure. After the technician assesses the KHI information, further debugging is required to determine the specific reason for the fault.

You should capture KHI information during normal operations to provide a baseline for support personnel when detecting fault situations.

## Key Health Indicators Using the CLI

Use the procedures in this section to display Key Health Indicator (KHI) information using the CLI.

## Displaying KHI Performance Information

Use the following commands to display KHI information about the performance of the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display buffer performance and utilization statistics:
 

```
show khi performance buffer-pool [{slot[-slot] [, ...]]}
```
3. Show current utilization, 5-minute average utilization, and 5-minute high water mark with date and time of event:
 

```
show khi performance cpu [{slot[-slot] [, ...]]}
```
4. Display memory performance and utilization statistics on the specified slot or all slots:
 

```
show khi performance memory [history | {slot[-slot] [, ...]]}
```

### Note

Depending on the hardware platform, you can display virtual memory history.

5. Display process performance and utilization statistics on the specified slot or all slots:
 

```
show khi performance process [{slot[-slot] [, ...]]}
```
6. Display thread performance and utilization statistics on the specified slot or all slots:
 

```
show khi performance pthread [{slot[-slot] [, ...]]}
```
7. Display internal memory management resource performance and utilization statistics on the specified slot or all slots:
 

```
show khi performance slabinfo [{slot[-slot] [, ...]]}
```

### Example

```
Switch:1>show khi performance buffer-pool 1
Slot:1
  CPP:
    UsedFBuffs: 12
    FreeFBuffs: 3060
    RxQ0FBuffs: 0
    RxQ1FBuffs: 0
    RxQ2FBuffs: 0
    RxQ3FBuffs: 0
    RxQ4FBuffs: 0
    RxQ5FBuffs: 0
    RxQ6FBuffs: 0
    RxQ7FBuffs: 0
    TxQueueFBuffs: 0
    NoFbuff: 0

  Network stack system:
    UsedMbuf: 244
    FreeMbuf: 47606
    SocketMbuf: 19

  Network stack data:
    UsedMbuf: 4
    FreeMbuf: 10748

  Letter API message queue:
    QHigh: 0
    QNormal: 0
```

```

FreeQEntries: 51200

Switch:1>show khi performance cpu 1
Slot:1
  Current utilization: 9
  1-minute average utilization: 9
  1-minute high water mark: 14 (06/20/16 06:03:08)
  5-minute average utilization: 8
  5-minute high water mark: 10 (06/19/16 08:35:58)

```

Depending on the switch hardware, any one of the following output can display for **show khi performance memory** [{slot[-slot][, ...]}].

```

Switch:1>show khi performance memory 1
Slot:1
  Used: 514560 (KB)
  Free: 521260 (KB)
  Current utilization: 49 %
  5-minute average utilization: 49 %
  5-minute high water mark: 22 (10/08/14 14:48:01)

```

```

Switch:1>show khi performance memory 1
Slot:1
  Used: 1684000 (KB)
  Free: 2321704 (KB)
  Current utilization: 42 %
  5-minute average utilization: 41 %
  5-minute high water mark: 41 (%)
  10-minute average utilization: 41 %
  10-minute high water mark: 41 (%)
  1-Hour average utilization: 41 %
  1-Hour high water mark: 41 (%)
  1-Day average utilization: 41 %
  1-Day high water mark: 41 (%)
  1-Month average utilization: 39 %
  1-Year average utilization: 0 %

```

Depending on the hardware platform, you can display virtual memory history using **show khi performance memory history**.

```

Switch:1>show khi performance memory history
Slot:1
Values indicate VMSize in KB

Pid    Pname                5-Min   10-Min   1-Hour   1-Day   1-Month  1-
Year

Variable Definitions

Use the data in the following table to use the **show khi performance** command.

| Variable                                                                                                                       | Value                                               |
|--------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| <i>{slot[-slot][, ...]}</i>                                                                                                    | Specifies the slot number. Valid slot is 1.         |
| <i>history</i>                                                                                                                 | Specifies virtual memory consumed for each process. |
| <b>Note:</b><br>Depending on the hardware platform, the system displays this parameter in <b>show khi performance memory</b> . |                                                     |

## Displaying KHI Control Processor Information

Display key health information about the type of packets and protocols received on a port. This command helps debug high CPU utilization issues.

### About This Task

You can use the packets-per-second information in the output to identify where the bulk of packets destined for the CPU enter the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display statistics for control packets that go to the control processor:

```
show khi cpp port-statistics [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

### Example

```
Switch:1>show khi cpp port-statistics
=====
                KHI CPP Details - Port Statistics
=====
Port          Packet Type                Rx Packets  Rx Diff  Rx Pps  Tx Packets  Tx Diff  Tx Pps
-----
1653 seconds since issuing the last KHI command.
2/2          Ether2_LLDP(3)              0           0         0       2233        1         0
2/2          LLC_BPDU(128)              0           0         0       33508       10        0
2/2          LLC_TDP(134)               11100        4         0       11090       4         0
2/3          Ether2_LLDP(3)              0           0         0       2233        56        0
2/3          LLC_BPDU(128)              16           0         0       33504       837       0
2/3          LLC_TDP(134)               11100       278         0       11090       278       0
2/4          Ether2_LLDP(3)              0           0         0       2233        56        0
2/4          LLC_BPDU(128)              2           0         0       33508       837       0
2/4          LLC_TDP(134)               11100       278         0       11090       278       0
```

### Variable Definitions

Use the data in the following table to use the **show khi cpp port-statistics** command.

| Variable                                                           | Value                                                                                                                                                                                                               |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). |

## View KHI Segmented Management Instance Information

Use the following commands to view Key Health Indicator (KHI) for segmented management instance interface information of the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.

- View KHI management instance statistics:

**Note**

This command and all parameters do not apply to all hardware platforms.

```
show khi mgmt statistics [clip | oob | vlan]
```

**Example**

```
Switch:1>show khi mgmt statistics
```

```
=====
=====
                                     Packet Counters - Interface Mgmt-oob
=====
=====
```

| Packet Type             | Rx Packets | Tx Packets | Rx Packets Dropped |
|-------------------------|------------|------------|--------------------|
| Telnet                  | 1034       | 682        | 0                  |
| Ntp                     | 0          | 0          | 173                |
| Dhcp                    | 0          | 0          | 837                |
| OtherUdpWellKnown       | 0          | 0          | 1182               |
| Arp-reply               | 74         | 303        | 0                  |
| Arp-request             | 59915      | 74         | 0                  |
| IcmpV6-nd-nbr-solicit   | 0          | 1          | 0                  |
| IcmpV6-nd-router-advert | 27         | 0          | 0                  |

## Clear KHI Information

KHI information can be cleared globally across the whole device. Use the command to clear the CPP port statistics or Segmented Management Instance statistics.

**Procedure**

- Enter Privileged EXEC mode:
 

```
enable
```
- Clear CPP statistics:
 

```
clear khi cpp port-statistics
```
- Clear segmented management instance statistics:

**Note**

This step does not apply to VSP 8600 Series.

```
clear khi mgmt statistics
```

## Displaying KHI Fabric Extend ONA Status

### About This Task

#### Note

This feature only applies to platforms that have an Open Networking Adapter (ONA) connected to it.

Use the following command to display the current status of the Fabric Extend ONA, which includes release information.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display the ONA status:  

```
show khi fe-ona status
```

### Example

The following output displays the `show khi fe-ona status` when the ONA is operating normally.

```
Switch:1#show khi fe-ona status

=====
                        ONA STATUS
=====
ONA Device Status : UP
Running Release Name : v1.0.0.0int006-3-g9749735-dirty
Last Image Upgrade Status : UPGRADE_SUCCESS
Last Image File Used For Upgrde: gdb-secure_ona.tgz
-----
```

The following examples display the output when communication from the switch to the ONA is disrupted. Note that the `ONA Down reason` lists the cause of the failure. The reason changes depending on the context of the failure.

The following output displays when the configuration push from the switch to the ONA fails:

```
Switch:1#show khi fe-ona status

=====
                        ONA STATUS
=====
ONA Device Status : DOWN
ONA DOWN reason : ONA_CONFIG_DOWNLOAD_FAILED
Running Release Name :
Image Upgrade Status : UNKNOWN
-----
```

The following output displays when the port connecting to the ONA device port is DOWN:

```
Switch:1#show khi fe-ona status

=====
                        ONA STATUS
=====
ONA Device Status : DOWN
ONA DOWN reason : ONA_DEVICE_PORT_DOWN
-----
```

```
Running Release Name :
Image Upgrade Status : UNKNOWN
Image File Is Being Used For Upgrade :
-----
```

The following output displays when the switch is not receiving LLDP packets from the ONA:

```
Switch:1#show khi fe-ona status

=====
                        ONA STATUS
=====
ONA Device Status : DOWN
ONA DOWN reason : ONA_LLDP_TIMEOUT
Running Release Name :
Image Upgrade Status : UNKNOWN
-----
```

**Note**

On the switch console, the following log message precedes all three of the above cases:  
 CP1 [03/22/71 09:30:15.336:UTC] 0x00378601 00000000 GlobalRouter  
 ONA WARNING ONA device status detected down

## Displaying KHI Fabric Extend ONA Global Information

### About This Task

**Note**

This feature only applies to platforms that have an Open Networking Adapter (ONA) connected to it.

Use the following command to display Fabric Extend ONA global information such as port numbers, IP addresses, and MTU.

### Procedure

1. Enter Privileged EXEC mode:  
 enable
2. Display the ONA global information:  
 show khi fe-ona detail

### Example

```
Switch:1#show khi fe-ona detail

=====
                        ONA RUNTIME INFORMATION
=====
ONA Port Number : 1/15
ONA Management Address : 100.1.1.11
Tunnel Source IP Address : 198.51.100.11
ONA LLDP Port Status : Enabled
ONA Device Port Status : UP
ONA Device Status : UP
MTU : 1000
ONA Network Port Number : 1/35
ONA Mac (ARP) Address : 10:cd:ae:69:b6:50
```

```

ONA Source VlanId : 1050
ONA Source VlanIP : 192.0.2.1
ONA Gateway IP : 192.0.2.1
ONA Management IP Mask : 255.255.255.0
ONA Bootmode : 1
ONA Uptime : 0 day(s), 00:00:00
pbit-to-dscp-map p0=16 p1=20 p2=24 p3=30 p4=36 p5=40 p6=48 p7=46
-----

```

### Note

In the above example, the switch receives LLDP packets with the Management IP address of the ONA over the ONA Port (1/15). The switch extracts the ONA Management IP from the LLDP packet and resolves the ARP of the ONA over the network port (1/35). After the switch resolves the ARP of the ONA IP, the `show khi fe-ona detail` updates the following details:

- ONA Network Port Number
- ONA Mac(ARP) Address
- ONA Source VlanId

Note the following in regard to the `show khi fe-ona detail` output shown above:

- `ONA Source VlanIP : 192.0.2.1`—This is the IP address of the switch VLAN that switches traffic to the ONA network port. In the above output, this is VLAN 1050.
- `ONA Gateway IP : 192.0.2.1`—This is the ONA gateway IP address that the switch gets by querying the ONA. The ONA receives this gateway IP from the DHCP server.

### Important

The `ONA Source VlanIP`, and `ONA Gateway IP` addresses must be the same for the tunnels to come up and the traffic to switch.

## Key Health Indicators Using EDM

Use the procedures in this section to display KHI information using EDM.

### Clearing KHI Statistics

#### About This Task

Clear KHI statistics.

#### Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand the **Configuration > Edit** folders.
3. Click **Chassis**.
4. Click the **CPP Stats Control** tab.
5. Select the statistics you want to clear.
6. Click **Apply**.

**CPP Stats Control** Field Descriptions

Use the data in the following table to use the **CPP Stats Control** tab.

| Name                  | Description             |
|-----------------------|-------------------------|
| <b>PortStatsClear</b> | Clears port statistics. |

## Displaying KHI Port Information

**About This Task**

Use the following commands to display key health information about the types of control packets and protocols received on a port and sent to the control processor.

**Procedure**

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **CPP Stats** tab.

**CPP Stats** Field Descriptions

Use the data in the following table to use the **CPP Stats** tab.

| Name              | Description                                                                  |
|-------------------|------------------------------------------------------------------------------|
| <b>Port</b>       | Identifies the slot and port.                                                |
| <b>Packet</b>     | Shows the packet type.                                                       |
| <b>PacketName</b> | Shows the name of the packet.                                                |
| <b>RxPackets</b>  | Indicates the number of received packets on the port for the packet type.    |
| <b>TxPackets</b>  | Indicates the number of transmitted packets on the port for the packet type. |

## View KHI Segmented Management Instance Statistics Information

**About This Task****Note**

This procedure does not apply to VSP 8600 Series.

Use the following procedure to view key health information about the types of control packets and protocols received on a port and sent to the segmented management instance interface.

**Procedure**

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Expand **Mgmt Instance**.

3. Select **Stats**
4. Select the **KHI** tab.
5. To clear KHI statistics for a management interface, select an **InstanceId** and select **Clear Stats**.

### ***KHI*** Field Descriptions

Use the data in the following table to use the **KHI** tab.

| Name              | Description                                                                   |
|-------------------|-------------------------------------------------------------------------------|
| <b>InstanceId</b> | Shows the management interface instance.                                      |
| <b>PacketType</b> | Shows the packet type.                                                        |
| <b>PacketName</b> | Shows the name of the packet.                                                 |
| <b>RxPackets</b>  | Shows the number of received packets on the port for the packet type.         |
| <b>TxPackets</b>  | Shows the number of transmitted packets on the port for the packet type.      |
| <b>RxDropped</b>  | Shows the number of received packets dropped on the port for the packet type. |

# Layer 2 Security

---

[Layer 2 Security for IPv4 and IPv6 Deployments](#) on page 2024

[Layer 2 Security Configuration Using the CLI](#) on page 2043

[Layer 2 Security Configuration using EDM](#) on page 2084

[Layer 2 security example scenarios](#) on page 2108

## Layer 2 Security for IPv4 and IPv6 Deployments

---

This section describes Layer 2 security concerns and the security features you can use to mitigate them.

### Security Features for IPv4 Deployments:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

### Security Features for IPv6 Deployments:

- First Hop Security (FHS)
- DHCP Snooping and IPv6 Neighbor Discovery Inspection
- IP Source Guard for IPv6 addresses

## Dynamic ARP Inspection (DAI)

**Table 142: Dynamic ARP Inspection (DAI) product support**

| Feature                      | Product         | Release introduced |
|------------------------------|-----------------|--------------------|
| Dynamic ARP Inspection (DAI) | 5420 Series     | VOSS 8.4           |
|                              | 5520 Series     | VOSS 8.2.5         |
|                              | VSP 4450 Series | VOSS 6.1           |
|                              | VSP 4900 Series | VOSS 8.1           |
|                              | VSP 7200 Series | VOSS 6.1           |
|                              | VSP 7400 Series | VOSS 8.0           |
|                              | VSP 8200 Series | VOSS 6.1           |
|                              | VSP 8400 Series | VOSS 6.1           |
|                              | VSP 8600 Series | Not Supported      |
|                              | XA1400 Series   | Not Supported      |

Dynamic ARP Inspection (DAI) is a security feature that validates ARP packets in the network.

Without DAI, a malicious user can attack hosts, switches, and routers connected to the Layer 2 network by poisoning the ARP caches of systems connected to the subnet, and intercepting traffic intended for other hosts on the subnet. DAI prevents these attacks by intercepting, logging, and discarding the ARP packets with invalid IP to MAC address bindings.

The switch dynamically builds the address binding table from the information gathered from the DHCP requests and replies when DHCP Snooping is enabled. The switch pairs the MAC address from the DHCP request with the IP address from the DHCP reply to create an entry in the DHCP binding table. For more information, see [Create DHCP Binding Table Entries](#) on page 2102.

When you enable DAI, the switch filters ARP packets on untrusted ports based on the source MAC and IP addresses seen on the switch port. The switch forwards an ARP packet when the source MAC and IP address matches an entry in the address binding table. Otherwise, the switch drops the ARP packet.

### Note

- For DAI to function, you must enable DHCP Snooping globally.
- Configure DAI on a VLAN to VLAN basis.

DAI cannot be enabled on:

- Private VLANs (Etree)
- SPBM B-VLANs
- MLT port members

## First Hop Security

First Hop Security (FHS) improves local network security by employing a number of mitigation techniques. This section describes the base set functionality which provides protection from a wide host

of rogue or mis-configured users, and this can be extended with additional features for different deployment scenarios. For example, see the following topology.

#### Sample Topology

In the following topology, Layer 2 switch SW-1 is connected to another Layer 2 switch SW-2. SW-2 is connected to three hosts and SW-1 is connected to two hosts.

In this network, if FHS is enabled only on SW-1, then it can only save the nodes which are directly connected to it. To protect the good node connected to SW-2, the FHS must be enabled on SW-2.

**Figure 180: First Hop Security topology**

First Hop Security contains the majority of the RIPE 554 mandatory requirements for Layer 2 switches. This includes the following:

- DHCPv6 Guard or DHCPv6 filtering
- RA Guard or Router Advertisement filtering

#### DHCPv6 security concerns

The enhancements in IPv6 provide better security in certain areas, but some of these areas are still open to exploitation by attackers. This section identifies the IPv6 FHS concerns associated with Dynamic Host Configuration Protocol version 6 (DHCPv6).

DHCPv6 (RFC 3315) describes how a host can acquire an IPv6 address and other configuration options from a server that is available on its local link. DHCPv6 is described as a stateful protocol. In other words, DHCPv6 can operate in a stateless fashion where it provides configuration information to nodes and does not perform address assignments (RFC 3736). In addition, it can operate in a stateful manner, where it assigns IPv6 addresses and configuration information to hosts that request it.

As in IPv4 DHCP, DHCPv6 is susceptible to rogue server attacks. In other words, if DHCPv6 is used to provide IPv6 addresses to the hosts, an attacker that managed to insert a rogue DHCPv6 server in the

link can potentially assign addresses and configuration options to the link hosts. In turn, the attacker can deploy man-in-the-middle, traffic interception, or blackhole traffic, similar to those in the stateless address autoconfiguration scenario. Therefore, it is important to use DHCP protections for both IPv4 and IPv6.

### *DHCPv6 Guard*

**Table 143: DHCPv6 Guard product support**

| Feature      | Product         | Release introduced |
|--------------|-----------------|--------------------|
| DHCPv6 Guard | 5420 Series     | VOSS 8.4           |
|              | 5520 Series     | VOSS 8.2.5         |
|              | VSP 4450 Series | VOSS 5.0           |
|              | VSP 4900 Series | VOSS 8.1           |
|              | VSP 7200 Series | VOSS 5.0           |
|              | VSP 7400 Series | VOSS 8.0           |
|              | VSP 8200 Series | VOSS 5.0           |
|              | VSP 8400 Series | VOSS 5.0           |
|              | VSP 8600 Series | Not Supported      |
|              | XA1400 Series   | Not Supported      |

DHCPv6 Guard is a type of security for IPv6 deployments in an enterprise environment, it provides Layer 2 security to DHCPv6 clients by protecting them against rogue DHCPv6 servers. The basic concept of DHCPv6 Guard is that a Layer 2 device filters DHCPv6 messages meant to DHCPv6 clients, based on a number of different criteria. The basic filtering criterion is, the DHCPv6 server generated packets which are received on non-server ports or from an untrusted server will be dropped by the Layer 2 device.

Various levels of granularity are provided. Following are the policies that are supported:

- Port based filtering using device role (server or client)
- Server or relay agent IPv6 address based filtering
- Advertising IPv6 prefix based filtering
- DHCPv6 packet filtering based on Server Preference checks

The following figures are DHCPv6 topology samples:

**Figure 181: DHCPv6 Topology 1**

**Figure 182: DHCPv6 Topology 2**

**DHCPv6 Guard Policies Configuration**

You can configure DHCPv6 Guard policies using CLI, SNMP and EDM. The following policies are supported for DHCPv6 Guard.

Port-based Filtering Using Device-role

Port-based filtering using device-role is an interface-level configuration. Only a DHCPv6 server or relay agent can send a DHCPv6 advertisement or reply. By configuring the device-role attached to the port (whether it is a client or server), the rogue server generating DHCPv6 advertisement or reply packets can be blocked if these packets are received on a port configured as a client. Device-role can be applied only on port, and not on MLT, SMLT, or VLAN. If you configure device-role on an MLT, SMLT, or VLAN, you must configure same device-role on all the MLT, SMLT, or VLAN member ports.

In DHCPv6 Guard Topology 1, only DHCPv6 server packets (that is, advertisement, reply) received on a port configured as a Server port accept the packets and process them for security validation and

forwarding. The Client port drops the packets if it receives packets generated from a DHCPv6 rogue server.

#### Server or Relay Agent IPv6 Address Based Filtering

Server or relay agent IPv6 address-based filtering enables the verification of the advertised DHCPv6 server and relay address in messages with the configured authorized server access list. In DHCPv6 Guard Topology 1 and Topology 2, you can configure the access list to accept DHCPv6 server packets from a specific Source IPv6 address such as a DHCPv6 server or DHCPv6 relay IPv6 address.

#### Advertising IPv6 prefix-based filtering

Advertising IPv6 prefix-based filtering enables verification of the advertised prefixes in DHCPv6 reply messages with the configured authorized prefix list.

#### Server preference-based filtering

Server preference-based filtering enables verification by checking if the advertised preference (in preference option) is greater than or less than the specified limit.

#### *RA Guard*

**Table 144: IPv6 Router Advertisement (RA) Guard product support**

| Feature                              | Product         | Release introduced |
|--------------------------------------|-----------------|--------------------|
| IPv6 Router Advertisement (RA) Guard | 5420 Series     | VOSS 8.4           |
|                                      | 5520 Series     | VOSS 8.2.5         |
|                                      | VSP 4450 Series | VOSS 5.0           |
|                                      | VSP 4900 Series | VOSS 8.1           |
|                                      | VSP 7200 Series | VOSS 5.0           |
|                                      | VSP 7400 Series | VOSS 8.0           |
|                                      | VSP 8200 Series | VOSS 5.0           |
|                                      | VSP 8400 Series | VOSS 5.0           |
|                                      | VSP 8600 Series | Not Supported      |
|                                      | XA1400 Series   | Not Supported      |

IPv6 hosts can configure themselves automatically when connected to a routed IPv6 network through ICMPv6 router discovery messages. When the host is connected to the network for the first time, it sends a link-local router solicitation multicast request for its configuration parameters. If the host is configured correctly, routers respond to the request with a Router Advertisement (RA) packet. The RA packet contains network-layer configuration parameters.

In addition to filtering RAs, RA Guard introduces the concept of router authorization proxy. Instead of each node on the link analyzing RAs and making an individual decision, a legitimate node-in-the-middle performs the analysis on behalf of all other nodes on the link.

Stateless and statefull RA Guard functions are available. The switch supports only the stateless RA Guard function.

Stateless RA Guard examines incoming RAs and decides whether to forward or block them based on the information found in the message or in the Layer 2 device configuration. The following list identifies the typical information available in the received frames that are used for RA validation:

- Port on which the frame is received
- Source IPv6 address
- Prefix list which RA carries
- Link-Layer address of the sender

After the Layer 2 device successfully validates the RA packet content against the configuration, the RA is forwarded to its destination, whether unicast or multicast. If the validation fails, the RA is dropped at the Layer 2 device.

### RA Guard policies description

This section describes the RA Guard policies. The following policies are supported for RA Guard:

- Port-based filtering using device role (host or router)
- Source IPv6 based filtering
- Advertised IPv6 prefix-based filtering
- Source MAC address-based filtering
- RA packet for managed address configuration flag validation
- RA packet for hop count limit validation
- RA packet for Router Preference validation

#### Port-based Filtering Using Device-role

This configuration is an interface-level configuration. According to Neighbor Discovery (ND) RFC 4861, only the IPv6 router can generate the RA packets. By configuring the device-role attached to the port whether it is a host or router, the rogue host which is generating RA packets can be blocked. Device-role can be applied only on a port, and not on an MLT, SMLT, or VLAN. If you configure device-role on an MLT, SMLT, or VLAN, you must configure the same device-role on all the MLT, SMLT, or VLAN member ports.

In the following topology, the switch is connected to a Layer 3 router and three hosts. Because the router is directly connected to port 1/2, the device-role of the port 1/2 is configured in Router mode. The other hosts are connected to ports 1/3, 1/4, and 1/5, and the device-role of ports 1/3, 1/4, and 1/5 are configured in Host Mode.

The host connected to the port 1/4 is a rogue host and if it is trying to send RA packets, then the switch drops those RA packets received on the interface 1/4 as the device-role of this port is Host Mode.

**Figure 183: RA Guard Topology1**

IPv6 Source Address Based Filtering

An IPv6 source address based filtering policy enables the source IPv6 address verification of the RA packets against the configured RA source IPv6 list.

The following figure shows the RA packet format. RA Guard policy verifies the IPv6 source address (SrcIP) in the IPv6 Header against the configured RA source IPv6 list.

**Figure 184: IPv6 ICMP RA Data Packet Online**

Advertised IPv6 Prefix-based Filtering

Advertised IPv6 prefix-based filtering enables verification of the advertised prefixes in inspected messages against the configured RA prefix list.

The following figure illustrates the IPv6 ICMP RA data packet outline. This RA Guard policy verifies the RA (Prefix Information) in ICMPv6 data against the configured RA prefix list.

**Figure 185: IPv6 ICMP RA Data Packet Outline**

Source MAC Address-based Filtering

Source MAC address-based filtering enables the source MAC address of the RA packets verification against the configured authorized MAC list.

The following figure illustrates the IPv6 Ethernet packet. This RA Guard policy verifies the received RA packets source MAC address against the configured authorized MAC access list.

**Figure 186: IPv6 Ethernet Packet**

RA packet for managed address configuration flag validation

In the RA packets, there is an “M” flag (managed address configuration flag) that can be configured to indicate that the address assignments are available through DHCPv6. This means that DHCPv6 takes care of the interface address assignment in that LAN segment. If a filtering policy is enabled, then all the RA packets without an “M” flag are dropped. By default, this validation is not performed.

The following figure illustrates IPv6 ICMP RA data packet outline for managed address configuration.

**Figure 187: IPv6 ICMP RA data packet outline**

RA packet for hop count limit validation

RA packet for hop count limit validation policy verifies the advertised RA message if the hop count limit is within the configured hop count limit. If the received hop count limit is not within the configured limit, then those RA packets are dropped.

The following figure illustrates IPv6 ICMP RA data packet outline for hop count limit validation.

**Figure 188: IPv6 ICMP RA data packet outline**

RA packet for router preference validation

The RA packet contains the Router Preference as part of the flags field. This can be high, medium, or low. This filtering policy option verifies if the advertised default router preference parameter value is lower than or equal to a specified limit.

The following figure illustrates IPv6 ICMP RA data packet outline for router preference validation.

**Figure 189: IPv6 ICMP RA data packet outline for router preference validation**

*Capturing and verifying FHS specific packets against the configured policies*

First Hop Security filters can be installed only if FHS is enabled globally. The DHCPv6 Guard or RA Guard filters are created as a part of First Hop Security filter with port bit mask “0”.

The following list identifies the high-level tasks to capture DHCPv6 packets received on a physical port:

1. Enable FHS globally.
2. Enable DHCPv6 Guard or RA Guard globally.
3. Create a DHCPv6 Guard or an RA Guard policy.
4. Configure RA Guard or DHCPv6 Guard device role on the port.
5. Attach DHCPv6 Guard and/or RA Guard policy to a physical port if needed.

On configuring RA Guard or DHCPv6 Guard device role on the port, the appropriate port bitmask for that port will be updated in the data path filter.

The RA or DHCPv6 sever initiated packets received on trusted ports (router or server ports) will be sent to the local CPU for further validations. If these packets pass the RA Guard and DHCPv6 Guard validation, they will be forwarded towards the intended host or DHCPv6 client; if not, they will be dropped by the switch.

*FHS limitations*

The following limitations exist in First Hop Security:

- Fragmented RA and DHCPv6 server initiated packets are dropped on the FHS enabled switch.
- DHCPv6 Guard and RA Guard do not work on devices connected on shared media or on tunneled interfaces.

- DHCPv6 Guard or RA Guard policies are not VLAN or MLT based.
- FHS is not supported on the Out Of Band (OOB) port on the switch.
- Packets received on FHS ports with more than one extension header, and if they are destined to link-local unicast or link-scope multicast address, are dropped as they cannot be classified as RA or DHCPv6 reply packets.
- The FHS functionality can be bypassed at the first hop switch, if the malicious packets are destined to global address, and have more than one extension header.
- If the FHS rules and IPv6 filters match for a packet, the IPv6 filter has precedence.
- In a Layer 2 VSN, packets are not filtered based on FHS rules. Enable FHS on the required UNI ports to protect the connected devices from FHS attacks.

### Guidelines for FHS configuration

Some of the FHS configurations need details on how they work and how they should be used. Following are the details:

1. FHS IPv6 Access lists are generic access/prefix lists which can be applied on IPv6 source address or the prefixes advertised in RA or DHCPv6 messages. If you filter on the basis of a particular IPv6 source address, you must configure the access list entry with complete source address with prefix-length value of 128. If you allow a group of source addresses within a prefix range, you must configure the IPv6 ACL entry with an appropriate prefix length and attach this IPv6 ACL to the appropriate match parameters in RA Guard or DHCPv6 Guard policies.

If you filter a particular prefix, you must configure an IPv6 access list entry with appropriate prefix and prefix-lengths. To filter based on prefix, prefix-lengths should be less than 128. Following is an example of IPv6 access list entry:

```
ipv6 fhs ipv6-access-list match_src_allow fe80:0:0:0:0:ff:fe00:113/128  
mode allow
```

#### Note

- a. If no IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy as a source ACL, then IPv6 source address in the incoming RA packets or packets from DHCP server will not be validated, and such packets will not be dropped due to source address validations.
  - b. If no IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy as a prefix ACL, then prefix information in incoming RA packets or packets from DHCP server will not be validated and these packets will not be dropped due to prefix validations.
  - c. The FHS access or prefix lists are different from IPv6 prefix lists. For FHS, the switch maintains a separate list (cannot reuse IPv6 prefix lists) as IPv6 prefix lists do not have any action associated with them, whereas FHS has an action associated with each ACL entry.
2. When an IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy and the address or prefix in the incoming RA Guard or DHCPv6 server packets received on port to which this RA Guard or DHCPv6 Guard policy is attached does not match any of the entries in that IPv6 ACL, the packet will be dropped by default. If you want to change this behavior to default (allow, for IPv6 ACLs), you can add an entry that matches all the packets and set the action as allow. To do this, use the following command:

```
ipv6 fhs ipv6-access-list no_match_src_def_allow 0:0:0:0:0:0:0:0/0
mode allow
```

3. IPv6 ACL entries with conflicting prefixes within an IPv6 ACLs are not allowed, and such configuration will fail with appropriate error message. Conflicting entries can be present in two or more different IPv6 ACLs.
4. The entries within an IPv6 ACL will be sorted in increasing order of IPv6 prefixes. If there are two entries with same prefix address within an ACL, then such entries will be ordered with increasing value of their prefix-lengths.
5. MAC ACL entries are ordered in the increasing order of MAC addresses within a MAC ACL. If none of the entries in the MAC ACL match the source MAC address of RA packet, then the packet will be dropped by default. If no MAC ACL is attached to an RA Guard policy, then the source MAC address of RA packets is not validated.
6. When matching for a prefix using IPv6 ACL entry, if you advertise a prefix with matching prefix but prefix-length lesser than configured prefix-length, then the packet has to be considered as no match and prefix matching process has to continue with remaining IPv6 ACL entries in that ACL.

The rationale behind this functionality is to avoid wrong configuration of access side devices. This functionality safeguards the devices in an access network if a wrongly configured IPv6 prefix is advertised or a malicious user is sending invalid (wrong) prefixes. For example, consider the following scenario:

Configure the prefix in ACL entry (without ge and le values): **ipv6 fhs ipv6-access-list ipv6\_acl\_entry\_1 2001:0123:4567:89ab::/64 mode allow**

Advertise the prefix in RA packet: **2001:0123:4567:89ab::/48**

This advertised prefix matches the configured IPv6 ACL entry and without this prefix-length check functionality, the packet is allowed to pass through. But, actually it is configuring all access devices in that network with wrong IPv6 configurations in different IPv6 network (**2001:0123:4567::/48**)

With prefix-length check functionality (explained above), this configuration is not allowed as advertised prefix length is not equal to configured prefix length. So, the wrong configurations of access devices is avoided.

7. Importance of “ge” and “le” parameters in an IPv6 ACL entry:

A user can optionally configure “ge” (greater than or equal to) and “le” (lesser than or equal to) parameters while configuring an IPv6 ACL entry. If the prefix advertised in a packet matches the configured prefix in an IPv6 ACL entry, and “ge” and “le” values are configured (not default) for that IPv6 ACL entry:

- The packet will be allowed to go through only if the prefix-length in the packet is within the range of configured “ge” and “le” values.
- If prefix lengths in the packet are not within the configured range of “ge” and “le” values (non-default values), then the packets would be considered as no match for that IPv6 ACL entry and search for matching IPv6 ACL entry continues within that IPv6 ACL.
- If no ge and le values are configured, those values by default are set to configured prefix length in that IPv6 ACL entry.
- ge and le values are allowed only if they are greater than configured prefix.
- When both are configured (not default values), ge value should always be smaller than le value.

These configurations provide more control over the advertised prefixes in RA or DHCPv6 packets.

8. As “ge” and “le” values are valid only for advertised prefixes, they will not be applied to IPv6 addresses, which are not prefixes. For such addresses, prefix match is considered as match for that IPv6 ACL entry and the corresponding action of that ACL entry is applied on that packet. “ge” and “le” configurations are irrelevant for the following:

- IPv6 source address in RA packet
- IPv6 source address in packets from DHCPv6 server (like DHCPv6 advertise, DHCPv6 reply)
- IPv6 address (temporary or non-temporary) advertised in packets from DHCPv6 server. For example, IPv6 addresses advertised in IANA option of DHCPv6 reply packets

9. Order of packet validations:

In RA or DHCPv6 packets received at the CP for FHS processing, the following order of processing is carried out:

- a. Packet parsing
- b. Checking for presence of IPv6 fragment header
- c. Checking if packets are RA packets or DHCPv6 packets from server (Advertise, Reply, Reconfigure, Relay-Reply)
- d. Basic validations:
  - Non-Link-Local source IPv6 address (only for RA packets)
  - L4 length validations
  - Checksum validations
- e. If an RA Guard or DHCPv6 Guard policy is attached to a port:
  - MAC ACL validations (if configured) (Only for RA packets)
  - IPv6 source address ACL validation (if configured)
  - IPv6 prefix ACL validations (if configured)
  - Other packet parameter validations like:
    - Managed config flag (RA)
    - ICMP hop limit (RA)
    - Router preference (RA)
    - Server preference (DHCPv6)

If any of these validations fail or if action associated with a match ACL entry indicates to DROP (or default drop if ACL is attached to corresponding policy but packet does not match any ACL entry in that ACL), then the packets are dropped and corresponding statistics are updated. If all these pass or actions related to all matched ACL entries are PERMIT, then the packet is allowed to go through.

10. Longest prefix match: If a packet matches multiple entries in an ACL, then the action associated with an entry with longest prefix match would be applied on the packet.
11. If a port is configured as untrusted (“host” as device role for RA Guard or “client” as device role for DHCPv6 Guard), all the FHS trusted traffic (RA packets for RA Guard or packets from DHCPv6 server for DHCPv6 Guard) are dropped in data path itself. Also for such drops, statistics are not incremented.

If a port is neither configured as trusted nor untrusted, then the FHS traffic (RA packets or DHCPv6 packets from DHCPv6 server) is switched as if FHS is not present.

## 12. Creation of FHS port policy mappings:

Until, and unless, any of the FHS parameters are configured on a port, port policy mappings are not created and thus with no port to policy mapping configured, the system does not display any entries while listing port policy mappings using the command **show ipv6 fhs port-policy**.

13. If a RA Guard or DHCPv6 Guard policy is attached to any of the ports, deletion of such policy is not allowed. In the contrary, to delete an RA Guard or DHCPv6 Guard policy, those policies need to be detached from all the ports in the switch. However, modification of an RA Guard or DHCPv6 Guard policy is allowed even if it is attached to ports.
14. If a MAC or IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy, you cannot delete the ACL itself. You can delete the entries from this policy even if it is attached to any policy. At least one entry needs to exist in a MAC or IPv6 ACL; you cannot delete the last entry in that ACL if that ACL is attached to any RA Guard or DHCPv6 Guard policy. You must detach that ACL from all the policies to delete that ACL. However, you can update the entries in that ACL even if it is attached to a policy.

If a port is configured as trusted (“Server” port for DHCPv6 Guard and “Router” port for RA Guard), then only one can attach a DHCPv6 Guard or RA Guard policy to that port. In the contrary, if any policy is attached to a port, the port role cannot be changed from trusted (“Server” port for DHCPv6 Guard and “Router” port for RA Guard) to other role (“Client” port for DHCPv6 Guard, “Host” port for RA Guard or “None” for both) until that policy is not detached from port.

## DHCP Snooping and Neighbor Discovery inspection

**Table 145: Dynamic Host Configuration Protocol Snooping and Neighbor Discovery Inspection product support**

| Feature             | Product         | Release introduced |
|---------------------|-----------------|--------------------|
| DHCP Snooping(IPv4) | 5420 Series     | VOSS 8.4           |
|                     | 5520 Series     | VOSS 8.2.5         |
|                     | VSP 4450 Series | VOSS 6.1           |
|                     | VSP 4900 Series | VOSS 8.1           |
|                     | VSP 7200 Series | VOSS 6.1           |
|                     | VSP 7400 Series | VOSS 8.0           |
|                     | VSP 8200 Series | VOSS 6.1           |
|                     | VSP 8400 Series | VOSS 6.1           |
|                     | VSP 8600 Series | Not Supported      |
|                     | XA1400 Series   | VOSS 8.0.50        |

**Table 145: Dynamic Host Configuration Protocol Snooping and Neighbor Discovery Inspection product support (continued)**

| Feature                              | Product         | Release introduced |
|--------------------------------------|-----------------|--------------------|

### *DHCP Snooping*

DHCP Snooping is a Layer 2 security feature, that provides network security by filtering untrusted DHCP messages received from the external network causing traffic attacks within the network. DHCP Snooping is based on the concept of trusted versus untrusted switch ports. Switch ports configured as trusted can forward DHCP Replies, and the untrusted switch ports cannot. DHCP Snooping acts like a firewall between untrusted hosts and DHCP servers.

**Note**

The switch supports:

- DHCP Snooping for both IPv4 and IPv6.
- Neighbor Discovery (ND) inspection for IPv6.

Security is critically important in an access network because various devices can connect to an access network that may not be administratively controlled by a single administrator. Stateless Address Autoconfiguration (SLAAC) and Duplicate Address Detection (DAD) mechanisms used by IPv6 are

more vulnerable to attacks from a malicious user. If any person, intentionally or unintentionally, configures an IP address on the device interface wrongly and advertises that IP address as one's own address during DAD mechanism initiated by other device, DAD initiated devices cannot assign this address. If a malicious user replies to all the DAD IP addresses as own address, none of the devices in the access network can assign any IP addresses to their interfaces. Thus, DoS attacks can be easily carried out by the malicious user making the entire network unfunctional. In another kind of attack, a malicious user can try to poison the neighbor cache of a host by sending ND packets with bogus MAC address which is learnt by other hosts into their neighbor table. Due to the infiltration of the bogus MAC address in the host's neighbor table, the packets destined to its neighbor is sent to the bogus MAC address and is eventually dropped or received by an unintended host.

In general, these kinds of attacks are carried out by sending different Neighbor Discovery (ND) packets – either through solicited ND packet exchanges or as a result of unsolicited ND packet exchanges triggered due to an event like the expiry of ND timers. These packets carry interface IP address information and link-layer address information. Other devices use this information to build their neighbor table for forwarding traffic to or through the malicious device. As part of ND inspection mechanism, ND (specifically, NS, NA, and redirect) packets from only trusted hosts are allowed to pass through and the packets from un-trusted hosts are dropped in the switch itself. Other network devices can safely use ND mechanisms for correctly assigning IP address to their interfaces resulting in a smooth traffic flow.

For validating the ND packets, the switch must first learn the trusted information by various mechanisms and store the information in a DHCP binding table. If the switch receives ND packets on an untrusted port, the packets are validated against entries in the DHCP binding table. If the ND packets pass the validation, the packets are forwarded. If the packets fail the validation, they are dropped in the switch itself. This process avoids invalid NA packets from propagating beyond the access switch.

DHCP Snooping and ND inspection feature protects the network from the following types of attacks:

- **User misconfigurations:** Host assigns an address which should not be used by the recipient device. ND inspection blocks this address in the access switch because binding entry does not exist for that address for that host.
- **DAD spoofing:** Malicious user claims that the address is taken even if it is not.
- **NUD spoofing:** Malicious host responds to NUD NS packets indicating that the address is still reachable via that host even if that neighbor is actually not reachable.
- **ND cache poisoning:** Malicious user sends different (invalid) link-layer addresses for a target IP address causing other hosts in the network to program bogus MAC for a given IP neighbor, as a result of which, the traffic gets black-holed or misused by malicious host.

#### *DHCP Binding Table*

DHCP Snooping builds and maintains a binding table, this binding table contains the MAC address, IP address, lease time, binding type, VLAN number, and port information that correspond to the local untrusted ports of the switch. When the switch receives a DHCPRELEASE or DHCPDECLINE broadcast message, DHCP Snooping performs a lookup of the MAC address in the binding table to determine if the port information in the binding table matches the port on which the message was received. If the port information matches, the DHCP packet is forwarded, otherwise it is dropped.

### *Trust Bindings*

A switch enabled with the Neighbor Discovery inspection feature allows NA packets through, if the packets are from a trusted host. To allow or deny Neighbor Advertisement (NA) packets, trust bindings must be established using following methods:

- Configuring the port connected to a device (or host) as trusted.
- Building a DHCP binding table which contains entries from trusted devices (or hosts) only. This DHCP binding table is used for validating NA packets.

This method of trust binding involves 2 processes:

- IP address learning (snooping) process

In this process an IP address is learnt through a trusted means and a DHCP binding table is built. The switch supports the DHCP binding table entry learning by:

- Statically configuring the entries
- Dynamically learning by DHCP Snooping packets

- NA packet validation (inspection) process

This process uses the DHCP binding table entries which are populated as part of IP address learning process to validate the incoming NA packets.

After the DHCP binding tables are built, the information gathered using trust binding is used to validate the ND packets. If the ND packets cannot be validated using this information, they are considered as packets received from an un-trusted host and are dropped by the switch.

### *Restrictions*

In addition to the FHS restrictions, DHCP Snooping and ND inspection have the following restrictions:

- Link-local address validation is not supported under ND inspection. Thus, an FHS enabled switch is vulnerable to attackers who try to attack with link-local addresses.
- As a 5-second timer is used to cleanup expired DHCP binding table entries, the expired DHCP binding table entries may remain in the DHCP binding table for up to 5 seconds after they expire.
- If a FHS-enabled switch gets rebooted, all the dynamically-learned binding entries get flushed and those entries need to be re-learned for ND inspection to pass. However, when the switch is rebooted, DHCP clients connected to it do not re-initiate DHCP learning, due to which, the switch cannot learn these assigned IP addresses. As a result, ND inspection fails for these addresses. To overcome this problem either DHCP client must learn the IP address again through DHCP mechanisms or the administrator must add static entries for these addresses.
- For IPv6, DHCP binding table entries learned through DHCP are not removed from the DHCP table on DHCP clients that release these addresses. The administrator must manually remove these entries once the addresses are released.
- A dynamic DHCP binding table entry is learned only using the DHCP mechanism. For other modes of address configuration on the host, a relevant DHCP binding table entry must be configured on the FHS switch so that ND packets from such host are not blocked due to ND inspection processing.
- DHCP Snooping is not supported on:
  - DHCP Relay
  - Etree
  - Private VLANs
  - Split Multi-Link Trunking (SMLT)

## IP Source Guard

**Table 146: IP Source Guard product support**

| Feature                | Product         | Release introduced |
|------------------------|-----------------|--------------------|
| IP Source Guard (IPv4) | 5420 Series     | VOSS 8.4           |
|                        | 5520 Series     | VOSS 8.2.5         |
|                        | VSP 4450 Series | VOSS 6.1           |
|                        | VSP 4900 Series | VOSS 8.1           |
|                        | VSP 7200 Series | VOSS 6.1           |
|                        | VSP 7400 Series | VOSS 8.0           |
|                        | VSP 8200 Series | VOSS 6.1           |
|                        | VSP 8400 Series | VOSS 6.1           |
|                        | VSP 8600 Series | Not Supported      |
|                        | XA1400 Series   | VOSS 8.0.50        |
| IP Source Guard (IPv6) | 5420 Series     | VOSS 8.4           |
|                        | 5520 Series     | VOSS 8.2.5         |
|                        | VSP 4450 Series | VOSS 6.1           |
|                        | VSP 4900 Series | VOSS 8.1           |
|                        | VSP 7200 Series | VOSS 6.1           |
|                        | VSP 7400 Series | VOSS 8.0           |
|                        | VSP 8200 Series | VOSS 6.1           |
|                        | VSP 8400 Series | VOSS 6.1           |
|                        | VSP 8600 Series | Not Supported      |
|                        | XA1400 Series   | Not Supported      |

IP Source Guard (IPSG) is a Layer 2 port-to-port feature that works closely with DHCP Snooping. It prevents IP spoofing by allowing only IP addresses obtained using DHCP Snooping. When you enable IPSG on an untrusted port with DHCP Snooping enabled, an IP filter is automatically created or deleted for that port based on the information stored in the corresponding DHCP Snooping binding table entry. When a connecting client receives a valid IP address from the DHCP server, the filter installed on the port allows traffic only from that assigned IP address.

You can configure IPSG on a port using the command line interface (CLI), the Enterprise Device Manager (EDM), or SNMP.

**Note**

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

**Important**

If you enable Application Telemetry, IPv6 Source Guard commands and configurations are blocked and not available on VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, and VSP 8000 Series switches.

The following table shows you how IPSG works with DHCP Snooping.

**Table 147: IP Source Guard and DHCP snooping**

| IP Source Guard configuration state | DHCP snooping configuration state | DHCP snooping Binding Entry action (untrusted ports)                                                                                                                                                                                                                                                                                                                                                   | IP Source Guard action                                                                    |
|-------------------------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| change from disabled to enabled     | enabled                           | creates a binding entry                                                                                                                                                                                                                                                                                                                                                                                | creates a filter for the IP address using the IP address from the binding table entry     |
| enabled                             | enabled                           | creates a binding entry                                                                                                                                                                                                                                                                                                                                                                                | creates a filter for the IP address using the IP address from the binding table entry     |
| enabled                             | enabled                           | deletes a binding entry                                                                                                                                                                                                                                                                                                                                                                                | deletes the IP filter and installs a default filter to block all IP traffic on the port   |
| enabled                             | enabled                           | deletes binding entries when one of the following conditions occur: <ul style="list-style-type: none"> <li>• a DHCP release packet is received</li> <li>• the port link is down</li> <li>• the lease time has expired</li> <li>• the port is removed from the VLAN</li> <li>• the VLAN is deleted</li> <li>• the port is set as trusted</li> <li>• the binding entries are manually deleted</li> </ul> | deletes the corresponding IP filter and installs a default filter to block all IP traffic |
| change from enabled to disabled     | enabled                           | not applicable                                                                                                                                                                                                                                                                                                                                                                                         | deletes the installed IP filter for the port                                              |
| disabled                            | enabled                           | creates a binding entry                                                                                                                                                                                                                                                                                                                                                                                | not applicable                                                                            |
| disabled                            | enabled                           | deletes a binding entry                                                                                                                                                                                                                                                                                                                                                                                | not applicable                                                                            |

### IPSG Limitations

- You can enable IP Source Guard (IPSG) only on a port that is DHCP Snooping and Dynamic ARP Inspection untrusted.
- The port must be a member of a VLAN. DHCP Snooping must be enabled globally and on the VLAN. You must also enable Dynamic ARP Inspection on the same VLAN.
- You cannot enable IPSG on MLT, SMLT, DMLT or LAG ports.
- You cannot enable IPSG on a brouter port.
- You cannot enable IPSG on ports that are members of a private VLAN.
- You cannot remove a port that is IPSG enabled from a VLAN. Similarly, you cannot delete a VLAN that has at least one port that is IPSG enabled.
- A maximum of 10 IP addresses are allowed on each IPSG enabled port. Correspondingly, a maximum of 10 IP filters are automatically created for each of those ports. When this number is reached, no more filters are set up and all traffic is dropped.
- On the switch, the total number of IP filters must not exceed 256. This limit includes both IP filters that are automatically created on IPSG ports and the manually created ACLs.
- IPv6 Security Filters and IPv6 Source Guard cannot coexist with Application Telemetry:
  - If there are IPv6 Security Filters or IPv6 Source Guard configurations on the system, the switch blocks you from enabling Application Telemetry.
  - If you do enable Application Telemetry, the switch blocks you from configuring IPv6 Security Filters or IPv6 Source Guard.

#### Note

This restriction applies to the VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series platforms only.

## Layer 2 Security Configuration Using the CLI

---

Use the following sections to help you configure Layer 2 security features and protect the network by mitigating various types of attacks, using the Command Line Interface (CLI).

### For IPv4 deployments, configure:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

### For IPv6 deployments, configure:

- First Hop Security (FHS)

#### Note

FHS does not solve all cases of denial of services like blocking flooding of the IPv6 messages.

- DHCP Snooping and IPv6 Neighbor Discovery Inspection

- IP Source Guard for IPv6 addresses

## DHCP Snooping Configuration Using CLI

The following section provides procedures to configure DHCP Snooping using the CLI.

### *Enable or Disable DHCP Snooping globally*

Use the following procedure to enable DHCP Snooping globally. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets to all required ports, both trusted or untrusted.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable DHCP Snooping globally:  

```
ip dhcp-snooping enable
```
3. Disable DHCP Snooping globally:  

```
no ip dhcp-snooping enable
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-snooping enable
```

#### Variable Definitions

The following table defines parameters for the **ip dhcp-snooping** command.

| Variable      | Value                                                                              |
|---------------|------------------------------------------------------------------------------------|
| <i>enable</i> | Enables or disables DHCP Snooping globally. By default, DHCP Snooping is disabled. |

### *Enable or Disable DHCP Snooping on a VLAN*

Use the following procedure to configure DHCP Snooping on a specific VLAN. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

If you enable DHCP Snooping globally, the agent determines whether to forward DHCP reply packets based on the DHCP Snooping mode of the VLAN and trusted state of the port.

#### Note

You cannot enable DHCP Snooping on Private VLANs (E-Tree) and SPBM B-VLANs.

#### Before You Begin

You must enable DHCP Snooping globally.

## Procedure

1. Enter VLAN Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```
2. Enable DHCP Snooping on the VLAN:  

```
ip dhcp-snooping enable
```
3. Disable DHCP Snooping on the VLAN:  

```
no ip dhcp-snooping enable
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 5
Switch:1(config-if)#ip dhcp-snooping enable
```

## Variable Definitions

The following table defines parameters for the **ip dhcp-snooping** command.

| Variable      | Value                                                    |
|---------------|----------------------------------------------------------|
| <i>enable</i> | Enables or disables DHCP Snooping on the specified VLAN. |

### Configure Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DHCP Snooping. By default, the trust factor is set to untrusted.

#### Note

For ports that are members of an MLT, DHCP Snooping must be configured using the MLT configuration mode.

## Before You Begin

You must enable DHCP Snooping globally.

**Procedure**

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the trust factor for the port:

```
ip dhcp-snooping <trusted|untrusted>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#ip dhcp-snooping trusted
```

**Variable Definitions**

The following table defines parameters for the **ip dhcp-snooping** command.

| Variable            | Value                                                     |
|---------------------|-----------------------------------------------------------|
| <trusted untrusted> | Specifies the trust factor of the port for DHCP Snooping. |

*Display DHCP Snooping Global Configuration*

Use the following procedure to display the global status of DHCP Snooping configuration.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the global configuration:

```
show ip dhcp-snooping
```

**Example**

```
Switch:1>show ip dhcp-snooping
=====
Dhcp Snooping General Info
=====
Dhcp Snooping                : Enabled
=====
```

*Display DHCP Snooping Interface Information*

Use the following procedure to view the DHCP Snooping interface information.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display DHCP Snooping brouter port information:
 

```
show ip dhcp-snooping interface [ gigabitEthernet [ {slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]] [ vrf WORD<1-16> | vrfids
WORD<0-512> ] | <1-4059> [ {slot/port[/sub-port]} [-slot/port[/sub-
port]] [,...]] [ vrf WORD<1-16> | vrfids WORD<0-512> ] | vrf
WORD<1-16> | vrfids WORD<0-512> ] | vrf WORD<1-16> | vrfids
WORD<0-512> ] ]
```
3. Display DHCP Snooping VLAN information:
 

```
show ip dhcp-snooping vlan <1-4059>
```
4. Display DHCP Snooping information for specific VRF name:
 

```
show ip dhcp-snooping vrf WORD<1-16>
```
5. Display DHCP Snooping information for specific VRF ID:
 

```
show ip dhcp-snooping vrfids WORD<0-512>
```

## Example

```
Switch:1>show ip dhcp-snooping interface gigabitEthernet
```

```

### Add Static Entries to DHCP Snooping Binding Table

Use the following procedure to add devices with a specified MAC address to the DHCP Snooping binding table.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Add the static entry to the DHCP Snooping binding table:
 

```
ip dhcp-snooping binding <1-4059> 0x00:0x00:0x00:0x00:0x00:0x00 ip
{A.B.C.D} port {slot/port[sub-port]} [expiry <0-2147483646>]
```

#### Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# ip dhcp-snooping binding 1 00-14-22-01-23-45 ip 10.10.10.01 port 1/2
expiry 2

```

## Variable Definitions

The following table defines parameters for the **ip dhcp-snooping binding** command.

| Variable                                                   | Value                                                        |
|------------------------------------------------------------|--------------------------------------------------------------|
| <1-4059>                                                   | Specifies the VLAN ID.                                       |
| 0x00:0x00:0x00:0x00:0x00:0x00                              | Specifies the MAC address of the DHCP client.                |
| ip {A.B.C.D}                                               | Specifies the IP address of the DHCP client.                 |
| port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Specifies the switch port to which the DHCP client connects. |
| expiry <0-2147483646>                                      | Specifies the expiry time (in seconds) for the DHCP client.  |

### Clear Entries from DHCP Snooping Binding Table

Use the following procedure to clear entries (static or dynamic) from the DHCP Snooping binding table.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Enter:  
clear ip dhcp-snooping binding [dynamic|static]

#### Example

```
Switch:1>enable
Switch:1#clear ip dhcp-snooping binding static
```

## Variable Definitions

The following table defines parameters for the **clear ip dhcp-snooping binding** command.

| Variable | Value                                                        |
|----------|--------------------------------------------------------------|
| static   | Clears static entries from the DHCP Snooping binding table.  |
| dynamic  | Clears dynamic entries from the DHCP Snooping binding table. |

### Display DHCP Snooping Binding Table Information

Use the following procedure to display the DHCP Snooping binding table, you can filter the entries displayed based on the type, port, or VLAN.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all binding entries:  
show ip dhcp-snooping binding

3. Display binding entries based on the MAC address or IP address:

```
show ip dhcp-snooping binding address [0x00:0x00:0x00:0x00:0x00:0x00 |
{A.B.C.D}]
```

4. Display binding entries configured on the ports:

```
show ip dhcp-snooping binding interface [gigabitEthernet{slot/port[/
sub-port]} [-slot/port[/sub-port]] [,...]]
```

5. Display binding entries configured on the VLANs:

```
show ip dhcp-snooping binding vlan <1-4059>
```

6. Display binding entries configured on a specific VRF:

```
show ip dhcp-snooping binding vrf WORD<1-16>
```

7. Display binding entries configured on a specific VRF ID:

```
show ip dhcp-snooping binding vrfids WORD<0-512>
```

8. Display a summary of the DHCP Snooping binding table:

```
show ip dhcp-snooping binding summary [<1-4059>] [vrf WORD<1-16>]
[vrfids WORD<0-512>] [{slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...]]
```

9. Display binding entries based on the type of entry:

```
show ip dhcp-snooping binding type [dynamic|static]
```

### Example

```
Switch:1>show ip dhcp-snooping binding
```

```

## Dynamic ARP Inspection Configuration Using CLI

The following section provides procedures to configure Dynamic ARP Inspection (DAI) using CLI.

## Enable or disable Dynamic ARP Inspection on a VLAN

You must enable DAI separately for each VLAN. When you enable DAI on a specific VLAN, the ARP packets are captured and inspected on that VLAN. DAI is disabled by default.

### Note

DAI cannot be enabled on Private VLANs (E-Tree) and SPBM B-VLANs.

## Before You Begin

You must enable DHCP Snooping globally.

## Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable DAI on the VLAN:

```
ip arp-inspection enable
```

3. Disable DAI on the VLAN:

```
no ip arp-inspection enable
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 5
Switch:1(config-if)#ip arp-inspection enable
```

## Variable Definitions

The following table defines parameters for the **ip arp-inspection** command.

| Variable      | Value                                          |
|---------------|------------------------------------------------|
| <i>enable</i> | Enables or disables DAI on the specified VLAN. |

## Configuring Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DAI. By default, the trust factor is set to untrusted.

### Note

For ports that are part of an MLT, DAI must be configured using the MLT configuration mode.

## Before You Begin

You must enable DHCP Snooping globally.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the trust factor for the port:

```
ip arp-inspection <trusted|untrusted>
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#ip arp-inspection trusted
```

## Variable Definitions

The following table defines parameters for the **ip arp-inspection** command.

| Variable            | Value                                           |
|---------------------|-------------------------------------------------|
| <trusted untrusted> | Specifies the trust factor of the port for DAI. |

## Display Dynamic ARP Inspection Interface Information

Use the following procedure to view the DAI interface information.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display DAI brouter port information:

```
show ip arp-inspection interface [ gigabitEthernet [ {slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]} [ vrf WORD<1-16> | vrfids
WORD<0-512> ] | <1-4059> [ {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]} [ vrf WORD<1-16> | vrfids WORD<0-512> ] | vrf
WORD<1-16> | vrfids WORD<0-512> ] | vrf WORD<1-16> | vrfids
WORD<0-512> ] ]
```

3. Display DAI VLAN information:

```
show ip arp-inspection vlan <1-4059>
```

4. Display DAI information for specific VRF name:

```
show ip arp-inspection vrf WORD<1-16>
```

5. Display DAI information for specific VRF ID:

```
show ip arp-inspection vrfids WORD<0-512>
```

**Example**

```
Switch:1>show ip arp-inspection interface gigabitEthernet 1/2
```

```

**FHS configuration**

Configure IPv6 FHS features to enable IPv6 link security and management over the Layer 2 links.

*Enable or Disable FHS Globally*

**About This Task**

You must enable First Hop Security globally for RA Guard or DHCPv6 Guard to be operational.

Enabling FHS globally installs the required filters for FHS. Disabling FHS, uninstalls these filters. By default, FHS is disabled.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable First Hop Security globally:  
`ipv6 fhs enable`
3. Disable First Hop Security globally:  
`no ipv6 fhs enable`  
  
OR  
  
`default ipv6 fhs enable`

### Managing the FHS IPv6 access list

#### About This Task

You can create an FHS IPv6 access list or add IPv6 prefixes to an existing IPv6 access list.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Create an FHS IPv6 access list or add IPv6 prefixes to an existing IPv6 access list:  
`ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>] [ge<0-128>] [le<0-128>] [mode <allow | deny>]`
3. Delete an FHS IPv6 access list or delete a particular IPv6 prefix from the IPv6 access list:  
`no ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>]`
4. Set the ge/le values and mode of the FHS IPv6 access list to default value:  
`default ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>] [ge|le|mode]`

### Example

```
Switch>enable
Switch#config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#ipv6 fhs ipv6-access-list ipv6_acl_1 fe80::221:2fff:fe31:5376/64
Switch(config)#
```

## Variable Definitions

The following table defines parameters for the **ipv6 fhs ipv6-access-list** command.

| Variable                                   | Description                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-64>                         | Specifies the IPv6 access list name.                                                                                                                                                                                                                                                                                                                           |
| <i>WORD</i> <0-46>                         | Specifies the IPv6 address or the prefix length to be added to the IPv6 access list.                                                                                                                                                                                                                                                                           |
| <i>ge</i> <0 -128>                         | Specifies the minimum value of prefix length advertised in prefix information of RA or DHCPv6 packets.<br>By default, the value is equal to the configured prefix length.<br><br><b>Note:</b><br>If you manually configure the value, ensure that it is greater than the configured prefix length. Also ensure, the ge value is always less than the le value. |
| <i>le</i> <0 -128>                         | Specifies the maximum value of prefix length advertised in prefix information of RA or DHCPv6 packets.<br>By default, the value is equal to the configured prefix length.<br><br><b>Note:</b><br>If you manually configure the value, ensure that it is greater than the configured prefix length.                                                             |
| <i>mode</i> < <i>allow</i>   <i>deny</i> > | Specifies the access mode.<br>By default, the value is allow.                                                                                                                                                                                                                                                                                                  |

### Displaying FHS IPv6 access list information

#### About This Task

Displays the current FHS IPv6 access list information.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the current FHS IPv6 access list information:  
show ipv6 fhs ipv6-access-list [*WORD*<1-64>]

#### Example

```
Switch:1# show ipv6 fhs ipv6-access-list

=====
                        IPv6 FHS Access List Table Info
=====
                                MASK-RANGE
ACC-LIST-NAME      IPV6-PREFIX      MASK FROM TO      MODE
-----
v6_acl1            1:0:0:0:0:0:1      64  64  64      Allow
v6_acl2            1:0:0:0:0:0:1      64  64  64      Allow
-----

All 2 out of 2 Total Num of ipv6 access list entries displayed
```

*Managing the FHS MAC access list***About This Task**

You can create an FHS MAC access list or add MAC addresses to an existing MAC access list.

**Procedure**

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Create an FHS MAC access list or add MAC addresses to an existing MAC access list:  

```
ipv6 fhs mac-access-list WORD<1-64> <0x00:0x00:0x00:0x00:0x00:0x00>
[mode <allow | deny>]
```
3. Delete an FHS MAC access list or delete a particular MAC address from the MAC access list:  

```
no ipv6 fhs mac-access-list WORD<1-64> <0x00:0x00:0x00:0x00:0x00:0x00>
```
4. Set the MAC ACL mode to its default value:  

```
default ipv6 fhs mac-access-list WORD<1-64>
<0x00:0x00:0x00:0x00:0x00:0x00> [mode]
```

**Variable Definitions**

The following table defines parameters for the **ipv6 fhs mac-access-list** command.

| Variable                                     | Description                                                  |
|----------------------------------------------|--------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i>                      | Specifies the MAC access list name.                          |
| <i>&lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</i> | Specifies the MAC address to be added or deleted.            |
| <i>mode &lt;allow   deny&gt;</i>             | Specifies the access mode.<br>By default, the value is Allow |

*Displaying FHS MAC access list information***About This Task**

Displays the current FHS MAC access list information.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display the current FHS MAC access list information:  

```
show ipv6 fhs mac-access-list [WORD<1-64>]
```

**Example**

```
Switch#show ipv6 fhs mac-access-list
=====

-----

```

*Displaying current FHS configuration*

### About This Task

Displays the current FHS configuration.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the current FHS configuration:  
show ipv6 fhs port-policy {slot/port[/sub-port]} [-slot/port[/sub-port]]  
[,...]

### Example

```

Switch:1#show ipv6 fhs port-policy
-----
IPv6 FHS Port Policy Info
-----
PORT  DHCPG-DEVICE-ROLE  DHCPG-POLICY          RAG-DEVICE-ROLE  RAG-POLICY
-----
1/1   Server             dhcp_poll              Router            ra_poll
-----
All 1 out of 1 Total Num of fhs port policy entries displayed
-----

```

## DHCPv6 Guard Policy Configuration

DHCPv6 Guard policy blocks DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents that forward DHCPv6 packets from servers to clients.

*Enable or Disable DHCPv6 Guard Globally*

### About This Task

Enabling DHCPv6 Guard globally installs filters on the configured interfaces. By default, DHCPv6 Guard is disabled.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable FHS globally:  
ipv6 fhs enable

3. Enable DHCPv6 Guard globally:  

```
ipv6 dhcp-guard enable
```
4. Disable DHCPv6 Guard globally:  

```
no ipv6 dhcp-guard enable
```
5. Set DHCPv6 Guard to its default value:  

```
default ipv6 dhcp-guard enable
```

### Manage the DHCPv6 Guard Policy

#### About This Task

Configure or modify the DHCPv6 Guard policy.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create a DHCPv6 Guard policy:  

```
ipv6 dhcp-guard policy WORD<1-64>
```
3. Delete a DHCPv6 Guard policy:  

```
no ipv6 dhcp-guard policy WORD<1-64>
```

#### Note

You cannot delete a policy that is already attached to a port.

#### Variable Definitions

The following table defines parameters for the **ipv6 dhcp-guard policy** command.

| Variable                | Description                                                |
|-------------------------|------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i> | Specifies the created or deleted DHCPv6 Guard policy name. |

### Attach a DHCPv6 Guard Policy to a Port

#### About This Task

Applies a DHCPv6 Guard policy to a specific interface.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply a DHCPv6 Guard policy.

```
ipv6 fhs dhcp-guard attach-policy WORD<1-64>
```

3. Detach a DHCPv6 Guard policy from an interface.

```
no ipv6 fhs dhcp-guard attach-policy
```

OR

```
default ipv6 dhcp-guard attach-policy
```

4. Enable device role verification attached to the port. By default, router is selected.

```
ipv6 fhs dhcp-guard device-role {client|server} attach-policy
WORD<1-64>
```

### Note

A DHCPv6 Guard policy can be attached to a port only if the device-role configured on that port is 'server'.

## Variable Definitions

The following table defines parameters for the **ipv6 fhs dhcp-guard attach-policy** and **ipv6 fhs dhcp-guard device-role** command.

| Variable                 | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i>  | Specify the name of the DHCPv6 Guard policy to be attached or detached. |
| <i>{client   server}</i> | Sets the DHCPv6 Guard device role as client or server.                  |

*Configure DHCPv6 Guard in dhcp-guard Mode*

## About This Task

Configures DHCPv6 Guard under dhcp-guard mode.

**Procedure**

1. Enter DHCP-guard Configuration mode.  
`enable`  
`configure terminal`  
`ipv6 fhs dhcp-guard policy WORD<1-64>`
2. Specify IPv6 access list to verify IPv6 source address of DHCPv6 packets..  
`match server access-list <ipv6-access-list-name>`
3. Remove DHCPv6 Guard filtering for the sender's IPv6 addresses.  
`no match server access-list`  
  
OR  
  
`default match server access-list`
4. Specify IPv6 prefix list to verify advertised prefixes.  
`match reply prefix-list <ipv6-prefix-list-name>`
5. Remove DHCPv6 Guard filtering for advertised prefixes.  
`no match reply prefix-list`  
  
OR  
  
`default match reply prefix-list`
6. Specify the minimum limit for verification of the advertised preference.  
`preference min-limit <0-255>`
7. Set the minimum limit for verification of the advertised preference to its default value.  
`default preference min-limit`
8. Specify the maximum limit for verification of the advertised preference.  
`preference max-limit <0-255>`
9. Set the maximum limit for verification of the advertised preference to its default value.  
`default preference max-limit`

## Variable Definitions

The following table defines parameters for the **dhcp-guard** configuration mode commands.

| Variable                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>match server access-list</code><br><code>&lt;ipv6-access-list-name&gt;</code> | <p>Enables verification of the sender's IPv6 address in inspected messages from the configured authorized device source access list specified.</p> <p><b>Note:</b><br/>If the access-list is not attached, the IPv6 source address in DHCPv6 packet is not validated.<br/>If the list is attached and it does not match any entries in IPv6 access list, the switch drops the DHCPv6 packet. If you wish to change this behavior, add an entry with IPv6 prefix "0::0/0" with the Allow option, which changes the default drop to default Allow.</p>                                     |
| <code>{ no   default }</code><br><code>match server access-list</code>              | Removes the sender's IPv6 address based DHCPv6 Guard filtering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>match reply prefix-list</code><br><code>&lt;ipv6-prefix-list-name&gt;</code>  | <p>Enables verification of the advertised prefixes in DHCPv6 reply messages from the configured authorized prefix list. If prefix-list is not configured, this check is bypassed.</p> <p><b>Note:</b><br/>If the access-list is not attached, the inspection does not occur.<br/>If the list is attached and advertised IPv6 address does not match any IPv6 prefixes in the list, the switch drops the DHCPv6 packet. If you wish to change this behavior, add an IPv6 access list entry with prefix 0::0/0 with the Allow option, which changes the default drop to default Allow.</p> |
| <code>{ no   default }</code><br><code>match reply prefix-list</code>               | Removes the advertised prefix-based DHCPv6 Guard filtering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>preference min-limit</code><br><code>&lt;0-255&gt;</code>                     | <p>Enables validation of advertised preference (in preference option) to check if it is greater than the specified limit. If preference is not specified, this field in the packet is not validated.</p> <p>While changing the preference limit, ensure the maximum limit is greater than the minimum limit.</p>                                                                                                                                                                                                                                                                         |
| <code>default preference min-limit</code>                                           | Sets the specified limit to its default value.<br>By default, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>preference max-limit</code><br><code>&lt;0-255&gt;</code>                     | <p>Enables validation of advertised preference (in preference option) to check if it is less than the specified limit. If preference is not specified, this field in the packet is not validated.</p> <p><b>Note:</b><br/>The preference value in the packet is not validated if both minimum and maximum values are zero.</p>                                                                                                                                                                                                                                                           |
| <code>default preference max-limit</code>                                           | Sets the specified limit to its default value.<br>By default, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

*Display the DHCPv6 Guard Policy***About This Task**

Displays DHCPv6 Guard policy information for all the configured DHCPv6 Guard policies or a particular policy.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display DHCPv6 Guard policy information:  

```
show ipv6 fhs dhcp-guard policy WORD<1-64>
```

**Example**

```
Switch:1# show ipv6 fhs dhcp-guard policy
=====
IPv6 DHCP Guard Policy Info
=====
POLICY-NAME          SERVER-ACC-LIST      REPLY-PREF-LIST     MIN-RTR-PREF  MAX-RTR-PREF
-----
dhcp_pol1            v6_acl1             v6_acl2              0              0
-----
All 1 out of 1 Total Num of dhcp-guard stats entries displayed
```

**Variable Definitions**

The following table defines parameters for the `show ipv6 fhs dhcp-guard policy` command.

| Variable                      | Description                                                                                                                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-64&gt;</code> | Displays DHCPv6 Guard policy information for all the configured DHCPv6 Guard policies.<br>Policy name is an optional parameter. If policy name is provided, only the DHCPv6 Guard policy of the specified policy-name is displayed. |

**RA Guard Configuration**

IPv6 RA Guard provides support to the administrator to block or reject unwanted RA Guard messages that arrive at the network switch platform. The routers use Router Advertisements (RAs) to announce themselves on the link. The RA Guard feature analyzes these RAs and filters out bogus RAs sent by unauthorized routers. The RA Guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. After the Layer 2 device validates the content of the RA packet against the configuration, it forwards the RA to its destination. If the RA packet validation fails, the RA is dropped.

*Enable or Disable RA Guard Globally***About This Task**

Enables RA Guard globally. By default, RA Guard is disabled.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable FHS globally:  
ipv6 fhs enable
3. Enable RA Guard globally:  
ipv6 fhs ra-guard enable
4. Disable RA Guard globally:  
no ipv6 fhs ra-guard enable
5. Set the RA Guard to its default value:  
default ipv6 fhs ra-guard enable

*Manage the RA Guard Policy***About This Task**

Configure or modify RA Guard policy. This command also enables the RA Guard configuration mode.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Create the RA Guard policy:  
ipv6 fhs ra-guard policy *WORD<1-64>*
3. Delete the RA Guard policy:  
no ipv6 fhs ra-guard policy *WORD<1-64>*

**Note**

You cannot delete a policy that is attached to a port.

**Variable Definitions**

The following table defines parameters for the **ipv6 fhs ra-guard policy** command.

| Variable                | Description                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i> | Specifies the name of the RA Guard policy to be created or deleted. This is a mandatory parameter in this command. |

*Configure RA Guard on an Interface***About This Task**

Attaches or detaches a RA Guard policy on the specific interface.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply a RA Guard policy.

```
ipv6 fhs ra-guard attach-policy WORD<1-64>
```

### Note

RA Guard device-role on the port has to be configured as 'router' before attaching any RA Guard policy to the port. If device-role on the port is not 'router', this command will fail with an appropriate error message.

3. Detach a RA Guard policy from an interface.

```
no ipv6 fhs ra-guard attach-policy
```

OR

```
default ipv6 fhs ra-guard attach-policy
```

4. Enable device role verification attached to the port.

```
ipv6 fhs ra-guard device-role {router|host} attach-policy WORD<1-64>
```

### Note

A DHCPv6 Guard policy can be attached to a port only if the device-role configured on that port is 'server'.

## Variable Definitions

The following table defines parameters for the **ipv6 fhs ra-guard attach-policy** and **ipv6 fhs ra-guard device-role** command.

| Variable                | Description                                                           |
|-------------------------|-----------------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i> | Specifies the name of the RA Guard policy to be attached or detached. |
| <i>{host   router}</i>  | Sets the RA Guard device role as host or router.                      |

*Configure RA Guard in RA Guard Mode*

### About This Task

Configures RA Guard in the RA Guard configuration mode.

## Procedure

1. Enter RA Guard Configuration mode.

```
enable
```

```
configure terminal
```

```
ipv6 fhs ra-guard policy WORD<1-64>
```

2. Configure the filter to match the IPv6 prefixes advertised in RA packets.

```
match ra-prefix-list WORD<1-64>
```

3. Remove RA Guard filtering for the advertised prefixes.

```
no match ra-prefix-list
```

OR

```
default match ra-prefix-list
```

4. Configure the filter to match the source MAC address of RA packets.

```
match ra-macaddr-list WORD<1-64>
```

5. Remove the source MAC address-based RA Guard filtering.

```
no match ra-macaddr-list
```

OR

```
default match ra-macaddr-list
```

6. Configure the filter to match source IPv6 address of RA packets.

```
match ra-srcaddr-list WORD<1-64>
```

7. Remove the source IPv6 address based RA Guard filtering.

```
no match ra-srcaddr-list
```

OR

```
default match ra-srcaddr-list
```

8. Enable managed address configuration flag verification in the advertised RA packet.

```
managed-config-flag <none | on | off>
```

9. Enable advertised hop count limit verification.

```
hop-limit {maximum | minimum} <0-255>
```

10. Enable the advertised default router-preference parameter value verification.

```
router-preference maximum {none | high | low | medium}
```

## Variable Definitions

The following table defines parameters to configure RA Guard policy.

| Variable                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| match ra-prefix-list<br><i>WORD&lt;1-64&gt;</i>        | Verifies the advertised prefixes in RA packets against the configured authorized prefix list.<br><br><b>Note:</b><br>RA packet's sender IPv6 address is not validated if no IPv6 source access list is attached to the RA Guard policy.<br>If the list is attached and if RA packet's sender IPv6 address does not match any entry in that IPv6 prefix list, then the RA packet is dropped. To change this behavior, add a entry with ipv6 prefix "0::0/0" with Allow option. The default value changes from Drop to Allow. |
| {no   default} match ra-prefix-list                    | Removes the advertised prefix-based RA Guard filtering                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| match ra-macaddr-list<br><i>WORD&lt;1-64&gt;</i>       | Verifies sender's source MAC address against the configured mac-access-list.<br><br><b>Note:</b><br>Advertised prefixes in RA packet are not validated if no IPv6 prefix list is attached to the RA Guard policy.<br>If the list is attached and if it does not match any MAC in the list, then the RA packet is dropped.                                                                                                                                                                                                   |
| {no   default} match ra-macaddr-list                   | Removes the source MAC address-based RA Guard filtering for the specified MAC address access list names.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| match ra-srcaddr-list<br><i>WORD&lt;1-64&gt;</i>       | Verifies sender's source IPV6 address against the configured list.<br><br><b>Note:</b><br>Inspection is not done if the access-list is not attached.<br>If the list is attached and if it does not match any IPv6 in the list, then the RA packet is dropped. To change the behavior, add a dummy IPv6 "0:0:0:0:0" to the list with Allow option. The default value changes from Drop to Allow.                                                                                                                             |
| {no   default} match ra-srcaddr-list                   | Removes the source IPv6 address-based RA Guard filtering for the specified IPv6 address access list names.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| managed-config-flag<br>< <i>none   on   off</i> >      | Verifies managed address configuration flag in the advertised RA packet.<br>By default, the value is none and check is bypassed.                                                                                                                                                                                                                                                                                                                                                                                            |
| hop-limit {maximum   minimum} < <i>0-255</i> >         | Verifies the advertised hop count limit. The limit value range is from 0 to 255. While changing the minimum or maximum value, ensure the maximum value is greater than the minimum value.<br>By default, the minimum and maximum limit are 0. In this case, the hop-limit check is bypassed.                                                                                                                                                                                                                                |
| router-preference maximum {none   high   low   medium} | Verifies if the advertised default router-preference parameter value is lower than or equal to a specified limit.<br>By default, the value is none and the check is bypassed.                                                                                                                                                                                                                                                                                                                                               |

*Display RA Guard Configuration***About This Task**

Display configured RA Guard policy information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display configured RA Guard policy information:

```
show ipv6 fhs ra-guard policy WORD<1-64>
```

**Example**

```
Switch:1# show ipv6 fhs ra-guard policy

**Variable Definitions**

The following table defines parameters for the **show ipv6 fhs ra-guard policy** command.

| Variable                | Description                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-64&gt;</i> | Displays the RA Guard policy for the specified policy-name. By default, all the configured RA Guard policies are displayed. |

**IPv6 Neighbor Discovery inspection configuration**

This section describes how to configure ND inspection on the switch and protect the network by mitigating the various types of attacks.

**Important**

Enable FHS globally before enabling ND inspection.

*Enabling ND inspection globally***Before You Begin**

Enable FHS globally for ND inspection to work.

### About This Task

Use this procedure to enable Neighbor Discovery (ND) inspection globally.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable ND inspection globally:  

```
ipv6 fhs nd-inspection enable
```

### Clear Neighbor Discovery Inspection Statistics

### About This Task

Use this procedure to clear the Neighbor Discovery inspection statistics.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Clear the Neighbor Discovery inspection statistics:  

```
clear ipv6 fhs statistics nd-inspection [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

#### Note

Alternatively, you can use the command `clear ipv6 fhs statistics all` to clear the ND inspection statistics along with RA guard statistics and DHCPv6 Guard statistics.

### Variable Definitions

The following table defines parameters for the `clear ipv6 fhs statistics nd-inspection` command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### Enabling Neighbor Discovery inspection on a VLAN

#### Before You Begin

Enable FHS globally for ND inspection to work.

#### About This Task

Use this procedure to enable Neighbor Discovery inspection on a VLAN.

**Procedure**

1. Enter VLAN Interface Configuration mode:  
`enable`  
`configure terminal`  
`interface vlan <1-4059>`
2. Enable Neighbor Discovery inspection on the VLAN:  
`ipv6 fhs nd-inspection enable`

*Enabling Neighbor Discovery inspection on a port***Before You Begin**

Enable FHS globally for ND inspection to work.

**About This Task**

Use this procedure to enable Neighbor Discovery inspection on a port

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:  
`enable`  
`configure terminal`  
`interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]`  
`[, ...]}`  
 **Note**  
If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
2. Enable Neighbor Discovery inspection on the port:  
`ipv6 fhs nd-inspection enable`

*Viewing Neighbor Discovery inspection status globally***About This Task**

Use this procedure to view the Neighbor Discovery inspection status globally

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Display the ND inspection status globally:  
`show ipv6 fhs status`

*Viewing Neighbor Discovery inspection status on a port***About This Task**

Use this procedure to view Neighbor Discovery inspection status on a port.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display port-wise ND inspection status:  
show ipv6 fhs port-policy

*Viewing Neighbor Discovery inspection statistics on a port***About This Task**

Use this procedure to view the Neighbor Discovery inspection statistics on a port or set of ports.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display ND inspection statistics on a port or a set of ports:  
show ipv6 fhs statistics nd-inspection {slot/port[/sub-port] [-slot/  
port[/sub-port]] [,...]}

**Variable Definitions**

The following table defines parameters for the **show ipv6 fhs statistics nd-inspection** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## IPv6 DHCP Snooping Configuration

This section describes how to configure IPv6 DHCP snooping on the switch and protect the network by mitigating the various types of attacks.

**Important**

Configure DHCPv6 Guard before enabling IPv6 DHCP snooping. DHCPv6 Guard classifies the ports as trusted or untrusted and extracts DHCPv6 reply packets received on trusted ports to the control path. For more information on how to configure DHCPv6 Guard, see [DHCPv6 Guard Policy Configuration](#) on page 2057.

### Creating a static Security Binding Table entry

Use this procedure to enable learning Security Binding Table (SBT) entries on all the VLANs where IPv6 DHCP snooping is configured.

#### About This Task

Use this procedure to create a static SBT entry.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a static SBT entry:

```
ipv6 fhs snooping static-binding ipv6-address WORD<0-46> vlan <1-4059>
mac-address 0x00:0x00:0x00 port {slot/port[/sub-port]}
```

#### Note

To delete an SBT entry, use the command `no ipv6 fhs snooping static-binding`.

#### Example

Add a static SBT entry.

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)#ipv6 fhs snooping static-binding ipv6-address
2001:DB8:89ab:cdef:0123:4567:89ab:cdef vlan 1000 mac-address 00:11:22:33:44:55 port 1/2
```

#### Variable Definitions

The following table defines parameters for the `ipv6 fhs snooping static-binding ipv6-address` command.

| Variable                                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mac-address</code><br><code>0x00:0x00:0x00</code> | Specifies the MAC address of the binding entry.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>port {slot/port[/sub-port]}</code>                | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                           |
| <code>vlan &lt;1-4059&gt;</code>                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>WORD&lt;0-46&gt;</code>                           | Specifies the IPv6 address for the binding entry.                                                                                                                                                                                                                                                                                                                                                                                      |

### Clearing a dynamic SBT entry

## About This Task

Use this procedure to clear all or a particular dynamic SBT entry.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear a dynamic SBT entry:  
clear ipv6 fhs snooping [vlan <1-4059>][ipv6-address WORD<0-46>]

## Example

Clear a dynamic SBT entry on a VLAN.

```
Switch:1> enable
Switch:1>clear ipv6 fhs snooping vlan 1000 ipv6-address
2001:DB8:89ab:cdef:0123:4567:89ab:cdef
```

## Variable Definitions

The following table defines parameters for the **clear ipv6 fhs snooping** command.

| Variable                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-address</i><br>WORD<0-46> | Specifies the IPv6 address for the binding entry to clear. You cannot specify an address without first specifying the VLAN.                                                                                                                                                                                                                                                                                                                                                                 |
| <i>vlan</i> <1-4059>              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br>If you do not specify a VLAN, the command clears all entries. |

*Enable IPv6 DHCP Snooping on a VLAN*

## Before You Begin

Enable IPv6 DHCPv6 Guard for IPv6 DHCP snooping to work.

## About This Task

Use this procedure to configure IPv6 DHCP snooping on a VLAN.

## Procedure

1. Enter VLAN Interface Configuration mode:  
enable  
  
configure terminal  
  
interface vlan <1-4059>
2. Configure IPv6 DHCP snooping on the VLAN:  
ipv6 fhs snooping dhcp enable

## Viewing IPv6 DHCP snooping and ND inspection status on a VLAN

### About This Task

Use this procedure to view IPv6 DHCP snooping and ND inspection status on a VLAN.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the IPv6 DHCP snooping and ND inspection status on a VLAN:  
show ipv6 fhs status vlan [<1-4059>]

### Example

View the status for all VLANs.

```
Switch:1#show ipv6 fhs status vlan
=====
                        IPv6 FHS VLAN Information
=====
VLAN-ID                DHCP-SNOOPING-STATUS    ND-INSPECTION-STATUS
-----
1                       Disabled                Disabled
3                       Disabled                Disabled
4                       Disabled                Disabled
22                      Disabled                Disabled
=====
All 4 out of 4 Total Num of FHS VLAN entries displayed
```

### Variable Definitions

The following table defines parameters for the **show ipv6 fhs status vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN ID, the command output includes all VLANs. |

## Viewing SBT entries

### About This Task

Use this procedure to view SBT entries.

### Procedure

1. Enter Privileged EXEC mode:  
enable

- View all SBT entries:

```
show ipv6 fhs snooping binding
```

- View the SBT entries by type:

```
show ipv6 fhs snooping binding type {dynamic | static}
```

- View the SBT entries by VLAN:

```
show ipv6 fhs snooping binding vlan <1-4059>[ipv6-address WORD<0-46>]
```

### Variable Definitions

The following table defines parameters for the **show ipv6 fhs snooping binding** command.

| Variable                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ipv6-address</i><br><i>WORD&lt;0-46&gt;</i> | Specifies the IPv6 address for the binding entry.                                                                                                                                                                                                                                                                                                                                                                          |
| <i>type {dynamic   static}</i>                 | Shows only dynamic binding entries or static binding entries.                                                                                                                                                                                                                                                                                                                                                              |
| <i>vlan &lt;1-4059&gt;</i>                     | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## IP Source Guard Configuration

The following sections provide procedural information you can use to configure IP Source Guard (IPSG) using the Command Line Interface (CLI).

### Note

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

### Enable IP Source Guard on a Port for IPv4 Addresses

#### About This Task

Enable IP Source Guard (IPSG) on a port to add a higher level of security to the port by preventing IP spoofing. When you enable IPSG on the interface, filters are automatically installed for the IPv4 addresses that are already learned on that interface.

### Important

Do not enable IPSG on MLT, DMLT, SMLT, LAG, trunk ports or ports that are a part of private VLANs.

## Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and Dynamic ARP Inspection.
- The port is an untrusted port enabled with both DHCP Snooping and Dynamic ARP Inspection.
- The port has enough resources allocated, to support the maximum number of 10 IP addresses allowed for IPSG.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPSG on the port:

```
ip source verify enable
```

3. Verify IPSG configuration:

```
show ip source verify interface gigabitEthernet [{slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]
```

## Example

Configure IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ip source verify enable
```

Verify the configuration.

```
Switch:1(config-if)#show ip source verify interface gigabitEthernet
```

```

### Variable Definitions

The following table defines parameters for the **ip source verify** command.

| Variable | Value                                |
|----------|--------------------------------------|
| enable   | Enables IP Source Guard on the port. |

### Disable IP Source Guard for IPv4 Addresses

#### About This Task

Disable IP Source Guard (IPSG) on a port to allow traffic from all IPv4 addresses to go through the port without being filtered.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable IPSG for IPv4 addresses:

```
no ip source verify
```

3. Verify IPSG configuration:

```
show ip source verify interface gigabitEthernet [{slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]
```

## Example

Disable IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#no ip source verify
```

Verify the configuration.

```
Switch:1(config-if)#show ip source verify interface gigabitEthernet 4/1

=====

```

*View IP Source Guard Configuration on a Port*

## About This Task

View IP Source Guard (IPSG) configuration on a port, with filters for IPv4 addresses.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPSG configuration:

```
show ip source verify interface gigabitEthernet [{slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]
```

## Example

```
Switch:1>show ip source verify interface gigabitEthernet 4/1

=====
Source Guard Port Info
=====
PORT          ENABLE          IPSC
NUM           ORIGIN
-----
4/1          true           RADIUS
-----

All 1 out of 1 Total Num of Ip Source Guard entries displayed
```

## Variable Definitions

The following table defines parameters for the **show ip source verify interface gigabitEthernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

### View IPv4 Address Bindings

#### About This Task

View the IPv4 address bindings that IP Source Guard (IPSG) allows.

#### Procedure

- To enter User EXEC mode, log on to the switch.
- View the allowed IPv4 address bindings for a specific interface:
 

```
show ip source binding [interface gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [[vlan <1-4059>]] [[vrf WORD<1-16>]] [[vrfids WORD<0-512>]]
```
- View the allowed IPv4 address bindings for a specific IP address:
 

```
show ip source binding {A.B.C.D}
```

#### Example

View the allowed IPv4 address bindings for the port 4/1.

```
Switch:1>show ip source binding interface gigabitEthernet 4/1

=====
IPSG Source Table
=====

-----
```

All 1 out of 1 Total IP Source Guard entries displayed

## Variable Definitions

The following table defines parameters for the **show ip source binding** command.

| Variable                                                                                               | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{A.B.C.D}</code>                                                                                 | Identifies the IPv4 address.                                                                                                                                                                                                                                                                                                                                  |
| <code>interface gigabitEthernet {slot/<br/>port[/sub-port] [-slot/port[/<br/>sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>vlan &lt;1-4059&gt;</code>                                                                       | Specifies the VLAN ID of the VLAN for which to view IPv4 address bindings.                                                                                                                                                                                                                                                                                    |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                      | Specifies the VRF name of the VRF for which to view the IPv4 address bindings.                                                                                                                                                                                                                                                                                |
| <code>vrfids WORD&lt;0-512&gt;</code>                                                                  | Specifies the VRF ID of the VRF for which to view IPv4 address bindings.                                                                                                                                                                                                                                                                                      |

## Enable IP Source Guard on a Port for IPv6 Addresses

### About This Task

Enable IP Source Guard (IPSG) on a port, to add a higher level of security to the port by preventing IP spoofing. When you enable IPSG on the interface, filters are installed for IPv6 addresses that are already learned on that interface.

#### Important

Do not enable IPSG on MLT, DMLT, SMLT, LAG, trunk ports or ports that are a part of private VLANs.

### Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port is an untrusted port enabled with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port has enough resources allocated, to support the maximum number of 10 IP addresses allowed for IPSG.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum number of allowed IPv6 addresses on a port:

```
ipv6 source-guard [max-allowed-addr <2-10>]
```

### Note

Ensure that you configure the maximum number of allowed IPv6 addresses on a port, before you enable IPSG on that port.

3. Enable IPSG on the port:

```
ipv6 source-guard enable
```

4. Verify IPSG configuration information on the port:

```
show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]
```

## Example

Enable IPSG on a port.

Configure the maximum allowed IPv6 addresses on port 4/1 as 10 and enable IPSG on that port.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ipv6 source-guard max-allowed-addr 10
Switch:1(config-if)#ipv6 source-guard enable
```

Verify the configuration.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port  Source Guard  Number of IPv6  Address
           Mode       address allowed overflow count
=====
4/1        Enabled      10              0
```

Optionally view all interfaces with IPSG enabled.

```
Switch:1(config-if)#show ipv6 source-guard interface enabled
Slot/Port  Source Guard  Number of IPv6  Address
           Mode       address allowed overflow count
=====
4/1        Enabled      4               0
3/1        Enabled      9               0
```

## Variable Definitions

The following table defines parameters for the **ipv6 source-guard** command.

| Variable                                   | Value                                                                                                                                                                                                           |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code>                        | Enables IP Source Guard on a port.                                                                                                                                                                              |
| <code>max-allowed-addr &lt;2-10&gt;</code> | Specifies the maximum number of IPv6 addresses allowed to transmit data through the port. The default value is 4.<br><br><b>Note:</b><br>To reset the value to default, IPSG must be disabled on the interface. |

### Disable IP Source Guard for IPv6 Addresses

#### About This Task

Disable IP Source Guard (IPSG) on a port to allow traffic from all IPv6 addresses to go through the port without being filtered.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable IPSG for IPv6 addresses on a port:

```
no ipv6 source-guard enable
```

3. Verify IPSG configuration on the port:

```
show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]
```

#### Example

Disable IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#no ipv6 source-guard enable
```

Verify the configuration.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port Source Guard Number of IPv6 Address
```

|     | Mode     | address allowed | overflow count |
|-----|----------|-----------------|----------------|
| 4/1 | Disabled | 10              | 0              |

### Clear IP Source Guard Overflow Counters

#### About This Task

Overflow counters consist of IPv6 addresses that are not added to IP Source Guard (IPSG) due to lack of filter resources. Use this procedure to clear the overflow counters for an IPSG port.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Clear the overflow counters:

```
ipv6 source-guard overflow-count clear
```

3. Verify the configuration on the port:

```
show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]
```

4. (Optional) View the overflow counters on all IPSG enabled ports:

```
show ipv6 source-guard interface enabled
```

#### Example

Clear overflow counters on the IPSG port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ipv6 source-guard overflow-count clear
```

Verify the configuration on port 4/1.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port Source Guard Number of IPv6 Address
          Mode          address allowed overflow count
=====
4/1       Enabled          10             0
```

Optionally view the overflow counters on all IPSG enabled ports.

```
Switch:1(config-if)#show ipv6 source-guard interface enabled
Slot/Port Source Guard Number of IPv6 Address
          Mode          address allowed overflow count
=====
```

|     |         |   |   |
|-----|---------|---|---|
| 4/1 | Enabled | 4 | 0 |
| 3/1 | Enabled | 9 | 0 |

View IP Source Guard Configuration for IPv6 Addresses

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPSG configuration on a specified interface:
 

```
show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```
3. View IPSG configuration on all IPSG enabled interfaces:
 

```
show ipv6 source-guard interface enabled
```

### Example

```
Switch:1#show ipv6 source-guard interface gigabitEthernet 4/1
```

```
Slot/Port  Source Guard  Number of  IPv6  Address
           Mode      address allowed  overflow count
=====
4/1        Enabled      4           0
```

```
Switch:1#show ipv6 source-guard interface enabled
```

```
Slot/Port  Source Guard  Number of  IPv6  Address
           Mode      address allowed  overflow count
=====
4/1        Enabled      4           0
4/2        Enabled      9           0
```

### Variable Definitions

The following table defines parameters for the **show ipv6 source-guard interface gigabitEthernet** command.

| Variable                                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enabled                                                                | Displays IPSG configuration on all IPSG enabled interfaces.                                                                                                                                                                                                                                                                                                                                                           |
| gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]] | Displays IPSG configuration on the specified interface. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

View IPv6 Address Bindings

### About This Task

View the IPv6 address bindings that IP Source Guard (IPSG) allows.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. View the allowed IPv6 address bindings:

```
show ipv6 source-guard binding [WORD<0-46>] [interface gigabitEthernet
 {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

### Example

View the IPv6 address bindings for port 1/3.

```
Switch:1>show ipv6 source-guard binding interface gigabitEthernet 1/3
Slot/Port   IPv6   Address
-----
1/3         2001::10:10:0:1
1/3         fe80::210:94ff:fe00:550b
-----
```

View the IPv6 address bindings for a specific IPv6 address.

```
Switch:1>show ipv6 source-guard binding fe80::210:94ff:fe00:550b
Slot/Port   IPv6   Address
-----
1/3         fe80::210:94ff:fe00:550b
-----
```

### Variable Definitions

The following table defines parameters for the **show ipv6 source-guard binding** command.

| Variable                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;0-46&gt;</i>                                                                  | Identifies the IPv6 address.                                                                                                                                                                                                                                                                                                                                  |
| interface gigabitEthernet { <i>slot/port[/sub-port] [-slot/port[/sub-port]] [,...]</i> } | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Layer 2 Security Configuration using EDM

Use the following sections to help you configure Layer 2 security features and protect the network by mitigating various types of attacks, using Enterprise Device Manager (EDM).

For IPv4 deployments, configure:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

## For IPv6 deployments, configure:

- First Hop Security (FHS)

### Note

FHS does not solve all cases of denial of services like blocking flooding of the IPv6 messages.

- DHCP Snooping and IPv6 Neighbor Discovery Inspection
- IP Source Guard for IPv6 addresses

## Dynamic ARP Inspection Configuration Using EDM

The following section provides procedures to configure Dynamic ARP Inspection (DAI) using EDM.

### Configure Dynamic ARP Inspection on VLANs

Use the following procedure to enable or disable DAI on one or more VLANs.

### Note

DAI cannot be enabled on Private VLANs (E-Tree) and SPBM B-VLANs.

### Before You Begin

You must enable DHCP Snooping globally.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **ARP Inspection**.
3. Click the **ARP Inspection-VLAN** tab.
4. In the row for the VLAN, double-click the **Enabled** field, and select **true** to enable DAI.
5. Click **Apply**.

### ARP Inspection-VLAN Field Descriptions

Use the data in the following table to use the **ARP Inspection-VLAN** tab.

| Name           | Description                                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>  | Specifies the VLAN ID.                                                                                                                                                                                                                                                                                |
| <b>Enabled</b> | Specifies if DAI is enabled or disabled for the particular VLAN. By default, DAI is disabled.                                                                                                                                                                                                         |
| <b>Origin</b>  | Specifies the origin of Address Resolution Protocol (ARP) Inspection configuration on the VLAN. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul> |

### Configure Dynamic ARP Inspection on Ports

Use the following procedure to set the trust factor associated with a port for DAI . By default, the trust factor is set to untrusted.

#### Note

For ports that are part of an MLT, DAI must be configured using the MLT configuration mode.

### Before You Begin

You must enable DHCP Snooping globally.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **ARP Inspection**.
3. Click the **ARP Inspection-port** tab.
4. In the row for the port, double-click the **IfTrusted** field, and select **trusted** or **untrusted** to set DAI.
5. Click **Apply**.

### ARP Inspection-port Field Descriptions

Use the data in the following table to use the **ARP Inspection-port** tab.

| Name             | Description                                                                                  |
|------------------|----------------------------------------------------------------------------------------------|
| <b>Port</b>      | Specifies the port on the switch.                                                            |
| <b>IfTrusted</b> | Specifies the trust factor for DAI on the specific port. By default, it is set as untrusted. |

## Configure FHS Globals

### About This Task

Use this procedure to enable FHS to enable DHCPv6 Guard, RA Guard, and ND-inspection globally, and to configure the lifetime for these policies.

### Procedure

1. From the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Globals** tab.
4. Select FHS global options.
5. Click **Apply** to save the changes.
6. (Optional) Click **Refresh** to update the results.

### Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

| Name                    | Description                                        |
|-------------------------|----------------------------------------------------|
| <b>Admin</b>            | Enables or disables the FHS policy.                |
| <b>RAGuardAdmin</b>     | Enables or disables the RA Guard policy.           |
| <b>DHCPv6GuardAdmin</b> | Enables or disables the DHCPv6 Guard policy.       |
| <b>NdInspectAdmin</b>   | Enables or disables Neighbor Discovery inspection. |

## IPv6 access list configuration

An IPv6 access list is created to verify the sender's IPv6 address in the inspected messages. You can create, view, or delete an IPv6 access list.

### *Creating IPv6 access list*

#### **About This Task**

Use this procedure to create an FHS IPv6 access list or add IPv6 prefixes to the existing IPv6 access list.

#### **Procedure**

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.
4. Click **Insert**.
5. Configure the parameters for the IPv6 access list.
6. Click **Insert**.

#### **IPv6 Access List field descriptions**

Use the data in the following table to use the **IPv6 Access List** tab.

| Name                 | Description                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Specify the IPv6 access list name to create the IPv6 access list.                                                                                                                         |
| <b>Prefix</b>        | Specify the IPv6 prefix for adding it to the IPv6 access list.                                                                                                                            |
| <b>PrefixMaskLen</b> | Specify the prefix length for adding it to the IPv6 access list. The value range is from 0 to 128. By default, the value is 0.                                                            |
| <b>MaskLenFrom</b>   | Specify the start mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry. |

| Name              | Description                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaskLenTo</b>  | Specify the end mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry. |
| <b>AccessType</b> | Select the access type to allow or deny the entry. By default, the access type is allow.                                                                                                |

**Note**

- **MaskLenFrom** and **MaskLenTo** must always be greater than or equal to the configured **PrefixMaskLen** for this IPv6 access list entry
- The **MaskLenFrom** value must always be less than or equal to the **MaskLenTo** value.

*View IPv6 access List***About This Task**

Use this procedure to display the IPv6 access list.

**Procedure**

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.

**IPv6 Access List field descriptions**

Use the data in the following table to use the **IPv6 Access List** tab.

| Name                 | Description                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Specify the IPv6 access list name to create the IPv6 access list.                                                                                                                         |
| <b>Prefix</b>        | Specify the IPv6 prefix for adding it to the IPv6 access list.                                                                                                                            |
| <b>PrefixMaskLen</b> | Specify the prefix length for adding it to the IPv6 access list. The value range is from 0 to 128. By default, the value is 0.                                                            |
| <b>MaskLenFrom</b>   | Specify the start mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry. |

| Name              | Description                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaskLenTo</b>  | Specify the end mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry. |
| <b>AccessType</b> | Select the access type to allow or deny the entry. By default, the access type is allow.                                                                                                |

**Note**

- **MaskLenFrom** and **MaskLenTo** must always be greater than or equal to the configured **PrefixMaskLen** for this IPv6 access list entry
- The **MaskLenFrom** value must always be less than or equal to the **MaskLenTo** value.

*Delete the IPv6 Access List***About This Task**

Use this procedure to delete the created IPv6 access list.

**Procedure**

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.
4. Select a row from the IPv6 access list to delete.
5. Click **Delete**.

## MAC access list configuration

A MAC access list is created to verify the sender's MAC address in the RA packet. You can view, create or delete a MAC access list.

*Create MAC Access List***About This Task**

Use this procedure to create a MAC access list or add a MAC address to the existing MAC access list.

**Procedure**

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.
4. Click **Insert**.
5. Configure the parameters for the MAC access list.
6. Click **Insert**.

**MAC Access List field descriptions**

Use the data in the following table to use the **MAC Access List** tab.

| Name              | Description                                                                           |
|-------------------|---------------------------------------------------------------------------------------|
| <b>Name</b>       | Specify a name to create a MAC access list.                                           |
| <b>Mac</b>        | Specify the MAC address to add to the MAC access list, in (xx:xx:xx:xx:xx:xx) format. |
| <b>AccessType</b> | Specify allow or deny. By default, the access type is allow.                          |

*View a MAC Access List***About This Task**

Use this procedure to display a configured MAC access list.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.

**MAC Access List field descriptions**

Use the data in the following table to use the **MAC Access List** tab.

| Name              | Description                                                                           |
|-------------------|---------------------------------------------------------------------------------------|
| <b>Name</b>       | Specify a name to create a MAC access list.                                           |
| <b>Mac</b>        | Specify the MAC address to add to the MAC access list, in (xx:xx:xx:xx:xx:xx) format. |
| <b>AccessType</b> | Specify allow or deny. By default, the access type is allow.                          |

*Delete a MAC Access List***About This Task**

Use this procedure to delete the created MAC access list.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.
4. Select a row from the MAC access list to delete.
5. Click **Delete**.

## DHCPv6 Guard Policy Configuration

Configure the DHCPv6 Guard policy to block DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents that forward DHCPv6 packets from servers to clients. You can view, create or delete a DHCPv6 Guard policy.

### Create DHCPv6 Guard Policy

#### About This Task

Use this procedure to create the DHCPv6 Guard policy to block DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.
4. Click **Insert**.
5. Configure the parameters for the DHCPv6 Guard policy.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

#### DHCPv6 Guard Policy Field Descriptions

Use the data in the following table to use the **DHCPv6 Guard Policy** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PolicyName</b>           | Specifies the policy name to create or modify DHCPv6 Guard policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ServerAccessListName</b> | <p>Enables verification of the sender IPv6 address in the DHCPv6 reply or advertisement packets against attached IPv6 server access list.</p> <p><b>Note:</b><br/>If the access-list is not attached, the source IPv6 address is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.</p> |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ReplyPrefixListName</b> | <p>Enables verification of the advertised prefixes in DHCPv6 reply messages against the attached prefix list. If not configured, this check is bypassed.</p> <p><b>Note:</b><br/>If the access-list is not attached, the advertised address/prefix is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.</p> |
| <b>PrefLimitMin</b>        | <p>Enables verification if the advertised preference (in reference option) is greater than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PrefixLimitMax</b>      | <p>Enables verification if the advertised preference (in preference option) is less than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.</p> <p><b>Note:</b><br/>If both the maximum and minimum limit is 0, this preference check is ignored.</p>                                                                                                                                                                                                                                                                   |

*View a DHCPv6 Guard Policy*

### About This Task

Use this procedure to display configured DHCPv6 Guard policies.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.

### DHCPv6 Guard Policy Field Descriptions

Use the data in the following table to use the **DHCPv6 Guard Policy** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PolicyName</b>           | Specifies the policy name to create or modify DHCPv6 Guard policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ServerAccessListName</b> | <p>Enables verification of the sender IPv6 address in the DHCPv6 reply or advertisement packets against attached IPv6 server access list.</p> <p><b>Note:</b><br/>If the access-list is not attached, the source IPv6 address is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.</p>                  |
| <b>ReplyPrefixListName</b>  | <p>Enables verification of the advertised prefixes in DHCPv6 reply messages against the attached prefix list. If not configured, this check is bypassed.</p> <p><b>Note:</b><br/>If the access-list is not attached, the advertised address/prefix is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.</p> |
| <b>PrefLimitMin</b>         | Enables verification if the advertised preference (in reference option) is greater than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PrefixLimitMax</b>       | <p>Enables verification if the advertised preference (in preference option) is less than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.</p> <p><b>Note:</b><br/>If both the maximum and minimum limit is 0, this preference check is ignored.</p>                                                                                                                                                                                                                                                                   |

### Delete a DHCPv6 Guard Policy

#### About This Task

Use this procedure to delete the created DHCPv6 Guard policy.

#### Note

If this policy is already attached to an interface, then this policy cannot be deleted.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.
4. Select a row from DHCPv6 Guard policies to delete.
5. Click **Delete**.

## RA Guard Policy Configuration

Configure RA Guard to block or reject unwanted or rogue RA messages that arrive at the network device platform. You can view, create or delete RA Guard policy.

### Create RA Guard Policy

#### About This Task

Use this procedure to create a RA Guard policy to block or reject unwanted or rogue RA messages that arrive at the network device platform.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.
4. Click **Insert**.
5. Configure the parameters for the RA Guard policy.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

### RA Guard Policy Field Descriptions

Use the data in the following table to use the **RA Guard Policy** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PolicyName</b>  | Specifies the name of the RA Guard policy to be created or modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SrcAddrList</b> | Specify the IPv6 access list name to verify the sender IPv6 address in the RA packets against the attached IPv6 access list.<br><br><b>Note:</b><br>The source address in the RA packet is not validated if the access-list is not attached. If the list is attached and the IPv6 source address in RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrefixList</b>        | <p>Specify the IPv6 prefix list name to verify the advertised prefixes in the RA packet against the attached IPv6 prefix list.</p> <p><b>Note:</b><br/>Advertised prefixes are not validated if the access-list is not attached.<br/>If the list is attached and the advertised prefix in the RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.</p> |
| <b>MacAddrList</b>       | <p>Specify the MAC list name to verify the sender source MAC address against the attached MAC access list.</p> <p><b>Note:</b><br/>The source MAC address in the RA packet is not validated if the access-list is not attached.<br/>If the list is attached and the source MAC address in the RA packet does not match any MAC address in the list, then the RA packet is dropped.</p>                                                                                                                                                           |
| <b>ManagedConfigFlag</b> | <p>Select the managed configuration flag to verify managed address configuration in the advertised RA packet.</p> <p>By default, none is selected and managed configuration flag validation is skipped.</p>                                                                                                                                                                                                                                                                                                                                      |
| <b>RouterPrefMax</b>     | <p>Select the router preference maximum to verify the if the advertised default router preference parameter value is lower than or equal to a specified limit.</p> <p>By default, none is selected and router preference validation is skipped.</p>                                                                                                                                                                                                                                                                                              |
| <b>HopLimitMin</b>       | <p>Specify the minimum hop limit to verify the advertised hop count limit.</p> <p>The value range is from 0 to 255<br/>By default, minimum hop limit is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>HopLimitMax</b>       | <p>Specify the maximum hop limit to verify the advertised hop count limit.</p> <p>The value range is from 0 to 255<br/>By default, the maximum hop limit is 0 and If both HopLimitMin and HopLimitMax are set to 0, then the hop limit parameter in the RA packet is not validated.</p>                                                                                                                                                                                                                                                          |

*View RA Guard Policy*

### **About This Task**

Use this procedure to display configured RA Guard policies.

## Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.

## RA Guard Policy Field Descriptions

Use the data in the following table to use the **RA Guard Policy** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PolicyName</b>  | Specifies the name of the RA Guard policy to be created or modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SrcAddrList</b> | <p>Specify the IPv6 access list name to verify the sender IPv6 address in the RA packets against the attached IPv6 access list.</p> <p><b>Note:</b><br/>The source address in the RA packet is not validated if the access-list is not attached. If the list is attached and the IPv6 source address in RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.</p> |
| <b>PrefixList</b>  | <p>Specify the IPv6 prefix list name to verify the advertised prefixes in the RA packet against the attached IPv6 prefix list.</p> <p><b>Note:</b><br/>Advertised prefixes are not validated if the access-list is not attached. If the list is attached and the advertised prefix in the RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.</p>               |
| <b>MacAddrList</b> | <p>Specify the MAC list name to verify the sender source MAC address against the attached MAC access list.</p> <p><b>Note:</b><br/>The source MAC address in the RA packet is not validated if the access-list is not attached. If the list is attached and the source MAC address in the RA packet does not match any MAC address in the list, then the RA packet is dropped.</p>                                                                                                                                                                         |

| Name                     | Description                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ManagedConfigFlag</b> | Select the managed configuration flag to verify managed address configuration in the advertised RA packet.<br>By default, none is selected and managed configuration flag validation is skipped.                                                                            |
| <b>RouterPrefMax</b>     | Select the router preference maximum to verify the if the advertised default router preference parameter value is lower than or equal to a specified limit.<br>By default, none is selected and router preference validation is skipped.                                    |
| <b>HopLimitMin</b>       | Specify the minimum hop limit to verify the advertised hop count limit.<br>The value range is from 0 to 255<br>By default, minimum hop limit is 0.                                                                                                                          |
| <b>HopLimitMax</b>       | Specify the maximum hop limit to verify the advertised hop count limit.<br>The value range is from 0 to 255<br>By default, the maximum hop limit is 0 and If both HopLimitMin and HopLimitMax are set to 0, then the hop limit parameter in the RA packet is not validated. |

*Delete an RA Guard Policy*

### About This Task

Use this procedure to delete the created RA Guard policy.

#### Note

If this policy is already attached to an interface, then you cannot delete this policy.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.
4. Select a row from the RA Guard policies to delete.
5. Click **Delete**.

## Port Policy Mapping Configuration

This configuration allows you to map the port with DHCPv6 Guard or RA Guard policy. You can view, create or delete the mappings.

*Create Port to Policy Mapping***About This Task**

Use this procedure to map a port to a RA Guard or DHCPv6 Guard policy, DHCPv6 Guard or RA Guard statistics.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.
4. Click **Insert**.
5. Configure the parameters for the port policy mapping.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

**Port Policy Mapping Field Descriptions**

Use the data in the following table to use the **Insert Port Policy Mapping** dialog box.

| Name                         | Description                                                                |
|------------------------------|----------------------------------------------------------------------------|
| <b>IfIndex</b>               | Specify the port.                                                          |
| <b>DHCPv6GuardPolicyName</b> | Enter an already-created DHCPv6 Guard policy name to map it with the port. |
| <b>RAGuardPolicyName</b>     | Enter an already-created RA Guard policy name to map it with the port.     |
| <b>Dhcpv6gDeviceRole</b>     | Select server or client configuration. The default is server.              |
| <b>RagDeviceRole</b>         | Select host or router configuration. The default is router.                |

*View Port Policy Mapping***About This Task**

Use this procedure to display port policy mapping information.

**Procedure**

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.

**Port Policy Mapping Field Descriptions**

Use the data in the following table to use the **Port Policy Mapping** tab.

| Name                         | Description                                                                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>               | Identifies the port.                                                                                                                                            |
| <b>Dhcpv6gDeviceRole</b>     | Specifies the DHCPv6 Guard device-role of the received port. If the device role is client and if it receives DHCPv6 reply then those packets should be dropped. |
| <b>DHCPv6GuardPolicyName</b> | Specifies the DHCPv6 Guard policy name associated with the port.                                                                                                |
| <b>TotalDHCPv6PktRcv</b>     | Shows the total number of DHCPv6 packets received on the DHCPv6 Guard enabled interface.                                                                        |
| <b>TotalDHCPv6PktDropped</b> | Shows the total number of DHCPv6 packets dropped due to DHCPv6 Guard filtering.                                                                                 |
| <b>RagDeviceRole</b>         | Specifies the RA Guard device-role.                                                                                                                             |
| <b>RAGuardPolicyName</b>     | Specifies the RA Guard policy name associated with the port.                                                                                                    |
| <b>TotalRAPktRcv</b>         | Shows the total number of RA packets received on the RA Guard enabled interface.                                                                                |
| <b>TotalRAPktDropped</b>     | Shows the total number of RA packets dropped due to RA Guard filtering.                                                                                         |
| <b>NDInspection</b>          | Enables or disables Neighbor Discovery (ND) inspection. The default is disabled.                                                                                |
| <b>TotNdPktRcv</b>           | Shows the total number of ND packets received on the RA Guard enabled interface.                                                                                |
| <b>TotNdPktDropped</b>       | Shows the total number of ND packets dropped due to RA Guard filtering.                                                                                         |
| <b>ClearDHCPGuardStats</b>   | Clears, if true, the DHCPv6 Guard statistics for the port.                                                                                                      |
| <b>ClearRAGuardStats</b>     | Clears, if true, the RA Guard statistics for the port.                                                                                                          |
| <b>ClearNDInspectStats</b>   | Clears, if true, the ND-inspection statistics for the port.                                                                                                     |

### Delete Port Policy Mapping

#### About This Task

Use this procedure to delete the created port policy mapping.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.
4. Select a row from Port Policy Mapping to delete.
5. Click **Delete**.
6. Click **Apply**.

## DHCP Snooping Configuration Using EDM

The following section provides procedures to configure DHCP Snooping using EDM.

### *Enable DHCP Snooping Globally*

Use the following procedure to enable DHCP Snooping globally. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping Globals** tab.
4. Select **Enabled**.
5. Click **Apply**.

### **DHCP Snooping Globals Field Descriptions**

Use data in the following table to use the **DHCP Snooping Globals** tab.

| Name           | Description                                                            |
|----------------|------------------------------------------------------------------------|
| <b>Enabled</b> | Enables DHCP Snooping globally. By default, DHCP Snooping is disabled. |

### *Configure DHCP Snooping on VLANs*

Use the following procedure to configure DHCP Snooping on a specific VLAN. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

If you enable DHCP Snooping globally, the agent determines whether to forward DHCP reply packets based on the DHCP Snooping mode of the VLAN and trusted state of the port.

#### **Note**

You cannot enable DHCP Snooping on Private VLANs (E-Tree) and SPBM B-VLANs.

### **Before You Begin**

You must enable DHCP Snooping globally.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping-VLAN** tab.
4. In the row for the VLAN, double-click the **DhcpSnoopingEnabled** field, and select **true** to enable DHCP Snooping.
5. Click **Apply**.

### DHCP Snooping-VLAN Field Descriptions

Use the data in the following table to use the **DHCP Snooping-VLAN** tab.

| Name                       | Description                                                                                                                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>              | Specifies the VLAN ID.                                                                                                                                                                                                                                                 |
| <b>DhcpSnoopingEnabled</b> | Specifies if DHCP Snooping is enabled or disabled for the particular VLAN. By default, DHCP Snooping is disabled.                                                                                                                                                      |
| <b>Origin</b>              | Specifies the origin of DHCP Snooping configuration on the VLAN. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul> |

### Configure Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DHCP Snooping. By default, the trust factor is set to untrusted on all ports.

#### Note

For ports that are members of an MLT, DHCP Snooping must be configured using the MLT configuration mode.

### Before You Begin

To enable DHCP Snooping on a port, you must enable DHCP Snooping globally.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping-port** tab.
4. In the row for the port, double-click the **DhcpSnoopingIfTrusted** field, and select **trusted** or **untrusted** to set DHCP Snooping.
5. Click **Apply**.

### DHCP Snooping-port Field Descriptions

Use data in the following table to use the **DHCP Snooping-port** tab.

| Name                         | Description                                                                                      |
|------------------------------|--------------------------------------------------------------------------------------------------|
| <b>Port</b>                  | Specifies the port on the switch.                                                                |
| <b>DhcpSnoopingIfTrusted</b> | Specifies if the switch ports are trusted for DHCP Snooping. By default, it is set as untrusted. |

### DHCP binding configuration

The following section provides procedures to configure the DHCP binding table using EDM.

## Create DHCP Binding Table Entries

Use the following procedure to add entries for devices with static IP addresses to the DHCP binding table.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Bindings** tab.
4. Click **Insert**.
5. In the **VlanId** field, enter the VLAN ID.
6. In the **MacAddress** field, enter the MAC address of the DHCP client.
7. In the **AddressType** field, select a value.
8. In the **Address** field, enter the IP address of the DHCP client.
9. In the **Interface** field, select a port.
10. In the **LeaseTime(sec)** field, enter the time in seconds.
11. Click **Insert**.
12. Click **Apply**.

### DHCP Bindings field descriptions

Use data in the following table to use the **DHCP Bindings** tab.

| Name                     | Description                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>            | Specifies the VLAN to which the DHCP client belongs.                                                                                                                                                                                                                 |
| <b>MacAddress</b>        | Specifies the MAC address of the DHCP client.                                                                                                                                                                                                                        |
| <b>AddressType</b>       | Specifies the type of address. The default address type is IPv4.                                                                                                                                                                                                     |
| <b>Address</b>           | Specifies the IP address assigned to the DHCP client.                                                                                                                                                                                                                |
| <b>Interface</b>         | Specifies the interface to which the DHCP client connects.                                                                                                                                                                                                           |
| <b>LeaseTime(sec)</b>    | Specifies the lease time (in seconds) of the particular DHCP binding entry. The time range is 0 to 2147483646 seconds.                                                                                                                                               |
| <b>TimeToExpiry(sec)</b> | Species the time of expiry (in seconds) of the DHCP binding entry.                                                                                                                                                                                                   |
| <b>EntryType</b>         | Specifies the type of the DHCP binding entry. <ul style="list-style-type: none"> <li>• If the entry was created through DHCP snooping, the type is learned(1).</li> <li>• If the entry was created through a management operation, the type is static(2).</li> </ul> |

### Viewing DHCP Binding Information

Use the following procedure to view all entries in the DHCP binding table.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **DHCP Snooping**.

3. Click the **DHCP Bindings** tab.

### DHCP Bindings field descriptions

Use data in the following table to use the **DHCP Bindings** tab.

| Name                     | Description                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>            | Specifies the VLAN to which the DHCP client belongs.                                                                                                                                                                                                                 |
| <b>MacAddress</b>        | Specifies the MAC address of the DHCP client.                                                                                                                                                                                                                        |
| <b>AddressType</b>       | Specifies the type of address. The default address type is IPv4.                                                                                                                                                                                                     |
| <b>Address</b>           | Specifies the IP address assigned to the DHCP client.                                                                                                                                                                                                                |
| <b>Interface</b>         | Specifies the interface to which the DHCP client connects.                                                                                                                                                                                                           |
| <b>LeaseTime(sec)</b>    | Specifies the lease time (in seconds) of the particular DHCP binding entry. The time range is 0 to 2147483646 seconds.                                                                                                                                               |
| <b>TimeToExpiry(sec)</b> | Species the time of expiry (in seconds) of the DHCP binding entry.                                                                                                                                                                                                   |
| <b>EntryType</b>         | Specifies the type of the DHCP binding entry. <ul style="list-style-type: none"> <li>• If the entry was created through DHCP snooping, the type is learned(1).</li> <li>• If the entry was created through a management operation, the type is static(2).</li> </ul> |

### SBT configuration

This configuration allows you to build a snooping binding table (SBT) which contains entries from only trusted devices or hosts. This SBT table is used to validate Neighbor Discovery (ND) packets. You can view, create, or delete the entries in the SBT.

### Create an SBT Entry

#### About This Task

Use this procedure to create an SBT entry.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.
4. Click **Insert**.
5. Configure the parameters for the snoop binding.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

### Snoop Binding field descriptions

Use the data in the following table to use the **Snoop Binding** tab. The system displays a subset of these fields if click **Insert**.

| Name                  | Description                                                          |
|-----------------------|----------------------------------------------------------------------|
| <b>VlanId</b>         | Specify the VLAN to which the snooped entry belongs.                 |
| <b>Ipv6Address</b>    | Enter the IPv6 address assigned to the IPv6 host.                    |
| <b>MacAddress</b>     | Enter the MAC address of the snooped entry.                          |
| <b>InterfaceIndex</b> | Specify the interface on which the entry is learnt.                  |
| <b>EntryType</b>      | Indicates the type of entry - static (1) or dynamic (2).             |
| <b>EntrySource</b>    | Indicates the method entry was learnt from - static (1) or dhcp (2). |
| <b>ValidTime</b>      | Indicates the valid time for the snooped entry.                      |
| <b>TimeToExpiry</b>   | Indicates the time to expiry of the snooped entry.                   |

## View SBT Entries

### About This Task

Use this procedure to display a configured SBT table.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.

Snoop Binding field descriptions

Use the data in the following table to use the **Snoop Binding** tab. The system displays a subset of these fields if click **Insert**.

| Name                  | Description                                                          |
|-----------------------|----------------------------------------------------------------------|
| <b>VlanId</b>         | Specify the VLAN to which the snooped entry belongs.                 |
| <b>Ipv6Address</b>    | Enter the IPv6 address assigned to the IPv6 host.                    |
| <b>MacAddress</b>     | Enter the MAC address of the snooped entry.                          |
| <b>InterfaceIndex</b> | Specify the interface on which the entry is learnt.                  |
| <b>EntryType</b>      | Indicates the type of entry - static (1) or dynamic (2).             |
| <b>EntrySource</b>    | Indicates the method entry was learnt from - static (1) or dhcp (2). |
| <b>ValidTime</b>      | Indicates the valid time for the snooped entry.                      |
| <b>TimeToExpiry</b>   | Indicates the time to expiry of the snooped entry.                   |

## Delete an SBT Entry

### About This Task

Use this procedure to delete an entry from the SBT table.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.
4. Select a row from the list to delete.
5. Click **Delete**.

## IP Source Guard Configuration using EDM

### Note

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

### *Enable IP Source Guard on a Port for IPv4 Addresses*

### About This Task

Enable IP Source Guard (IPSG) to add a higher level of security to a desired port by preventing IP spoofing. When you enable IPSG on the interface, filters are installed for IPv4 addresses that are already learned on that interface.

### Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port on which you want to enable IPSG is a member of a VLAN that is configured with both DHCP Snooping and Dynamic ARP Inspection.
- The port is an untrusted port enabled with both DHCP Snooping and Dynamic ARP Inspection.
- The port has enough resources allocated to support the maximum number of 10 IP addresses allowed for IPSG.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Source Guard**.
3. Click the **IP Source Guard-port** tab.
4. Double-click the **Mode** field
5. Select **ip** from the list, to enable IPSG.
6. Repeat the steps above to configure IPSG on additional ports.
7. Click **Apply** to save your changes.
8. Click **Refresh** to update the **IP Source Guard-port** tab.

### IP Source Guard-port field descriptions

Use the data in the following table to use the **IP Source Guard-port** tab.

| Name          | Description                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port</b>   | Identifies the port on which to enable IPSPG.                                                                                                                                                                                                                         |
| <b>Mode</b>   | Displays whether IPSPG is enabled on the port. The default is disabled.                                                                                                                                                                                               |
| <b>Origin</b> | Specifies the origin of Source Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul> |

#### *View IPv4 Address Bindings*

View the IPv4 address bindings that IPSPG allows.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Source Guard**.
3. Select the **IP Source Guard-addresses** tab.

### IP Source Guard-addresses field descriptions

Use the data in the following table to use the **IP Source Guard-addresses** tab.

| Field          | Description                                                       |
|----------------|-------------------------------------------------------------------|
| <b>Port</b>    | Indicates the port on which IPSPG is configured.                  |
| <b>Type</b>    | Indicates the address type.                                       |
| <b>Address</b> | Indicates the IPv4 address that is allowed by IPSPG on the port.  |
| <b>Source</b>  | Indicates the source of the IPv4 address, which is DHCP Snooping. |

#### *Configure IP Source Guard on a Port for IPv6 Addresses*

#### **About This Task**

Enable IPSPG to add a higher level of security to a desired port, by preventing IP spoofing. When you enable IPSPG on an interface, filters are automatically installed for the IPv6 addresses that are already learned on that interface.

## Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port is an untrusted port enabled with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port has enough resources allocated to support the maximum number of 10 IP addresses allowed for IPSG.

## Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Source Guard** tab.
4. Double-click the **InterfaceState** field.
5. Select a value from the list: **true** or **false**.
6. Double-click the **MaxAddr** field.
7. Enter the maximum number of IPv6 addresses that are allowed to transmit data on the port.
8. (Optional) To clear the overflow counters, double-click **ClearOverflowCount** and select **true**.
9. Click **Apply** to save your changes.
10. Click **Refresh** to update the **Source Guard** tab.

## Source Guard field descriptions

Use the data in the following table to use the **Source Guard** tab.

| Name                      | Description                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>            | Specifies a value that uniquely identifies the port.                                                                                                                                                                  |
| <b>InterfaceState</b>     | Specifies the state of the interface. The default value is false.                                                                                                                                                     |
| <b>MaxAddr</b>            | Specifies the maximum number of IPv6 addresses allowed to transmit data through the port. The default value is 4.<br><br><b>Note:</b><br>To reset the value to default, IPSG must first be disabled on the interface. |
| <b>OverflowCount</b>      | Specifies the number of IPv6 addresses for which filters are not added on the IPSG port, due to a lack of filter resources. The default value is 0.                                                                   |
| <b>ClearOverflowCount</b> | Specifies whether the overflow counter must be cleared. By default, the value is false.                                                                                                                               |

### View IPv6 Address Bindings

View the IPv6 address bindings that IPSG allows.

#### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Source Guard Binding** tab.

#### Source Guard Binding field descriptions

Use the data in the following table to use the **Source Guard Binding** tab.

| Field           | Description                                          |
|-----------------|------------------------------------------------------|
| <b>IfIndex</b>  | Specifies a value that uniquely identifies the port. |
| <b>IPv6Addr</b> | Specifies the binding entry for the IPv6 address.    |

## Layer 2 security example scenarios

The following sections describe configuration examples to configure Layer 2 security features for IPv4 and IPv6 deployments.

### FHS Deployment Scenario

In the following example, the Layer 2 switch “SW-1” is connected to another Layer 2 switch “SW-2”, two hosts and a DHCP server. Switch “SW-2” is connected to two other hosts and a router. Out of the two hosts connected to SW-2, one is a malicious host, which can generate bogus RA packets to advertise route prefix, and can also generate bogus DHCP reply packets to configure wrong IPv6 address or wrong default gateway. By doing this, it tries denial-of-service or Man-in-the-Middle attacks. These attacks must be prevented as it affects all the nodes present in the Layer 2 network and FHS can be effective in preventing these attacks.

These attacks can spread over the entire Layer 2 network and thus can affect the hosts connected to SW-2 as well as the hosts connected to SW-1. If you enable FHS only on SW-2, then it could only save the nodes which are directly connected to it. To prevent the good node connected to SW-1 from these attacks, the SW-1 switch also should be FHS enabled.

The following figure shows the FHS deployment scenario topology.

**Figure 190: FHS deployment topology**

By default, all the ports are trusted, until you configure DHCPv6 Guard or RA Guard policies.

See the following procedures to configure FHS RA Guard and DHCPv6 Guard for the preceding topology.

## Creating FHS IPv6 ACL

### About This Task

Filter IPv6 traffic by creating IPv6 Access Control Lists (ACLs) and applying them to the interfaces similar to the way that you create and apply IPv4 named ACLs.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Create an IP ACL name (ipv6\_acl\_1) to match the source IPv6 address of the router connected to the interface.
 

```
ipv6 fhs ipv6-access-list ipv6_acl_1
fe80:0:0:0:cef9:54ff:feb4:9481/128 mode allow
```

3. Create an IP ACL name (ipv6\_acl\_1) to match the source IPv6 address of the DHCPv6-server connected to the interface.

```
ipv6 fhs ipv6-access-list ipv6_acl_1
fe80:0:0:0:cef9:54ff:feb4:9481/128 mode allow
```

### What to Do Next

Create a First Hop Security MAC ACL.

## Creating an FHS MAC ACL

### About This Task

Filter the IPv6 traffic by creating a MAC access list with the ACL mode.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create a MAC ACL name (rtr\_smac) to match the source MAC of the router connected to the interface 1/2.  

```
ipv6 fhs mac-access-list mac_acl_1 00:11:22:33:44:66 mode allow
```

## Create a DHCPv6 Guard Policy for the Router

### About This Task

Create a DHCPv6 Guard policy to provide Layer 2 security to DHCPv6 clients by protecting them against rogue DHCPv6 servers.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter DHCP Guard mode with the DHCPv6 Guard policy name (dhcpv6g\_pol\_1). The DHCPv6 Guard policy for the interface is connected to a router.  

```
ipv6 fhs dhcp-guard policy dhcpv6g_pol_1
```
3. Configure the source IPv6 access list to allow only a DHCPv6 server replies that originate from the IPv6 address fe80:0:0:0:cef9:54ff:feb4:9481/128 and check the preceding IPv6 ACL configuration for ipv6\_acl\_1 list.  

```
match server access-list ipv6_acl_1
```
4. Verify the prefixes sent in the DHCPv6 server reply message so that the ipv6\_acl\_2 IPv6 ACL configuration allows only the prefix 1000::1/64.  

```
match reply prefix-list ipv6_acl_1
```

## Create an RA Guard Policy for the Router

### About This Task

Create a `rag_pol_1` RA Guard policy for the router and configure the source IPv6 access list to allow only the RA packets that originate from the source IPv6 address `fe80:0:0:0:cef9:54ff:feb4:9481/128`. This configuration verifies the prefixes sent in the RA packets.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enter the RA Guard mode and configure RA Guard policy (`rag_pol_1`) for the interface connected to a router.  
`ipv6 fhs ra-guard policy rag_pol_1`
3. Configure the source IPv6 access list to allow only RA packets originating from the source IPv6 address `fe80:0:0:0:cef9:54ff:feb4:9481/128`.  
`match ipv6 ra-srcaddr-list ipv6_acl_1`
4. Verify the prefixes sent in the RA packets so that the `rtr_pip` IPv6 ACL configuration allows only the prefix `60::0/64`.  
`match reply ra-prefix-list ipv6_acl_1`

## Attach FHS policies to the Interfaces

### About This Task

Attach the FHS policies to the interfaces.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure DHCPv6 Guard and RA Guard policies on the interface (1/2) that connects to the router.  
`interface ethernet 1/2`  
  
`ipv6 dhcp-guard attach-policy dhcpv6g_pol_1`  
  
`ipv6 ra-guard attach-policy rag_pol_1`

## IPv6 DHCP Snooping and ND Inspection Configuration Example

This section shows examples of IPv6 DHCP snooping and ND inspection configuration.

Enable DHCPv6 Guard, ND inspection, and First Hop Security.

```
ipv6 fhs dhcp-guard enable
ipv6 fhs nd-inspection enable
ipv6 fhs enable
```

Create VLAN 1000 and add port members.

```
vlan create 1000 type port-mstprstp 0
vlan members add 1000 1/1-1/10
```

Enable DHCPv6 snooping and ND inspection on VLAN 1000.

```
interface vlan 1000
ipv6 fhs snooping dhcp enable
ipv6 fhs nd-inspection enable
exit
```

Add static SBT entry.

```
ipv6 fhs snooping static-binding ipv6-address 2001:DB8:0:0:0001:02ff:fe03:0405 vlan 1000
mac-address 00:01:02:03:04:05 port 1/5
```

Set the DHCPv6 Guard device-role on port 1/1 of the device on which DHCPv6 Guard is configured.

```
interface gigabitEthernet 1/1
ipv6 fhs dhcp-guard device-role server
exit
```

Enable ND inspection on ports 1/2 through 1/10.

```
interface gigabitEthernet 1/2-1/10
ipv6 fhs nd-inspection enable
exit
```

View the status.

```
show ipv6 fhs port-policy
show ipv6 fhs status
show ipv6 fhs status vlan
show ipv6 fhs snooping binding
```

## Configure IP Source Guard

The following section describes a simple configuration example to configure IP Source Guard (IPSG) on a port.

When you enable IPSG on a port, filters are installed for the IPv4 or IPv6 addresses that are already learned on that port.

### Procedure

Enable DHCP Snooping globally on the switch and verify the configuration.

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable DHCP Snooping globally.

```
ip dhcp-snooping enable
```

3. Verify the configuration.

```
show ip dhcp-snooping
```

Enable DHCP Snooping and Dynamic ARP Inspection on the VLAN that the port is a member of.

4. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

5. Enable DHCP Snooping on the VLAN.

```
ip dhcp-snooping enable
```

6. Verify the configuration.

```
show ip dhcp-snooping vlan <1-4059>
```

7. Enable Dynamic ARP Inspection on the VLAN.

```
ip arp-inspection enable
```

8. Verify the configuration.

```
show ip arp-inspection vlan <1-4059>
```

9. Verify that the port on which you want to configure IPSG is a DHCP Snooping and a Dynamic ARP Inspection untrusted port.

```
show ip dhcp-snooping interface gigabitEthernet [{slot/port[/sub-port]}
[-slot/port[/sub-port]] [,...]]
```

```
show ip arp-inspection interface gigabitEthernet [{slot/port[/sub-
port]} [-slot/port[/sub-port]] [,...]]
```

Configure IPSG on a port and verify the configuration.

10. Perform one of the following steps to configure IPSG on a port, for IPv4 or IPv6 addresses.

- Enable and verify IPSG on a port for IPv4 addresses:

a. `ip source verify enable`

b. `show ip source verify interface gigabitEthernet [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`

- Enable and verify IPSG on a port for IPv6 addresses:

a. `ipv6 source-guard enable`

b. `ipv6 source-guard [max-allowed-addr <2-10>]`

#### Note

The default value is 4. To reset the value to default, IPSG must first be disabled on the interface.

c. `show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`

#### Examples

The following example describes how to enable IPSG on port 4/5 which is a member of VLAN 10, for IPv4 or IPv6 addresses.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#
```

Enable DHCP Snooping globally and verify the configuration.

```
Switch:1(config)#ip dhcp-snooping enable
Switch:1(config)#show ip dhcp-snooping
```

```
=====
                        Dhcp Snooping General Info

|                                                             | XA1400 Series   | Not Supported      |

## Licensing Fundamentals

This section provides conceptual information about licensing. Subsequent sections discuss how to acquire, install, and enable licenses.

### Factory Default Premier Trial License

New hardware switches include a Factory Default Premier Trial License to use all features (excluding MACsec). You can run the **extend-time-period** command up to three times to extend the trial license. You can configure all features, except MACsec, without restrictions and save the configuration.

You cannot configure new features after the trial period, but the switch continues to run with the existing configured features. If you reboot the switch after the trial period, and a valid software license is

not present, licensed features in the configuration are not loaded. You must install a valid license to enable licensed features.

| Factory Default Premier Trial License                                                                               |                              |
|---------------------------------------------------------------------------------------------------------------------|------------------------------|
| Platform                                                                                                            | Initial trial period in days |
| 5420 Series, 5520 Series, VSP 8600 Series                                                                           | 30                           |
| VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, XA1400 Series | 60                           |

#### Note

If a Premier license was installed and then revoked, the trial period cannot be extended.

#### Note

The evaluation period is based on the switch System Up Time.

To extend the factory default trial license, see [Extend the Factory Default Premier Trial License](#) on page 2131.

## Licensing for non-Universal Hardware

Non-Universal hardware products include:

- VSP 4450 Series
- VSP 4900 Series
- VSP 7200 Series
- VSP 7400 Series
- VSP 8200 Series
- VSP 8400 Series
- VSP 8600 Series
- XA1400 Series

### *License File Requirements for non-Universal Hardware*

The license file name must meet the following requirements:

- Maximum of 63 alphanumeric characters
- No spaces or special characters allowed
- Underscore (\_) is allowed
- The file extension supported varies by product:
  - VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series support license files with an `.xm1` extension.
  - VSP 4450 Series also supports license files generated by an older Avaya license generator that use `.dat` or `.lic` extensions.

*Feature Licensing for the VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series*

The VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series support a licensing model that includes Base Licenses and Premier Licenses. The Base License, which is included with the purchase of the switch, enables the basic networking capabilities of the device. You can purchase Premier Licenses separately to enable advanced features on the switch.

Licenses are tied to the switch Base MAC address. After you generate the license through the Extreme Networks Support Portal at <https://extremeportal.force.com/ExtrLicenseLanding>, you can install the license on the switch.

**Important**

If you require a change to, or regeneration of, legacy licenses for the VSP 4450 Series, send your email request to [datalicensing@extremenetworks.com](mailto:datalicensing@extremenetworks.com).

**Note**

Release 6.1.2 or later is required to support licenses generated through the Extreme Networks Support Portal.

Extreme Networks supports only a single host (system MAC address) for each license file. You cannot use the same license file on multiple hosts.

The software continues to support licenses generated by Avaya.

The following sections detail the different categories of licenses.

**Trial License**

Trial licenses enable users to test licensed features at any time. The following two types of Trial Licenses are available:

- Trial License that allows the use of all features excluding MACsec
- Trial License that allows the use of all features including MACsec

A Trial License is valid for 60 days. You can activate a Trial License once per switch.

The system generates warning messages to inform you about the time remaining in the license period. The alerts appear once every 5 days for the first 55 days, and then once daily for the last 5 days. If you reboot the switch after the 60-day period, and a valid software license is not present, the configuration does not load. You must install a valid license to enable licensed features.

**Base License**

A Base license gives customers the right to use Base software features on the switch.

### Premier License

Premier Licenses enable advanced features not available in the Base License. The following table provides information on the Premier Licenses that the switch supports.

| License type                | Supported features                                                                                                                                                                                                                                                                   |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Premier License             | <ul style="list-style-type: none"> <li>• DvR Controller</li> <li>• Extreme Integrated Application Hosting</li> <li>• Fabric Connect Layer 3 Virtual Services Networks (VSNs)</li> <li>• Greater than 16 BGP peers</li> <li>• VXLAN Gateway</li> </ul>                                |
| Premier with MACsec License | <ul style="list-style-type: none"> <li>• DvR Controller</li> <li>• Extreme Integrated Application Hosting</li> <li>• Fabric Connect Layer 3 Virtual Services Networks (VSNs)</li> <li>• Greater than 16 BGP peers</li> <li>• IEEE 802.1AE MACsec</li> <li>• VXLAN Gateway</li> </ul> |

### License Types and Part Numbers

The following table lists the license types and the associated part numbers.

| License Type                                                                      | Part Number / Order Code |
|-----------------------------------------------------------------------------------|--------------------------|
| VSP 4450 Series and VSP 4900 Series Premier License                               | 338836                   |
| VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series Premier License             | 380176                   |
| VSP 4450 Series and VSP 4900 Series Premier with MACsec License                   | 338835                   |
| VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series Premier with MACsec License | 380177                   |
| VSP 7400 Series Premier License                                                   | VSP-PRMR-LIC-P           |

#### *Port Licensing for the VSP 7200 Series*

The VSP 7200 Series hardware models are available with twenty four 1/10 GbE SFP/SFP+ and four 40 GbE QSFP+ ports enabled by default. You must purchase a Port License to enable the remaining ports on the switch. You can use the Port License alone or combined with a Premier License or Premier License with MACsec at any time. When combining these licenses, the old license file must be deleted and the new license file that has the combination of Port and Premier or Premier with MACsec must be installed and loaded on the switch.

See [Feature Licensing for the VSP 4450 Series, VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series](#) on page 2119 for more information about Premier License features.

The Port License order code is 386914.

### Note

Port Licenses are not available with Trial Licenses.

On a VSP 7200 Series switch that is port licensed, use the command **show interfaces gigabitEthernet** to view the licensed status of the ports on the switch.

The following example shows the partial output of the **show interfaces gigabitEthernet** command for the VSP 7254XSQ switch. View the `LICENSE STATUS` field. It can have one of the following values:

- `n/a`: Indicates that it is not a port that is activated by a port license.
- `locked`: Indicates that the port is locked and non-operational because the switch is port licensed and a valid port license is not present.

Attempting to enable a locked port, for example port 1/25, displays the error message `Error: port 1/25, Port License is required to enable this port.`

- `unlocked`: Indicates that the port is unlocked and is operational, because a valid port license is present.

```
Switch:1#show interfaces gigabitEthernet
```

### Feature Licensing for VSP 8600 Series

The VSP 8600 Series supports a licensing model that has two main categories of licenses: Base License and Feature Pack Licenses. A Base License enables base software features and one is required per IOC in the chassis. You require a Feature Pack License to enable additional features that are grouped into Feature Packs. These licenses are optional.

Licenses are tied to the switch Base MAC address. After you generate the license through Extreme Networks Support Portal at <https://extremeportal.force.com/ExtrLicenseLanding>, you can install the license on the switch.

#### Note

Release 6.1, or later, is required to support licenses generated through the Extreme Networks Support Portal.

#### Important

The software continues to support .xml licenses generated by Avaya.

The following sections detail the different categories of licenses supported on the VSP 8600 Series switch.

### Trial License

Use Trial Licenses to test the licensed features at any time. The following two types of Trial Licenses are available:

- Trial License that allows the use of all features excluding MACsec
- Trial License that allows the use of all features including MACsec

A Trial License is valid for 60 days. You can activate a Trial License once per switch.

The system generates warning messages to inform you about the time remaining in the license period. The system displays the alerts once every 5 days for the first 55 days, and then once daily for the last 5 days. If you reboot the switch after the 60-day period, and a valid software license is not present, the licensed features in the configuration are not loaded. You must install a valid license to enable the licensed features.

### Base License

A Base License allows you to use the Base software features on the switch. A Base License is required for each IOC module that you plan to install in the chassis. If the number of IOCs exceeds the licensed IOC quantity, the ports on the excess IOCs are license-locked and the system displays it administratively down.

The software validates the number of license entitlements against the IOC modules present and assigns the licenses sequentially to the I/O slots, starting from slot 1 to slot 8. For example, if you install modules in I/O slots 1 through 4 but only purchase three Base Licenses, the switch automatically assigns the licenses to slots 1 to 3. The ports on the module in slot 4 are in the license-locked state and the system displays it administratively down because the license entitlements on the switch are only for 3 IOCs. If you would like to override the default entitlement assignment, you can reassign it to a different slot by using the **license-grant** command.

You can increase the number of IOC module Base Licenses if you populate additional slots. You can use the IOC module Base License alone or combined with a Feature Pack License (one per chassis) at any time. When increasing or combining licenses, you must delete the old license file and install and load the new license file on the switch.

### Feature Pack Licenses

Features that are not available in the Base License are grouped into Feature Packs based on use case. You require a license to use a Feature Pack. A Feature Pack License applies to the entire chassis; you do not need to purchase this license type for each installed IOC module. Feature Pack Licenses are optional, incremental to the Base License and sold separately.

The following table provides information on the Feature Pack licenses that the VSP 8600 Series supports.

| License type                       | Supported features                                                                                                                                                                                                 |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Layer 3 Virtualization             | <ul style="list-style-type: none"> <li>Fabric Connect Layer 3 Virtual Services Networks (VSNs)</li> <li>DVR Controller</li> <li>Greater than 25 VRFs</li> <li>Greater than 17 BGP Peers</li> </ul>                 |
| Layer 3 Virtualization with MACsec | <ul style="list-style-type: none"> <li>Fabric Connect Layer 3 Virtual Services Networks (VSNs)</li> <li>DVR Controller</li> <li>Greater than 25 VRFs</li> <li>Greater than 17 BGP Peers</li> <li>MACsec</li> </ul> |

## VSP 8600 License types and part numbers

The following table provides the part numbers for the various licenses the VSP 8600 supports.

**Table 149: Supported licenses**

| License type                                                         | Part number/ Order code |
|----------------------------------------------------------------------|-------------------------|
| Base License - one per IOC Module                                    | 392259                  |
| Layer 3 Virtualization Feature Pack License - one per chassis        | 392670                  |
| Layer 3 Virtualization+MACsec Feature Pack License - one per chassis | 392671                  |

### *Subscription Licensing for XA1400 Series*

Each XA1400 Series device requires a subscription license.

Licenses are tied to the switch Base MAC address and switch model type. After you generate the license through Extreme Networks Support Portal at <https://extremeportal.force.com/ExtrLicenseLanding>, you can install the license on the switch.

#### Note

VOSS Release 8.0.50 or later is required to support subscription licenses generated through the Extreme Networks Support Portal.

### **Trial License**

Trial licenses enable users to test licensed features at any time. The following two types of Trial Licenses are available:

- Trial License that allows the use of all features excluding MACsec
- Trial License that allows the use of all features including MACsec

A Trial License is valid for 60 days. You can activate a Trial License once per switch.

The system generates warning messages to inform you about the time remaining in the license period. The alerts appear once every 5 days for the first 55 days, and then once daily for the last 5 days. If you reboot the switch after the 60-day period, and a valid software license is not present, the configuration does not load. You must install a valid license to enable licensed features.

### **Subscription License**

All subscription licenses support all VOSS features on the switch, plus software upgrades and technical support services entitlement during the license term. A one, three, or five year subscription license is required for each XA1400 Series device. Three services entitlement tiers of license are available: ExtremeWorks, PartnerWorks, and ExtremeWorks Premier.

A Subscription License is available in two bandwidth tiers of licenses: Small License and Medium License. A Small License enables up to 100 Mbps aggregate throughput Fabric Extend WAN tunneling connectivity, and a Medium License enables up to 500 Mbps aggregate throughput Fabric Extend WAN tunneling connectivity.

License expiry notifications are sent to the console and management station every 30 days until the last 30 days of the subscription. Then every 5 days until the last 9 days of the subscription, and then daily until the Subscription License expires.

When a subscription expires, notification messages are shown on the console and in the alarms database, indicating that the license is expired. Existing software functionality is not impaired upon subscription license expiry. However, software upgrades are disallowed until the new license is activated. Additionally, access to Software and Services GTAC support is suspended for the product until a valid license is activated.

### XA1400 Series License Types and Part Numbers

The following table provides the part numbers for the various licenses the XA1400 Series supports.

**Table 150: Supported licenses**

| Small Subscription Licenses (up to 100 Mbps) | Part number/ Order code          |
|----------------------------------------------|----------------------------------|
| 1 year, ExtremeWorks                         | FCVPN-100-EW-1Y<br>FSR100-EW-1YR |
| 1 year, PartnerWorks                         | FCVPN-100-PW-1Y                  |
| 1 year, ExtremeWorks Premier                 | FCVPN-100-EWP-1Y                 |
| 3 years, ExtremeWorks                        | FCVPN-100-EW-3Y<br>FSR100-EW-3YR |
| 3 years, PartnerWorks                        | FCVPN-100-PW-3Y                  |
| 3 years, ExtremeWorks Premier                | FCVPN-100-EWP-3Y                 |
| 5 years, ExtremeWorks                        | FCVPN-100-EW-5Y<br>FSR100-EW-5YR |
| 5 years, PartnerWorks                        | FCVPN-100-PW-5Y                  |
| 5 years, ExtremeWorks Premier                | FCVPN-100-EWP-5Y                 |

| Medium Subscription Licenses (up to 500 Mbps) | Part number/ Order code          |
|-----------------------------------------------|----------------------------------|
| 1 year, ExtremeWorks                          | FCVPN-500-EW-1Y<br>FSR500-EW-1YR |
| 1 year, PartnerWorks                          | FCVPN-500-PW-1Y                  |
| 1 year, ExtremeWorks Premier                  | FCVPN-500-EWP-1Y                 |
| 3 years, ExtremeWorks                         | FCVPN-500-EW-3Y<br>FSR500-EW-3YR |
| 3 years, PartnerWorks                         | FCVPN-500-PW-3Y                  |
| 3 years, ExtremeWorks Premier                 | FCVPN-500-EWP-3Y                 |
| 5 years, ExtremeWorks                         | FCVPN-500-EW-5Y<br>FSR500-EW-5YR |

| Medium Subscription Licenses (up to 500 Mbps) | Part number/ Order code |
|-----------------------------------------------|-------------------------|
| 5 years, PartnerWorks                         | FCVFN-500-PW-5Y         |
| 5 years, ExtremeWorks Premier                 | FCVFN-500-EWP-5Y        |

**Note**

500 Mbps Subscription Licenses are only supported on XA1480 devices.

## Licensing for Universal Hardware

The following topics apply to Extreme Networks 5420 Series and 5520 Series hardware. Because the 5420 Series and 5520 Series hardware support more than one Network Operating System (NOS) personality, they use a licensing scheme that is NOS agnostic.

### *License File Requirements for Universal Hardware*

The license file name must meet the following requirements:

- Maximum of 63 alphanumeric characters
- No spaces or special characters allowed
- Underscore (\_) is allowed
- The file extension is `.lic`.

### *Feature Licensing for Universal Hardware*

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. The universal hardware products share a unified license, which is NOS agnostic.

The Base License, which is included with the purchase of the switch, enables the basic networking capabilities of the device. You can purchase additional licenses separately to enable advanced features on the switch.

Licenses are tied to the switch serial number. After you generate the license through the Extreme Networks Support Portal at <https://extremeportal.force.com/ExtrLicenseLanding>, you can install the license on the switch manually. You can also use ExtremeCloud IQ to obtain licenses for universal hardware switches.

The following sections detail the different categories of licenses.

#### **Base License**

A Base license gives customers the right to use Base software features on the switch.

### Licenses for Advanced Features

Licenses enable advanced features not available in the Base License. The following table provides information on the features enabled by each license, if the hardware supports the feature. For information on supported features, see [VOSS Feature Support Matrix](#).

| License type                                                                                             | Supported features                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MACsec License<br><br><b>Note:</b> Exception: 5420 Series does not currently support MACsec in software. | IEEE 802.1AE MACsec                                                                                                                                                                                                                                |
| Premier License                                                                                          | <ul style="list-style-type: none"> <li>• DvR Controller (5520 Series only)</li> <li>• Fabric Connect Layer 3 Virtual Services Networks (VSNs)</li> <li>• Greater than four OSPF active Interfaces</li> <li>• Greater than two BGP peers</li> </ul> |

### License Types and Part Numbers

The following table lists the license types and the associated part numbers.

| License Type                                                                                                                             | Part Number / Order Code |
|------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| MACsec License for 5420 Series and 5520 Series<br><br><b>Note:</b> Exception: 5420 Series does not currently support MACsec in software. | 5000-PRMR-LIC            |
| Premier License for 5420 Series and 5520 Series                                                                                          | 5000-PRMR-LIC            |

### ExtremeCloud™ IQ Pilot License

ExtremeSwitching 5420 Series and 5520 Series switches include a one-year subscription to an ExtremeCloud™ IQ Pilot license.

#### Note

The entitlement period starts the day the switch ships from Extreme Networks or an Extreme Networks distribution partner.

ExtremeCloud IQ enables end-to-end network management and operations, delivering a fully integrated, extensible platform that simplifies the design, deployment, and security of networks from the edge to the data center, while simultaneously unlocking valuable IT and business insights. To activate these premium Pilot level capabilities, go to <https://www.extremenetworks.com/universal-switch-xiq-pilot/>.

### *Install and Uninstall Licenses on Universal Switches*

This topic explains how to obtain, activate, and transfer licenses on universal hardware switches.

## Obtain and Install a License

For universal hardware switches, you can activate a license on the switch using either of the following methods:

- Manual activation by obtaining the license activation file from the [Extreme Networks Support portal](#).
- Automated activation using ExtremeCloud IQ. For information about using ExtremeCloud IQ for bulk automated license activation, go to <https://www.extremenetworks.com/support/documentation/extremecloud-iq>.

To obtain and install a license, follow these steps:

### Note

You should have received by email a license voucher after your purchase of a switch. You will need the voucher ID number on this email to generate a license.

For manual license generation and installation:

1. Upgrade the switch so that it is running the most recent GA version of the software.

To download the latest GA software, visit the [Extreme Networks Support portal](#).

2. Follow manual activation instructions for license generation available on the [Extreme Networks Support portal](#): **Products > Products Home > ExtremeSwitching > Universal > VOSS (for your switch) > Activation Instructions.**
3. Download the license file onto the switch.
4. Install the license, using the command `load-license license_filename`.

VOSS verifies the license and activates the features that correspond to the license category (MACsec or Premier).

For more information, see either of the following:

- [License Installation using CLI](#) on page 2129
- [License Installation using EDM](#) on page 2135

## Transfer a License

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

For more information, see either of the following:

- [Revoke a License](#) on page 2131 (using CLI)
- [Revoke a License](#) on page 2139 (using EDM)

To transfer a license from a defective switch to a replacement switch (RMA), follow these steps.

1. Go to the [Extreme Networks Support portal](#).
2. Select **Assets > Licenses Home**.
3. Select **License Transfer**.
4. Enter the serial number of the defective unit, replacement unit serial number, and the RMA/case number.

5. Generate the new license, following the process in step 2 in [Obtain and Install a License](#) on page 2128.
6. Download the license file onto the switch.
7. Install the license, using the command `load-license license_filename`.

## License Installation using CLI

Install and manage a license file for the switch by using the Command Line Interface (CLI).

### Note

This section applies to multiple platforms. The command syntax and example outputs may not be identical on all hardware platforms.

## Install a License File

Install a license file on the switch to enable licensed features.

### Before You Begin

- File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.
- You must enable File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP) in the boot configuration flags depending on which protocol you use to download the license file to the device.
- Ensure that you have the correct license file with the base MAC address of the switch on which you need to install the license. Otherwise, the system does not unblock the licensed features.

### About This Task

You can use the same procedure to load Avaya-generated license files on a VSP 4450 Series switch.

### Procedure

1. From a remote station or PC, use FTP or TFTP to download the license file to the device and store the license file in the `/intflash` directory.
2. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
3. Load the license:  
`load-license <filename>`

### Note

If filename parameter is not used and more than one valid license file exists in the `/intflash/` directory, the switch uses the license with the highest capability.

### Examples

Use FTP to transfer a license file from a PC to the internal flash on the device:

```
C:\Users\jsmith>ftp 192.0.2.16
Connected to 192.0.2.16 (192.0.2.16).
```

```

220 FTP server ready
Name (192.0.2.16:(none)): rwa
331 Password required
Password:
230 User logged in
ftp> bin
200 Type set to I, binary mode
ftp> put L3VWithMACsec.xml /intflash/L3VWithMACsec.xml
local: L3VWithMACsec.xml remote: /intflash/L3VWithMACsec.xml
227 Entering Passive Mode (192,0,2,16,4,2)
150 Opening BINARY mode data connection
226 Transfer complete
101 bytes sent in 2.7e-05 secs (3740.74 Kbytes/sec)
ftp>

```

Log in to the device and load the license. The following example shows a successful operation.

```

Switch:1(config)#load-license L3VWithMACsec.xml
Switch:1(config)#CP1 [06/12/15 15:59:57.636:UTC] 0x000005bc 00000000 GlobalRouter SW INFO
License Successfully Loaded From </intflash/L3VWithMACsec.xml> License Type -- L3V with
MACsec

```

The following example shows an unsuccessful operation.

```

Switch:1(config)#load-license license_Switch_example.xml
Switch:1(config)#CP1 [06/12/15 15:58:48.376:UTC] 0x000006b9 00000000 GlobalRouter SW
INFO Invalid license file /intflash/license_Switch_example.xml HostId is not Valid

CP1 [06/12/15 15:58:48.379:UTC] 0x000005c4 00000000 GlobalRouter SW INFO No Valid
License found.

```

### Variable Definitions

The following table defines parameters for the **copy** command.

| Variable  | Value                                                                                       |
|-----------|---------------------------------------------------------------------------------------------|
| <a.b.c.d> | Specifies the IPv4 and IPv6 address of the TFTP server from which to copy the license file. |
| <file>    | Specifies the name of the license file when copied to the flash.                            |
| <srcfile> | Specifies the name of the license file on the TFTP server.                                  |

The following table defines parameters for the **load-license** command.

| Variable   | Value                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <filename> | Specifies the name of the license file in the /intflash directory. Use the CLI Help to see the number of characters allowed for the switch. |

## Revoke a License

Revoke a license on the switch if you need to transfer the license to a different switch.

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

### Note

This procedure only applies to 5420 Series and 5520 Series.

### About This Task

The **no license** command invalidates the feature license and generates a revocation certificate, which is the first step to releasing the license entitlement back to the license entitlement manager (LEM). The revocation certificate is contained in a file where the first part of the file name is the switch serial number and the file extension is .rvk.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Revoke a license:  
`no license <macsec | premier>`

### Note

5420 Series does not currently support MACsec in software.

### Example

Revoke the Premier license.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no license premier
Successfully revoked license of type <PRD-5000-PRMR>, revocation certificate available at
"/intflash/2011G-00165-PRD-5000-PRMR.rvk"
```

## Extend the Factory Default Premier Trial License

Use the following procedure to extend the Factory Default Premier Trial License on your switch.

You can run the **extend-time-period** command up to three times to extend the evaluation license in 30-day increments for an additional 90 days.

### Note

This procedure does not apply to VSP 8600 Series.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Extend the trial software license on your device:  
extend-time-period

### Note

You must reboot your switch after each license extension.

## Example

Extend the trial license period for 30-days:

```
Switch:1>enable
Switch:1#extend-time-period
Are you sure you want to reset the box to apply changes? (y/n) y
```

## Show a License File

Display the existing software licenses on your device. If the switch uses a Factory Default Premier Trial License, the output shows the time remaining in the trial period.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the existing software licenses on your device:  
show license

### Examples

### Note

Example outputs might not be identical on all hardware platforms.

The following output shows time remaining on a Trial License for a universal hardware platform when the trial period is extended:

```
Switch:1>show license

BASE License      : Available, Perpetual
PREMIER License:  Factory Default Evaluation
                   Evaluation, 120 days
                   Remaining Days: 117
MACSEC License:   Available, Perpetual
                   Date and Time of Generation: 2020/09/17 00:00:00

*****
Features requiring a Premier license:
- Layer 3 VSNs
- MACsec
- Distributed Virtual Routing(DvR) Controller
- >16 BGP Peers
```

The following output is shows time remaining on a Trial License for non-universal hardware when the trial period is extended:

```
Switch:1>show license

License Type           : 1) BASE
                      : 2) PREMIER TRIAL (non-Base features)

Premier TrialPeriodRemainingDays : 117

*****
Features requiring a Premier license:
- Layer 3 VSNS
- MACsec
- Distributed Virtual Routing(DvR) Controller
- VXLAN GATEWAY
- >16 BGP Peers
- Insight Virtualization
```

The following output is for a VSP 4450 Series switch that uses legacy Avaya .dat licenses. The output for the **show license** command for legacy licenses shows non-zero values for MD5 of Key and MD5 of File:

```
Switch:1>show license

License file name      : /intflash/premier.dat
License Type          : PREMIER
MD5 of Key            : 7ce34d20 0caf0074 6657d928 1b4a0a18
MD5 of File           : 9e0e5a4c 4855efb1 90909c11 bb870d84
Generation Time       : 2015/08/12 01:53:39
Expiration Time       :
Base Mac Addr         : b4:47:5e:37:9a:00
flags                 : 0x00000001 SINGLE
memo                  :

*****
Features requiring a Premier license:
- Layer 3 VSNS
- MACsec
- Distributed Virtual Routing(DvR) Controller
- >24 VRFs
```

The output for .xml licenses on some platforms shows all zeroes for MD5 of Key and MD5 of File:

```
Switch:1>show license

License file name      : /intflash/premier_macsec.xml

License Type          : PREMIER+MACSEC (includes Base features)
MD5 of Key            : 00000000 00000000 00000000 00000000
MD5 of File           : 00000000 00000000 00000000 00000000
Generation Time       : 2015/2/26 11:09:53
Expiration Time       :
Base Mac Addr         : b0:ad:aa:46:f0:00
flags                 : 0x00000001 SINGLE
memo                  :
```

```
*****
Features requiring a Premier license:
- Layer 3 VSNS
- MACsec
- Distributed Virtual Routing (DvR) Controller
- VXLAN GATEWAY
- >24 VRFs
- >16 BGP Peers
*****
```

The following **show license** command output is from a platform that supports Base Licenses per IO slot and Feature Pack Licenses.

```
Switch:1>show license

License file name      : /intflash/.sys/Base.xml
License Type          : BASE
Duration Type         : Perpetual
Generation Time       : 2017/01/05 20:57:22
Expiration Time       :
Host ID              : F873A2045000
*****
Features requiring a L3V + MacSec license:
- Layer 3 VSNS
- MACsec
*****

Number of IO license entitlements: 8
License granted for slots      : 1 2 5 8
*****
```

The following **show license** command output is from an XA1400 Series platform that supports Subscription Licenses.

```
Switch:1>show license

License file name      : FCVFN500-EW-5YR.xml
License Type          : FCVFN500-EW-5YR
Duration Type         : TimeBased
Generation Time       : 2019/06/10 06:50:08
Expiration Time       : 2024/06/08
Host ID              : DCB808B66000
*****
```

The following **show license** command output is from a universal hardware platform that supports Base, Premier, and MACsec licenses.

```
Switch:1>show license

BASE License: Available, Perpetual
PREMIER License: Available, Perpetual
Date and Time of Generation: 2020/10/20 13:51:00
MACSEC License: Available, Perpetual
Date and Time of Generation: 2020/10/20 13:55:00
*****
```

## Assign a Base License to an IOC module slot

The system validates the number of license entitlements against the IOC modules present and assigns the licenses sequentially to the I/O slots, starting from slot 1 to slot 8.

If you install a module in a slot that has a license assigned and later, when the module is moved to another slot that does not have a license assigned, you can reassign the license to the new slot by using the **license-grant** command.

### Note

This procedure only applies to VSP 8600 Series.

## About This Task

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Load the license on the slot and enable the ports on the IOC module:  
`license-grant slot {slot[-slot] [, ...]}`
3. Release the license from a slot:  
`no license-grant slot {slot[-slot] [, ...]}`

### Example

Load the license on the specified slot and enable the ports on the IOC module:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#license-grant slot 2
License granted for slot: 2
Switch:1(config)#
```

## License Installation using EDM

Install and manage a license file for the switch by using Enterprise Device Manager (EDM).

### Note

This section applies to multiple platforms. The fields may not be identical on all hardware platforms.

## Install a License File

Install a license file on the switch to enable licensed features.

### Before You Begin

- You must store the license file on a file server.
- Ensure that you have the correct license file with the base MAC address of the switch on which you need to install the license. Otherwise, the system does not unblock the licensed features.

## About This Task

You can use the same procedure to load legacy Avaya license files on a VSP 4450 Series switch.

IPv4 and IPv6 addresses are supported.

## Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **File System**.
3. Select the **Copy File** tab.
4. In the **Source** box, type the IP address of the file server where the license file is located and the name of the license file.
5. In the **Destination** box, type the flash device and the name of the license file.  
The license file name must have a file extension of .xml.
6. Select **start**.
7. Select **Apply**.  
The license file is copied to the flash of the device. The system displays the status of the file copy in the Result field.
8. In the navigation pane, expand **Configuration > Edit**.
9. Select **Chassis**.
10. Select the **System** tab.
11. In **ActionGroup1**, select **loadLicense**.
12. In **LicenseFileName** box, type the name of the license file.
13. Select **Apply**.
 

**Important**  
If the loading fails, the switch cannot unlock the licensed features and reverts to base functionality.
14. On the **System** tab, in **ActionGroup1**, select **saveRuntimeConfig**.
15. Select **Apply**.

### **Copy File** Field Descriptions

Use the data in the following table to use the **Copy File** tab.

| Name               | Description                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Source</b>      | Identifies the device and file name to copy. You must specify the full path and filename, for example, <deviceip-ftp server>:/<filename> |
| <b>Destination</b> | Identifies the location to which to copy the source file with the filename, for example, /intflash/<filename>                            |

| Name          | Description                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b> | Starts or stops the copy process.                                                                                                                                                                                                                                                       |
| <b>Result</b> | Specifies the result of the copy process: <ul style="list-style-type: none"> <li>• none</li> <li>• inProgress</li> <li>• success</li> <li>• fail</li> <li>• invalidSource</li> <li>• invalidDestination</li> <li>• outOfMemory</li> <li>• outOfSpace</li> <li>• fileNotFound</li> </ul> |

### **System** Field Descriptions

Use the data in the following table to use the **System** tab.

| Name                                | Description                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>sysDescr</b>                     | Shows the system assigned name and the software version.                                                       |
| <b>sysUpTime</b>                    | Shows the elapsed time since the system last started.                                                          |
| <b>sysContact</b>                   | Configures the contact information.                                                                            |
| <b>sysName</b>                      | Configures the name of this device.                                                                            |
| <b>sysLocation</b>                  | Configures the physical location of this device.                                                               |
| <b>VirtualIpAddr</b>                | Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file. |
| <b>VirtualNetMask</b>               | Configures the net mask of the virtual management IP address.                                                  |
| <b>VirtualIpv6Addr</b>              | Specifies the virtual IPv6 address.                                                                            |
| <b>VirtualIpv6PrefixLength</b>      | Specifies the length of the virtual IPv6 address prefix (in bits).                                             |
| <b>DnsDomainName</b>                | Configures the default domain for querying the DNS server.                                                     |
| <b>LastChange</b>                   | Displays the time since the last configuration change.                                                         |
| <b>LastVlanChange</b>               | Displays the time since the last VLAN change.                                                                  |
| <b>LastStatisticsReset</b>          | Displays the time since the statistics counters were last reset.                                               |
| <b>LastRunTimeConfigSave</b>        | Displays the last run-time configuration saved.                                                                |
| <b>DefaultRuntimeConfigFileName</b> | Displays the default Run-time configuration file directory name.                                               |
| <b>ConfigFileName</b>               | Specifies the name of a new configuration file.                                                                |

| Name                                                                                                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Revoke a License

Revoke a license on the switch if you need to transfer the license to a different switch.

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

### Note

This procedure only applies to 5420 Series and 5520 Series.

### About This Task

The **revokeLicensePremier** or **revokeLicenseMacsec** parameter invalidates the feature license and generates a revocation certificate, which is the first step to releasing the license entitlement back to the license entitlement manager (LEM). The revocation certificate is contained in a file where the first part of the file name is the switch serial number and the file extension is .rvk.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System** tab.
4. In **ActionGroup1**, select either **revokeLicensePremier** or **revokeLicenseMacsec**.
5. Select **Apply**.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Select **Apply**.

### *System* Field Descriptions

Use the data in the following table to use the **System** tab.

| Name                           | Description                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>sysDescr</b>                | Shows the system assigned name and the software version.                                                       |
| <b>sysUpTime</b>               | Shows the elapsed time since the system last started.                                                          |
| <b>sysContact</b>              | Configures the contact information.                                                                            |
| <b>sysName</b>                 | Configures the name of this device.                                                                            |
| <b>sysLocation</b>             | Configures the physical location of this device.                                                               |
| <b>VirtualIpAddr</b>           | Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file. |
| <b>VirtualNetMask</b>          | Configures the net mask of the virtual management IP address.                                                  |
| <b>VirtualIpv6Addr</b>         | Specifies the virtual IPv6 address.                                                                            |
| <b>VirtualIpv6PrefixLength</b> | Specifies the length of the virtual IPv6 address prefix (in bits).                                             |

| Name                                                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## View License File Information

### About This Task

View information about the license file for the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **License** tab.

### *License field descriptions*

Use the data in the following table to use the **License** tab.

| Name                 | Description                                                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FileName</b>      | Indicates the file name of the current license.<br><br><b>Note:</b><br>If this field is empty it indicates that there is no license installed on the switch.           |
| <b>LicenseType</b>   | Indicates the level type of the current license.                                                                                                                       |
| <b>DurationType</b>  | Indicates the duration type of the current license.                                                                                                                    |
| <b>RemainingDays</b> | Indicates the days left before the factory default trial period or subscription license expires.<br><br><b>Note:</b><br>For other license types, the field displays 0. |

| Name                  | Description                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GenerationTime</b> | Indicates the date on which the license file was generated.<br><br><b>Note:</b><br>If there is no license installed on the system, this field displays 0000000000000000 H. |
| <b>ExpirationTime</b> | Indicates the date on which the license file expired.<br><br><b>Note:</b><br>If there is no license installed on the system, this field displays 0000000000000000 H.       |

### **System** Field Descriptions

Use the data in the following table to use the **System** tab.

| Name                                | Description                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>sysDescr</b>                     | Shows the system assigned name and the software version.                                                       |
| <b>sysUpTime</b>                    | Shows the elapsed time since the system last started.                                                          |
| <b>sysContact</b>                   | Configures the contact information.                                                                            |
| <b>sysName</b>                      | Configures the name of this device.                                                                            |
| <b>sysLocation</b>                  | Configures the physical location of this device.                                                               |
| <b>VirtualIpAddr</b>                | Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file. |
| <b>VirtualNetMask</b>               | Configures the net mask of the virtual management IP address.                                                  |
| <b>VirtualIpv6Addr</b>              | Specifies the virtual IPv6 address.                                                                            |
| <b>VirtualIpv6PrefixLength</b>      | Specifies the length of the virtual IPv6 address prefix (in bits).                                             |
| <b>DnsDomainName</b>                | Configures the default domain for querying the DNS server.                                                     |
| <b>LastChange</b>                   | Displays the time since the last configuration change.                                                         |
| <b>LastVlanChange</b>               | Displays the time since the last VLAN change.                                                                  |
| <b>LastStatisticsReset</b>          | Displays the time since the statistics counters were last reset.                                               |
| <b>LastRunTimeConfigSave</b>        | Displays the last run-time configuration saved.                                                                |
| <b>DefaultRuntimeConfigFileName</b> | Displays the default Run-time configuration file directory name.                                               |

| Name                                                                                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Assign a Base License to an IOC Module Slot

### About This Task

The system validates the number of license entitlements against the IOC modules present and assigns the licenses sequentially to the I/O slots, starting from slot 1 to slot 8.

If you install a module in a slot that has a license assigned and later, when the module is moved to another slot that does not have a license assigned, you can reassign the license to the new slot.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Click **Chassis**.
3. Click the **License Grant** tab.
4. Do any one of the following:
  - To assign a license to a slot, double-click the cell in the **SlotGrant** column, and change the value to **true**.
  - To release a license from a slot, double-click the cell in the **SlotGrant** column and then change the value to **false**.
5. Click **Apply**.

### *License Grant* field descriptions

Use the data in the following table to use the **License Grant** tab.

| Name             | Description                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Slot</b>      | Specifies the IO slot number. Valid slots are 1 to 8.                                                                                                                                                           |
| <b>SlotGrant</b> | Specifies the license status on the IO slot. <ul style="list-style-type: none"><li>• <b>True</b> if valid license is granted to the slot</li><li>• <b>False</b> if license is not granted to the slot</li></ul> |

# Link Aggregation Control Protocol

---

- [Link Aggregation Overview on page 2145](#)
- [MultiLink Trunking with LACP on page 2146](#)
- [LACP configuration considerations on page 2149](#)
- [Important Information and Restrictions on page 2150](#)
- [LACP configuration using CLI on page 2151](#)
- [LACP configuration using EDM on page 2165](#)

The following sections provide the concepts and procedures you need to configure the Link Aggregation Control Protocol (LACP) to dynamically aggregate links as they become available to a trunk group.

## Link Aggregation Overview

---

Link aggregation provides link level redundancy and increases load sharing. Use Link aggregation to bundle the ports into a port group, which is represented as one logical interface to the Media Access Control (MAC) layer.

The switch supports the following types of link aggregation:

- MultiLink Trunking (MLT)—a statically configured link bundling method. MLT is not standards based, but it interoperates with static link methods of other vendors.
- IEEE 802.3ad based link aggregation, through the Link Aggregation Control Protocol (LACP), dynamically aggregates links as they become available to a trunk group. Link Aggregation Control Protocol dynamically detects whether links can be aggregated into a link aggregation group (LAG) and does so after links become available. Link Aggregation Control Protocol also provides link integrity checking at Layer 2 for all links within the LAG.

Both MLT and IEEE 802.3ad based link aggregation are point-to-point functions.

The switch software offers LACP functionality layered with MLT. This document uses the term MLT with LACP to refer to this functionality.

## Split MultiLink Trunking (SMLT)

Split MultiLink Trunking (SMLT) is an option that improves Layer 2 (bridged) resiliency by providing for the addition of failure redundancy with subsecond failover, on top of all standard MLT link failure protection and flexible bandwidth scaling functionality. Use SMLT to connect a device that supports some form of link aggregation, be it a switch or a server, to two distinct separate SMLT endpoints or switches. These SMLT devices form a virtualized Switch Cluster through the SPBM cloud and are referred to as a Virtual Inter-Switch Trunk (vIST) Core Switch pair.

For more information, see the following sections:

- [Virtual Inter-Switch Trunk \(vIST\)](#) on page 2334
- [Simplified Virtual-IST](#) on page 2336
- [Split MultiLink Trunking](#) on page 2339

## LACP with SMLT

You can use LACP on SMLT configurations. The switch provides modifications to the LACP in SMLT configurations. LACP-capable devices can connect to an SMLT aggregation pair.

### Note

Virtual IST is not supported on LACP-enabled MLTs.

## VLACP with SMLT

You can also configure Virtual LACP (VLACP) with an SMLT configuration. VLACP is a modification that provides end-to-end failure detection. VLACP is not a link aggregation protocol.

VLACP implements link status control protocol at the port level. This mechanism periodically checks the end-to-end health of a point-to-point or end-to-end connection. You can run VLACP on single ports or on ports that are part of an MLT.

### Note

Do not configure VLACP on LACP-enabled ports. VLACP does not operate properly with LACP.

## MultiLink Trunking with LACP

---

MultiLink Trunking (MLT) with Link Aggregation Control Protocol (LACP) manages ports and port memberships to form a link aggregation group (LAG). Use Link Aggregation Control Protocol to gather one or more links to form a LAG, which a Media Access Control (MAC) client treats as a single link. Link Aggregation Control Protocol can dynamically add or remove LAG ports, depending on availability and state.

## IEEE 802.3ad overview

The IEEE 802.3ad standard comprises service interfaces, the LACP, the Marker Protocol, link aggregation selection logic, a parser or multiplexer, frame distribution, and frame collection functions.

The following illustration shows the major functions of IEEE 802.3ad defined as multiple link aggregation.

**Figure 191: Link aggregation sublayer (according to IEEE 802.3ad)**

The link aggregation sublayer comprises the following functions:

- frame distribution

This block takes frames submitted by the MAC client and sends them for transmission on the appropriate port based on a frame distribution algorithm employed by the Frame Distributor.

Frame distribution also includes an optional Marker Generator/Receiver used for the Marker Protocol. The switch only implements the Marker Receiver function. For more information about the frame distribution algorithm, see [MLT traffic distribution algorithm](#) on page 2337.

- frame collection

This block passes frames received from the various ports to the MAC client. Frame collection also includes a Marker Responder used for the Marker Protocol.

- aggregator parser or multiplexers

During transmission operations, these blocks pass frame transmission requests from the Distributor, Marker Generator, and Marker Responder to the appropriate port.

During receive operations, these blocks distinguish among Marker Request, Marker Response, MAC Client Protocol Data Units (PDU), and pass the blocks to the appropriate entity (Marker Responder, Marker Receiver, and Collector, respectively).

- aggregator

The combination of frame distribution and collection, and aggregator parser or multiplexers.

- aggregation control

This block configures and controls link aggregation. It incorporates LACP for the automatic communication of aggregation capabilities between systems and automatic configuration of link aggregation.

- control parser/multiplexers

During transmission operations, these blocks pass frame transmission requests from the aggregator and Control entities to the appropriate port.

During receive operations, these blocks distinguish Link Aggregation Control Protocol Data Units (LACPDUs) from other frames. The blocks pass, passing the LACPDUs to the appropriate sublayer entity and all other frames to the aggregator.

## 802.3ad link aggregation principles

Use link aggregation to group ports together to form a link group to another device. Link groups increase aggregate throughput between devices and provide link redundancy.

Link aggregation employs the following principles and concepts:

- A MAC client communicates with a set of ports through an aggregator, which presents a standard IEEE 802.3 service interface to the MAC client. The aggregator binds to one or more ports within a system.
- The aggregator distributes frame transmissions from the MAC client to various ports, collects received frames from the ports, and transparently passes the frames to the MAC client.
- A system can contain multiple aggregators serving multiple MAC clients. A port binds to a single aggregator at a time. A MAC client is served by a single aggregator at a time.
- The Link Aggregation Control function binds ports to aggregators within a system. The control function aggregates links, binds the system ports to an appropriate aggregator, and monitors conditions to determine if a change in aggregation is needed. Network managers can manually provide link aggregation control by manipulating the link aggregation state variables (for example, keys). You can also use LACP to automatically determine, configure, bind, and monitor link aggregation.
- LACP uses peer exchanges across links to continually determine the aggregation capability of the links and provide the maximum level of aggregation capability between a pair of systems.
- Frame ordering is maintained for certain sequences of frame exchanges between MAC Clients. The distributor ensures that all frames of a conversation pass to a single port. The collector passes frames to the MAC client in the order they are received from the port. The collector can select frames received from the aggregated ports. Because the frames are not ordered on a single link, this guarantees that frame ordering is maintained for all conversations.
- Conversations move among ports within an aggregation for load balancing and for maintaining availability if a link fails.
- Each port is assigned a unique, globally administered MAC address.

After entities initiate frame exchanges within the link aggregation sublayer, the source address is the MAC address. An example of an entity that initiates frame exchanges is LACP and Marker Protocol exchanges.

- Each aggregator is assigned a unique, globally administered MAC address that is used from the perspective of the MAC client, both as a source address for transmitted frames and as the destination address for received frames. You can use one of the port MAC addresses in the associated LAG as the MAC address of the aggregator.

## Input/output port redundancy

You can use the MLT link aggregation mechanism to protect I/O ports. MLT is compatible with 802.3ad static, and provides a load sharing and failover mechanism to protect against module, port, fiber, or complete link failures.

You can use MLT with Link Access Control Protocol (LACP) disabled or use LACP enabled by itself.

## LACP configuration considerations

---

You can configure priorities, keys, modes, and timers for the LACP.

### LACP priority

You can configure LACP priority at the system and port level as follows:

- Port priority—determines which ports are aggregated into a LAG that has more than eight ports configured to it.
- System priority—generates the switch ID after communicating with other systems. As a best practice, use the default value. If you need to change it, first disable the LACP, and then enable it again after you change the value.

### LACP keys

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

- Keys do not have to match between two LACP peers.

### LACP timers

You can customize failover times by changing the LACP timer attributes (fast periodic time, slow periodic time, and aggregate wait time). Values are set by default to match the IEEE 802.3ad values. If you change the values, they must match on the ports participating in aggregation between two devices.

Changes to LACP timer values at the global level are reflected on all ports. However, you can change the LACP timer values for each port level. After you change an LACP timer globally, this value is set on all ports. The global timer value overwrites the local port value irrespective of the LACP state. You must configure port values that differ from the global values.

The switch software uses the following LACP timers:

- fast periodic timer—200 to 20 000 milliseconds (ms); default 1000 ms
- slow periodic timer—10 000 to 30 000 ms; default 30000 ms
- aggregation-wait timer—200 to 2000; default 2000

You cannot aggregate a link if it does not receive an LACPDU for a period of timeout x slow periodic time = 3 x 30 seconds = 90 seconds. If you use the fast periodic time, the timeout period is 3 x 1000 ms = 3 seconds. You must make timer changes to all ports participating in link aggregation and to the ports on the partnering node.

Configuration changes to the LACP timers are not reflected immediately. Link Aggregation Control Protocol timers do not reset until the next time you restart LACP globally or on a port. This ensures consistency with peer switches.

After you enable LACP on a port, the timer values are set at the port level. You must toggle the LACP status after timer values change. This does not impact existing ports unless you toggle the LACP status on the port.

## LACP modes

LACP uses two active and passive modes.

- Active mode—ports initiate the aggregation process. Active mode ports aggregate with other active mode ports or passive mode ports.
- Passive mode—ports participate in LACP but do not initiate the aggregation process. You must partner passive mode ports with active mode ports for aggregation to occur.

## LACP and private VLANs

- When using LACP, configure the private-vlan at the interface level.

## Link aggregation scaling

For the latest applicable scaling information, see [VOSS Release Notes](#) for the version of the software running on the switch.

## Important Information and Restrictions

---

Before you use the switch, review the following important information and restrictions.

### LACP with Simplified vIST/SPB NNI links

You should not use LACP on SPB NNI MLT links or on the Simplified Virtual IST.

## vIST VLAN IP addresses

Do not configure a Rendezvous Point (RP) or Bootstrap Router (BSR) on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the **ip pim enable** command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and RP
related configurations, as unicast packets to virtual IST vlan IP
address from outside of virtual IST vlan subnet will be dropped. Use
Loopback or CLIP interface IP address for BSR and RP related
configurations.
```

## Simplified vIST and egress port-based filters

On Simplified vIST nodes, egress port-based filters may not work for IP multicast routed traffic because vIST internal filter rules (to prevent duplicate traffic) have higher precedence than user-created filters.

### Note

- This issue is specific to IP multicast routed traffic only.
- Egress port-based filters work for Layer 2 multicast, broadcast and unicast traffic.

## LACP configuration using CLI

---

This section describes how to configure and manage link aggregation using the Command Line Interface (CLI), including Link Aggregation Control Protocol (LACP), to increase the link speed and redundancy for higher availability.

MultiLink Trunking (MLT) with LACP manages switch ports and port memberships to form a link aggregation group (LAG). Configure LACP to allow dynamic bundling of physical ports to form a single logical channel.

You can describe the LACP in terms of link aggregation operations within a single system. You can configure a single piece of equipment so it contains more than one system (from the point of view of the link aggregation operation).

### Before You Begin

- Changes to LACP made at the global level overrides and resets all port level settings.

### Important

After you globally configure the LACP system priority, it applies to all LACP-enabled aggregators and ports. After you enable the LACP on an aggregator or port, it uses the global system priority value.

- After you make a timer change, restart the LACP (globally or on the port) so the changes are consistent across the link.

**Important**

Configuration changes to LACP timers are not reflected immediately. LACP timers are not reset until the next time LACP is restarted globally or on a port. This action ensures consistency with peer switches.

- The switch does not support standby ports for LACP aggregation groups.

## Configuring global LACP parameters

Configure LACP parameters globally. After you configure the LACP system priority globally, it applies to all LACP-enabled aggregators and ports. After you enable the LACP on an aggregator or a port, it uses the global system priority value.

A change to the global parameter configuration takes effect after you restart the LACP globally or on each port.

### About This Task

**Important**

Changes made at the global level override and reset all port level settings.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Change the system priority:

```
lACP system-priority <0-65535>
```

3. Configure additional LACP parameters as required:

```
lACP enable [aggr-wait-time <200-2000>] [fast-periodic-time  
<200-20000>] [slow-periodic-time <10000-30000>] [smlt-sys-id  
<0x00:0x00:0x00:0x00:0x00:0x00> ] [system-priority <0-65535> ]  
[timeout-scale <2-10>]
```

If you do not configure the optional parameters, the system uses the default values.

### Example

```
Switch:1(config)#lACP fast-periodic-time 2000  
Switch:1(config)#lACP enable
```

*Variable definitions*

Use the data in the following table to use the **lacp** command.

| Variable                                              | Value                                                                                                                  |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>aggr-wait-time</i> <200-2000>                      | Configures the aggregation wait time (in milliseconds) globally. The default value is 2000.                            |
| <i>enable</i>                                         | Enables LACP globally. The default value is disabled.                                                                  |
| <i>fast-periodic-time</i> <200-20000>                 | Configures the fast periodic time (in milliseconds) globally. The default value is 1000.                               |
| <i>slow-periodic-time</i> <10000-30000>               | Configures the slow periodic time globally. The default value is 30000.                                                |
| <i>smlt-sys-id</i><br><0x00:0x00:0x00:0x00:0x00:0x00> | Configures the LACP system ID globally. Enter a MAC address in the following format:<br>0x00:0x00:0x00:0x00:0x00:0x00. |
| <i>system-priority</i> <0-65535>                      | Configures the LACP system priority globally. The default value is 32768.                                              |
| <i>timeout-scale</i> <2-10>                           | Configures the timeout scale globally. The default value is 3.                                                         |

**Configure LACP on a Port****Important**

Changes made at the global level override and reset the port-level configuration.

Configure LACP on a port to enable or disable LACP on the selected ports.

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

**Before You Begin**

When enabling or disabling LACP on a port, as a best practice, disable the port first and re-enable the port after the configuration is complete.

**About This Task**

The minimum LACP configuration is as follows:

- Assign a given key to a set of ports. In the following procedure steps, you must assign the key before you enable LACP on the port.
- Assign the same key to an MLT with no members. The ports will automatically become MLT members.

Keys do not need to match between two LACP peers.

A port can operate in active or passive mode. You can configure a port to be an individual link or an aggregated link.

#### Note

When using LACP with private VLANs, configure the private VLAN at the interface level.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an LACP key:

```
lacp key <1-512|defVal>
```

3. Change the LACP mode:

```
lacp mode <active|passive>
```

4. Change the port priority:

```
lacp priority <0-65535>
```

5. (Optional) Change the system priority:

```
lacp system-priority <0-65535>
```

6. Configure aggregation for the port:

```
lacp agrgr-wait-time <200-2000>[aggregation enable]
```

If you do not configure the optional parameter, the system uses the default values.

7. Configure parameters for the partner device at the opposite end of the link:

#### Note

All parameters beginning with **partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

```
lacp partner-key <0-65535|defVal>
```

```
lacp partner-port <0-65535>
```

```
lacp partner-port-priority <0-65535>
```

```
lacp partner-state <0-255 | 0x0-0xff>
```

```
lacp partner-system-id 0x00:0x00:0x00:0x00:0x00:0x00
```

```
lacp partner-system-priority <0-65535>
```

8. Configure additional LACP parameters as required:

```
lacp enable [fast-periodic-time <200-20000>] [slow-periodic-time
<10000-30000>] [timeout-time <long|short>] [timeout-scale <2-10>]
```

If you do not configure the optional parameters, the system uses the default values.

9. Enable LACP aggregation:

```
lacp aggregation enable
```

### Examples

Configure LACP on ports 1/2 and 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2-1/3
Switch:1(config-if)#lacp key 100
Switch:1(config-if)#lacp aggregation enable
Switch:1(config-if)#lacp enable
```

Return the key to the default value:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2-1/3
Switch:1(config-if)#no lacp aggregation enable
Switch:1(config-if)#default lacp key
Switch:1(config-if)#lacp aggregation enable
```

### Variable Definitions

The following table defines parameters for the **lacp** command.

#### Note

All parameters beginning with **partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

| Variable                                       | Value                                                                                                                                                                                                                |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>aggr-wait-time</i> <200-2000>               | Configures the aggregation wait time (in milliseconds) for this port. The default is 2000.                                                                                                                           |
| <i>aggregation enable</i>                      | Enables aggregation on the port, which makes it an aggregated link.                                                                                                                                                  |
| <i>enable</i>                                  | Enables LACP for this port. The default is disabled.                                                                                                                                                                 |
| <i>fast-periodic-time</i> <200-20000>          | Configures the fast periodic time (in milliseconds) for this port. The default is 1000 ms.                                                                                                                           |
| <i>key</i> <1-512 defVal>                      | Configures the aggregation key for this port.<br>Enter the aggregation key value or defVal (1024 + IfIndex)<br>To return a configured key to the default value, you must first disable LACP aggregation on the port. |
| <i>mode</i> { <i>active</i>   <i>passive</i> } | Configures the LACP mode to be active or passive.                                                                                                                                                                    |

| Variable                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>partner-key &lt;0-65535&gt;</code>                             | Configures the partner administrative key.                                                                                                                                                                                                                                                                                                                                                 |
| <code>partner-port &lt;0-65535&gt;</code>                            | Configures the partner administrative port value.                                                                                                                                                                                                                                                                                                                                          |
| <code>partner-port-priority &lt;0-65535&gt;</code>                   | Configures the partner administrative port priority value.                                                                                                                                                                                                                                                                                                                                 |
| <code>partner-state &lt;0-255   0x0-0xff&gt;</code>                  | Configures the partner administrative state bitmask. Specify the partner administrative state bitmap in the range 0x0-0xff. The bit to state mapping is Exp, Def, Dis, Col, Syn, Agg, Time, and Act.<br>For example, to set the two partner-state parameters <ul style="list-style-type: none"> <li>Act = true</li> <li>Agg = true</li> </ul> specify a value of 0x05 (bitmap = 00000101). |
| <code>partner-system-id &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code> | Configures the partner administrative system ID. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00.                                                                                                                                                                                                                                                                        |
| <code>partner-system-priority &lt;0-65535&gt;</code>                 | Configures the partner administrative system priority value.                                                                                                                                                                                                                                                                                                                               |
| <code>priority &lt;0-65535&gt;</code>                                | Configures the port priority. The default value is 32768. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                                                                                                                       |
| <code>slow-periodic-time &lt;10000-30000&gt;</code>                  | Configures the slow periodic time for this port. The default is 30000 ms. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                                                                                                       |
| <code>system-priority &lt;0-65535&gt;</code>                         | Configures the system priority for this port. The default is 32768.                                                                                                                                                                                                                                                                                                                        |
| <code>timeout-scale &lt;2-10&gt;</code>                              | Configures a timeout scale for this port. The default value is 3. The LACP timeout is equal to the slow periodic time or fast periodic time multiplied by the timeout-scale, depending how you configure the timeout-time variable.                                                                                                                                                        |
| <code>timeout-time {long short}</code>                               | Configures the timeout to either long or short.                                                                                                                                                                                                                                                                                                                                            |

## Configure LACP on an MLT

Configure an MLT with LACP to use the dynamic link aggregation function.

### About This Task

#### Important

Attach ports to an aggregator only if their system priorities are the same; otherwise, they are considered to be operating in two different switches. You can attach ports to an aggregator only if their keys are the same.

When you add a VLAN to a dynamic MLT, only the active ports of the MLT are added as port members of the VLAN. Ports configured with the same aggregation key, but not active, are not added to the

VLAN. If these inactive ports become active later, the system does not automatically add them to the VLAN port member list.

You must add all inactive ports to the VLAN. If you do not add the inactive ports to the VLAN, when they become active later, hashing can result in choosing a newly active port for traffic forwarding. Because the port is not a port member of the VLAN, traffic will be dropped. When you add the VLAN to the MLT, also add the inactive aggregation ports to the VLAN. You may need to disable LACP on the inactive ports before you can add them to the VLAN. Because the ports are inactive, disabling LACP does not cause a traffic interruption.

Similarly when you remove a VLAN from a dynamic MLT, all active ports of the MLT are removed from the VLAN port member list but the inactive members are not removed. You must remove the inactive aggregation members from the VLAN.

If you later configure a port for the same aggregation, you must add this port to all VLANs that are members of the MLT.

### Procedure

1. Enter MLT Interface Configuration mode:
 

```
enable

configure terminal

interface mlt <1-512>
```
2. Configure LACP on an MLT:
 

```
lacp enable [key <0-512>] [system-priority <0-65535>]
```

### Example

Enable LACP and configure the LACP key on MLT 3:

```
Switch:1(config)# interface mlt 3

Switch:1(config-mlt)# lacp enable key 1281
```

### Variable definitions

Use the data in the following table to use the **lacp** command.

| Variable                                     | Value                                                                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code>                          | Enables LACP on the MLT interface.                                                                                                                         |
| <code>key &lt;0-512&gt;</code>               | Configures the LACP aggregator key for a specific MLT. <ul style="list-style-type: none"> <li>• <code>0-512</code> is the LACP actor admin key.</li> </ul> |
| <code>system-priority &lt;0-65535&gt;</code> | Configures the LACP system priority for a specific MLT. <ul style="list-style-type: none"> <li>• <code>0-65535</code> is the system priority.</li> </ul>   |

## Configuring LACP and Private VLANs

### About This Task

Use the following procedure to configure Link Aggregation Control Protocol (LACP) on a private VLAN.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable trunking:

```
encapsulation dot1q
```

3. Set private VLAN port type:

```
private-vlan [isolated|promiscuous|trunk]
```

### Example

```
Switch:1(config)#interface GigabitEthernet 1/6
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#private-vlan promiscuous
Switch:1(config-if)#exit
```

```
Switch:1(config)#interface GigabitEthernet 1/37
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#private-vlan promiscuous
```

## Configuring LACP on a VLAN

Use this procedure to configure LACP on a VLAN.

### About This Task

#### Important

Configuration at the global level overrides and resets all settings at the VLAN level.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure global aggregation wait time for the VLAN:  

```
lacp aggr-wait-time <200-2000>
```
3. Enable LACP:  

```
lacp enable
```
4. Configure the global periodic time:  

```
lacp enable [fast-periodic-time <200-20000>] [slow-periodic-time <10000-30000>]
```

If you do not configure the optional parameters, the system uses the default values.

5. Configure a global LACP system ID.  

```
lacp smlt-sys-id 0x00:0x00:0x00:0x00:0x00:0x00
```
6. Configure the system priority:  

```
lacp system-priority <0-65535>
```
7. Configure the timeout-scale:  

```
lacp timeout-scale <2-10>
```

### Example

```
Switch:1(config)#interface vlan 20
Switch:1(config-if)#lacp fast-periodic-time 2000
Switch:1(config-if)#lacp enable
```

### Variable definitions

Use the data in the following table to use the **lacp** command.

| Variable                                            | Value                                                                                                                                                                                                                              |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>aggr-wait-time</i> <200-2000>                    | Configures the aggregation wait time (in milliseconds) globally. The default is 2000.                                                                                                                                              |
| <i>enable</i>                                       | Enables LACP for the VLAN. The default is disabled.                                                                                                                                                                                |
| <i>fast-periodic-time</i> <200-20000>               | Configures the fast periodic time (in milliseconds) globally for the VLAN. The default is 1000 ms.                                                                                                                                 |
| <i>slow-periodic-time</i> <10000-30000>             | Configures the slow periodic time globally for the VLAN. The default is 30000 ms.                                                                                                                                                  |
| <i>smlt-sys-id</i><br>0x00:0x00:0x00:0x00:0x00:0x00 | Configures the LACP system ID globally.                                                                                                                                                                                            |
| <i>system-priority</i> <0-65535>                    | Configures the LACP system priority globally.                                                                                                                                                                                      |
| <i>timeout-scale</i> <2-10>                         | Configures a timeout scale for the VLAN. The default value is 3. The LACP timeout is equal to the slow periodic time or fast periodic time multiplied by the timeout-scale, depending how you configure the timeout-time variable. |

## Viewing LACP configuration information

View LACP configuration information to determine the LACP parameters and to ensure your configuration is correct.

### Procedure

1. View the global configuration:

```
show lacp
```

2. View LACP administrative information for the local device:

```
show lacp actor-admin interface [gigabitethernet]
```

OR

```
show lacp actor-admin interface gigabitethernet [vid <1-4059>] [{slot/  
port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

3. View LACP operational information for the actor device:

```
show lacp actor-oper interface [gigabitethernet]
```

OR

```
show lacp actor-oper interface gigabitethernet [vid <1-4059>] [{slot/  
port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

4. View LACP timer information:

```
show lacp extension interface [gigabitethernet]
```

5. View LACP interface configuration information

```
show lacp interface
```

OR

```
show lacp interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-  
port] [-slot/port[/sub-port]] [,...]}
```

OR

```
show lacp interface mlt [<64-6399>]
```

OR

```
show lacp interface mlt [id<1-512>]
```

6. View LACP administrative information for the partner device:

```
show lacp partner-admin interface [gigabitethernet]
```

OR

```
show lacp partner-admin interface gigabitethernet [vid <1-4059>]  
[{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. View LACP operational information for the partner device:

```
show lacp partner-oper interface [gigabitethernet]
```

OR

```
show lacp partner-oper interface gigabitethernet [vid <1-4059>]
[{{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Example

```
Switch:1# show lacp
```

```
=====
                        Lacp Global Information
=====
SystemId: 00:24:7f:a1:70:00
SmltSystemId: 00:00:00:00:00:00
Lacp: enable
system-priority: 32768
  timeout-admin: 3
fast-periodic-time-admin: 1000
slow-periodic-time-admin: 30000
  aggr-wait-time-admin: 2000
  timeout-oper: 3
fast-periodic-time-oper: 2000
slow-periodic-time-oper: 30000
  aggr-wait-time-oper: 2000
```

In the following example output, `aggr` indicates the port has become part of an aggregation. `indi` indicates individual.

```
Switch:1(config-if)# show lacp actor-admin interface gigabitethernet 1/1
```

```
=====

## Displaying LACP Statistics for Specific Ports

Display individual LACP statistics for specific ports to manage network performance.

**Note**

Slot and port information can differ depending on hardware platform.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. View statistics for specific ports:  

```
show interfaces GigabitEthernet statistics lacp [{slot/port[/sub-port]}
[-slot/port[/sub-port]][,...]]
```

**Example**

View LACP statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics lacp
```

```
=====
                          Port Stats LACP
=====

*Variable Definitions*

Use the data in the following table to use the **show interfaces GigabitEthernet statistics lacp** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]} [-slot/port[/sub-port]][,...]</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## LACP configuration using EDM

MultiLink Trunking (MLT) with Link Aggregation Control Protocol (LACP) manages switch ports and port memberships to form a link aggregation group (LAG). Configure LACP to allow dynamic bundling of physical ports to form a single logical channel.

### Note

The switch does not support standby ports for LACP aggregation groups.

## Configuring global LACP parameters

Use LACP parameters to manage switch ports and their port memberships to form link aggregation groups (LAG). Link Aggregation Control Protocol (LACP) can dynamically add or remove LAG ports, depending on their availability and states.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **LACP Global** tab.
4. To enable LACP globally, select the **Enable** check box.
5. Configure the remaining parameters as required.

### Important

Configuration changes to the LACP timers are not effective immediately. Link Aggregation Control Protocol timers are not reset until the next time LACP is restarted globally or on a port. This ensures consistency with peer switches.

6. Click **Apply**.

### **LACP Global** field descriptions

Use the data in the following table to use the **LACP Global** tab.

| Name                        | Description                                                                                                                                                                                    |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Enable</b>               | Enables or disables LACP globally.                                                                                                                                                             |
| <b>SystemPriority</b>       | Configures the system priority for all LACP enabled aggregators and ports.<br>The default value is 32768.                                                                                      |
| <b>FastPeriodicTime</b>     | Configures the number of milliseconds between periodic transmissions that use short timeouts. Sets this value to all LACP-enabled ports. The range is 200-20000.<br>The default value is 1000. |
| <b>FastPeriodicTimeOper</b> | Displays the operating value of the fast periodic timer on the port.<br>The default value is 1000.                                                                                             |

| Name                        | Description                                                                                                                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SlowPeriodicTime</b>     | Configures the number of milliseconds between periodic transmissions that use long timeouts. All LACP enabled ports get the same value from this setting. The range is 10000–30000. The default value is 30000. |
| <b>SlowPeriodicTimeOper</b> | Displays the operating value of the slow periodic timer on the port. The default value is 30000.                                                                                                                |
| <b>AggrWaitTime</b>         | Configures the number of milliseconds to delay aggregation to allow multiple links to aggregate simultaneously. The range is 200–2000. The default value is 2000.                                               |
| <b>AggrWaitTimeOper</b>     | Displays the operating value of the aggregate wait timer on the port. The default value is 2000.                                                                                                                |
| <b>TimeoutScale</b>         | Configures the value used to calculate timeout time from the periodic time. All LACP-enabled ports get the same value from this setting. The range is 2–10. The default value is 3.                             |
| <b>TimeoutScaleOper</b>     | Displays the operating value of the timeout scale on the port. The default value is 3.                                                                                                                          |
| <b>SysId</b>                | Specifies the LACP system ID. The default value is f8:73:a2:00:90:00.                                                                                                                                           |
| <b>SmltSysId</b>            | Specifies the LACP system ID for Split MultiLink Trunking (SMLT).                                                                                                                                               |

## Configuring LACP parameters

Configure LACP parameters to manage LACP information.

### About This Task

#### Important

The switch does not support standby ports for LACP aggregation groups.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **LACP** tab.
4. Double-click a field to change the value.
 

You cannot edit grey-shaded fields in the table.
5. Click **Apply**.

**LACP** field descriptions

Use the data in the following table to use the **LACP** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>                 | The unique identifier the local system allocates to this aggregator. This attribute identifies an aggregator instance among the subordinate managed objects of the containing object. This value is read-only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>MACAddress</b>            | The six octet read-only value carrying the individual MAC address assigned to the aggregator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ActorSystemPriority</b>   | The two octet read-write value indicating the priority value associated with the actor system ID. The default value is 32768.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ActorSystemID</b>         | The six octet read-write MAC address value used as a unique identifier for the system that contains this aggregator. From the perspective of the link aggregation mechanisms, only a single combination of actor system ID and system priority are considered. No distinction is made between the values of these parameters for an aggregator and the ports that are associated with it. The protocol is described in terms of the operation of aggregation within a single system. However, the managed objects provided for the both the aggregator and the port allow management of these parameters. The result permits a single piece of equipment to be configured by management to contain more than one system from the point of view of the operation of link aggregation, which is useful in the configuration of equipment that has limited aggregation capability. |
| <b>AggregateOrIndividual</b> | Indicates whether the aggregator represents an aggregate (true) or an individual link (false).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ActorAdminKey</b>         | Specifies the current administrative value of the key for the aggregator, which is a 16-bit read-write value. The administrative key value can differ from the operational key value. This key needs to match the LAG key. The default value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ActorOperKey</b>          | Displays the current read-only operational value of the key for the aggregator. The operational key value can differ from the administrative key value. The meaning of particular key values is of local significance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>PartnerSystemID</b>       | The six octet read-only MAC address value consisting of the unique identifier for the current protocol partner of this aggregator. A value of zero indicates that there is no known partner. If the aggregation is manually configured, the value is assigned by the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PartnerSystemPriority</b> | The two octet read-only value that indicates the priority value associated with the partner system ID. If the aggregation is manually configured, this system priority value is a value assigned by the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PartnerOperKey</b>        | The current operational value of the key for the aggregator current protocol partner, which is a 16-bit read-only value. If the aggregation is manually configured, the value is assigned by the local system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configure LACP on a Port

### Important

Changes made at the global level override and reset the port-level configuration.

Configure LACP on a port to enable LACP.

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

### Before You Begin

When enabling or disabling LACP on a port, as a best practice, disable the port first and re-enable the port after the configuration is complete.

### About This Task

The minimum LACP configuration is as follows:

- Assign a given key to a set of ports. In the following procedure steps, you must assign the key before you enable LACP on the port.
- Assign the same key to an MLT with no members. The ports will automatically become MLT members.

Keys do not need to match between two LACP peers.

A port can operate in active or passive mode. You can configure a port to be an individual link or an aggregated link.

### Note

When using LACP with private VLANs, configure the private VLAN at the interface level.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **LACP** tab.
5. To assign an LACP key, configure **ActorAdminKey**.
6. Select **Apply**.
7. To enable LACP on the port, select **AdminEnable**.
8. Configure the remaining parameters as required.
9. Select **Apply**.

### *LACP Field Descriptions*

Use the data in the following table to use the **LACP** tab.

All parameters beginning with **Partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

| Name                        | Description                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>          | Enables LACP status for the port.<br>The default value is false.                                                                                     |
| <b>OperEnable</b>           | Displays the operational status of LACP for the port.<br>The default value is false.                                                                 |
| <b>FastPeriodicTime</b>     | Specifies the number of milliseconds between periodic transmissions using short timeouts for all LACP enabled ports.<br>The default value is 1000.   |
| <b>FastPeriodicTimeOper</b> | Displays the operating value of the fast periodic timer on the port.<br>The default value is 1000.                                                   |
| <b>SlowPeriodicTime</b>     | Specifies the number of milliseconds between periodic transmissions using long timeouts for all LACP enabled ports.<br>The default value is 30000.   |
| <b>SlowPeriodicTimeOper</b> | Displays the operating value of the slow periodic timer on the port.<br>The default value is 30000.                                                  |
| <b>AggrWaitTime</b>         | Specifies the number of milliseconds to delay aggregation so multiple links can aggregate simultaneously.<br>The default value is 2000.              |
| <b>AggrWaitTimeOper</b>     | Displays the operating value of the aggregate wait timer on the port.<br>The default value is 2000.                                                  |
| <b>TimeoutScale</b>         | Assigns the value used to calculate timeout time from the periodic time. Configure this value for all LACP-enabled ports.<br>The default value is 3. |
| <b>TimeoutScaleOper</b>     | Displays the operating value of the timeout scale on the port.<br>The default value is 3.                                                            |
| <b>ActorSystemPriority</b>  | Specifies the two octet read-write value indicating the priority value associated with the actor system ID.<br>The default value is 32768.           |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ActorSystemID</b>     | <p>Displays the six octet read-write MAC address value used as a unique identifier for the system that contains this aggregator.</p> <p>From the perspective of the link aggregation mechanisms, only a single combination of actor system ID and system priority are considered, and no distinction is made between the values of these parameters for an aggregator and the ports that are associated with it; that is, the protocol is described in terms of the operation of aggregation within a single system. However, the managed objects provided for the aggregator and the port both enable management of these parameters. The result of this is to permit a single piece of equipment to be configured by management to contain more than one system from the point of view of the operation of link aggregation. This can be of particular use in the configuration of equipment that has limited aggregation capability.</p> |
| <b>ActorAdminKey</b>     | <p>Configures the aggregation key for this port. The administrative key value can differ from the operational key value. This key must match the LAG key.</p> <p>To return a configured key to the default value, you must first disable LACP aggregation on the port.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ActorOperKey</b>      | <p>Displays the current operational value of the key for the aggregator. The operational key value can differ from the administrative key value. The meaning of particular key values is of local significance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SelectedAggID</b>     | <p>Displays the identifier value of the aggregator that this aggregation port has currently selected. Zero indicates that the aggregation port has not selected an aggregator, either because it is in the process of detaching from an aggregator or because there is no suitable aggregator available for it to select.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>AttachedAggID</b>     | <p>Displays the identifier value of the aggregator to which this aggregation port is currently attached. Zero indicates that the aggregation port is not currently attached to an aggregator.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ActorPort</b>         | <p>Displays the port number locally assigned to the aggregation port. The port number is communicated in LACPDUs as the Actor_Port.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ActorPortPriority</b> | <p>Specifies the priority value assigned to this aggregation port.</p> <p>The default value is 32768.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ActorAdminState</b>            | <p>Configures one or more of the following:</p> <ul style="list-style-type: none"> <li>• <b>lACPActive</b> - Configures the LACP mode to be active.</li> <li>• <b>lACPShortTimeout</b> - Configures the timeout to short.</li> <li>• <b>aggregation</b> - Enables aggregation on the port, which makes it an aggregated link.</li> </ul> <p>By default, only lACPActive is enabled. These values enable administrative control over the values of LACP_Activity, LACP_Timeout, and aggregation.</p> |
| <b>ActorOperState</b>             | <p>Displays a string of eight bits, corresponding to the current operational values of Actor_State as transmitted by the actor in LACPDUs. The default value is lACPActive.</p>                                                                                                                                                                                                                                                                                                                     |
| <b>PartnerAdminSystemPriority</b> | <p>Specifies the current administrative value of the port number for the protocol partner. The assigned value is used, along with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPortPriority, to achieve manually configured aggregation. The default value is 0.</p>                                                                                                                                                                             |
